INFORMS ANNUAL MEETING
HOUSTON, WE SOLVE PROBLEMS
OCTOBER 22-25
2017

Great minds ~~think alike.~~ choose different.

Choose TURNER.

Work on exciting challenges with Big Data, Analytics, Machine Learning, and Artificial Intelligence.

Create big, bold ideas as TURNER leads the transformation of the media and content business with data-driven insights and industry-leading technology.

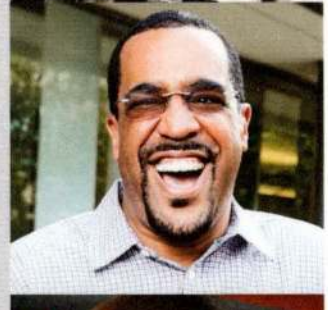
Choose different for your career, at the global media company with some of the most valuable entertainment and news brands in the world.

Interested in learning more about career opportunities at TURNER?

Send your resume to: informsconference@turner.com.

Honors and Awards

2017 INFORMS' Innovative Applications of Analytics Award



2016 ANA Genius Awards: Marketing Analytics Science

2016 ARF Great Mind Award in Analytics Leadership

2016 TVOT Achievement in Advanced Advertising Award

2015 ANA Genius Awards: Excellence in Pioneering Analytics Innovation

2015 Emmy for Engineering and Technology

How to Navigate the Technical Sessions

There are four primary resources to help you understand and navigate the Technical Sessions:

- This Technical Session listing, which provides the most detailed information. The listing is presented chronologically by day/time, showing each session and the papers/abstracts/authors within each session.

The Session Codes

Time Blocks

Sunday - Monday

8:00am - 9:30am
10:00am - 10:50am
11:00am – 12:30pm
1:30pm – 3:00pm
3:10pm - 4:00pm
4:30pm – 6:00pm

Tuesday

7:30am - 9:00am
9:40am - 10:30am
10:30am - 12:00pm
12:05pm - 1:35pm
2:00pm - 3:30pm
3:40pm - 4:30pm
4:35pm – 6:05pm

Wednesday

7:30am - 9:00am
9:40am - 10:30am
10:30am - 12:00pm
12:30pm - 2:00pm

Rooms and Locations /Tracks

All tracks / technical sessions will be held in the George R. Brown Convention Center. Rooim numbers are shown on the Quick Reference and in the Technical session listings.

Monday and Tuesday Plenary talks will be held in Hilton- Ballroom of Americas, Level 2

Sunday, 8:00 - 9:30AM

■ SA02

Decision Analytic Approaches to Green Infrastructure Solutions

Sponsored: Decision Analysis

Sponsored Session

Chair: Fengwei Hung, Johns Hopkins University, Baltimore, MD, 21218, United States, hfengwe1@jhu.edu

Co-Chair: Melissa A. Kenney, University of Maryland, College Park, MD, 20740, United States, kenney@umd.edu

1 - Needs Title

Snehasis Mukhopadhyay, IUPUI, Indianapolis, IN, United States, smukhopa@iupui.edu, Andrew Hoblitzell, Meghna Babbar-Sebens

WRESTORE is a stakeholder-driven design system that optimizes best management practices for the Eagle Creek Watershed in Indiana. The system provides resources on conservation programs and enables stakeholders to visualize the impacts of alternative practices on the watershed. The system utilizes fuzzy logic, neural networks, and deep learning for user modeling, and uses an interactive genetic algorithm with mixed initiative interaction for exploratory search and exploitative optimization. In this talk, we will provide a discussion of the current implementation of the system, as well as a brief discussion of ongoing work and future plans for the system.

2 - Understanding Residential Low Impact Development at the Home Owner Level

Domenico Amodeo, George Washington University, Washington, DC, 20052, United States, dcamodeo@email.gwu.edu

Environmental engineers and economist have studied the patterns of adoption for green technology. Many of these studies rely on regression and aggregated data. We developed a zero-truncated negative binomial regression model using parcel level data. However, we argue that regression is an inadequate method for predicting home owner adoption of LID. A graph based method is presented to identify configurations of LID emerging from residential property owners who are presented with a municipal incentive to adopt. We argue that understanding the configurations that emerge may provide insight into homeowners motivations and the effectiveness of incentive programs.

3 - A Two-stage Stochastic Programming Model for Adaptive Stormwater Management with Green Infrastructure

Fengwei Hung, Johns Hopkins University, 3400 N Charles St. Ames Hall 313, Baltimore, MD, 21218, United States, hfengwe1@jhu.edu

Adaptive management (AM) can be viewed as a multi-stage planning problem with the emphasis on learning by doing and uncertainty. The proposed model considers the decision maker's risk attitudes and the potential learning in latter stages. Risk is modeled in the form of conditional value of risk (CVaR) and learning is defined as the process of updating random distributions which are assumed to depend on the investment now (1st stage decisions). This method can explore the risk-expected value tradeoffs accounting for what we may be able to learn from doing. Finally, we show an example to demonstrate how this model works.

4 - Optimal Planning of Green Infrastructure Placement in an Urban Watershed under Precipitation Uncertainty

Masoud Barah, University of Tennessee, Knoxville, TN, United States, mbarah@utk.edu, Anahita Khojandi, Jon Hathaway, Xueping Li

Urbanization, infrastructure degradation, and climate change have overwhelmed most stormwater management systems across the nation or rendered them ineffective. Green Infrastructures (GIs) are low-cost strategies that can contribute to stormwater management. We develop a stochastic programming model to determine the optimal placement of GIs across a set of candidate locations in a watershed to minimize the excess runoff in medium-term precipitation uncertainties. We calibrate the model using rainfall projections and stormwater system's hydrologic responses to them. We provide optimal GI placement in a watershed and perform sensitivity and robustness analyses to provide insights.

310C

An Introduction to Two-Stage Stochastic Mixed-IntegerProgramming

Invited: Tutorial

Invited Session

Chair: Jiming Peng, University of Houston, Houston, TX, United States, jopeng@Central.uh.edu

Co-Chair: Rajan Batta, University at Buffalo (SUNY), 410 Bell Hall, University at Buffalo (SUNY), Buffalo, NY, 14260, United States, batta@buffalo.edu

1 - An Introduction to Two-Stage Stochastic Mixed-Integer Programming

Simge Kucukyavuz, University of Washington, Box 352650, Industrial & Systems Engineering, Seattle, WA, 98195, United States, simge@uw.edu, Suvrajeet Sen

This paper provides an introduction to algorithms for two-stage stochastic mixed integer programs. Our focus is on methods which decompose the problem by scenarios representing randomness in the problem data. The design of these algorithms depend on where the uncertainty appears (right-hand-side, recourse matrix and/or technology matrix) and where the continuous and discrete decision variables are (first-stage and/or second-stage). In addition we provide computational evidence that, similar to other classes of stochastic programming problems, decomposition methods can provide desirable theoretical properties (such as finite convergence) as well as enhanced computational performance when compared to solving a deterministic equivalent formulation using an advanced commercial MIP solver.

■ SA03A

Grand Ballroom A

Applied Probability in Finance

Sponsored: Applied Probability

Sponsored Session

Chair: Markus Pelger, Stanford University, Stanford, CA, 94305, United States, mpelger@stanford.edu

1 - Determinant of Clearinghouse Margins

Agostino Capponi, Columbia University, 500 W. 120th Street, New York, NY, 10027, United States, ac3827@columbia.edu

We analyze regulatory credit default swap (CDS) data to investigate drivers of clearinghouse margins, exploiting explicitly linked portfolio exposures and collateralizing assets. We document several stylized facts, including heterogeneity of clearing member portfolios, significant time variation in margin levels, and clustering of portfolio return on margins around the mean. Our results show that the advent of margin spirals relies on commonality in exposures, as shocks to common credit exposures can be destabilizing, whereas idiosyncratic shocks are stabilized by clearinghouse margining rules.

2 - Law of the Few: Economics of the Tipping Point

Nan Chen, Chinese University of Hong Kong, William M.W. Mong Engineering Bldg, Rm 609, Shatin N.T., Hong Kong, nchen@se.cuhk.edu.hk, Steven Kou, Yan Wang

Large regime switch due to social interaction, known as the tipping point, is of great interest in sociology and economics. Two empirical features related to this phenomenon are local conformity/global diversity and punctuated equilibrium effect. The former refers to that a significant conformity can be found within a given community but in other separate communities the same issue is approached by different ways. The latter feature means that the dynamics of a given community tend to have a long period of the dominance of one opinion, punctuated by bursts of opinion shifts. In this paper we propose a simple stochastic model to incorporate the above two features of an interacting population.

3 - Adaptive Learning and Stability of Equilibria in a Dynamic Model with Informed Investors

Yiwen Shen, Columbia Business School, New York, NY, United States, YShen21@gsb.columbia.edu, Paul Glasserman, Harry Mamaysky

We propose a dynamic model of securities trading between overlapping generations of informed and uninformed investors. We assume becoming informed is costly, and the quality of learnable information improves with the ratio of informed investors. Investors form beliefs about how price volatility depends on the quality of learnable information. We show the beliefs could be self-fulfilling in a low volatility market. With such beliefs, our economy is characterized by high and low information equilibria, both of which are locally stable but with periodic transitions between each other. We discuss the model's implications for trading volume, investors' welfare, and boom-bust cycles.

4 - Estimating Latent Asset-pricing Factors from Large-dimensional Data

Markus Pelger, Stanford University, 312 Huang Engineering Center, 475 Via Ortega, Stanford, CA, 94305, United States, mpelger@stanford.edu, Martin Lettau

We develop an estimator for latent factors in a large-dimensional panel of financial data that can explain expected excess returns. Statistical factor analysis based on Principal Component Analysis (PCA) has problems identifying weak factors that are important for asset pricing. Our estimator searches for high Sharpe-ratio factors that can explain both the expected return and covariance structure. We derive the statistical properties of the new estimator and show that it can find asset-pricing factors, which cannot be detected with PCA, even if a large amount of data is available. Our factors accommodate a large set of anomalies better than notable four- and five-factor alternative models.

■ SA03B

Grand Ballroom B

Dynamic Pricing

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Hamid Nazerzadeh, USC Marshall School of Business, Los Angeles, CA, 90089, United States, hamidnz@marshall.usc.edu

Co-Chair: Negin Golrezaei, University of Southern California, Pasadena, CA, 91106, United States, golrezae@usc.edu

1 - Dynamic Pricing and Information Aggregation in Sports Betting Markets

Adam Schultz, University of Chicago-Booth School of Business, 5532 South Kenwood Ave, Apt 208, Chicago, IL, 60637, United States, adam.schultz@chicagobooth.edu, John R. Birge, N. Bora Keskin

In this paper, we explore how market makers use dynamic pricing as a mechanism to aggregate information in a biased prediction market. We collect a novel data set of time series data to study a sports betting market, including Twitter data to control for breaking news events that lead to information changes in the market. After investigating how market makers adjust prices in this context, we present an approach to estimate potential bias in bettors' beliefs about game outcomes. This model allows us to perform a counterfactual analysis in which we characterize the optimal point spread for the market maker for each game. We use this model to analyze market makers' policies and expected profit performance.

2 - On the Efficacy of Static Prices for Revenue Management in the Face of Strategic Customers

Yiwei Chen, Singapore University of Technology and Design, Singapore, Singapore, yiwei_chen@sutd.edu.sg, Vivek Farias

We consider a RM problem wherein a monopolist seller seeks to maximize revenues from selling a fixed inventory of a product to customers who arrive over time. Customers are forward looking. We allow for multi-dimensional customer types. We allow for a customer's disutility from waiting to be positively correlated with his valuation. We show that static prices proposed by Gallego and van Ryzin [1994] that study a myopic customer RM problem continue to remain asymptotically optimal in the regime where inventory and demand grow large. Irrespective of regime, the optimal static price captures at least 63.2% of the seller's revenue under an optimal dynamic mechanism.

3 - Multidimensional Binary Search for Contextual Decision-making

Ilan Lobel, NY, United States, ilobel@stern.nyu.edu, Renato Paes Leme, Adrian Vladu

We consider a multidimensional search problem that is motivated by questions in contextual decision-making such as dynamic pricing. Nature selects a state from a d-dimensional unit ball and then generates a sequence of d-dimensional directions. After receiving a direction, we have to guess the value of the dot product between the state and the direction. Our goal is to minimize the number of times when our guess is more than away from the true answer. We construct a polynomial time algorithm that we call Projected Volume achieving regret O(d log d), which is optimal up to a log d factor. The algorithm combines a volume cutting strategy with a new geometric technique that we call cylindrification.

4 - Dynamic Pricing in High-dimensions

Adel Javanmard, USC Marshall School of Business, 300A Bridge Hall, University of Southern California, Los Angeles, CA, 90089, United States, ajavanma@marshall.usc.edu, Hamid Nazerzadeh

We study the pricing problem where a firm sells a large number of products, described via a wide range of features, to customers that arrive over time. The firm is oblivious to market values of products. However, it can gain information about valuations based on previous binary feedbacks on whether products were sold at the posted prices. This setting is motivated in part by the prevalence of online marketplaces that allow for real-time pricing. We propose a dynamic policy (RMLP) that leverages the sparsity structure of the demand space and provably achieves an asymptotically optimal revenue.

Grand Ballroom C

Customer and Server Behavior in Queues

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Mirko Kremer, Frankfurt School of Finance and Management gGmbh, Frankfurt, 60314, Germany, m.kremer@fs.de

1 - Mismanaging the Quality-speed Tradeoff in Congested Environments

Mirko Kremer, Frankfurt School of Finance and Management, Frankfurt, 60314, Germany, m.kremer@fs.de, Francis de Véricourt

The tradeoff between diagnostic accuracy and speed permeates many manufacturing and service settings. We present the results from a set of controlled laboratory experiments designed to test the predictions of a formal sequential testing model that captures this tradeoff in a setting where the gathering of additional information (i.e., diagnostic testing) is likely to improve diagnostic judgments, but may also increase congestion in the system. We find that decision makers are insufficiently sensitive to congestion, with an aversion to stopping a diagnostic process in the face of increasing system congestion. On the other hand, decision makers are overly sensitive to diagnostic signals, with a tendency to stop a diagnostic process immediately after the first test result, even at low congestion levels that render additional testing inexpensive. As a result of these behavioral patterns, besides substantial heterogeneity in how they trade off quality and speed, the majority of decision makers manage their system with both lower-than-optimal diagnostic accuracy and higher-than-optimal congestion cost.

2 - The Effects of Discrete Work Shifts on Non-terminating Queues

Robert Batt, University of Wisconsin-Madison, Madison, WI, 53706, United States, bob.batt@wisc.edu, Diwas S.KC, Bradley R. Staats, Brian Patterson

We study an emergency department to see how the finite-length shift structure impacts productivity and quality. Using simulation, we show that policies thatprohibit starting new patients near the end of the shift can lead to improved system throughput.

3 - An Empirical Study of Customer Spillover Learning about Service Quality

Andres I. Musalem, Universidad de Chile, Beauchef 851, Santiago, 8370456, Chile, amusalem@duke.edu

We study social learning in a multi-arm bandit setting where each of a sequence of arriving customers chooses between alternative service providers with uncertain quality, observing only the outcomes from other customers' service experiences. In a series of experiments, we test the key theoretical prediction that the social learning process results in insufficient exploration, relative to a „centralized" benchmark regime where customers learn about the providers' quality from their own (previous) choices.

320A

Sustainable and Socially Responsible Operations

Sponsored: Manufacturing & Service Oper Mgmt, Sustainable Operations

Sponsored Session

Chair: Can Zhang, Georgia Institute of Technology, Atlanta, GA, 30309, United States, czhang2012@gatech.edu

Co-Chair: Atalay Atasu, Georgia Institute of Technology, Atlanta, GA, 30308, United States, atalay.atasu@scheller.gatech.edu

1 - Agricultural Support Prices in Developing Economies: Operational Analysis and its use in Policy Making

Tharanga Kumudini Rajapakshe, University of Florida, 10287, SW. 37th Place, Gainesville, FL, 32608, United States, tharanga@ufl.edu

In this paper, we offer analytically-supported insights on several fundamental aspects of the Guarenteed Support Price scheme by analyzing a Stackelberg game between a homogenous population of small farmers and a social planner. To understand the welfare implications of the GSP scheme on its main stakeholders, we characterizethe equilibrium operational decisions of the farmers and the equilibrium value of the GSP.

2 - The Value of Strategic Farmers, Social Entrepreneurs and For-profit Firms in Crop Planting Decisions

Wenbin Wang, Shanghai University of Finance and Economics, Shanghai, China, wang.wenbin@mail.shufe.edu.cn, Ming Hu, Yan Liu

We study how farmers of heterogeneous production costs make crop-planting decisions over time to maximize their incomes. We consider both strategic farmers, who rationally anticipate the near-future prices and naive farmers, who shortsightedly react to recent crop prices. We find self-interested behavior of strategic farmers alone can reduce price volatility and benefit all farmers. In the absence of strategic farmers, an optimally-designed pre-season procurement contract, offered by a social entrepreneur or for-profit firm, also brings benefit to farmers as well as to the firm itself. However, a poorly designed contract may distort the market and drive non-contract farmers out of business.

3 - Inter-dependency among Mitigation, Preparedness, and Response Decisions in Disaster Management Cycle

Shabnam Rezapour, Florida International University, Miami, FL, United States, srezapou@fiu.edu, Reza Zanjirani Farahani, Alfonso J. Pedraza Martinez

This research explores the interdependency between the stages of mitigation (fortifying stocks), preparedness (locating stocks), and response (distributing stocks timely) in disaster management cycle. Using a stochastic model, the focus is on minimizing the total logistics costs. We show that controlled decentralization, centralization, and decentralization are the best locating strategy to minimize logistics costs for expensive goods, for cheap goods, and in relief networks with high transportation cost. Stock fortification (in mitigation stage) makes it possible to have short response intervals (in response stage) and fulfill demand with less number of stocks (in preparedness stage).

4 - Perishable Inventory Sharing in a Two-location System

Can Zhang, Georgia Institute of Technology, 499 Northside Circle NW, Apt 315, Atlanta, GA, 30309, United States, czhang2012@gatech.edu, Turgay Ayer, Chelsea C. White

Motivated by a platelet inventory management problem in a local hospital network, we study an inventory sharing problem for perishable products in a two-location system. We derive structural properties of the optimal policy and present managerial insights that are significantly different from those in existing studies for traditional non-perishable products.

■ SA06

320C

Design and Evaluation of Differentiated Care Interventions

Sponsored: Health Applications

Sponsored Session

Chair: Diana Maria Negoescu, University of Minnesota, Minneapolis, MN, 55455, United States, negoescu@umn.edu

1 - Machine Learning Discovery of Longitudinal Patterns of Depression and Suicidal Ideation

Jue Gong, University of Washington, Industrial and Systems Engineering, MEB B14 BOX 352650, Seattle, WA, 98195, United States, gongjue@uw.edu, Gregory E. Simon, Shan Liu

Depression is often accompanied by thoughts of self-harm which are a strong predictor of subsequent suicide attempt and suicide death. We used artificial neural networks to extract latent structures from the trajectory data of depressive symptoms in an on-going treatment population from electronic health record. We discovered correlations between patients' depression symptoms (PHQ-8) and suicidal ideation (the 9th question of PHQ) through cross-correlation analysis. This work paves the way toward the development of personalized depression monitoring and suicide prevention strategies.

2 - Optimal Learning of the Tumor Response Parameters Distribution in Spatiotemporally Integrated Radiotherapy

Ali Ajdari, University of Washington, Seattle, WA, United States, ajdari@uw.edu, Archis Ghate

One of the key assumptions in the linear-quadratic formulation of the radiotherapy problem is that the distribution of uncertainty in tumor-response parameters is known to the treatment planner. Recent advances in imaging techniques however, have brought forth the possibility of relaxing this assumption and using tumor-images acquired over the treatment course to learn patient-specific parameter distributions. Therefore, the goal in this study is to learn the tumor's response while optimally dosing a patient over the treatment course.

3 - Response-adaptive Design of Dose-finding Trials

Amir Nasrollahzadeh, Clemson University, Clemson, SC, United States, snasrol@g.clemson.edu, Amin Khademi

In Clinical trials human participants are assigned to one or more interventions to evaluate the effects of those interventions on health-related outcomes. In a standard dose-finding trial, patients are randomly assigned to predetermined doses such that the number of patients assigned to each dose is roughly equal. Such a design may be inefficient. A better strategy is adaptive design in which modifications are made to dose assignments, while the study is in progress. We consider a response-adaptive dose-finding clinical trial where the decision maker is interested in identifying the optimal dose, and allocation of future patients to doses is based on knowledge gained from previous outcomes

4 - Personalized Prediction of Glaucoma Progression under Different Target Eye Pressure Levels

Pooyan Kazemian, Harvard University, 50 Staniford Street, 9th Floor, Room 930B, Boston, MA, 02114, United States, pooyan.kazemian@mgh.harvard.edu, Mariel Sofia Lavieri, Mark P. Van Oyen, Joshua Stein

Using perimetric and tonometric data from two randomized clinical trials, we developed and validated Kalman filter models for fast-, slow-, and non-progressing patients with glaucoma. Our models identify patient type and generate personalized and dynamically-updated forecasts of glaucoma progression under different target eye pressure levels. This approach can help eye doctors determine an appropriate treatment regimen and tailor care to individual patients.

■ SA07

Medicaid Fraud Detection and Prevention

Sponsored: Health Applications

Sponsored Session

Chair: Elham Torabi, James Madison University, torabiex@jmu.edu

1 - Medicaid Fraud Detection and Prevention: A Systems Approach

Elham Torabi, Assistant Professor, James Madison University, 1933 Buttonwood Ct., Harrisonburg, VA, 22802, United States, torabiex@jmu.edu, Verbus Counts

Medicaid fraud and abuse result in significant waste of resources. Any dollar saved in the Medicaid program can be used in improving access for those who need care. Auditing Medicaid claims and investigating fraudulent activities is time and money consuming. Therefore, what is crucially needed more than ever is mechanisms that prevent fraud. We propose a systems approach for Medicaid fraud inspection and prevention that maximizes the risk of committing fraud for providers serving Medicaid population.

2 - The Lifecycle of Maturity for Organizations to Fight Fraud

Arnie Greenland, Robert H. Smith School of Business, 4342 Van Munching Hall, College Park, MD, 20742, United States, agreenland@rhsmith.umd.edu

Organizations that are faced with the daunting task of detecting, reducing and eventually eliminating fraud differ greatly in their capabilities to succeed in that endeavor. In this paper, the author will propose a natural lifecycle of development that organizations traverse in developing the data and capabilities to improve their ability to effectively fight fraud; and he will offer some examples, appropriately masked. While the paper will focus primarily on the data and organizational requirements, the author will also discuss the key analytical tools, capabilities and skill sets required as part of the organizational development process.

3 - What Indicators Matter for Fraud Identification in Healthcare and to what Extend do they Matter

Didem Egemen, PhD Candidate, Integrity Management Services Inc., Alexandria, VA, United States, didem@gwu.edu, Paulo Macedo, Sewit Araia

Detecting healthcare fraud is not a straightforward process since it requires outlier detection methods for large number of indicator. In this study, we recommend combining different methods, which are Mahalanobis distance, Singular Value Decomposition, and One Class Classification. Our goal is to obtain outliers within healthcare providers by taking into account the different information provided by these three methods and try to reduce the number of false positives. For this purpose, the observations flagged differently by these methods are compared by using Multivariate Lorenz curves and the equivalence of these Lorenz curves are tested by using the Bootstrapping method.

Smart and Connected Health

Sponsored: Health Applications

Sponsored Session

Chair: Muge Capan, Christiana Care Health System, Wilmington, DE, 19801-3082, United States, mcapan@ncsu.edu

1 - Data-Driven Approach to Early Warning System Implementation

Stephen Hoover, MS, Christiana Care Health System, Value Institute, Newark, DE, United States, Stephen.Hoover@ChristianaCare.org

Early warning systems are designed to alert healthcare providers to changes in patient status. Despite good intentions, poor implementations can lead to an increase in alert burden and alarm fatigue. We will discuss the prospective analysis of the impact of early warning systems' on alerts prior to implementation from both an analytical modeling and information technology perspective. Post-implementation results will also be presented.

2 - Signaling Sepsis and Forecasting the Unexpected Transfer to Upgraded Resources in Sepsis

Muge Capan, Associate Director of Health Systems Optimization, Newark, DE, Muge.Capan@ChristianaCare.org, Kristen Miller

Signaling Sepsis, funded by the National Library of Medicine, creates an evidence-based framework to optimize sepsis clinical decision support. One of its quality improvement projects, FUTURE (Forecasting the Unexpected Transfer to Upgraded Resources in sepsis), uses gamification to elicit predicted patient outcomes from healthcare teams, thus enabling patient-level feedback, raising sepsis awareness, and identifying clinicians who best predict patient decompensation.

3 - Computer-aided Multimodal Health Monitoring System with Wearable Microfluidic Sweat Sensors

Daehan Won, Binghamton University, Vestal, NY, United States, dhwon@binghamton.edu

Quantitative, simple, and low-cost analysis of biofluids is essential to prevent and diagnosis variety of health conditions along with the understanding metabolisms of human physiology. Therefore, we introduce a new health-related information monitoring framework; various chemicals in human sweat will be measured and analyzed by a newly designed wearable sensors and the mobile application respectively. Our unified framework will hold great potentials for future applications.

4 - Patient-centered and Personalised Scheduling of Colonoscopy Appointment

Karmel Shehadeh, University of Michigan, Ann Arbor, MI, 48109, United States, ksheha@umich.edu, Amy Cohn

We consider the problem of scheduling colonoscopy patients in an endoscopy unit, recognizing the impact of the quality of the pre-procedure bowel preparation that the patient must undergo in the variability of procedure duration. High-quality preparation can lead to short procedure duration while poor preparation can make the procedure much longer. Combined with patient no-show and arrivals uncertainties, this duration structure contributes to a schedule with many outliers. We use simulation and stochastic programming to analyze and improve the scheduling of colonoscopy patients. Attention is paid to the competing schedule metrics, including patient waiting, provider idle and over times

Minimizing Food Waste

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Dorothee Honhon, University of Texas at Dallas, Richardson, TX, 75080, United States, dorothee.honhon@utdallas.edu

Co-Chair: Xiajun Amy Pan, University of Florida, Gainesville, FL, 32611-7169, United States, amy.pan@warrington.ufl.edu

1 - Package Size and Pricing Decisions with a Bulk Sale Option

Ismail Kirci, University of Texas at Dallas, 800 West Campbell Road, Richardson, TX, 75080, United States, Ismail.Kirci@utdallas.edu, Dorothee Honhon, Alp Muharremoglu

We investigate the package size and pricing decisions of a retailer selling a perishable product to a population of heterogeneous consumers who differ in their valuation of the product. We also study the pricing decision when the retailer sells the product in bulk and compare bulk sale with package sale in terms of retailer's profit and consumers' waste.

2 - Food Distribution and Food Waste in Food for Education Programs

Debjit Roy, Indian Institute of Management, House Number 308, IIM. Ahmedabad, Vastrapur, Ahmedabad, 560078, India, debzitt@gmail.com, Elena Belavina

Mid-day meal schemes are popular government subsidized schemes run in developing economies, which incentivizes children to attend school. What factors can improve the effectiveness of such state-run food distribution schemes? We develop an empirical model to identify the factors and develop a daily demand estimation model for different school categories.

3 - Policies to Minimise Food Waste in Retail Environment

Emel Aktas, Cranfield University, School of Management, Bedfordshire, Cranfield, MK43 0AL, United Kingdom, emel.aktas@cranfield.ac.uk, Akunna Oledinma, Hafize Sahin, Zahir Irani, Amir Sharif, Samsul Huda, Zeynep Topaloglu, Mehran Kamrava

Food retail is one of the largest sectors both in the UK and the US. IGD predicts the UK food and grocery market to reach £200bn over the next five years. Supermarkets sell 60-90% of all fresh fruits and vegetables, with high levels of imported produce. We focus on fresh fruits and vegetables due to their high value and perishability. We build a causal loop of the fresh fruits and vegetables supply chain in Qatar, considering imported and locally grown produce, the demand, and the waste due to inefficient operational processes and consumer behavior. Using the deSolve library in R, we test inventory control policies based on service levels, lot sizes, and demand across a range of fresh produce categories.

4 - Shelf Space Optimization of Perishable Products

Arzum E. Akkas, Boston University, 100 Memorial Drive, 8-11C, Cambridge, MA, 02142, United States, aakkas@bu.edu

In practice, shelf lives within a product category can vary significantly due to product characteristics such as sugar content and pungency levels (e.g. 3 months versus 6 months); yet, shelf life information is not considered when configuring planograms. This paper examines the shelf space allocation problem from the perspective of the relationship between shelf life and expiration.

Operational Issues in Organ Transplants

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Baris Ata, University of Chicago, Chicago, IL, 60637, United States, Baris.Ata@chicagobooth.edu

Co-Chair: Ali Cem Randa, The University of Chicago-Booth School of Business, 5807 South Woodlawn Avenue, Chicago, IL, 60637, United States, randa@chicagobooth.edu

1 - Optimizing Simultaneous-offering Mechanism of Cadaveric Organs

Tinglong Dai, Johns Hopkins University, 100 International Dr, Baltimore, MD, 21202, United States, dai@jhu.edu

In this study, we consider an OPO's problem of determining the optimal batch size of simultaneous offers made to transplantation centers. We model the strategic interaction among transplant centers both within and across batches, generating structural properties and computational insights.

2 - Patient Centered Organ Acceptance Decisions in Kidney Transplant

Sanjay Mehrotra, Northwestern University, Dept of I.E./ M.S.C246 Tech Inst., 2145 Sheridan Road, Evanston, IL, 60208-3119, United States, mehrotra@iems.northwestern.edu

It is not always clear if an offered kidney should be accepted by a patient. We will present results from a patient centered model for accepting an offered kidney that quantifies its benefits using a decision tree. The parameters of the tree are quantified using appropriate statistical models, which will also be presented.

3 - Personalized Wait Time Estimates for Kidney Transplant Offers

Nikolaos Trichakis, Massachusetts Institute of Technology, 100 Main Street, E62-576, Cambridge, MA, 02143, United States, ntrichakis@mit.edu, Chaithanya Bandi, Phebe T. Vayanos

We deal with the problem of estimating the wait time until a patient on the kidney national wait list is offered an organ of desired quality, based on the patient's own characteristics and knowledge of the wait list status. We discuss the unique challenges this estimation problem poses, and argue that existing estimation methods are inadequate. We use a maximum likelihood process to calibrate our method, based only on data that patients observe in practice. Using highly-detailed historical data, we conduct numerical experiments that show our method to significantly outperform existing ones.

4 - An Empirical Analysis of the Effect of Kidney Allocation Policies on Patient Behavior

A. Cem Randa, University of Chicago-Booth School of Business, 5807 S Woodlawn Avenue, Chicago, IL, 60637, United States, randa@chicagobooth.edu, Baris Ata

Organ Procurement and Transplantation Network (OPTN) allocates deceased donor kidneys to the patients based on an additive point system. The patients accumulate points for waiting time and other factors, and organs are offered to patients according to their points. The patients carry no obligation to accept any organ offers. OPTN continuously updates the weight of factors that are affecting contributing to point system, in order to have a more effective allocation policy. However, this effort excludes the patient behavior. We will develop an empirical model to capture the affect of patient behavior in this system and evaluate different counterfactual policies empirically.

Behavioral Operations in Services

Sponsored: Manufacturing & Service Oper Mgmt, Service Operations

Sponsored Session

Chair: Mor Armony, New York University, New York, NY, 10012, United States, marmony@stern.nyu.edu

1 - Experiment of Hospital Unit Admission Decision Behavior under Congestion

Song-Hee Kim, University of Southern California, Bridge Hall 307A, Los Angeles, CA, 90089, United States, songheek@marshall.usc.edu, Jordan Tong

Hospital inpatient units have limited capacity. We explore how physicians make admission decisions in order to understand how to improve this important decision-making process. Specifically, in a controlled laboratory experiment setting, we observe and compare admission decision-making behaviors based on current unit occupancy and severity of arriving patient conditions.

2 - Allocating Inpatient Beds to Off-service Patients: Tradeoffs and Consequences

Hummy Song, The Wharton School, University of Pennsylvania, 560 Jon M. Huntsman Hall, 3730 Walnut Street, Philadelphia, PA, 19104, United States, hummy@wharton.upenn.edu, Anita L. Tucker, Ryan Graue, Sarah Moravick, Julius J. Yang

Given a highly variable patient census at the service level yet a fixed allocation of inpatient beds to services, a significant portion of admitted patients become "off-service" patients. These patients are physically located in a bed that belongs to a different service (e.g., general surgery) while still being cared for by a physician of the service (e.g., cardiac medicine). We examine the tradeoffs and consequences of assigning incoming patients to an off-service bed as opposed to an on-service bed.

3 - The Influence of Customer Emotions in Chat Service Operations

Galit Yom-Tov, Technion - Israel Institute of Technology, Techbion City, Haifa, 32000, Israel, gality@technion.ac.il, Anat Rafaeli, Daniel Altman, Monika Westphal, Michael Natapov, Neta Barkay

We develop a sentiment analysis tool for objective assessment of customer emotions in interactions between service agents and customers. We then explore customer sentiment of real customer-agent interactions in three companies. Our analyses shed light on the presence of positive and negative emotion in customer service, and identify patterns of customer emotion over the course of an interaction. The analyses quantify the link between customer emotions, service quality measures, and agent behaviour. We discuss implications of using automated sentiment analysis tools for the management of service centers.

4 - Strategic Capacity Management in Outpatient Care with No-shows and Rescheduling

Yunchao Xu, New York University, 44 W 4th Street, KMC#8-152, New York, NY, 10012, United States, yxu4@stern.nyu.edu, Mor Armony, Nan Liu

An important factor that determines whether a patient will show up or not for his scheduled appointment is how easy to reschedule if he chooses not to show up. In this talk, we discuss how an outpatient care provider should manage her practice by considering such patient strategic behavior. While this work is motivated by healthcare, our models and insights can also be applied to appointment-based services in other settings.

Empirical Studies of Supply Chains and Production

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Ken Moon, The Wharton School, Philadelphia, PA, 19104, United States, kenmoon@wharton.upenn.edu

1 - Impact of Order-fulfillment Service Levels on Customer Value

Nitish Jain, London Business School, Sussex Place, Regent's Park, London, NW1 4SA, United Kingdom, njain@london.edu, Karan Girotra, Andres I. Musalem

Faster fulfillment of an order is one of the key service components for online retailers. Based on a detailed transactional data on fulfillment performance (actual and promised) and on subsequent purchase patterns, we impute the economic value of faster and timely fulfillment to online retailers.

2 - Estimating the Operational Costs of Pricing

Ioannis Stamatopoulos, University of Texas at Austin, McCombs School of Business, 2110 Speedway B6000, Austin, TX, 78705, United States, yannis.stamos@mccombs.utexas.edu, Soheil Ghili

We leverage detailed data from an international retailer who adopted the electronic shelf label technology to some - but not all - of its stores to identify the underlying operational costs of pricing. We impose a simple model for pricing on that data and use the adoption shock to separate the effects of menu costs on prices from those of changes in demand trends. Our approach can be thought of as a structural implementation of the difference-in-difference identification strategy.

3 - Does Ration Gaming Drive the Bullwhip Effect?

Robert Louis Bray, 830 Hinman Ave, 2s, Evanston, IL, 60202, United States, robertlbray@gmail.com

We model a single-supplier, 73-store supply chain as a dynamic discrete choice problem. We estimate the model with transaction-level data, spanning 3,251 products and 1,370 days. We find two phenomena: ration gaming (strategic inventory hoarding) and the bullwhip effect (the amplification of demand variability along the supply chain). We estimate that the bullwhip effect would be 12% smaller in the counterfactual scenario without ration gaming incentives, confirming the long-standing hypothesis that ration gaming causes the bullwhip effect.

4 - Managing High Worker Turnover: Productivity & Peer Effects on Modern Production Lines

Ken Moon, The Wharton School, Philadelphia, PA, 19104, United States, kenmoon@wharton.upenn.edu

We study the drivers and consequences of high worker turnover in modern, large-scale production processes. Leveraging a uniquely rich dataset drawn from China-based final assembly, testing, and packaging (FATP) facilities producing millions of units of consumer electronic goods per week, we study the role of peer effects in worker turnover and quantify the effects of such turnover on production outcomes. We prescribe policies to both manage turnover and mitigate its effects: in practice, managers lack guidance on the optimal mix of control versus mitigation and often suspect that they may undervalue worker experience.

Health Care, Strategy and Policy

Contributed Session

Chair: Ashlea Milburn, University of Arkansas, Fayetteville, AR, United States, ashlea.bennett@uark.edu

1 - The Impact of Bundled Payment Policy On Health Care Operations

Yiming Fan, University of Science and Technology of China, Hefei, 230026, China, jinkui0612@163.com

Healthcare reimbursements in China have been traditionally based on a fee-for-service (FFS) scheme, leading to the rapid increase in healthcare costs, since FFS provides incentives for high volume of care, rather than efficient care. During the healthcare reform, a new reimbursement scheme, called bundled payment (BP), is introduced in order to remove such incentives. In this paper, we aim to empirically study the impact of BP on the operational performances of a healthcare system using a data set from Anhui New Rural Cooperative Medical System.

2 - Comparative Two Types of the Value Co-creation Model of Long-term Care for the Elder in Taiwan

Ching-Fang Wu, PhD Student, Nation Cheng Kung University, No.1, University Road, Tainan City, Taiwan (R.O.C), 701, Taiwan, r48021037@mail.ncku.edu.tw, Shih-Chieh Fang, Ching-Ying Huang

The purpose of this research is to examine the elderly customers' satisfaction and well-being from customer Effort in Value Co-creation Activities point of view. Besides, we compare two different models of long-term care and try to find which factors affect customer satisfaction and quality of life. This study is a quantitative study conducted by questionnaires. There are two types of Subjects for the questionnaires, one is the elder who lives in the day-care center, the other one is in the hospital-based institution. Three parts of the questionnaires which are demographic and living characteristics, value co-creation activities, satisfaction, and life satisfaction scale.

3 - Multiple Chronic Condition Patterns in Baby Boomers, Generation X, and Early Millennials

Ajit Appari, University of Texas Health Science Center at Houston, 1200 Pressler Street, RAS.W-310, School of Public Health, Houston, TX, 77030, United States, ajit.appari@uth.tmc.edu, Maria Ukhanova, Robert O. Morgan

Multiple chronic conditions (MCC) in working-age adults pose enormous burden to the American economy. Critical gaps exist in our understanding of MCC patterns and their geographic variation among working-age adults. In this study we analyzed claims data on 451,694 individuals, continuously enrolled with a leading insurer in Texas during 2008-2013. Using Exploratory Factor Analysis, we determined five major patterns- Metabolic, Cardiovascular, Musculoskeletal, Liver-Immune Disorder, and Neurologic-Pain. Next, logistic regression was used to identify community socioeconomic factors (zip code) that correlate with MCC risk, adjusting for selection bias using Heckman's approach.

4 - A Study of the 2008 Subprime Mortgage Crisis' Impact on Taiwanese Pregnant Women and Their Children Development by an Epigenetic Approach

Jonathan Tong, PhD Program Student, National Taiwan University, 7F., No. 28, Ln.325, Zhungjing Rd., Taipei, 110, Taiwan, d03323003@ntu.edu.tw

Previous studies show that embryo will change functionally relevant to cellular and physiological phenotypic traits without involving a change in the nucleotide sequence, nor in DNA sequence, when pregnant women endure external/environmental impacts. This study will investigate Taiwanese children born in the period of economic crisis 2008 based an epigenetic approach and see if such changes also include some critical social cognitive capabilities.

5 - A Study of Co-occurrence of Multiple Chronic Conditions using Online Healthcare Forums

Juxihong Julaiti, PhD Student, Penn State University, 445 Waupelani Drive, Apt J1, State College, PA, 16801-4445, United States, jpj5196@psu.edu

In recent years participation in online forums to discuss health related issues is increasing. We study the on-line forums to study the relationship between multiple chronic conditions and resources allocation. We use linear, logistic regression, random forest to derive the relationships. The results indicate that: 1) patients with cancer and depression are more likely to participate in online forums; 2) patients with costly chronic conditions are more likely to use online forums; 3) whether a patient has cardiovascular disease, arthritis are significant variable to predict if the patient will have asthma etc.

6 - Dispensing Medical Countermeasures in Public Health Emergencies via Home Health Agencies and Points of Distribution

Ashlea Bennett Milburn, University of Arkansas, 4207 Bell Engineering Center, Fayetteville, AR, 72701, United States, ashlea.bennett@uark.edu, Anna Hudgeons, Charleen McNeill

A major concern regarding emergency preparedness at the state government level involves the handling and dispensing of the Strategic National Stockpile of medicinal supplies. This research utilizes simulation modeling to determine if using home health agencies (HHAs) in addition to Points of Distribution (PODs) to dispense SNS supplies can provide aid in a more timely fashion than using PODs alone. The comparative effectiveness of the two dispensing methods is demonstrated via a case study of pandemic influenza in Northwest Arkansas.

Analytics and Incentives for Efficient Healthcare Delivery

Sponsored: Manufacturing & Service Oper Mgmt, Healthcare Operations

Sponsored Session

Chair: Hamsa Sridhar Bastani, Stanford University, Stanford, CA, 94305, United States, hsridhar@stanford.edu

1 - Yardstick Competition for Hospital Queues

Nicos Savva, London Business School, London, United Kingdom, nsavva@london.edu, Tolga Tezcan, Ozlem Yildiz

In this paper, we first show that the hospital reimbursement system currently used in practice does not incentivize hospitals to reduce waiting times. We then propose a modification which can achieve socially optimum investment without placing an onerous informational burden on hospital payers.

2 - Misaligned Incentives in Kidney Exchange

Itai Ashlagi, Stanford University, Department of Management Sci. and Engr., Stanford, CA, 94305, United States, iashlagi@stanford.edu

Growth of live-donor kidney exchange has stagnated although an increasing number of transplant centers are facilitating exchanges through large national exchanges, in isolation or in small consortiums with other centers. Using a novel dataset we document significant fragmentation and heterogeneity in participation by centers, an adversely selected and hard to match national exchange pool, and inefficient transplants outside the largest exchange. Using a simple supply and demand model we estimate the inefficiency and in the current market and calculate a rewards scheme that would be implemented by the optimal mechanism.

3 - Exploiting the Natural Exploration in Contextual Bandits

Hamsa Sridhar Bastani, IBM Thomas J. Watson Research Center, Yorktown Heights, NY, United States, hamsab@wharton.upenn.edu, Mohsen Bayati, Khashayar Khosravi

The contextual bandit literature focuses on an exploration-exploitation tradeoff because exploration-free greedy policies may yield poor performance in general. However, greedy policies are desirable when experimentation is costly or unethical (e.g., clinical settings). We posit a sufficient set of additional assumptions under which a greedy policy is asymptotically optimal. Next, we present Greedy-First, a new algorithm that uses observed data to determine whether to follow a greedy policy or to explore. This algorithm is asymptotically optimal without our additional assumptions, and significantly reduces experimentation in simulations.

4 - Dynamic Bandit Approach for Personalized Treatment

Yonatan Mintz, UC Berkeley, San Francisco, CA, United States, ymintz@berkeley.edu, Anil Aswani, Philip Kaminsky, Elena Flowers, Yoshimi Fukuoka

Personalized fitness tracking devices enable the implementation of data driven exercise programs intended to treat sedentary lifestyles. Despite the prevalence of these devices, many individuals have a hard time adhering to the recommended programs since they may be incompatible with an individual's schedule or provide ineffective motivation. In this talk, we address this problem by leveraging the data and infrastructure of mobile fitness tracking devices to personalize exercise programs for participating individuals. We develop a multi-armed bandit approach to adaptively learn each participant's exercise preferences to personalize their exercise programs and increase adherence.

Demand Learning

Sponsored: Manufacturing & Service Oper Mgmt, Supply Chain

Sponsored Session

Chair: Yiangos Papanastasiou, University of California Berkeley, Berkeley, CA, 94720, United Kingdom, yiangos@haas.berkeley.edu

1 - Dynamic Selling Mechanisms for Product Differentiation and Learning

N. Bora Keskin, Duke University, Fuqua School of Business, 100 Fuqua Drive, Durham, NC, 27708-0120, United States, bora.keskin@duke.edu, John R.Birge

We consider a firm that designs a menu of vertically differentiated products for a population of customers with heterogeneous quality sensitivities. The firm faces an uncertainty about production costs. We characterize the structure of the firm's optimal dynamic learning policy and construct simple and practically implementable policies that are near-optimal.

2 - Bayesian Dynamic Learning and Pricing with Strategic Customers

Xi Chen, New York University, 44 W. 4th St, NYU. KMC Room 8-50, New York, NY, 10012, United States, xchen3@stern.nyu.edu, Zizhuo Wang

In this talk, we study such a learning problem when the customer is aware of the seller's policy, and thus may behave strategically when making a purchase decision. We propose a randomized Bayesian policy (RBP), which updates the posterior belief of the customer in each period with a certain probability. We show that the seller can learn the customer type exponentially fast with the RBP even if the customer is strategic, and the regret is bounded by a constant. We also propose policies that achieve asymptotically optimal regrets when only a finite number of price changes is allowed.

3 - Dynamic Pricing with Online Product Reviews

Dongwook Shin, Hong Kong University of Science and Technology, Kowloon, Hong Kong, dwshin@ust.hk
Dongwook Shin, Columbia University, New York, NY, 10027, United States, dwshin@ust.hk, Assaf Zeevi

We investigate how the presence of product reviews affects a dynamic-pricing monopolist who strives to maximize its total expected revenue. To formulate the problem in tractable form, we first study a fluid model, which is a good approximation when the volume of sales is large. In the context of the fluid formulation, the optimal pricing policy can be characterized in a closed-form, which is leveraged to design pricing policies that perform well with respect to the underlying revenue maximization problem. Lastly, we discuss the impact of product reviews on learning when the monopolist operates without knowing the demand function a priori.

4 - A Tutorial on Thompson Sampling

Daniel Russo, Northwestern University, Chicago, IL, United States, dan.joseph.russo@gmail.com

Thompson sampling is an algorithm for online decision problems where actions are taken sequentially in a manner that must balance between exploiting what is known to maximize immediate performance and investing to accumulate new information that may improve future performance. The algorithm addresses a broad range of problems in a computationally efficient manner and is therefore enjoying wide use. I will present selected examples and insights from a recent tutorial on Thompson sampling. The talk will focus on applications in revenue management, and on practical challenges like nonstationarity, prior specification, and the need for approximate posterior inference.

1 - The Need for Speed: Effects of Uncertainty Reduction in Patenting

Mike Horia Teodorescu, Doctoral Candidate, Harvard Business School, Soldiers Field Road, Wyss House, Boston, MA, 02163, United States, miketeod@hbs.edu

How does patent acceleration affect startup growth? Using a novel dataset obtained through a year-long government study, I look at the strategic implications of patent acceleration for startups and venture capital investors. The paper builds on the markets for technology literature. The empirical approach is a differences-in-differences regression to determine the effects of a previously unstudied executive policy change on the entrepreneurship ecosystem. A novel technique based on natural language processing is employed for firm matching.

2 - Multi-dimensional Proximity and Knowledge Networks of Product and Process Innovation

Owais Anwar Golra, Doctoral Researcher, University of Edinburgh, 29 Buccleuch Place, Edinburgh, EH89JS, United Kingdom, S1256783@sms.ed.ac.uk

Informal networks among manufacturing firms play important role in the transfer of knowledge in Industrial clusters. Proximity facilitates networking process, however our understanding is limited about the relationship between proximity dimensions and innovation networks. Particularly, it is unclear, how proximity dimensions shape the knowledge network of product and process innovations? We studied these networks in a textile cluster in Pakistan, and find significant influence of four proximity dimensions, excluding institutional proximity, on the network formation. Notably, the impact of proximity on process innovation network is stronger than the impact on product network.

3 - Strategic Information Technology Alignment, External Knowledge & Innovation Performance: An Empirical Study

Mahmoud Abdullah, PhD Student, Yuan Ze, Zong Li, Taiwan, elakhdary@gmail.com

This study draws on the strategic IT alignment perspective & the knowledge-based view (KBV) to explain the impacts of the alignment between IT strategy and external search activities on firm innovation performance. Since the focus of our study comprise both IT and business strategy. This study is using the key informant approach to collect data from senior IT executives and business strategic planners in the Taiwanese manufacturing firms.

4 - Technical Entrepreneurship in the Large Firm

Eliezer Geisler, Illinois Institute of Technology, Chicago, IL, 60661, United States, geisler@stuart.iit.edu, Giuseppe Turchetti

This paper explores the technical entrepreneurship (or "Intrapreneurship) in the large firm. We review the relevant literature with a focus on: what are the variables which impact the activities and the performance of entrepreneurs in a large firm? What are the barriers and facilitators to technical entrepreneurs as they pursue their endeavors in the large firm? These and similar questions are explored from a theoretical perspective by describing the state of the art in this topic. We explore the streams in the literature which explore these questions and we extract relevant propositions from this literature.

5 - Optimal Duration of Innovation Contests

Sidika Tunc, University College London, Level 38 One Canada Square, Canary Wharf, London, E14 5AA, United Kingdom, sidika.tunc.16@ucl.ac.uk, C.Gizem Korpeoglu, Ersin Korpeoglu

In an innovation contest, an organizer decides on the contest duration and award to elicit solutions to an innovation-related problem from a number of independent agents. Each agent exerts effort to develop her solution by incurring a cost. This cost of effort decreases with the contest duration, and the quality of her solution depends on the agent's uncertainty and productivity. We show that the agent's effort increases with the contest duration, but the organizer limits the contest duration to guarantee agents' participation in the contest. We also show that the optimal contest duration and award increase with the agent's uncertainty and decrease with the agent's productivity.

Markov Decision Processes and Applications

Sponsored: Applied Probability

Sponsored Session

Chair: Daniel F. Silva, Auburn University, Auburn, AL, 36849, United States, silva@auburn.edu

1 - Optimizing the Interaction between Residents and Attending Physicians

Hayriye Ayhan, Georgia Institute of Technology, School of Industrial & Systems Eng, 755 Ferst Dr NW, Atlanta, GA, 30332-0205, United States, hayhan@isye.gatech.edu, Sigrun Andradottir

We analyze how attending physicians should allocate their time between the residents they supervise and their own responsibilities. Under the assumptions that the work of the attending physician can be preempted, and that a holding cost is incurred when residents and patients wait for a conference with the attending physician, we show that there are only two policies that could maximize the long-run average reward. Namely, it is optimal for the attending physician to start having consultations with the residents either when the residents can no longer examine new patients or as soon as there is a patient ready for conference. We then characterize when each of these policies is profitable.

2 - Control Policies for Queueing Systems with Time Windows

Tugce Isik, Clemson University, 112 Summey St. Unit 2, Clemson, SC, 29631, United States, tisik@clemson.edu, Bahar Cavdar

We focus on a queueing system where each job has a preferred time window for service. Every job in the system must be served by the end of the time window, and jobs may need to be outsourced if the capacity is not enough. Both early service and outsourcing are penalized. We show that the cost-optimal policy has a monotone structure and is of threshold-type when there is a single class of jobs. Based on these results, we develop a policy improvement heuristic and evaluate its performance.

3 - Discard or Install: Upgrading in the Presence of Spare Parts Stock

Joni Driessen, j.p.c.driessen@tue.nl, Alan Scheller-Wolf, Joachim Jacob Arts, Geert-Jan Van Houtum

We study how a company should manage an upgrade of a capital-intensive product when they have a number of old items (operating and spare parts) to be replaced by new items. The company must trade off the savings from exploiting the current old inventory versus the superior performance of the new items. We model this problem as a Markov Decision Process, and we decide in each period: (i) to replace any failed item by a new or old item, or not to replace it at all; (ii) and how many old item spare parts to salvage. We prove properties of the optimal policy, and generate insights into a replacement policy in general.

4 - Near-optimal Control of Complex Authentication Systems

Oguz Toragay, Auburn University, 257 S.Gay Street, Dexter Arms A208, Auburn, AL, 36830, United States, ozt0008@auburn.edu, Daniel F.Silva

We consider an authentication system, with several methods available, where requests arrive from users of several classes. The decision maker must dynamically assign each incoming request to a method, with the objective of maximizing security and minimizing latency and cost. We model the problem as a multi-class, parallel queueing system and solve it using MDP. The structure of optimal policies in systems with only one finite-capacity method is known. We use this structure to propose a new heuristic approach to construct near-optimal policies. Numerical experimentation shows that our approach offers near-optimal performance for a wide range of parameters.

Stochastic Networks and Queueing in Applied Probability I

Sponsored: Applied Probability

Sponsored Session

Chair: Harsha Honnappa, Purdue University, West Lafayette, IN, 47906, United States, honnappa@gmail.com

1 - Analysis of Abandonments in Ticket Queues: A Bayesian Approach

Kaan Kuzu, University of Wisconsin-Milwaukee, Sheldon B. Lubar School of Business, P.O. Box 742, Milwaukee, WI, 53201-0742, United States, kuzu@uwm.edu, Refik Soyer

Ticket queues collect interval censored data for customer abandonment. The abandonment of a customer is only realized when the ticket for that customer is called for service and the customer does not show up. Using a modulated Poisson process model as the framework, we develop parametric and semi-parametric models and their Bayesian analysis to predict abandonment counts on any interval. We also explore the impact of covariates such as queue position, number of servers, and day of the week on predicted abandonment counts. The proposed models are implemented on a real ticket queue data set to provide managerial insights on server allocation.

2 - Delay Announcements with Customer Response

Rouba Ibrahim, University College London, MS&I Department, UCL, Gower Street, London, WC1E 6BT, United Kingdom, rouba.ibrahim@ucl.ac.uk, Mor Armony, Achal Bassamboo

We study the accuracy of the last-to-enter-service (LES) delay announcement in service systems where customers respond to the announcements.

3 - Optimal Production Rates for Large Scale Systems under Time-varying Demand

Chihoon Lee, Stevens Institute of Technology, Hoboken, NJ, 07030, United States, clee4@stevens.edu, Yunan Liu, Xin Liu, Ling Zhang

Continuous manufacturing has received much of recent attention both in academia and industry. We consider production systems with a time-varying demand, perishable inventory, and abandonment of backorders. The system incurs inventory-related costs of holding and perishment, and demand-related costs of waiting and abandonment. We study the finite-time production planning to minimize the sum of the demand and production related costs. We use fluid models to derive time-dependent production rates that are asymptotically optimal as the system scale increases; specifically, we prove a limit theorem to verify the asymptotic effectiveness of the optimal solution.

4 - Club Queues

Jamol Pender, Cornell University, 206 Rhodes Hall, Ithaca, NY, 14850, United States, jjp274@cornell.edu, Andrew Daw

In many stochastic systems, the arrival process may exhibit clustering behavior. This behavior is typically seen in financial markets and is also seen at nightclubs in New York City and Las Vegas. Using martingales, we derive exact moments and moment generating function for an infinite server queue that is driven by a Hawkes process and has phase type service. We show via simulation that the moments well approximate the simulated moments. As an application, we apply our results to study a queueing process described as the Club queue. As a result, we derive the optimal rate at which a bouncer should allow clubgoers to go inside the club using optimal control theory with the mean of our Hawkes queueing process.

Disruption Risk Management

Sponsored: Manufacturing & Service Oper Mgmt, iFORM

Sponsored Session

Chair: Nitin Bakshi, University of Utah, Salt Lake City, UT, 84112-8939, United States, nitin.bakshi@eccles.utah.edu

1 - Disruption Risk and Optimal Sourcing in Multitier Supply Networks

Dan Andrei Iancu, Stanford University, 655 Knight Way, Stanford, CA, 94107, United States, daniancu@stanford.edu, Robert Swinney

We study sourcing in a supply chain with three levels: a buyer, tier 1 suppliers, and tier 2 suppliers prone to disruption from, e.g., natural disasters. The buyer may not directly dictate which tier 2 suppliers are used but may influence the sourcing decisions of tier 1 suppliers via contract parameters. We show that the buyer's optimal strategy depends critically on the degree of overlap in the supply chain: if tier 1 suppliers share tier 2 suppliers, resulting in a "diamond-shaped" supply chain, the buyer relies less on direct mitigation (procuring excess inventory and multisourcing in tier 1) and more on indirect mitigation (inducing tier 1 suppliers to mitigate disruption risk).

2 - Risky Suppliers or Risky Supply Chains

Yixin Wang, University of Michigan, 701 Tappan Street R4323, Ross School of Business, Ann Arbor, MI, 48104, United States, iriswang@umich.edu, Jun Li, Ravi Anupindi

Past research has focused on the interaction between a buyer and its immediate suppliers. Propagation of risks, however, can extend beyond a firm's direct linkages. The sub-tier supply network structure may also aid or prevent such risk propagation. This paper focuses on a particular sub-tier network structure, viz., sharing of tier-2 suppliers, empirically studies its prevalence, and quantifies its association with the financial risk of tier-0 firms in the high-tech industry.

3 - Mitigating Disruption Cascades in Assembly Networks

Shyam Mohan, London Business School, Baker Street, PhD Office, London, NW1 4SA, United Kingdom, smohan@london.edu, Nitin Bakshi

The losses from supply chain disruptions arise not only due to direct damage at firms (from idiosyncratic disruptions), but also from the interruption of normal operations because of lack of supply; that is, due to disruption cascades from suppliers in the adjacent tiers and beyond. To curtail such losses, firms can make ex-ante investments in mitigation and recovery strategies. In this paper, we examine a game-theoretic framework to characterize equilibrium investments and payoffs of firms in an assembly network. We show that limited information about the network structure suffices for firms to make optimal investments.

4 - Learning (or not) from Precursors to Disasters

Heikki Peura, Imperial College London, London, United Kingdom, h.peura@imperial.ac.uk, Nitin Bakshi

Disasters are invariably preceded by more frequent precursor events. These events embed valuable information about the root cause of a disaster, and thereby facilitate risk assessment. But to learn from precursors, a managing firm typically relies on the reports of a contractor, who is often also responsible for mitigating the occurrence of these incidents. We show how firms may fail to learn from precursor events due to the resulting intertwined problems of moral hazard (on risk mitigation) and hidden information (on reporting precursors).

Management of Innovation, Technology and Services

Sponsored: Technology, Innovation Management & Entrepreneurship

Sponsored Session

Chair: Juliana Hsuan, Copenhagen Business School, jh.om@cbs.dk

1 - The Impact on the Pricing of Hotel Rooms using New Technology

Eric Bentzen, Copenhagen Business School, Frederiksberg, Denmark, eb.om@cbs.dk

In this paper we will investigate the dynamic pricing of hotel rooms among customers who use online booking apps. Online booking apps allow you to start making reservations directly using apps on smartphones, ipads, and PCs. The empirical results based on data from 2016-2017 show that the pricing structure depends on the type of customer, time of the year, number of hotels and the number of days in advance a hotel is booked.

2 - Nescience: A Key Ingredient to Managing Innovation

Nitin Mayande, Nike, 6249 NE Carillion Drive, Unit 201, Hillsboro, OR, 97124-8097, United States, nitin.mayande@nike.com, Charles M. Weber, Rainer P. Hasenauer

Aristotle's dictum scio nescio (I know that I don't know) may serve as a source of enhanced performance for organizations. Awareness of nescience sets the direction for further inquiry, as managers tend to move in the direction that they believe will reduce nescience most. However, nescience is difficult to quantify, so, to date, managers have primarily relied on intuition. Observing business analytics practices in three industries—semiconductor manufacturing, medical diagnostics and social media analytics—suggests that nescience can be measured using metrics from information theory.

3 - Directionality in Online Social Networks
Nitin Mayande, Nike, 6249 NE Carillion Drive, Unit 201, Hillsboro, OR, 97124-8097, United States, nitin.mayande@nike.com, Charles M. Weber

Relationships within social networks have been treated as reciprocal relationships in most cases within extant theory (Burt, 1976, Burt and Doreian, 1982, Granovetter, 1973). There have been a few studies in which directionality has been taken as a factor (Allen, 1977, Roger, 1983). However, the impact of considering directionality in a social network has not been studied in detail. In order to understand the impact of considering directionality, this study bifurcates the process of interaction (reciprocal) into consumption phase and propagation phase. The early results show that within a directed network, the consumption and propagations phases can behave very differently from each other.

4 - Measuring the Modularization of Industrial Service Processes
Juliana Hsuan, Professor, Copenhagen Business School, Solbjerg Plads 3 B.5.27, Frederiksberg, DK-2000, Denmark, jh.om@cbs.dk, Thomas Frandsen

We examine how complex industrial service processes can be measured through the lenses of service modularization strategies. The measured degree of modularity sharpened our understanding of the role of standardization and component reuse on creating architecture flexibility. It also provided a foundation for analyzing the short- and long-term impact of service innovation.

Appointment Scheduling with No-Show and Unpunctual Patients

Invited: InvitedHealthcare Systems and Informatics

Invited Session

Chair: Paul Brooks, Virginia Commonwealth University, Richmond, VA, 23284, United States, jpbrooks@vcu.edu

1 - Multimodularity in the Stochastic Appointment Scheduling Problem with Discrete Arrival EPOCHS
Christos Zacharias, Assistant Professor, University of Miami, 5250 University Drive, Room 401 K/E, Coral Gables, FL, 33146, United States, czacharias@bus.miami.edu, Tallys Yunes

We address the problem of designing appointment scheduling strategies that account for patients' no-show behavior, non-punctuality, emergency walk-ins and general stochastic service times. We demonstrate that the optimal scheduling strategy minimizes a multimodular function and how to perform local search in polynomial time.

2 - Overbooking Rules in Outpatient Clinics when Considering No-shows and Cancellations
Shannon Harris, The Ohio State University, 1005 W. 5th Avenue, Unit 535, Columbus, OH, 43212-3085, United States, harris.2572@osu.edu, Jerrold H. May, Luis G. Vargas

In this paper we propose rules for overbooking patients in an outpatient clinic over a scheduling horizon. We incorporate direct and indirect waiting time, overtime, no-shows, and cancellations to inform the overbooking decisions. Rules for overbooking up to two patients per day, when making a pair-wise decision between two days, are expressed analytically. Numerical solutions for overbooking greater than two patients are provided. The effect of no-shows and cancellations on overbooking is also discussed.

3 - Predictive Analysis of Missed Medical Appointments/no-shows
Asil Oztekin, University of Massachusetts Lowell, 333 1st Street, Unit 210, Lowell, MA, 01850-2580, United States, asil_oztekin@uml.edu

Patients not showing up for clinical appointments (No-Shows) is a huge drain on the healthcare resources and costs several millions nationwide. The dataset has 300,000 medical appointment records and 15 variables. The purpose of this analysis is to predict whether a patient would show up for his appointment or not and to investigate why patients miss their scheduled appointments. The CRISP-DM approach is adopted to provide a framework to ensure potentially-useful deliverables for medical practice. This study aims to recognize if there are any key patterns to this type of "no-show" behavior.

Economic Models in Revenue Management

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Dan Zhang, University of Colorado, Boulder, CO, 80309, United States, dan.zhang@colorado.edu

Co-Chair: Xiao Huang, John Molson School of Business, Concordia University, Montreal, QC, H3G 1M8, Canada, xiao.huang.2009@marshall.usc.edu

1 - An Analytical and Empirical Look at Hotel Standby Upgrades
Pelin Pekgun, University of South Carolina, Columbia, SC, 29208, United States, Pelin.Pekgun@moore.sc.edu, Ovunc Yilmaz, Mark Ferguson, Guangzhi Shang

In this research, we first develop an analytical model of premium room and standby upgrade pricing under an uncertain market size, and examine how and when standby upgrades can provide additional revenue for a hotel. We then follow up with an empirical study, utilizing a hotel chain's booking and standby upgrades data, to understand the decision-making process of a guest facing standby upgrades, and the extent of the strategic guest behavior. Our findings provide guidance for hoteliers to use standby upgrade programs more effectively based on the hotel type and guest behavior.

2 - Created Unequal Bundling with Crowdsourced Products
Lu Wang, University of Toronto, Rotman School of Management, 105 St. George Street, Toronto, ON, M5S.3E6, Canada, lu.wang12@rotman.utoronto.ca, Ming Hu

As consumer buying habits are trending toward more simple and hassle-free experiences, more and more companies are jumping into the innovative business model of subscription services. Subscription providers such as Spotify, Netflix and OneGo (an all-you-can-fly subscription service provider) crowdsource products/services from many vendors and bundle them for the price of one. The collected subscription fees for the bundle then are allocated according to the realized contributions by each crowdsourced product. We examine the incentive compatibility of different parties under various bundling strategies.

3 - Service Product Design and Consumer Refund Policies
Xiao Huang, John Molson School of Business, Concordia University, 1455 De Maisonneuve Blvd. West, Montreal, QC, H3G 1M8, Canada, xiao.huang@concordia.ca, Dan Zhang

We consider a firm serving heterogeneous consumers with imperfect signals on their quality valuations. The firm can customize offering qualities, customize refund rates, or customize both. We show that a wide range of menu can be optimal depending on valuation heterogeneity and signal quality. Even with the liberty of customization, the firm may still offer standard quality or refund policy. Interestingly, aggregate consumer surplus does not increase with generous refund, and the seller may not have incentive to improve the signal quality even if it is cost-less.

4 - Managing Hotel Cancellations
Dan Zhang, University of Colorado, Leeds School of Business, University of Colorado, Boulder, CO, 80309, United States, dan.zhang@colorado.edu, Xiao Huang, Jian Wang

We use hotel transaction data to investigate customer cancellation behavior. We show that cancellation rates are highly correlated with booking rates and the posted rates at the time of cancellation. We discuss the implications of our findings on hotel pricing policies.

Using Field Experiments to Optimize Operations

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Spyros Zoumpoulis, Paris, 75005, France, spyros.zoumpoulis@insead.edu

Co-Chair: Ruomeng Cui, Bloomington, IN, 47401-7739, United States, cuir@indiana.edu

1 - The Value of Fit Information in Online Retail: Evidence from a Randomized Field Experiment

Santiago Gallino, Dartmouth College, 100 Tuck Hall, Hanover, NH, 03755, United States, santiago.gallino@tuck.dartmouth.edu, Antonio Moreno Garcia

Virtual fitting-room technologies can provide information about how a product fits a particular customer in a novel way and mitigate the stress that the existing information gap generates in the retailers supply chain. By implementing a series of randomized field experiments, we study the value of virtual fit information in online retail.

2 - Mobile Messaging for Offline Group Formation in Prosocial Activities: A Large Field Experiment

Tianshu Sun, University of Southern California, 3670 Trousdale Parkway, Bridge Hall, BR.I.310B, Los Angeles, CA, 90089, United States, tianshus@marshall.usc.edu, Guodong (Gordon) Gao, Ginger Zhe Jin

We study whether and how charities can use mobile messaging to leverage individuals' social ties and encourage offline prosocial activities in groups. In particular, we run a randomized field experiment with 80,000 blood donors and study how behavioral interventions and economic rewards motivate offline group formation. We find that commonly used interventions like reminder message and individual reward are ineffective in motivating group donation. In contrast, a newly proposed group reward is effective, and tends to attract different types of donors. Structural estimation further reveals mechanisms, and suggests group reward is 4 times more cost-effective than rewarding individual donors.

3 - Field Experiments with Restaurant Table-top Technology: How Do We Select What We Eat?

Dmitry Sumkin, INSEAD, Rue de Montebelo 10, Fontainebleau, 77300, France, dmitry.sumkin@insead.edu, Serguei Netessine

We conduct field experiments using tablet-based restaurant menus which allow us to randomize location of dishes and design of the menu. We identify menu designs that allow restaurants to increase sales by exploiting customer search patterns using table-top technology.

4 - Optimizing Promotion Targeting using Field Experiments

Spyros Zoumpoulis, INSEAD, Boulevard de Constance, Fontainebleau, 77305, France, spyros.zoumpoulis@insead.edu, Theodoros Evgeniou, Duncan I.Simester, Artem Timoshenko

We investigate how firms can use the results of field experiments to optimize marketing decisions, training and testing our policies on a series of two large scale field experiments. We discuss how to optimize the targeting of promotions, how to efficiently evaluate targeting policies, and how to optimally target non-responders (i.e., people who did not respond to past promotions) using the timing of the responses of responders.

Ride-sharing Platforms 2

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Ozan Candogan, University of Chicago, Chicago, IL, 27708, United States, ozan.candogan@chicagobooth.edu

Co-Chair: Daniela Saban, Stanford GSB, Palo Alto, CA, 94304, United States, dsaban@stanford.edu

1 - Surge Pricing and its Spatial Supply Response

Francisco Castro, Columbia University, New York, NY, United States, fcastro19@gsb.columbia.edu, Omar Besbes, Ilan Lobel

Our work seeks to understand the structure of ride-sharing platforms' pricing strategies in a geographical network with self-interested supply agents. We anchor our analysis on a Stackelberg game. The platform sets prices at every node and drivers react by choosing whether to relocate to different nodes. We establish that an equilibrium for the drivers' game always exists, and we give structural properties of this equilibrium. Surprisingly, to give the "right" incentives to drivers, the platform may need to set prices higher than those that would balance supply and demand. Our results show how flexible supply impacts the optimal pricing policy and how supply incentive constraints shape it.

2 - On-demand Service Platforms

Terry Taylor, University of California Berkeley, 545 Student Services #1900, 2220 Piedmont Avenue, Berkley, CA, 94720, United States, taylor@haas.berkeley.edu

An on-demand service platform (e.g., Uber, Instacart) connects waiting-time sensitive customers with independent service providers. This paper characterizes how two defining features of an on-demand service platform—congestion-driven delay and service provider independence—impact the platform's optimal per-service price and wage.

3 - Pricing and Optimization in Shared Vehicle Systems

Siddhartha Banerjee, Cornell University, 229 Rhodes Hall, Ithaca, NY, 14853, United States, sbanerjee@cornell.edu, Daniel Freund, Thodoris Lykouris

We develop a framework for optimizing shared-vehicle systems, modeled using closed queueing networks. Our approach gives the first efficient algorithms with rigorous guarantees for several common demand-supply balancing controls, including pricing, rebalancing and matching, in the process simplifying and extending several recent results. Moreover, our framework, which is based on a novel convex relaxation coupled with a new infinite-projection and pullback technique, may prove useful for proving approximation bounds in other settings.

4 - Spatial Pricing of Taxi Rides

Nasser Barjesteh, University of Chicago, 5242 S Kenwood Avenue, Apt 2, Chicago, IL, 60615, United States, barjesteh@chicagobooth.edu, Baris Ata, Sunil Kumar

We study the pricing of taxi rides based on their pickup location. We introduce a structural model that captures the Spatial and inter-temporal variations in demand and the distribution of the destinations of the customers, the distances between locations, and the strategic relocations of the taxis. The goal is to use the model with the estimated parameters to find the spatial pricing scheme that maximizes the consumer surplus.

Innovation, Product, and Project Management

Invited: New Product Development

Invited Session

Chair: Morvarid Rahmani, Georgia Institute of Technology, Atlanta, GA, 30308-1149, United States, morvarid.rahmani@scheller.gatech.edu

1 - Procurement Contracting under Product Recall Risk

Yue Zhang, Duke University, 5507 Butterfly Lane, Apt 207, Durham, NC, 27707, United States, yueyue.zhang@duke.edu, Lauren Xiaoyuan Lu, Jayashankar M.Swaminathan, Gang Wang

Managing product quality and mitigating the financial impact of product recalls pose great challenges to manufacturers due to demand uncertainty and non-contractibility of suppliers' quality effort. To understand the interdependence of supply chain quantity and quality decisions, we develop a procurement contractual framework under both demand and recall risks. We consider a model in which a manufacturer outsources to a supplier the production of a component, which is subject to potential quality failure leading to a product recall. We analyze two settings: a pull system in which the supplier makes the quantity decision and a push system in which the manufacturer makes the quantity decision.

2 - Optimal Contracts in Decentralized Projects

Theodore D. Klastorin, University of Washington, ISOM.Department, Box 353226, Seattle, WA, 98195-3226, United States, tedk@u.washington.edu, Michael R.Wagner

We consider a serial stochastic decentralized project where a client subcontracts the work to an independent contractor. Using a Stackelberg game, we analyze several different types of contracts including incentive, fixed price, and cost plus contracts. We show that certain types of contracts maximize the expected client profit and derive conditions that define the optimal parameters for these contracts.

3 - Archetypes of Entrepreneurship: From Ideas to Products to Funding
Hyunwoo Park, The Ohio State University, Columbus, OH, 43210, United States, park.2706@osu.edu, Asifur Mehedi, Aleksi Aaltonen

We analyze a series of interviews with entrepreneurs using text mining to extract representative features. We focus on identifying different pathways of how entrepreneurs develop ideas into viable products or services. Since different products and services have different funding requirements, we further investigate the relationship between the idea-product pathways and funding types and amount by augmenting our sample with startup funding data.

4 - Incentives and Competition in Innovation Contests with Public Submissions: Can "Star" Power Help or Hurt Competition?
Anant Mishra, George Mason University, Fairfax, VA, United States, amishra6@gmu.edu, Jesse Bockstedt, Cheryl Druehl

Innovation contests allow firms to harness specialized skills of participants with diverse backgrounds for solving challenging business problems. We use detailed data on contest and contestant characteristics from a popular online logo-design contest platform with public submissions to examine the role of incentives on the competitive environment of contests.

Applications and Innovations in DEA

Invited: Data Envelopment Analysis

Invited Session

Chair: Andrew L. Johnson, Texas A&M University, 3131 TAMU, 4033 Emerging Technologies Bldg, College Station, TX, 77843-3131, United States, ajohnson@tamu.edu

1 - Robust Benchmarking and Efficiency Estimation using Quantiledea (QDEA): Methodology and Statistical Properties
Joseph Atwood, Montana State University, Bozeman, MT, United States, jatwood@montana.edu, Saleem Shaik

LP DEA models can estimate efficiency metrics but suffer from sensitivity to outliers and data noise. Quantile-DEA (qDEA) enables the analyst to use LP while allowing up to q-percent of data points to lie external to the efficiency hull. Procedures utilized in qDEA are applicable to a broader class of "relaxed constraint" LP problems where the analyst wishes to allow up to a proportion of endogenously identified constraints to be violated. We present the theory of relaxed constraint LP models, the qDEA model, the statistical properties of qDEA estimators, and examples where qDEA is used to address data outliers and obtain quantile performance benchmarks.

2 - Nutrient Profiling using Data Envelopment Analysis
Thomas Raymond Sexton, Professor, Stony Brook University, 5 Linden Lane, Farmingville, NY, 11738-1154, United States, Thomas.Sexton@StonyBrook.edu, Christine Pitocco

Nutrient profiling models summarize the complex array of nutritional data associated with a food item to help consumers make better food purchasing decisions. Many models rely on somewhat arbitrary thresholds that change over time. We use Data Envelopment Analysis to develop a novel and highly flexible nutrient profiling model that requires no thresholds. We illustrate the model on purported "superfoods."

3 - Beyond DEA: How What We Learned from DEA Can Be Used in Analytics
Jose H. Dula, Virginia Commonwealth University, Richmond, VA, 23284, United States, jdula@vcu.edu

Much of today's big data is non-parametric. The concepts and tools used in DEA can be adapted and extended to many aspects of the analytics of such data. Familiarity with DEA means understanding sophisticated optimization duality relations widely used in computational geometry. DEA algorithms can be applied directly to all sorts of data to extract interesting information. The additive model in DEA involves the L1 norm, an intensely explored norm in analytics because of its desirable robustness properties. In this talk we discuss how knowledge of DEA can prepare researchers to make contributions in big data analytics.

4 - Lost Economies of Scope and Merger Gains in Norwegian Electricity Industry
Ørjan Myland, Inland Norway University of Applied Sciences, Lillehammer, Norway, Orjan.Mydland@inn.no

In 2016, the Norwegian Parliament amended the Energy Act, with changes taking effect from 2019. The amended legislation will introduce strict separation of all generation- and distribution companies within the electricity industry in Norway. Economies of scope studies from Norway shows evidence of large economies of scope. Further, the companies in the industry could utilize the economies of scale potential if they would merge. In this paper, I perform merger analysis to investigate best- and worst scenario outcomes regarding the cost effects on the industry from the amendments in the Norwegian Energy act.

Market Design

Invited: Auctions

Invited Session

Chair: Martin Bichler, Technische Universitat Munchen, Munich, 85748, Germany, bichler@in.tum.de

1 - Core-Selecting Auctions in the Laboratory
Marion Ott, RWTH Aachen University, Templergraben 64/V, Aachen, 52062, Germany, marion.ott@rwth-aachen.de, Alexander Heczko, Thomas Kittsteiner

We experimentally analyze core-selecting auctions (CSA) and find that they perform better than Vickrey auctions. The proportions of efficient allocations are similar in both types of auctions, but the proportions of stable (core) allocations and the revenue are higher in the CSA. We observe this for two different informational setups, one in which theory predicts the better performance of the CSA and one in which it does not. We trace the causes of the performance differences back to patterns in bids and find that bidders in the CSA react to incentives to deviate from reporting truthfully in the predicted direction, though less pronounced than predicted.

2 - The Value of Sharing Intermittent Spectrum
Rakesh Vinay Vohra, University of Pennsylvania, Economics Department, 3718 Locust Walk, Philadelphia, PA, 19104, United States, rvohra@sas.upenn.edu, Randall Berry, Micheal Honig, Thanh Nguyen, Vijay Subramanian

Recent initiatives by regulatory agencies to increase spectrum resources available for broadband access include rules for sharing spectrum with high-priority incumbents. We study a model in which wireless Service Providers (SPs) charge for access to their own exclusive-use (licensed) band along with access to an additional shared band. The shared band is intermittently available with some probability, due to incumbent activity, and when unavailable, any traffic carried on that band must be shifted to licensed bands.

3 - On the Design of Combinatorial Exchanges
Martin Bichler, Technische Universitat Munchen, Department of Informatics, Boltzmannstr. 3, Munich, 85748, Germany, bichler@in.tum.de

Linear and anonymous competitive equilibrium prices are desirable in multi-item auctions, but unfortunately they do not always exist in non-convex markets. We discuss the market design for a large-scale combinatorial exchange for fishery access rights. The specifics of the allocation problem lead to different ways on how allocation and payments are computed. We analyze trade-offs of different payment rules relevant to an auction designer. Similar market design problems can be found in other parts of the world and other application domains.

4 - Reducing Congestion through Information Design
Sanmay Das, Washington University in St. Louis, Dept. of Computer Science & Engg., One Brookings Dr, CB 1045, Saint Louis, MO, 63130, United States, sanmay@wustl.edu, Emir Kamenica, Renee Mirka

We consider the problem of designing information structures in games of uncertain congestion, like road traffic networks where the level of traffic is unknown. Using the framework of Bayesian persuasion, we show that we can devise signal structures that mitigate congestion and improve social welfare.

Methods and Models for Big Network Data

Sponsored: Artificial Intelligence

Sponsored Session

Chair: Bin Zhang, PhD, University of Arizona, Tucson, AZ, 85721, United States, binzhang@arizona.edu

1 - When will a Repost Cascade Settle Down?
Chi Chen, Tsinghua University, Beijing, China, chenchi14@mails.tsinghua.edu.cn

Repost cascades play a critical role in information diffusion on social media. Substantial previous work has studied various aspects of repost cascades such as growth, burst and recur, however, when a repost cascade will settle down remains to be an open problem. Existing models cannot be directly applied to solve the problem because of sensitiveness of feature based models and assumption of point process based models. In this paper, we propose a novel definition "settling time" and develop a model to get rid of the restriction in previous studies. We conduct experiments on Sina Weibo dataset whose results show that our model achieves over 10% performance gain than the previous approaches.

2 - Estimating External Motivating Factors in Interorganizational Social Media: Peer Effects and Organizational Influences
Bin Zhang, Assistant Professor, University of Arizona, 1130 E. Helen St, Rm 430Z, Tucson, AZ, 85721, United States, binzhang@arizona.edu, Kexin Zhao, Xue Bai

Interorganizational social media (IOSM) enable professionals belonging to different organizations to share knowledge online. Knowledge sharing requires social interactions within and beyond the community boundary. Thus influences from external entities likely play an important role in encouraging individuals' participation. In this research, we study external motivating factors generated from peer effects and organizations. We apply a novel econometric identification method to analyze a unique dataset collected from an IOSM. We find that external motivating factors from peers and organizations are influential in determining community participation.

3 - Are Electronic Cigarettes a Safer Substitute for Cigarettes for Asthma Patients a Network Based Research
Wenli Zhang, University of Arizona, Tucson, AZ, United States, wenlizhang@email.arizona.edu, Sudha Ram

Asthma affects millions of US adults. Among all the asthma triggers, one of the biggest risk factors is smoking. However, smoking is one of the most difficult addictions to break. It is believed that the use of Electronic Nicotine Delivery Systems (ENDS) may be considered as a low risk substitute for tobacco use for asthma patients. Studies show that people exposed to an ENDS post on social media may be more easily persuaded if the message is from credible sources (e.g., friends or reliable news media), which may have influence on the adoption of ENDS. The research objective of this study is to explore the key conversations and the propagation of ENDS usage among asthma users on social media.

4 - A Model-free Solver for Arbitrary Graph Problems: Predicting Solutions with Deep Learning
Stefan Feuerriegel, University of Freiburg, Platz der alten Synagoge, Freiburg, 79098, Germany, stefan.feuerriegel@is.uni-freiburg.de, Nil-Jana Akpinar

Graph problems require extensive manual effort due to the mathematical derivation of exact solvers or heuristics. As an alternative, we propose a deep learning methodology that can approximate solutions without the need for a mathematical model of the problem. Our innovative approach merely requires problem-solution pairs, based on which it then learns the underlying mechanism in order to solve the problem. The key is here a memory network for making predictions from arbitrary data structures. This work studies its computational performance and derives bounds.

Nicholson Student Paper Competition I

Invited: Nicholson Student Paper Prize

Invited Session

Chair: Hayriye Ayhan, Georgia Institute of Technology, School of Industrial & Systems Eng, 755 Ferst Dr NW, Atlanta, GA, 30332-0205, United States, hayhan@isye.gatech.edu

Co-Chair: Cole Smith, Clemson University, 110 Freeman Hall, Clemson, SC, 29634, United States, jcsmith@clemson.edu

1 - Dynamic Matching for Real-time Ridesharing
Erhun Ozkan, University of Southern California, Los Angeles, CA, United States, erhunozkan@gmail.com

In a ridesharing system such as Uber or Lyft, arriving customers must be matched with available drivers. We propose to base the matching decisions on the solution to a continuous linear program (CLP) that accounts for (i) the differing arrival rates of customers and drivers in areas of the city, (ii) how long customers are willing to wait for driver pick-up, and (iii) the time-varying nature of all the aforementioned parameters.

2 - Tractable Distributionally Robust Optimization with Data
Zhi Chen, National University of Singapore, Singapore, chenzhi.james@gmail.com

We present a framework for distributionally robust optimization that could encompass a variety of statistical information including constraints on expectation, conditional expectation, and disjoint confidence sets with uncertain probabilities defined by phi-divergence. We also show that the Wasserstein-based ambiguity set has an equivalent formulation via our ambiguity set, which enables us to tractably approximate a Wasserstein-based distributionally robust optimization problem with recourse.

3 - On Deterministic Reformulations of Distributionally Robust Joint Chance Constrained Optimization
Weijun Xie, Georgia Institute of Technology, Atlanta, GA, wxie33@gatech.edu

A joint chance constrained optimization problem (CCP) involves uncertain constraints that are jointly required to be satisfied with probability exceeding a prespecified threshold. In a distributionally robust joint CCP (DRCCP), the joint chance constraint is required to hold for all probability distributions of the stochastic parameters from a given ambiguity set. We consider DRCCP involving convex nonlinear uncertain constraints and an ambiguity set specified by convex moment constraints.

4 - Multi-agent Online Learning under Imperfect Information:Algorithms, Theory and Applications
Zhengyuan Zhou, Stanford University, Stanford, CA, zyzhou@stanford.edu

We consider multi-agent online learning under imperfect information, where the reward structures of agents are given by a general continuous game. After introducing a general equilibrium stability notion for continuous games, we examine the online mirror descent (OMD) algorithm and show that its last iterate converges to variationally stable Nash equilibria under certain assumptions. We also propose a delayed mirror descent algorithm that relies on the repeated leveraging of past information.

Drone Delivery Systems – I

Invited: Invited Drone Delivery Systems

Invited Session

Chair: James F. Campbell, University of Missouri-St Louis, Saint Louis, MO, 63121-4499, United States, campbell@umsl.edu

1 - A Branch and Bound Approach to the TSP with Drone and Related Heuristics
Stefan Poikonen, PhD Candidate, University of Maryland-College Park, 3406 Tulane Dr., Apt. 22, Hyattsville, MD, 20783, United States, spoikone@math.umd.edu, Bruce L.Golden

The traveling salesman problem with a drone (TSP-D) is a hybrid truck and drone model of delivery. A drone may ride atop a truck. Trucks may deliver packages directly. Alternatively, the drone may carry a package from the truck to a customer then return to the top of the truck to swap batteries. This system benefits from the drone's use of the crow-fly metric and parallelization of work, yet mitigates concerns about limited drone range. Computational results, both exact and heuristic, will be shown. We greatly expand the size of problems that may be solved optimally. Comparisons to other solution methods in the literature will be made.

2 - Optimization of Parcel Delivery with a Truck and Drones Combination

Alice E. Smith, Auburn University, 3301 Shelby Center, Dept of Industrial/Sys Engineering, Auburn, AL, 36849, United States, smithae@auburn.edu, Mehmet Gulsen, Chase Murray

The use of drones in parcel delivery has the potential to lower delivery cost and shorten delivery times. Deploying multiple drones in parcel delivery will further speed-up the process, but this brings new challenges in terms of synchronizing the schedules of the drones and the truck. This research presents an operational framework of a multiple drone - truck integrated delivery system. Realistic technical constraints for the drones such as payload capacity and endurance limit are taken into consideration. With the objective of minimizing total delivery time, the routes for each drone and the truck are determined using an integrated optimization approach.

3 - Delivery with Trucks and Drones

James F. Campbell, University of Missouri-St Louis, College of Bus. Administration, One University Boulevard, Saint Louis, MO, 63121-4499, United States, campbell@umsl.edu

Delivery drones (unmanned vehicles) provide a new opportunity for delivery of small packages. The presentation considers continuous approximation models for three delivery options from a depot: single-stop drone trips, multi-stop truck tours, and multi-stop hybrid truck-drone tours where drones are launched from and return to trucks. Different tour time limits allow high service levels to be modeled and fixed costs for depots allow deign of multi-depot delivery systems with drones.

1 - Modeling Crew Itineraries and Delays in the National Air Transportation System

Keji Wei, Dartmouth College, Hanover, NH, United States, keiji.wei.th@dartmouth.edu, Vikrant Naze

We propose, optimize and validate a methodological framework for estimating the extent of the crew-propagated delays and disruptions (CPDD). We identify the factors that influence the extent of the CPDD, and incorporate them into a robust crew scheduling model. We develop a fast heuristic approach for solving the inverse of this robust crew scheduling problem to generate crew schedules that are similar to real-world crew scheduling samples. We develop a sequence of exact and heuristic techniques to quickly solve the forward problem within a small optimality gap for network sizes that are among the largest in robust crew scheduling literature. Computational results using four large real-world airline networks demonstrate that the crew schedules produced by our approach generate propagation patterns similar to those observed in the real world. Extensive out-of-sample validation tests indicate that the parameters calibrated for one network perform reasonably well for other networks. We provide new insights into the perceived tradeoff between planned costs and delays costs as reflected by actual airline crew schedules. Finally, we present a general approach to estimate the CPDD for any given network using our methodological framework under a variety of data availability scenarios.

2 - Service Improvement and Cost Reduction for Airlines: Optimal Policiesfor Managing Arrival and Departure Operations under Uncertainty

Heng Chen, University of Nebraska-Lincoln, CBA 250, 1240 R.Street, Lincoln, NE, 68588, United States, heng@unl.edu

We study four novel operational problems related to flight arrivals and departures at airports under the uncertainty of operating conditions, and demonstrate the potential dollar-based value that can be generated through stochastic models within the context of airline and airport operations. We derive both tactical and strategic policies to improve efficiency and sustainability for airlines and the society, which can enhance service quality and strengthen market position for the airlines involved.

1 - Assessing Inventory Performance via Warehouse Structural Embeddedness

Kedong Chen, University of Minnesota, Minneapolis, MN, United States, chen3548@umn.edu, Hung-Chung Su, Kevin W. Linderman

How a business entity is embedded in its network of the same others will affect its operational performance. Such an effect of structural embeddedness becomes further salient when supply and warehouse networks become increasingly complex due to business expansion. Through analyzing proprietary datasets from China's leading logistics management company, we identify the duality of the effect of a warehouse's structural embeddedness on its inventory performance. Specifically, a distribution center (DC)'s direct ties are negatively associated with the DC's inventory turnover and stockout rate, while the association becomes positive for the DC's indirect ties in its tier-1 ego network.

2 - A Dynamic Agent-based Model of Inter-firm Strategic Interaction

Duncan Robertson, Loughborough University, SBE, Loughborough, United Kingdom, d.a.robertson@lboro.ac.uk

We present a dynamic model of inter-firm strategic interaction where firms compete for customers within an competitive market. We develop an agent-based model where firms move in a strategic space in order to capture customers. The competitive landscape faced by a firm changes not only as the result of firm-firm interactions but also from the indirect interaction between firms and customers. We present results for different strategies and show when they should be used.

3 - A Contingency Framework for Disparate Tradeoffs in Manufacturing Strategy on a Duality Time Perspective

Zongjian Chen, Associate Professor, Huazhong University Of Science & Technology, Luoyu Road 1037, Wuhan, 430074, China, chenzjem@mail.hust.edu.cn

I introduce a contingency framework that relates digitization of manufacturing to the definitions of the performance frontier concept of a manufacturing unit, paying particular attention to the question of how to mix competitive priorities and competitive capabilities in manufacturing strategy. On a duality time perspective, this study investigates the assumptions, rationales and methodologies of the framework for disparate strategic tradeoffs.

4 - Acquisitions as Second Order Dynamic Capability: Understanding Indirect Contextual Impact

Vivek Peeraji Jirnal, PhD Student, XLRI, Room No 26 B.Block, GMP, XLRI, C. H. Area, Jamshedpur, 831001, India, jirnalvivek@gmail.com

We utilize the recent contributions in dynamic capability literature to identify acquisition learning as a second order dynamic capability. We build a model to understand the indirect impact that acquisition capability in its different forms (weak and strong) can cause, based on a) firms absorptive capacity, b) firms combinative capability, and c) the level of environmental dynamism. Our study goes beyond previous acquisition literature by designing comprehensive parameters to capture contextual multidimensionality and its contribution in impact variance of acquisitions, captured through six different forms of impact of acquisition capability.

5 - The Evolution of Productive Organizations

Francisco Brahm, University of Cambridge, Trumpington 10, Cambridge, CB2 1AG, United Kingdom, fb435@cam.ac.uk, Joaquin Poblete

We develop a evolutionary game-theory model to study the origins of partnerships, guilds, cooperatives, and other knowledge-based organizations. On every period, a population of agents adopts a technology that confers fitness but can be affected by environmental changes. These agents might display individual or social learning. We show that social learning does not enhance the fitness of the population. Then, we show that by organizing a portion of the population into a small group that has a lower cost of social learning the fitness of the population increases. The model provides several propositions regarding organization size, adaptation to uncertainty, who innovates, and the role of secrecy.

1 - Minimizing Completion Time Variance in Service Industries using Heuristic Approaches

Chandrasekharan Rajendran, IIT.Madras, Dept. of Mgmt. Studies, IIT Madras-Chennai, Chennai, 600040, India, crajiitm@gmail.com

The problem of scheduling customers or jobs in a service system or in a manufacturing system is an important operational issue. Minimizing the completion-time variance (CTV) of customers is an important performance measure when customers require an uniform treatment, i.e., each customer spends approximately the same time in the system or waits for service as every other entity. In this work, an existing branch-and-bound algorithm is first analyzed for minimizing the CTV and a correction on the lower bound is presented. Based on this, a simple heuristic to solve the problem is proposed.

2 - Determining Risk Type of Customers at Financial Institutions using Machine Learning Algorithms

Suchithra Rajendran, Pennsylvania State University, 265 Blue Course Drive, Apt 3E, State College, PA, 16803, United States, sur205@psu.edu, Sharan Srinivas

Financial institutions are constantly facing the problem of approving loans to high-risk customers. It has been reported in the literature that there are several financial institutions becoming bankrupt due to loan defaulting. In this research, five machine learning approaches are developed to classify the customers as high risk and low risk based on several parameters such as age, salary and past history on defaulting. The methods are compared using several performance measures such as sensitivity, specificity and accuracy to determine the best performing rule.

3 - An Integrated Supplier Selection and Lot Sizing Policy Considering Total Quantity Discount and Quality Constraint

Sang Jin Kweon, PhD, Pennsylvania State University, Industrial and Manufacturing Engineering, 232 Leonhard Building, University Park, PA, 16802, United States, rossa1984@gmail.com, Xin Li, Jose Antonio Ventura, Barbara Venegas, Seong Wook Hwang

This paper studies a joint supplier selection and lot sizing problem with quality constraint. Suppliers are capacitated and offer total quantity discount (TQD). Under TQD, the product unit price depends on the total order quantity (TOQ) for the supplier over a certain time period. Order quantities can have integer or continuous values. For each case, given a supplier and the TOQ for it, a procedure to derive the optimal order quantities and number of orders is developed. A near-optimal algorithm that combines Lagrangian relaxation and dynamic programming is proposed to solve the problem.

4 - Preference Based Scheduling in a Healthcare Provider Network

Deepak Agrawal, Pennsylvania State University, 310 Leonhard Building, University Park, PA, 16802, United States, dua143@psu.edu, Guodong Pang, Soundar Kumara

Healthcare is delivered by a complex network of physicians, clinic facilities and patients with different priorities and preferences. Traditional appointment scheduling systems do not consider the network effect. Motivated by this, we study the advanced scheduling problem with multiple clinic locations and physicians where patients can visit any clinic location and provider of their preference. We develop theoretical bounds on the performance gap with respect to the best achievable policy and propose a performance improvement heuristic to solve the problem. Further, we conduct numerical experiments to show that our proposed model outperforms the scheduling policies used in practice.

Sponsored: Service Science

Sponsored Session

Chair: Robin Qiu, Pennsylvania State University, Malvern, PA, 19355, United States, robinqiu@psu.edu

Co-Chair: Aly Megahed, IBM Research-Almaden, San Jose, CA, 95123, United States, aly@gatech.edu

1 - Managing Market Thickness in Online B2B Markets

Wenchang Zhang, Robert H.Smith School of Business, 12001 Old Columbia Pike, Apt 811, Silver Spring, MD, 20904, United States, wzhang@rhsmtih.umd.edu, Kostas Bimpikis, Wedad J.Elmaghraby, Ken Moon

Platforms can obtain sizable returns by operationally managing their market thickness, i.e., the availability of supply-side inventory. Using data from a natural experiment on a major B2B auction platform specializing in the $424 billion secondary market for liquidating retail merchandise, we find that thickening the platform's market by consolidating the ending times of auctions to certain weekdays substantially increases its revenue by 6.5%, due primarily to the bidders' participation frictions. We study two complementary design levers to calibrate and control the platform's market thickness in the face of complex demand-side decision making: listing policy and a recommendation system.

2 - Examining Impacts of Clinical Practice Variation on Operational Performance: Implications for Bundled Payment Reform Models

Seokjun Youn, Texas A&M.University, 320 Wehner Building, 4217 Texas A&M.University, College Station, TX, 77840-4217, United States, syoun@mays.tamu.edu, Gregory R. Heim, Subdoha Kumar, Chelliah Sriskandarajah

Motivated by bundled payment policies that aim to reduce practice variation, this study examines whether and how lower variations in clinical practice relate to hospital operational performance. Analyzing six years of data from hospitals in NY and FL states, we provide our empirical findings. We believe better measurement and understanding of practice variation's antecedents and consequences can lead managers and policy-makers to better design bundled payment reform models, the target opportunity of which is to reduce waste by decreasing variabilities in care-delivery processes.

3 - Linking Delay Announcements, Abandonment, and Staffing: A Behavioral Perspective

Eric Michael Webb, eric.michael.webb@gmail.com, Kurt Bretthauer, Qiuping Yu

Using field data from a call center, we study the behavioral determinants of customers' queue abandonment decisions in the presence of delay announcements. We relax traditional behavioral assumptions on how customers should behave. Customers exhibit loss aversion with respect to time losses in queue, becoming much more likely to abandon if forced to wait longer than expected. Customers also exhibit a decreasing base hazard rate. Longer announced wait times increase customer abandonment behavior and customers are often strategic in their arrival decisions. By accounting for our insights, firms may significantly reduce their staffing levels without increasing customers' overall waiting time.

1 - Bi-objective Mixed Integer Linear Programming for Managing Building Clusters with a Shared Electrical Energy Storage

Rui Dai, University of South Florida, Tampa, FL, United States, ruidai@mail.usf.edu

Building clusters allow buildings to collaborate and reduce their operational cost. However, since each building is treated as an independent decision maker, fairness havs to be addressed in these collaborative environments. We address these issues on building clusters with an electrical energy storage shared between two buildings with deterministic demand. We introduce three strategies, and develop a bi-objective mathematical formulation for each strategy with several linearization techniques such as piecewise McCormick relaxation. Experiment results demonstrate the efficacy of our proposed linearization techniques, and compare all three strategies in terms of fairness and freedom.

2 - The Box-Line Algorithm for Mixed Integer Biobjective Optimization

Diego Pecin, Georgia Tech, Atlanta, GA, United States, diegopecin@gmail.com

Recent years have seen a surge of new algorithms for solving multiobjective integer programs, especially for the pure integer case. The presence of continuous variables presents significant challenges to discovery of the nondominated frontier, and development of algorithms for the mixed integer case have lagged. Here, we present a new algorithm for mixed integer problems with two objectives, which generalizes the Balanced Box Method (BBM) for pure integer programs. The computational performance of the Box-Line Algorithm is compared with that of existing methods on benchmark problems, in terms of its overall run-time, and its ability to approximate the frontier if terminated early.

3 - Linear Programming Filtering Algorithms for a Class of Biobjective Optimization Problems over the Efficient Set
Daniel Jornada, Ford Motor Company, Dearborn, MI, United States, danieljornada@gmail.com

This presentation deals with a class of biobjective optimization problems over the efficient that is reformulated as a biobjective mixed binary linear program (BOMBLP).Two objective space search algorithms are proposed. Computational experiments suggest that both algorithms run faster than existing general purpose objective space search procedures.

Turgay Ayer, Georgia Institute of Technology, School of Industrial and Systems Engineering, Groseclose 417, Atlanta, GA, 30332, United States, ayer@isye.gatech.edu, Can Zhang, Chenxi Zeng, Chelsea C. White, Kevin Lee, Mary Deck, V. Roshan Joseph

We describe a regional-level cryoprecipitate (cryo)-collection project at the American Red Cross Southern Region (ARC-SR). The implementation of our proposed solution resulted in a significant improvement: about 1,000 more cryo units at a slightly lower collection cost, resulting in an approximately 40% reduction in per-unit cryo collection cost. Based on the successful implementation at the ARC-SR, the ARC plans to implement our proposed model at its 10 other cryo production facilities.

2 - The New York City Off-Hour Delivery Program: A Business andCommunity-Friendly Sustainability Program
Trilce Encarnacion, Rensselaer Polytechnic Institute, 110 8th Street, Jonsson Engineering Center # 4049, Troy, NY, 12180, United States, encart@rpi.edu, José Holguín-Veras, Stacey Hodge, Jeffrey Wojtowicz, Caesar Singh, Cara Wang, Miguel Jaller, Felipe Aros-Vera, Kaan Ozbay, Michael Marsico, Andrew Weeks, Michael Replogle, Charles Ukegbu, Xuegang Ban, Matthew Brom, Shama Campbell, Ivan Sanchez-Díaz, Carlos Alberto Gonzalez-Calderon, Alain Kornhauser, Mark Simon, Susan McSherry, Xia Yang, Asheque Rahman, Diana Gineth Ramirez-Rios, Lokesh Kalahashti, Johanna Amaya, Michael Silas, Brandon Allen, Brenda Cruz

The New York City Off-Hour Delivery program, a private-public-academic partnership, implemented policy designed with the help of OR/MS, including behavioral micro-simulation. By successfully inducing more than 400 commercial establishments in NYC to accept OHD, economic benefits accrued are considerable: carriers reduced costs by 45%; receivers enjoy more reliable deliveries and reduce inventory; trucks reduced emissions up to 67%. Total economic benefits exceed $20 million per year.

1 - Decision Support for Choosing among Projects: Handling Multi-dimensional Efficiency and Equity Concerns
Özlem Karsu, Bilkent University, Ankara, 06800, Turkey, ozlemkarsu@yahoo.co.uk, Nur Kaynar

We develop interactive algorithms that will help policy makers make choices among a set of projects. The projects are evaluated based on their benefits to different population groups and there are multiple benefit types to consider. We assume that both efficiency and equity are relevant and hence the problem is a multicriteria decision making problem. Our computational experiments demonstrate the satisfactory performance of the algorithms. We believe that such decision support tools may be of great use in practice and help in moving towards fair and efficient service provision.

2 - Will Aging Voting Machines Cause Long Waiting Lines
Muer Yang, University of St. Thomas, 1000 Lasalle Avenue, TMH 451E, Minneapolis, MN, 55403, United States, yangmuer@stthomas.edu

As the majority of voting machines in use today approach or exceed their expected lifetime, there is an impending crisis from the increased number of voting machine failures expected in the upcoming elections. This study examines and quantifies the impact of aging machines on voter wait times via simulation. The reliability issue of aging voting machines might not be as serious as predicted.

3 - One- or Two-Channel Subsidies? Donor Funding for Drug Availability
Iva Petrova Rashkova, Washington University in St. Louis, Washington University in St Louis, St Louis, MO, 63130, United States, irashkova@wustl.edu

Abstract: We study the decision of a donor subsidizing health programs by allocating a limited budget between the commercial and non-commercial distribution channels. The two channels differ in their affordability to patients and quantity yield per-unit subsidy. We show that the variability of the random yield in the non-commercial channel generates inter-channel cannibalization and reduces total consumption. Thus, efforts of the donor should be focused on reducing this variability. We evaluate the consumption improvement of the optimal subsidy using historical data from three donor organizations.

4 - An Interdiction Model for Delaying Adversarial Attacks in Information Technology Supply Chains

Kaiyue Zheng, University of Wisconsin-Madison, 5002 Sheboygan Avenue, Apt 202, Madison, WI, 53705, United States, kzheng23@wisc.edu

IT supply chain risks from adversarial attacks are sophisticated, hard to detect, and likely to have severe consequences. We propose an interdiction model that prioritizes cost-effective security mitigations to maximally delay adversarial attacks in IT supply chains. We consider attacks originated from multiple adversaries with different capacities and perceptions of supply chain vulnerabilities, each of which aims to find a "critical path" through the attack surface to complete attack goals. We address uncertainty regarding mitigation effectiveness by incorporating random delaying times. A Lagrangian heuristic is proposed that identifies near-optimal solutions efficiently.

5 - Designing Intervention Scheme for Electric Vehicle Market

Ece Zeliha Demirci, Eindhoven University of Technology, De Lismortel 42-250, Rektorluk Binasi EA325, Eindhoven, 5612AR, Netherlands, edemirci@bilkent.edu.tr, Nesim K. Erkip

Real life examples indicate that a central authority needs to intervene to the supply chain of electric vehicle so that their adoption level is increased towards socially desirable levels. In this study, we consider an intervention scheme composed of investing in demand-increasing strategies and rebates. We introduce a model that determines a utility maximizing intervention scheme and further investigate the model. Also, we conduct a numerical study based on the available electric vehicle market data from California.

1 - Congestion Reduction through Efficient Empty Container Movement

Santiago Carvajal, University of Southern California, 731 W. 30th Street, Apt 6, Los Angeles, CA, 90007, United States, scarvaja@usc.edu, Maged M.Dessouky

The optimization problem for efficiently routing multi-container trucks to better reposition both loaded and empty containers is studied. Our formulation adds the multi-container truck to the empty container reuse problem. Our aim is to efficiently route trucks by reducing the number of truck trips, thus decreasing transportation costs, and reducing the natural environmental impact of transporting goods.

2 - Vehicle Routing Problem for Smart Street Sweeping using GIS

EunSu Lee, New Jersey City University, 160 Harborside Plaza 2, #234H, Jersey City, NJ, 07311, United States, elee3@njcu.edu

Every city faces unique budget situation and public policy on the activities of street sweeping. This study assess the effectiveness of current system in Jersey City, NJ and proposes a smart street sweeping system using geographic information systems (GIS). The method minimizes citywide total operating costs while improving public services.

3 - Code Assignment for Parcel Distribution Network

Byung-In Kim, POSTECH, Industrial & Management Engineering, 77 Cheongam-Ro, Nam-Gu, Pohang, Kyungbuk, 37673, Korea, Republic of, bkim@postech.ac.kr, JaeSang Park

We consider a parcel distribution network consisting of multiple hubs and hundreds of spokes, in which the category code for each spoke is important. Parcels are collected at spokes, sorted based on their category codes, sent to hubs and sorted, and sent to their destination spokes. Parcels may go through multiple hubs. A spoke can send parcels to a given number of hubs and each hub has the sorting capacity and the limited number of connecting spokes. We propose a mathematical formulation and develop an algorithm of category code assignment to spokes and corresponding network flow design.

4 - Robust Ride-Sharing with Client Clustering under Travel Time Uncertainty

Sung Hoon Chung, Binghamton University, P.O. Box 6000, Binghamton, NY, 13902, United States, schung@binghamton.edu, Yinglei Li

We consider a ride-sharing system in which information on riders (clients) and drivers (servers) is updated and drivers' routes need to be calculated quickly. We assume travel times between pick-up locations are subject to uncertainty, and propose a robust optimization approach to handle it properly. To achieve computational tractability, we employ the insertion algorithm in conjunction with tabu search method, and propose a cluster-first-route-second approach to find heuristic solutions. In particular, the greedy algorithm and k-means algorithm are used to group the client nodes and their respective results, along with non-clustering case outcomes, are compared.

Scheduling in Practice

Invited: Project Management and Scheduling

Invited Session

Chair: Emrah Cimren, Nike, 1 SW Bowerman Dr, Beaverton, OR, 97005, United States, Emrah.Cimren@nike.com

1 - Stable Matching and Sustainable Cost Allocation for Real-time Ride-sharing System

Pengyu Yan, University of Electrolic Sicence and Technology of Chnia, No.2006, Xiyuan Ave, West Hi-Tech Zone, 611731, Chengdu, 611731, China, yanpy@uestc.edu.cn, Cynthia Chen, Zhiqin Luo, Chengbin Chu

Ride-sharing, a sustainable transportation mode, allows drivers to flexibly share idle seats in their vehicles with others. This paper addresses a stable matching solution conception in a real-time ride-sharing system with considering the benefits of the self-interested users. We first formulate a stable matching model that generates an acceptable matching solution for most of the users. The loss of the system efficiency of four existing cost allocation methods are investigated. We propose a sustainable cost allocation method that guarantee the optimal system efficiency of a stable matching solution. The numerical experiment indicate the effectiveness of our proposed method.

2 - Speedscaling in Flow Shops with Lot Streaming
Kan Fang, Tianjin University, Tianjin, China, kfang@tju.edu.cn, Michael L.Pinedo

The variable frequency drives on electrical motors have become more attractive in manufacturing to save their energy. We consider using speed scaling techniques to solve the flow shop lot streaming problems. We investigate the structural properties of optimal schedules and the computational complexity of various scheduling problems.

3 - Optimality of a Priority Policy for a Server Scheduling Problem with a Deteriorating Server
Jefferson Huang, Cornell University, Ithaca, NY, 14853, United States, jefferson.huang@cornell.edu, Mark E. Lewis, Cheng-Hung Wu

We consider a server scheduling problem motivated by the control of semiconductor manufacturing systems, where the service rate depends on both the class of the job and the degree to which the server has deteriorated. Conditions are given under which a priority policy is optimal. The case where the server may be preemptively repaired is also considered.

4 - Scheduling for Map-reduce Jobs
Vaneet Aggarwal, Purdue University, 315 N. Grant St., West Lafayette, IN, 47906, United States, vaneet@purdue.edu, Tian Lan

The Map-Reduce computing framework rose to prominence with datasets of such size that dozens of machines on a single cluster were needed for individual jobs. The interesting aspect of map-reduce job scheduling is that the reduce jobs can start when all the map tasks have finished. We give competitive scheduling algorithms for such job scheduling procedures where the release times of jobs depend on completion times of others.

1 - Crowdfunding Lender Team Structure and Lending Behavior
Bin Wang, University of Texas Rio Grande Valley, Edinburg, TX, United States, bin.wang@utrgv.edu, Diego Escobari

The proliferation of crowdfunding in the last few years has drawn academic researchers' interest. Specifically, many have examined lending behavior and borrowers' success of person-to-person (P2P) lending. The current research proposes to examine how lender team structure affect lending behavior and campaign success. Using data collected from Kiva.com, a leading P2P platform connecting lenders and borrowers from around the world, we examine how the network positions of lending team captains and members affect their lending behavior and the success of crowdfunding campaigns.

2 - Evaluating Observational Learning in Competitive Two-sided Crowdsourcing Market: A Bayesian Inferential Approach
Emmanuel Ayaburi, PhD Candidate, The University of Texas at San Antonio, One UTSA Circle, San Antonio, TX, 78249, United States, emmanuel.ayaburi@utsa.edu, Zhechao (Charles) Liu, Yoris A. Au

This study examines the effect of observational learning by both buyers and creatives (suppliers) in the increasingly popular crowdsourcing market. Using a Bayesian framework, we estimate two structural models that capture buyers and creatives' utility. Our results show that both buyers and creatives actively exercise observation learning from various market signals, and such learning leads to a more accurate prediction of market outcome and strong network effects. Our findings provide important insights on how crowdsourcing market participants can leverage the influence of the information signals present in the market to enhance their utility and promote a sustainable growth of the market.

3 - Crafting Personalized Incentives: A Randomized Field Experiment in an Online Dating Platform
Ting Li, Erasmus University, T09-14, Burg Oudlaan 50, Rotterdam, 3000DR, Netherlands, tli@rsm.nl, Rodrigo Belo

Heterogeneity across consumers often leads to diverse responses to incentives. We develop a method that accounts for consumer heterogeneity and maximizes consumer life-time value (CLTV), by personalizing incentives in scenarios of multiple conversion outcomes. We use data from a real-world randomized experiment in an exclusive online dating platform to create uplift models that predict changes in consumer behavior. We apply these methods in a new out-of-sample randomized experiment and find considerable improvements in CLTV, when compared to randomly assigned incentives. We explore the effectiveness of personalized incentives across consumers and discuss implications for business.

1 - The Behavioral Promise and Pitfalls in Compensating Operations Managers
Shan Li, Assistant Professor, Baruch College, City University of New York, 55 Lexington Avenue, New York, NY, 10010, United States, shan.li@baruch.cuny.edu, Kay-Yut Chen, Ying Rong

We theoretically and behaviorally studied Profit-Sharing and Target-with-Bonus compensation schemes in an inventory management context. Our experimental data reveals behavioral promise and pitfalls of the two widely used incentive compensation schemes, and it further suggests systematic deviations from the theoretical benchmarks. Based on the experimental findings, we manipulate the behaviors and engineer the design of the compensation scheme through two additional treatments, to explore potential improvement of the mechanism. Our results have implications for the design of incentive schemes in practice.

2 - Service Systems with Unknown Quality and Customer Anecdotal Reasoning
Hang Ren, UCL.School of Management, Flat 52, Nansen Village, 21 Woodside Avenue, London, N12 8RW, United Kingdom, hang.ren.13@ucl.ac.uk, Tingliang Huang

We consider a service system where customers do not know the distribution of uncertain service quality and cannot estimate it fully rationally; instead, they form beliefs by taking the average of anecdotes. The sample size measures to what extent customers are boundedly rational. We characterize customers' joining behavior and the server's pricing, quality, and information disclosure decisions. As customers gather more anecdotes, the server may first decrease and then increase price, and the revenue is U-shaped. Interestingly, more anecdotes may induce a lower quality. Moreover, a low (high)-quality service provider may (not) disclose quality information if the sample size is small (large).

3 - Non-binding Goals in Teams: A Real-effort Coordination Experiment
James Fan, juf187@smeal.psu.edu

We experimentally investigate the efficacy of non-binding (wage-irrelevant) team goals. In our study, participants act as either team workers or managers. A manager can set a non-binding goal for the team production, which is determined by the minimum (or weak-link) performance of its workers. Consistent with our theory, we find evidence that the team production increases when managers are able to set goals. This effect is stronger when goals are challenging but attainable for weak-link workers. We also find evidence that many managers assign goals that are too challenging for weak-link workers, resulting in suboptimal team production and profits.

4 - Trust Among Executives
Yanchong Zheng, Massachusetts Institute of Technology, Sloan School of Management, 100 Main Street, E62-578, Cambridge, MA, 02139, United States, yanchong@mit.edu, Emily Choi, Ozalp Ozer

We integrate the results of a social network survey and a forecast information sharing experiment to determine whether and how trust and trustworthiness impact high-ranking executives' decisions in a dyadic supply chain. The members of our executive sample have on average 17 years of work experience. Over half of them hold C-level positions in world-leading organizations. We demonstrate that executives are significantly motivated by trust and are more cognizant of when to rely on trust in their business decisions than non-experienced individuals. These results offer valuable insights into how organizations can better leverage executives' trust intelligence to improve supply chain efficiency.

Chair: Dilek Onkal, Bilkent University, Ankara, 06800, Turkey, onkal@bilkent.edu.tr

1 - The Effects of the Availability Bias on Facebook Users' Perception of Privacy Risks Over Time

Kathleen M. Whitcomb, University of South Carolina, Moore School of Business, Management Science Dept, Columbia, SC, 29208, United States, whitcomb@moore.sc.edu

Past studies have shown that a short-term increase in risk perception for an activity or event can be achieved by exposing individuals to a vivid image known to induce negative affect. This effect has been demonstrated even when the image is unrelated to the activity. It has been hypothesized that the increase in risk perception generated by a vivid image inducing negative affect persists longer when the image is relevant to the target activity. We report the results of an experiment which demonstrates that a relevant negative image results in both a more enduring and greater increase in risk perception than does an irrelevant negative image.

2 - Cognitive Debiasing Training in Judgmental Frecasting: An Experimental Study

Jorge Alvarado Valencia, PhD, Colombia, Pontificia Universidad Javeriana, Bogota, Colombia, jorge.alvarado@javeriana.edu.co, Jaime Vargas, Lina Merchan

In order to reduce well-known cognitive biases in judgmental time series forecasting (noise modelling, small unjustified adjustments and overoptimism) a short cognitive debiasing training was tested against forecasting techniques training and no training at all with students in a judgmental adjustment task . Results show that cognitive debiasing training reduced small unjustified adjustments, but did not reduce noise modelling and was no better than absence of training. Forecasting techniques training led to a reduction in accuracy, mainly due to unjustified adjustments.

3 - Effects of Scenario Tone on Judgmental Forecast Adjustments

Dilek Onkal, Bilkent University, Faculty of Business Administration, Ankara, 06800, Turkey, onkal@bilkent.edu.tr, Paul Goodwin, M. Sinan Gonul

When presented with forecasts, users typically respond by judgmentally adjusting these predictions to incorporate their experience, intuition, and informational asymmetries. However, such adjustments may not always improve forecast accuracy; hence the need for support tools to improve communication and information sharing between forecasters and decision-makers. This research investigates the effects of providing differently-toned scenarios as forecast advice on individual and group-based judgmental predictions. Findings suggest important directions for designing and implementing effective forecast management systems to support both the providers and users of forecasts.

Large-scale Data Analytics in Urban Transportation Modeling I

Sponsored: TSL, Urban Transportation

Sponsored Session

Chair: Shanjiang Zhu, George Mason University, Fairfax, VA, 22030, United States, szhu3@gmu.edu

Co-Chair: Zhen Qian, Carnegie Mellon University, Pittsburgh, PA, 15213, United States, seanqian@cmu.edu

1 - Assessing Travel Behavior Responses to Washington Metro SafeTrack Project using Smartphone App Data

Shanjiang Zhu, George Mason University, Nguyen Engineering Building, Suite 1300, 4400 University Drive Ms 6c1, Fairfax, VA, 22030, United States, szhu3@gmu.edu, Zhuo Yang, Lei Zhang

This study investigates the behavioral reactions to the Washington Metro SafeTrack Project, a series of accelerated safety projects that required either single-track operations, or complete closure of a line segment. Longitudinal travel trajectories data were collected using a smartphone app among transit riders who used to use metro before the service disruptions. Algorithms were developed to infer the travel choices before, during, and after the network disruptions, which are crucial for assessing the impact of the unprecedented maintenance work at the Washington Metro. Findings from this study could help to inform agencies who are struggling with the aging infrastructure in the US.

2 - Spatio-temporal Analysis of Urban Mobility of Transit Users from Smart Card Transactions Data

Laiyun Wu, SUNY-Buffalo, 326 Bell Hall, University at Buffalo, Buffalo, NY, 14226, United States, laiyunwu@buffalo.edu, Jee Eun Kang, Samiul Hasan

Characterizing individual trajectories is critical to understand the dynamics of human mobility and design reliable mobility models. The recent availability of Automatic Fare Collection (AFC) data has diversified the ways to understand human mobility, especially for the patterns of different type of transit users (e.g., regular workers, students, seniors and disabled persons). In this paper, we measure travel distance, travel time and stay time at activity locations for various user groups and present the statistical distributions of these characteristics.

3 - Bayesian Optimization to Fuse Large Scale Transportation Data Sets into Simulation Models

Laura Schultz, George Mason University, Fairfax, VA, 22032, United States, lschult2@gmu.edu, Vadim Sokolov, Joshu Auld, Dominik Karbowski, Aymeric Rousseau

In this paper we present Bayesian optimization techniques for calibrating large scale transportation models. Specifically, we address the problem of updating integrated demand-network models using dynamic traffic flow data, collected on freeways. We present several Bayesian optimization techniques and a distributed data flow framework, that allows scalable execution on highly parallel architectures. We demonstrate our approach using empirical results from the calibration of Chicago's metropolitan area transportation model, with 10 million travelers and 28 million daily trips.

The Structural Modeling and Machine Learning Applications for Issues in Information Systems

Sponsored: Information Systems

Sponsored Session

Chair: Lin Hao, University of Notre Dame, Notre Dame, IN, 46556, United States, lhao@nd.edu

1 - How Much is an Image Worth? Airbnb Property Demand Estimation Leveraging Large Scale Image Analytics

Shunyuan Zhang, Carnegie Mellon University, 5562 Hobart Street, Apartment 614, Pittsburgh, PA, 15217, United States, shunyuaz@andrew.cmu.edu, Dokyun Lee, Param Vir Singh, Kannan Srinivasan

We investigate the economic impact of images and lower-level image factors that influence demand in Airbnb. Using DiD analyses on a nine-month Airbnb panel data of 8211 properties, we find units with verified photos generate approximately 7% more demand. Leveraging computer vision techniques to classify image quality, we show 52.5% of this effect comes from high image quality. Next, we identify 12 human-interpretable image attributes and evaluate their economic impacts. Results suggest direct impacts of the attributes on demand. The study contributes to and bridges literature which traditionally ignored either demand side (photography) or systematic image characterization (marketing).

2 - A Dynamic Structural Model of Online Learning: Heterogeneous Studying Plan and the Peer Effect

Ruoxin Zhou, Peking University, Beijing, China, zhourx@pku.edu.cn, Fei Ren

This paper studies how online learning users dynamically adjust their learning plan every day given their preset deadlines, learning history, and peer effect. We develop a dynamic structural model in which users maximize utility considering the intertemporal trade-off between current and future learning amount. Theoretical properties enable us to distinguish forward-looking from myopic users, and we empirically test for forward-looking consumption patterns. We use a two-stage method to estimate structural parameters, and conduct counterfactual simulations to see how to help users learn better.

3 - Reward-based Crowdfunding Platform Design

Shahryar Doosti, University of Washington, Mackenzie Hall, Seattle, WA, 98195, United States, shahryar@uw.edu, Yong Tan, Shengsheng Xiao

With the emergence of reward-based crowdfunding platforms, there are a growing number of projects benefiting from crowd participation in their fund-raising process. With increasing competition, failed campaigns have been also increased. At the same time, there are multiple choices for entrepreneurs to design their campaigns in terms of design, reward scheme, and goal which can affect the success of the project. In this study, we use different methods of data mining to shed light on the important design questions in front of fund-seekers.

4 - Fostering Innovation: Exploration is not Everybody's Cup of Tea
Vipul Aggarwal, University of Washington, 5263 University Avenue NE, Apt 103, Seattle, WA, 98105, United States, aggarv@uw.edu, Elina Hwang

Innovation thrives on the creative application of existing and new ideas to create new products or concepts. The existing research on the ability of analogies to inspire innovative ideas treats the conceptual distance between the analogy and the target problem as a hammer. Our research aims to bring nuance to this hammer of problem-solving. We investigate the impact of analogical distance on the ability of users to ideate in an open innovation setting. We use state-of-the-art NLP techniques of paragraph vectors and structural topic models to construct our feature set. We find that the effects of analogy distance varies with user types and are also contingent upon the source of the analogies.

5 - Social Ties and the Quality of User-generated Content
Jin Yue, School of Economics and Management, Tsinghua University, Beijing, 100084, China, jiny.13@sem.tsinghua.edu.cn

The social networking mechanism is ubiquitous in content communities. However, the effect of social ties on user contribution behavior is unclear. This study explores how social ties influence the quality of user-generated content from the perspectives of social learning and motivation. Results from a social question-and-answer community reveal that the number of followings of a user enhances the quality of his/her future answers, whereas the number of followers diminishes the quality of such answers. Moreover, the influence of followings comes from their behaviors (i.e., number of answers) rather than their community status (i.e., number of followers and number of agrees).

Storage, Handling, and Picking

Sponsored Session

1 - Sizing a Block Stacking Storage System
Hueon Lee, PhD Candidate, University of Arkansas, 4121 Bell Engineering Center, 1 University of Arkansas, Fayetteville, AR, 72701, United States, hueonlee@uark.edu, Kelly Sullivan, John A. White

Block stacking is a commonly used storage method for palletized loads. As the name implies, unit loads are stacked on top of each other. Stacks are arranged in storage rows having different depths. Given a set of adopted row depths and inventory cycles of product lots, the floor space required for a block stacking storage system is determined by staggering replenishment schedules of multiple lots and assigning a row depth to a product lot. We employ integer programming to obtain the replenishment schedule and assignment of products to row depths to minimize required space. Numerical results are provided for the heuristic algorithm we developed.

2 - Design Challenges and Performance Analysis of the AGV-pick System
Kaveh Azadeh, PhD Candidate, Rotterdam School of Management Erasmus University, Burgemeester Oudlaan 50, Mandeville Building T09-41, Rotterdam, 3062PA, Netherlands, azadeh@rsm.nl, Debjit Roy, Debjit RoyB.M. De Koster

Recently, an AGV-based pick system is developed to minimize the pickers travel time for filling large orders. In such systems, the AGV automatically go to the pick location to wait for the picker to arrive. Once the picker puts the item into a customer's tote carried by the AGV, the AGV goes to the next location. When the order is complete, the AGV brings it to the depot. Due to a parallel movement among the pickers and the AGVs, analysis of such systems is complex. In this research, we attempt to develop queuing network models to capture the realistic movement of the AGVs and the pickers in the system and develop solution methods for performance evaluation.

3 - Modeling Service Priority at Landside Terminal Resources: Exact Analysis and Approximations
Debjit Roy, Indian Institute of Management, Ahmedabad, India, debjit@iima.ac.in

We develop an exact approach to model service priority of train over truck containers by one automated stacking crane at landside container terminals using an imbedded Markov chain analysis. We further develop an approximate analysis approach to model service priority of train over truck containers with multiple automated stack cranes.

4 - Inbound Storage Block Stacking Optimization for Vehicle Assembly Factories
Yulian Zeng, Georgia Institute of Technology, 2618 Druid Oaks NE, Atlanta, GA, 30329, United States, yulian.zeng@gmail.com

We focus on optimizing inbound parts storage center configuration exploiting rack-less block stacking in vehicle assembly factories. Given parts storage and throughput requirements and stacking constraints, the objective is to determine the center size (rows, row length & depth) and to assign parts to stack locations, so as to minimize induced costs. We report on large-scale experimentation for a major-brand carmaker factory.

Autonomous Vehicles: From Planning to Vehicle Control

Invited: TSL, Intelligent Transportation Systems (ITS)

Invited Session

Chair: Michael Levin, The University of Texas at Austin, 7205 Hart Ln, Apt 1002, Austin, TX, 78731, United States, michaellevin@utexas.edu

1 - Optimal Design of Autonomous Vehicle Zones in Transportation Networks
Zhibin Chen, University of Michigan, 2244 Saint Francis Drive, Apt 209, Ann Arbor, MI, 48104, United States, chipin@umich.edu, Fang He, Yafeng Yin, Yuchuab Du

It is envisioned that in the future government agencies will dedicate certain areas of road networks to autonomous vehicles (AVs) to facilitate the formulation of vehicle platoons. We present a mathematical framework for the optimal design of AV zones in a general network. Since AVs may apply different routing principles outside of and within the AV zones, a novel mixed routing equilibrium model is proposed to capture such behaviors. A mixed-integer bi-level programming model is then formulated to optimize the deployment plan of AV zones.

2 - Auction-based Reservations of Network Trajectories for Autonomous Vehicles
Michael Levin, The University of Texas at Austin, 7205 Hart Ln, Apt 1002, Austin, TX, 78731, United States, michaellevin@utexas.edu

Auctions have been proposed to determine vehicle access to road infrastructures. Although high value-of-time vehicles may be willing to pay tolls or auction bids, many would rather make a single payment that guarantees a travel time for their entire trip. We present a combinatorial assignment algorithm for reserving space-time trajectories with priority determined by auction. Traffic flow follows the cell transmission model. Reservation-based intersection control is used to ensure that reserved trajectories are followed. Winning vehicles tend to have lower travel times, although variability is high. In addition, the trajectory reservation system reduced overall congestion in the network.

3 - Optimal Geometric Design of Parking Facilities for Autonomous Vehicles
Mehdi Nourinejad, University of Toronto, 193 Silverlinden Drive, Toronto, ON, L4B4G6, Canada, mehdi.nourinejad@mail.utoronto.ca, Sina Bahrami, Matthew Roorda

Existing parking facilities are designed according to city guidelines without any accommodation for Autonomous vehicles (AV). With AVs, however, the geometric design of parking facilities will change for two reasons. First, AVs can be parked closer to each other and less space will be taken in total. Second, AVs can be relocated automatically within the parking lot. By optimally relocating the AVs, more vehicles can be packed into each parking facility. This paper addresses the following: (i) what is the optimal geometric design for AV parking facilities, (ii) how to relocate the vehicles within the facility, and (iii) how to stack the AVs in the facility to minimize the expected number of relocations.

4 - A Fuzzy Logic-based Approach for Determining Driving Mode under Partially or Highly Autonomous Vehicle
Lin Liu, Chongqing University, Chongqing, China, liulin@cqupt.edu.cn, Yong Hoon Kim, Yongfu Li, Srinivas Peeta

A partially or highly autonomous vehicle is capable of being operated in autonomous mode by an on-board self-driving controller, or in manual mode by a human driver. This study proposes a fuzzy logic-based approach to determine a competence level of the human driver and the on-board self-driving controller. The experimental validation shows the effectiveness of the proposed approach to determine the driving mode of autonomous vehicle.

Agriculture Analytics at IBM Research

Invited: Agricultural Analytics

Invited Session

Chair: Robin Lougee, IBM Research, Yorktown Heights, NY, 10598, United States, rlougee@us.ibm.com

1 - Precision Agriculture leveraging IoT and Curated Satellite Data Analytics

Ranjini Guruprasad, IBM.Research India, Manyata Embassy Business Park, Bangalore, Karnataka, 560045, India, ranjinib@in.ibm.com, Jagabondhu Hazra

Increasing agricultural productivity is key to raising GDP growth in India, as well as lifting millions of people out of poverty. Digitization, mobile and cognitive technologies have the opportunity to play a pivotal role to enable this future. At IBM Research - India, we are combining multiple global satellite based information sources to compute agronomic insights at sub-acre level. Farmers can now tap the sophisticated output of cognitive analytics to get predictive insight at the right time to manage scarce groundwater-based irrigation, optimize the timing/amount of fertilizers & pesticides, minimize wastage, etc. This presentation will cover few use cases specific to India/SA.

2 - Modeling of Expert Knowledge for Crop Cultivation

Tatsuya Ishikawa, IBM Research - Tokyo, 19-21, Nihonbashi Hakozaki-cho, Chuo-ku, Tokyo, 103-8510, Japan, Ishikawa@jp.ibm.com, Yasuteru Kohda, Hironobu Takagi

We are facing a risk of losing skills of crop cultivation due to the retirements of aging expert farmers in Japan. Their key knowledge is adaptive decision-making such as appropriate temperature settings in greenhouses depending on stages of development in crops and environmental conditions. In this talk, we present a framework which combines (1) measurements of crop growth and environment, (2) simulation models of these dynamics with data assimilation, and (3) model-based adaptive control. We discuss the capability of our framework to model farmer's decision-making.

3 - Geospatial Analytics Powered by IBM Pairs Big-data Platform

Siyuan Lu, IBM, 1101 Kitchawan Road, Yorktown Heights, NY, 10598, United States, lus@us.ibm.com, Marcus Freitag

The PAIRS geospatial analytics platform is a big-data service of IBM Research that aims at reducing the barrier for analytics or machine-learning on large-scale and disparate spatio-temporal data sources such as weather, satellite, land-classification, lidar, census, sensors, etc. Incoming data is curated on the unified nested PAIRS grid, and derived analytics layers, such as evapotranspiration, are automatically populated as new timestamps of the underlying data arrive. The users may upload their own data in additional layers of the same grid, and perform their analytics on a mix of open and proprietary layers. In this talk the PAIRS architecture and analytics on top of it will be discussed.

Multi-Firm Decision Making

Sponsored: Financial Services

Sponsored Session

Chair: Daniel Mitchell, University of Minnesota, damitche@umn.edu

1 - Robust Portfolio Selection with Transaction Costs

Jingnan Chen, Singapore University of Technology and Design, 20 Dover Drive, Singapore, 138682, Singapore, jingnan_chen@sutd.edu.sg, Ning Zhang

We propose a robust and sparse portfolio selection model to obtain portfolios that are insensitive to parameter estimation errors and have low transaction costs. Two components of transaction costs, i.e., the broker'scommission and the market maker's spread, are both considered. We adopt a distributional robust approach to maximize the worst-caseexpected utility over a set of distributions with the same first- and second-order moment information, and impose l0 and l1 regularization to account for transaction costs. The inclusion of l0 norm results in a non-convex and non-smooth optimization program and we develop an efficient algorithm to find the optimal portfolio.

2 - A Hybrid Approach to the 1/n Portfolio Tracking Problem

Oliver Strub, University of Bern, Schuetzenmattstrasse 14, FM.Quantitative Methoden, Bern, 3012, Switzerland, oliver.strub@pqm.unibe.ch, Norbert Trautmann

The 1/N portfolio strategy corresponds to investing an equal amount in all N stocks from a given investment universe. This strategy exhibits desirable empirical risk-return properties, but causes substantial management costs if N is large. We consider the problem of tracking the 1/N portfolio's returns by investing in a small subset of the N stocks only. We propose a hybrid approach to this problem based on an iterated greedy heuristic and quadratic programming. In a computational experiment with real-world data, we demonstrate that the proposed approach leads to a high tracking accuracy.

3 - Pricing of Cyber Insurance Contracts in a Network Model

Kerstin Weske, Gottfried Wilhelm Leibniz Universität Hannover, Welfengarten 1, Hannover, 30167, Germany, weske@stochastik.uni-hannover.de, Matthias A. Fahrenwaldt, Stefan Weber

We investigate a novel approach for pricing cyber insurance. The considered cyber threats, such as viruses and worms, diffuse in a data network. The spread of the cyber infection is modeled by an interacting Markov chain. Conditional on the underlying infection, the occurrence and size of claims are described by a marked point process. We develop a novel mean-field approach to compute prices of cyber insurance contracts. Several numerical case studies illustrate the impact of the network topology.

4 - Regulation of Financial Networks

Dan Mitchell, University of Minnesota, 111 Church Street SE, Minneapolis, MN, 55455, United States, damitche@umn.edu, Stathis Tompaidis

We consider a financial system in which individual institutions are organized in a directed network representing random payoffs from financial instruments and a regulator is able to set capital requirements for each firm in the network. The regulator sets these capital requirements to reduce the risk of systemic failure to the whole system.

Advances in Location Theory

Sponsored: Location Analysis

Sponsored Session

Chair: Oded Berman, University of Toronto, Toronto, ON, M5S 3E6, Canada, berman@rotman.utoronto.ca

1 - Maximal Collaborative Cover Problems with an Application to Hazardous Materials Emergency Response and a Case Study from China

Jiahong Zhao, McMaster Unviersity, Hamilton, ON, Canada, zhaoj77@mcmaster.ca, Peng Hu, Vedat Verter

An efficient emergency system can reduce the risk derived from hazmat network. We restrict our attention to reducing the waiting time and propose a methodology of optimizing multiple emergency sources. We generate the hazmat network based on urban road, and calculate the response time for different hospitals and fire stations. A new model is modified to decide the locations of multiple sources, where the locations are optimized according to minimizing the gap of each hospital and fire station. To solve this model, a solution procedure is designed from generic algorithm. This methodology is applied to the problem in Chengdu, China, and the results provides a significant reduction in waiting time.

2 - Location and Pricing of a Mobile Food Vending Facility using Public Data

Rajan Batta, University at Buffalo, Buffalo, NY, United States, batta@buffalo.edu, Rishabh Bhandawat

The aim of this talk is to formulate a location problem for a market entrant mobile food vendor to maximize profits based only on public data. Specifically, the model suggests dynamic location and service quality decisions (cuisine, price and other service criteria) from online yelp reviews, customer's proximity to the facility along with geographic and demographic data. The error in prediction is reduced by including other facilities and reviews.

3 - Generalised Facility Location and Design Problem

Dmitry Krass, University of Toronto, Rotman School of Management, 105 St George Street, Toronto, ON, M5S.3E6, Canada, krass@rotman.utoronto.ca, Robert Aboolian, Oded Berman

We present a general problem that can be used to represent a wide variety of known location and design models, including models with elastic demand, competitive facilities, different customer allocation rules, etc. While the general model has non-linearities in both the objective and the constraint, these can be removed by exploiting the special structure. This leads to a solvable MIP formulation.

4 - Modeling Global Facility Decisions for a Supply Chain Coordinator

Ram Gopalan, Rutgers, The State University of New Jersey, 227 Penn Street, Camden, NJ, 08102, United States, ram.gopalan@gmail.com, Snehamay Banerjee, Damodar Golhar

A Supply Chain Coordinator (SCC) is an intermediary between raw material suppliers, contract manufacturers and retailers. The SCC does not own plant capacity or raw material, but performs a disintermediating role in supply chain finance by orchestrating the contract manufacturing of customized products for various globally dispersed retailers. The SCC exploits differences in manufacturing costs at various candidate facilities, but also bears the operational risk if demand at end retailers is significantly different from forecasts. This research addresses a facility choice and capacity selection (FC-CS) problem for a SCC who is customizing a product with pronounced counter-seasonal demand.

Advances in Simulation Optimization and its Applications

Sponsored: Simulation

Sponsored Session

Chair: Loo Hay Lee, National University of Singapore, Singapore, 119260, Singapore, iseleelh@nus.edu.sg

1 - Improving Ordinal Transformation by Combining Multiple Low-fidelity Models

Si Zhang, Shanghai University, Shang-Da Road No. 599, Shanghai, 200444, China, zhangsi817@sina.com, Chun-Hung Chen, Jie Xu, Edward Huang

Simulation optimization problems are usually large-scaled and reqire a very high computing cost to solve them. Previous works on a new framework known as ordinal transformation (OT) provides a method that makes use of a low-fidelity approximate model to speed up optimization. In this work we study how to improve the quality of using low-fidelity models when there are two or more low-fidelity models.

2 - Efficient Nested Simulation for Risk Management of Variable Annuities

Ben Feng, University of Waterloo, Waterloo, ON, Canada, ben.feng@uwaterloo.ca

Variable annuities are popular insurance products that enable policyholders to enjoy both insurance protections and investment returns.Dynamic hedging for variable annuities requires computationally intensive nested Monte Carlo simulation experiments. We propose, analyze, and examine efficient simulation procedures to estimate the expected shortfall of the hedging errors for different variable annuities.Our procedure first infers the ranking of hedging losses from a baseline simulation model then concentrate the simulation budget on the inferred "tail scenarios". As shown by our numerical experiments, such concentration of simulation effort greatly improves efficiency.

3 - Machine Learning and Sample Path Analysis for Large Scale Ranking and Selection

Giulia Pedrielli, Arizona State University, Tempe, AZ, 85281, United States, giulia.pedrielli.85@gmail.com, John W. Fowler

The advancement of machine learning methods as well as computing capabilities has opened possibilities to solve discrete optimization problems over large sets. We propose an algorithm that uses unsupervised learning to support ranking and selection when a large number of solutions are present. Paired comparisons are used to provide a three level scoring to individual solutions for clustering and then optimally allocate computational budget to the solutions for estimation. The comparison uses sample path information relying on memory availability on the machine, while trying to minimize the amount of new observations required.

4 - Exploring an Input Parameter Space with a Limited Simulation Budget

Xilun Chen, Arizona State University, 600 S Dobson Road, Unit 110, Mesa, AZ, 85202, United States, Xilun.Chen@asu.edu, K. Selcuk Candan

Complex simulators, such as for predicting epidemics, require a large number input parameters and generate a large space of observations. Consequently, simulation ensembles are expensive to generate and difficult to explore. In practice, given a simulation budget, one needs to identify an ensemble that includes the most informative simulations to help explore the simulation space. Recognizing this challenge, we propose a novel SimExplorer method that uses partial observations to guide the selection process for new simulations to execute. We show that this process can effectively identify new interesting simulations to run, while balancing the overall fit against the partial observation.

Energy and Climate Themes in Transportation

Sponsored: Transportation Science & Logistics

Sponsored Session

Chair: Benjamin Leibowicz, The University of Texas-Austin, Graduate Program in Operations Research and Indust, Austin, TX, United States, bleibowicz@utexas.edu

1 - Hydrogen Supply Chain Analysis for Fuel Cell Vehicles using Wind Energy in Texas

Kazunori Nagasawa, University of Texas-Austin, Austin, TX, United States, nagasawa@utexas.edu, F. Todd Davidson, Michael E. Webber

This work will develop methods to help private and public stakeholders better assess the opportunity for manufacturing, transmitting, and distributing renewable hydrogen, and will use Texas as a case study. This work will include identifying potential locations for hydrogen production via electrolysis and wind power, while accounting for the spatial variance in future consumption centers, and the trade-offs in different infrastructure solutions.

2 - Shared Autonomous Electric Vehicle (SAEV) Operations and Emissions Savings

Krishna Gurumurthy, University of Texas-Austin, Stop C1700, Austin, TX, 78712, United States, Kara Kockelman

Shared Autonomous Vehicles (SAVs) will offer new travel options, with smaller vehicles and better engine use delivering lower emissions. Use of electric vehicles can further reduce energy demands and human exposure to pollution. These studies simulate SAV and SAEV vehicle use around Austin for emissions and cost estimates. One uses different battery-range, fleet-size and charging-speed scenarios to assess fleet profitability and customer service times. While a gasoline hybrid-electric (HEV) SAV fleet typically performs better than EV fleets. SAEVs come close with longer ranges and fast-charging. Higher gas prices, carbon taxes and environmental policies may stimulate their demand.

3 - Policy Recommendations for a Transition to Sustainable Mobility Based on Historical Diffusion Dynamics of Transport Systems

Benjamin D.Leibowicz, University of Texas-Austin, ETC 5.128D, 204 E. Dean Keeton St. C2200, Austin, TX, 78712-1591, United States, bleibowicz@utexas.edu

This study analyzes historical data on the diffusion dynamics of transport systems in the United States. The methodology systematically compares the relative timing of diffusion processes for infrastructure, vehicles, and travel. A striking regularity observed across transport systems is that the diffusion of infrastructure precedes the adoption of vehicles, which precedes the expansion of travel. On the "chicken-and-egg conundrum" of infrastructure provision, findings thus support the view that infrastructure comes first.

Airport Capacity Management

Sponsored: Aviation Applications

Sponsored Session

Chair: Konstantinos G. Zografos, Lancaster University, Lancaster, LA1 4YX, United Kingdom, k.zografos@lancaster.ac.uk

1 - Airport-centric vs Airline-centric Approaches in Demand Management

Alexandre Jacquillat, Carnegie Mellon University, 5000 Forbes Avenue, Office 2118J, Pittsburgh, PA, 15213, United States, ajacquil@andrew.cmu.edu, Vikrant Vaze

Airport scheduling interventions can mitigate, or control, congestion through limited changes in flight schedules. However, significant flexibility exists regarding the design of the underlying schedule optimization. The outcomes of centralized (airport-centric) approaches may not coincide with the distributed (airline-centric) objectives. This talk presents two advances: (i) scheduling approaches that balance centralized objectives of efficiency and reliability with distributed objectives of inter-airline equity, and (ii) game-theoretic approaches that identify opportunities of airline strategic behaviors, or lack thereof. Theoretical and computational results are shown.

2 - Integrating Series in the Simultaneous Allocation of Slots on a Network of Airports

Paola Pellegrini, IFSTTAR, Villeneuve d'Ascq, France, paola.pellegrini@ifsttar.fr, Tatjana Boli , Lorenzo Castelli, Raffaele Pesenti

Airport capacity of many airports is managed through the airport slots. SOSTA is an integer linear programming formulation for the simultaneous allocation of slots at all European airports, considering aircraft turnaround. It reproduces the current process by bringing optimization into it, improving the resulting slot allocation. The original formulation however cannot be used to allocate slots for the entire scheduling season since it does not consider the allocation of a series of slots. In this work, we study possible approaches for overcoming this limitation.

3 - Modelling Efficiency, Fairness and Acceptability in Airport Slot Scheduling Decisions

Jamie Fairbrother, Centre for Transport and Logistics (CENTRAL), Lancaster University Management School, Fylde College, Mathematics and Statistics, Lancaster, LA1 4YW, United Kingdom, j.fairbrother@lancaster.ac.uk, Konstantinos G. Zografos

We propose and solve a slot scheduling model which optimizes efficiency and considers fairness and airline acceptability. We introduce a new congestion based fairness measure and we allow airlines to express their preferences regarding the satisfaction of their slot requests. We apply the proposed model to a medium size congested airport to assess the impact of existing and modified IATA slot scheduling guidelines on fairness and efficiency.

4 - Multimarket Contact and Capacity: Evidence from the United States Airline Industry

Hao Su, University of Maryland-College Park, Robert H. Smith School of Business, College Park, MD, 20742, United States, haosu@rhsmith.umd.edu, Martin E.Dresner

This paper will examine the relationship between multimarket contact (MMC) and airline capacity. Based on the literature, we hypothesize that: (1) MMC negatively affects capacity and (2) MMC has a more negative effect on a carrier's capacity when that market is not important to the carrier. Based on U.S. air carrier traffic data with carefully defined markets, we hypothesize that MMC will be associated with lower route capacity and that this effect is greater on less important routes. Our findings may provide evidence for the mutual forbearance hypothesis, suggesting that MMC may facilitate tacit collusion on the supply of capacity.

MIF Paper Competition

Sponsored: Minority Issues

Sponsored Session

Chair: Lauren Berrings Davis, North Carolina A&T State University, Greensboro, NC, 27411, United States, lbdavis@ncat.edu

Co-Chair: Sean Barnes, University of Maryland-College Park, College Park, MD, 20742, United States, sbarnes@rhsmith.umd.edu

1 - Minority Issues Forum Award

Karen T.Hicklin, University of North Carolina at Chapel Hill, B-24 Hanes Hall, Chapel Hill, NC, 27599-3260, United States, khicklin@email.unc.edu

The annual MIF Paper Competition features paper submissions covering an array of topics from members of the MIF community. The prize committee evaluated submissions based on importance of the topic, appropriateness of the approach, and impact of the paper within its respective area. Four finalists have been selected to present their research: Alp Akcay and Canan Corlu (Simulation of inventory systems with unknown input models: A data driven approach), Michelle Alvarado and Lewis Ntaimo (Chemotherapy appointment scheduling under uncertainty using mean-risk stochastic integer programming), Esra Buyukhtahtakin and Joseph C. Hartman (A mixed-integer programming approach to the parallel replacement problem under technological change) and Maria Mayorga, Emmett Lodree, and Justin Wolczynski (The optimal assignment of spontaneous volunteers).

2 - Simulation of Inventory Systems with Unknown Demand Models

Canan Corlu, Eindhoven University of Technology, Eindhoven, Netherlands, na, Alp Akcay

Assuming the availability of limited demand data, we consider the stochastic simulation of an inventory system with unknown demand distributions. Building on a nonparametric Bayesian approach, we propose a simulation replication algorithm that estimates a service level for the inventory system without making any assumptions on the functional form of the demand models. We illustrate our approach in a single-product inventory simulation.

3 - Chemotherapy Appointment Scheduling under Uncertainty using Mean-Risk Stochastic Integer Programming

Lewis Ntaimo, Texas A&M.University, 3131 TAMU, College Station, TX, 77843, United States, ntaimo@tamu.edu, Michelle Alvarado

Chemotherapy involves a series of appointments over several weeks and the timing of these appointments is critical to the patient's healing process. However, oncology clinics often find it very challenging to schedule large volumes of cancer patients for chemotherapy due to limited resources and data uncertainties such as nurse availability, patient acuity levels and appointment durations. In this work, we develop risk-averse stochastic integer programming models and algorithms towards solving this problem. Computational results based on real data show that the new approach significantly reduces patient waiting times and nurse overtime.

4 - A Mixed-Integer Programming Approach and New Cutting Planes for the Parallel Replacement Problem under Technological Change

Esra Buyuktahtakin, New Jersey Institute of Technology, Newark, NJ, United States, esratoy@njit.edu, Joseph Hatrman

The parallel replacement problem under economies of scale (PRES) determines minimum-cost keep-and-replace decisions for a group of assets. We study the MIP formulation of PRES under technological change (PRES-T), such that newer, technologically advanced assets have higher capacity than assets purchased earlier. We provide optimal solution characteristics and insights into the economics of the problem and derive new cutting planes for optimizing it. Computational experiments on the USPS fleet management case illustrate that the inequalities are quite effective in solving PRES-T instances.

5 - The Optimal Assignment of Spontaneous Volunteers

Maria Esther Mayorga, North Carolina State University, 400 Daniels Hall, Dept. of Industrial & Systems Engineering, Raleigh, NC, 27695, United States, memayorg@ncsu.edu, Emmett Lodree, Justin Wolczynski

In this presentation, a queuing model is formulated to accurately represent the dynamics of assigning spontaneous volunteers to tasks (or jobs) in a post-disaster setting. In particular, we model volunteers as servers with not only stochastic arrivals but also with stochastic abandonment times. We formulate a continuous-time Markov decision process and find an optimal policy for volunteer allocation under the relatively stable recovery phase of post-disaster management. We then test the optimal policy against heuristic policies using a simulation model. We also test the performance of these policies under relaxed assumptions.

Advanced Maintenance Models

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Yisha Xiang, Lamar University, Beaumont, TX, United States, yxiang@lamar.edu

1 - Bayesian Degradation Based Reliability Growth with Uncertain Effectiveness of Corrections

Cesar Ruiz Torres, University of Arkansas, Fayetteville, AR, 72701, United States, caruizto@email.uark.edu, Haitao Liao, Edward A. Pohl

Modern products continue to be made increasingly complex meanwhile are still expected to be more reliable. To meet the increasing reliability requirements, reliability growth tests must be conducted in a fast and effective way. We propose a Bayesian reliability growth method to estimate and improve the reliability of a product based on multiple degradation processes of the product. We assume that each degradation process can be modeled by an Inverse-Gaussian process, but the initial degradation and the parameters of corrective actions are unknown. A Copula approach is utilized to model the dependencies between the multiple failure modes. A simple case study is provided to demonstrate the model.

2 - Reliability Analysis of Repairable Systems with Incomplete Failure Time Data

Wujun Si, Wayne State University, 4815 Fourth Street, Room 2167, Detroit, MI, 48202, United States, wujun.si@wayne.edu, Qingyu Yang, Leslie Monplaisir, Yong Chen

In many real situations, the failure time data of a repairable system may not be fully observed. Most existing reliability studies concerned with missing failure time data assume the system repair is either perfect or minimal. In this paper, we conduct reliability analysis of repairable systems subject to missing failure time data when the repair is general. A maximum likelihood estimation method is developed for the model parameter estimation. Simulation and case studies are conducted to illustrate the developed methods.

3 - Spare Parts Prediction Considering Uncertain Installed Base: A Review and Future Study

Tongdan Jin, Texas State University, 601 University Drive, Ingram School of Engineering, San Marcos, TX, 78666, United States, tj17@txstate.edu, Jose F.Espiritu, Heidi Taboada

Maintenance and spares inventory model are often studied based on a static installed base. When a new product is released, the installed base is likely to increase due to the market growth. As a result, the demand for spare parts turns to be nonstationary. This talk discusses the recent advances in spare parts provisioning in a non-stationary setting. We introduce superposition renewal theory, review spares forecasting model, characterize lead-time demand, and discuss the future research opportunities.

4 - Condition Based Maintenance for Wind Turbines Considering Complex Conditions

Zhigang Will Tian, University of Alberta, 5-8J Mechanical Engineering Building, Department of Mechanical Engineering, Edmonton, AB, T6G 2G8, Canada, ztian@ualberta.ca, Fangfang Ding, Hao Xu

Condition based maintenance strategy aims to develop predictive maintenance schedules based on equipment health conditions. Wind turbines are subject to varying load due to changing wind speed and directions. In this study, wind turbine component health conditions are predicted considering complex varying external conditions, and condition based maintenance schedules are developed based on the predicted future health conditions.

5 - Opportunistic Preventive Maintenance Scheduling for a Multi-unit Series System

Yisha Xiang, Lamar University, 2626 Cherry Engineering Building, Beaumont, TX, United States, yxiang@lamar.edu, Zhicheng Zhu, Bo Zeng

In a complex multi-unit system, opportunistic maintenance is an effective way to reduce system maintenance cost. The center problem of opportunistic maintenance is to decide which component should be maintained in a decision point under the uncertainty of the components' life time. In this research, we consider a stochastic opportunistic preventive maintenance for a multi-unit series system, and develop a two-stage deterministic equivalent problem for approximation. Numerical example is given to illustrate the proposed model. Our results show that potential saving can be achieved from optimal opportunistic preventive maintenance.

State-of-the-Art Renewable Energy Modeling and Analysis

Invited: Energy and Climate

Invited Session

Chair: John Bistline, Electric Power Research Institute, Electric Power Research Institute, Jbistline@epri.com

Co-Chair: Delavane Diaz, Electric Power Research Institute, Electric Power Research Institute, Washington, DC, 20005, United States, ddiaz@epri.com

1 - Advanced Methods for Modeling the Integration of Variable Resource Renewable Energy Technologies in the Electric Power Sector

Kelly Eurek, National Renewable Energy Laboratory, Golden, CO, United States, Kelly.Eurek@nrel.gov

Because renewable power is a rapidly growing component of the electricity system, robust representations of renewable technologies should be included in capacity-expansion models. This is a challenge because modeling the electricity system—and, in particular, modeling renewable integration within that system—is a complex endeavor. This presentation highlights the major challenges of incorporating renewable technologies into capacity-expansion models and shows examples of how NREL's Regional Energy Deployment System (ReEDS) model address those challenges.

2 - The Economic Geography of Variable Renewable Energy

John Bistline, Electric Power Research Institute, Los Angeles, CA, United States, john.bistline@gmail.com

Regional differences in electric sector capacity mixes, wind and solar resource potentials, and markets have important implications for resource planning and policy design, especially for variable renewable energy. Despite the proliferation of state-based policies, capacity planning models have only recently incorporated the temporal and spatial resolution necessary to evaluate economic and environmental effects from such regional market linkages. This talk will summarize novel treatments of these areas in EPRI's US-REGEN energy-economic model and will describe analyses of renewables-focused policies, which underscore the importance of capturing the spatial dependence of impacts.

3 - Representing Energy Storage in Power System Models with Variable Renewable Energy

Audun Botterud, MIT, Argonne National Laboratory, Cambridge, MA, 02140, United States, audunb@mit.edu

We discuss the representation of energy storage in modeling of power systems and electricity markets with increasing shares of renewable energy. In particular, we focus on modeling of electrochemical batteries with improved representation of degradation, losses, and power limits. We present examples of short- and long-term analysis of energy storage applications in the power grid, including energy arbitrage, unit commitment, and generation expansion planning.

Data Mining Best Paper Award I

Sponsored: Data Mining

Sponsored Session

Chair: Tong Wang, University of Iowa, Pappajohn Business Building, 21 East Market Street, Iowa City, IA, 52245, United States, tong-wang@uiowa.edu

1 - Learning Cost-Effective and Interpretable Treatment Regimes

Himabindu Lakkaraju, Stanford University, Escondido Village, 119 Quillen Court, Stanford, CA, 94305, United States, himalv@cs.stanford.edu

Decision makers, such as doctors, make crucial decisions such as recommending treatments to patients on a daily basis. These decisions typically involve weighing the potential benefits of taking an action against the costs involved. In this work, we aim to automate this task of learning cost-effective, interpretable and actionable treatment regimes from observational data. We formulate this as a problem of learning a decision list - a sequence of if-then-else rules - that maps characteristics of subjects (eg., diagnostic test results of patients) to treatments. We propose a novel objective to construct this decision list which maximizes outcomes for the population, and minimizes overall costs. Since we do not

observe the outcomes corresponding to counterfactual scenarios in observational data, we use techniques from causal inference literature to infer them. We model the problem of learning a decision list as a Markov Decision Process (MDP) and employ a variant of the Upper Confidence Bound for Trees (UCT) strategy which leverages customized checks for pruning the search space effectively. Experimental results on real world observational data capturing judicial bail decisions and treatment recommendations for asthma patients demonstrate the effectiveness of our approach.

2 - Data Science Based Simulation and Optimization of Soybean Variety Selection

Durai Sundaramoorthi, Washington University in Saint Louis, St. Louis, MO, 63131, United States, dsundaramoorthi@gmail.com

Humanity is facing the greatest challenge of feeding itself. The World Food Programme estimates that about 795 million people do not have adequate food to have a healthy life. About 3.1 million children die every year because of poor nutrition. As a small part of addressing this great humanitarian challenge, this research proposes an analytics framework for growing the optimal soybean varieties. Selecting soybean varieties for planting is an important decision that has significant implications for the yield of the farm. With many soybean varieties available along with the data on yield performance collected over several years at various farm locations, the seed-mix selection is a highly intriguing decision to modern day farmers. To aid soybean-mix selection, this research evaluates five data mining models - Regression Trees (RT), Random Forest (RF), Boosted Trees (BT), Multivariate Adaptive Regression Splines (MARS), and Artificial Neural Network (ANN) - as the predictive algorithms for the soybean yield. Using a data set collected between 2008 and 2014 by Syngenta, an agribusiness, we evaluate these models and choose RT as the most suitable algorithm to inform simulation of soybean yield under different weather conditions. We formulated a simulation-based optimization problem to determine the optimal soybean-mix to minimize the risk associated with the yield. As a result, Syngenta is equipped to make soybean-mix recommendations to the farmers.

3 - Tensor Mixed Effects Model with Applications in Nanomanufacturing Inspection

Xiaowei Yue, Georgia Institute of Technology, 755 Ferst Drive NW, ISYE, Atlanta GA, 30332, United States, xwy@gatech.edu"

Raman mapping technique has been used to do in-line quality inspections of nanomanufacturing process. In such an application, a massive high dimensional Raman mapping data with mixed effects are generated. In general, fixed effects and random effects in the multi-array Raman data are associated with different quality characteristics such as fabrication consistency, uniformity, defects et al. The existing tensor decomposition methods cannot separate mixed effects, and existing mixed effects model can only handle matrix data instead of high dimensional multi-array data. In this paper, we propose a tensor mixed effects (TME) model to handle massive in-line high dimensional Raman mapping data with complex structure. The proposed TME model can (i) separate fixed effects and random effects in a tensor domain; (ii) exploit the correlations along different dimensions; and (iii) realize efficient parameter estimation by a proposed iterative double Flip-Flop method. Properties of the TME model and existence and identifiability of parameter estimation are investigated. Numerical analysis demonstrates the efficiency and accuracy of the parameter estimation in the TME model. Convergence and empirical asymptotic properties are discussed in the simulation and surrogate data analysis. The Real case study shows an application of the TME model in quantifying the influence of alignment on carbon nanotubes buckypaper.

4 - Dynamic Multivariate Functional Data Modeling via Sparse Subspace Learning

Chen Zhang, National University of Singapore, Singapore, 117576, Singapore, zhangchen@u.nus.edu

Though multivariate functional data are common in many applications, they have not been comprehensively investigated yet, with several challenges to be solved. In particular, they are naturally high-dimensional and have complex cross-correlation structure. Some functions are strongly correlated with similar features, while some others may have almost no correlations with quite diverse features. Furthermore, the cross-correlation structure may even change over time due to the system evolution. With this regard, this paper presents a dynamic subspace learning method for multivariate functional data modeling. In particular, we consider different functions come from different disjoint subspaces, and only functions of the same subspace have correlations with each other. The subspaces can be automatically identified and learned by formulating the problem as a sparse regression. By allowing but regularizing the regression change over time, we can describe the cross-correlation dynamics. The model can be efficiently estimated by the fast iterative shrinkage-thresholding algorithm (FISTA), and the features of every subspace can be extracted using the smooth multi-channel functional PCA. Numerical studies together with case studies demonstrate the efficiency and applicability of the proposed methodology.

Interpretable Machine Learning

Sponsored: Data Mining

Sponsored Session

Chair: Berk Ustun, Massachusetts Institute of Technology, Cambridge, MA, 02139, United States, ustunb@mit.edu

1 - Optimized Risk Scores

Berk Ustun, Massachusetts Institute of Technology, 20 Highland Avenue 2, Cambridge, MA, 02139, United States, ustunb@mit.edu, Cynthia Rudin

Risk scores are simple models to quickly assess risk by adding and subtracting a few small numbers. Such models are widely used in healthcare and criminal justice, but are built ad hoc. We present a new approach to learn risk scores that are optimized for feature selection, integer coefficients, and operational constraints. We formulate the risk score problem as a MINLP, and design a new cutting plane algorithm to solve it efficiently. Our approach can fit optimized risk scores in a way that scales linearly in the sample size, provides a proof of optimality, and addresses complex constraints without parameter tuning. We illustrate its benefits by building customized risk scores for medical applications.

2 - Interpretable and Interactive Approximations of Black Box Models

Himabindu Lakkaraju, Stanford University, Escondido Village, 119 Quillen Court, Stanford, CA, 94305, United States, himalv@cs.stanford.edu, Ece Kamar, Rich Caruana, Jure Leskovec

We propose Black box Explanations through Transparent Approximations, a novel framework for constructing global explanations of any black-box classifier. We develop a novel objective function which learns a small number of compact decision sets each of which explains black box model behavior in unambiguous, well-defined regions of feature space. Our framework also allows users to interactively explore how the black box model behaves in different subspaces. To our knowledge, this is the first approach which produces explanations of black box classifiers via joint optimization of unambiguity, fidelity, interpretability, while allowing users to explore its behavior based on their preferences.

3 - Interpretable Two-level Boolean Rule Learning

Dennis Wei, IBM Thomas J. Watson Research Center, Yorktown Heights, NY, 10598, United States, dwei@us.ibm.com, Guolong Su, Kush R. Varshney, Dmitry M. Malioutov

We develop a novel optimization framework for learning two-level Boolean rules for classification, in both conjunctive (AND-of-ORs) and disjunctive (OR-of-ANDs) normal forms. Two objective functions are introduced to trade off classification accuracy and interpretability, where we use 0-1 error and Hamming loss to characterize accuracy and sparsity to characterize interpretability. We propose efficient optimization procedures based on linear programming relaxation, block coordinate descent, and alternating minimization. Experiments show that our algorithms based on Hamming loss provide good tradeoffs between accuracy and sparsity with improvements over the state-of-the-art.

Vehicle Routing with Service Network Design Considerations

Sponsored: Transportation Science & Logistics

Sponsored Session

Chair: Marco Schutten, University of Twente, Faculty of Management and Governance, P.O. Box 217, Enschede, 7500 AE, Netherlands, m.schutten@utwente.nl

Co-Chair: Ali Alyasiry, The University of Queensland, Brisbane, Australia, a.alyasiry@uq.edu.au

1 - A Hub Location and Vehicle Routing Problem with Time Windows

Jeremy Castaing, Llamasoft Inc, Ann Arbor, MI, 48104, United States, jeremy.castaing@llamasoft.com, Duyi Li

A common extension of the vehicle routing problem (VRP) in real-life transportation system is to model hubs. Hubs are facilities that consolidate shipments between distribution centers and customers. We discuss an approach to extend a classic VRP algorithm to consider hubs and also time windows. The algorithm is integrated in Supply Chain Guru software developed by Llamasoft Inc.

2 - Large Neighborhood Heuristics for the Two-echelon Multi-depot Vehicle Routing Problem Arising in City Logistics
Jiang Da-Pei, Tongji University,School of Economics and Management, Tongji Building A, Siping Road 1500, Shanghai, China, 56jdp@tongji.edu.cn

Two-echelon distribution systems are quite common in city logistics under electronic commerce. First-level vehicles located in the depots carry the demands from depots to the satellites, then demands are transfer to the second-level vehicles, then delivery to customers and fulfillment the time windows. In this paper, we introduce a two-echelon multi-depot vehicle routing problem with tasks synchronization problem (2E-MDVRP-TS). We propose an adaptive large neighborhood search to solve this problem. Our method used existing operators that in the literature and developed some new operators designed specifically for the problem considered, later evaluated on some benchmarks.

3 - An Exact Algorithm for the Pickup and Delivery Problem with Time Windows and its Variants
Ali Alyasiry, The University of Queensland, St. Lucia Campus, Brisbane, 4072, Australia, a.alyasiry@uq.edu.au, Michael Forbes

Research on exact methods to solve the pickup and delivery problem with time windows (PDPTW) and its variants has mainly focused on branch and price and cut algorithms. We propose a novel exact approach based on fragments - a series of pickup and delivery requests starting and ending with an empty vehicle. Using fragments, we formulate an optimistic network flow model with side constraints and use lazy constraints to cut off any illegal solutions generated while solving the resultant integer program. Results confirm that this approach is competitive with existing methods.

4 - Multi-hop Driver-parcel Matching Problem with Time Windows
Marco Schutten, University of Twente, Enschede, Netherlands, m.schutten@utwente.nl, Wenyi Chen, Martijn Mes

Crowdsourced shipping can result in significant economic and social benefits (e.g., faster deliveries and congestion reduction). With the aim of using the spare capacities along the existing transportation flows of the crowd to deliver small-to-medium freight volumes, we introduce the multi-driver multi-parcel matching problem and propose a general ILP formulation, which incorporates drivers' maximum detour, capacity limits, and the option of transferring parcels between drivers. The numerical study shows that crowdsourced shipping can be an economic viable and sustainable option.

Analysis of Complex Manufacturing Data

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Zhou Qiang, University of Arizona, zhouq@email.arizona.edu

Co-Chair: Jianguo Wu, University of Texas-El Paso, El Paso, TX, 79968, United States, jwu2@utep.edu

1 - Multivariate Profile Monitoring using Gaussian Process Models
Salman Jahani, Research Assistant, University of Wisconsin-Madison, Madison, WI, 53706, United States, jahani@wisc.edu

Recently, considerable attention has been paid to profile monitoring. While most of the research is focused on monitoring univariate profiles, this study focuses on multivariate profile monitoring using a multivariate Gaussian process (MGP) model. In this regards, first, using MGP the structure of profiles is determined; then based upon this baseline structure, a distance-based statistic is proposed to monitor the stability of profile over time.

2 - Size Distribution Estimation of 3D Particle Clusters in Metal Matrix Nanocomposites Considering Sampling Bias
Jianguo Wu, University of Texas-El Paso, 500 W University Ave, Engineering Building, Room A-244, El Paso, TX, 79968, United States, jwu2@utep.edu

Nanoparticle clustering phenomenon is a critical quality issue in metal matrix nanocomposites manufacturing. Accurate estimation of the 3D cluster size distribution based on the 2D cross-section images is essential for quality assessment, quality control, and process optimization. The existing studies often draw conclusions with observable samples, which are inherently biased because large clusters more likely to be intersected by SEM images compared with small ones. This paper takes into account this sampling bias and proposes two statistical approaches, namely, the maximum likelihood estimation (MLE) and the method of moments (MM), to estimate the distribution parameters accurately.

3 - Diagnosis of Multi-scale Spatial Point Interaction
Qiang Zhou, University of Arizona, Rm314, 1127 E James E. Rogers Way, Tucson, AZ, 85721, United States, q.zhou@arizona.edu

We propose a novel diagnosis method for spatial point data in manufacturing, based on decomposition of a K function-based T2 statistic. The method can independently analyze point interactions at multiple spatial scales, which is particularly useful for fault diagnosis when the process is out-of-control.

Sponsored Session

Chair: Xinwei Deng, Department of Statistics, Virginia Tech, Blacksburg, VA, 24061, United States, xdeng@vt.edu

1 - Nonparametric Modeling and Prognosis of Condition Monitoring Signals: A Transfer Learning Approach Based on Multivariate Gaussian Convolution Processes
Raed Al Kontar, University of Wisconsin-Madison, 1513 University Avenue, Room 3255, Madison, WI, 53706, United States, alkontar@wisc.edu

In this paper, an alternative view on modeling condition monitoring signals is proposed. This view draws its roots from transfer learning and is based on sharing convolved latent functions between training and testing units. The advantageous features of our method are highlighted with a case study for automotive lead-acid batteries.

2 - S3T: An Efficient Score-statistic for Spatio-Temporal Surveillance
Junzhou Chen, Georgia Institute of Technology, Atlanta, GA, United States, na@tbd.org

We present an efficient score statistic to detect the emergence of a spatially and temporally correlated signal, which is called the S3T statistic. The signal may cause a mean shift, and (or) a change in the covariance structure. The score statistic can capture both spatial and temporal change and hence is particularly powerful in detecting weak signals. Our score method is computationally efficient and statistically powerful. The main theoretical contribution is an accurate analytical approximation on the false alarm rate of the detection procedure, which can be used to calibrate a threshold analytically. Simulated and real-data examples demonstrate the good performance of our procedure.

3 - Adaptive Importance Sampling for Determining Resistance Levels in Reliability-based System Design
Qiyun Pan, University of Michigan, 1205 Beal Avenue, Department of IOE, Ann Arbor, MI, 48109-2117, United States, qiyun@umich.edu

In order to design reliable systems, resistance level determination becomes crucial in many applications. At the design stage, resistance level can be estimated using stochastic simulations. However, estimation results using the crude Monte Carlo sampling are highly uncertain. We present a new adaptive algorithm to improve the estimation accuracy.

4 - Bayesian Sequential Calibration using Detailed Sample Paths
Bo Wang, Rensselaer Polytechnic Institute, Troy, NY, United States, wangb13@rpi.edu

Simplified simulation models are often used to guidethe decision-making for complex stochastic systems. To faithfullyassess the mean performance of the real system, we developa new calibration approach incorporating the detailed output-sample paths in a sequential manner, that can efficiently use thesimulation resources and achieve better accuracy.

Sponsored: Energy, Natural Res & the Environment Environment & Sustainability

Sponsored Session

Chair: Victoria Chen, University of Texas, vchen@uta.edu

1 - Design and Analysis of Computer Experiments Approach for Green Building

Shirish Rao, The University of Texas-Arlington, Arlington, TX, United States, shirish.rao@mavs.uta.edu

Building structures have significant impact on environment and energy consumption. Buildings can be designed so that their energy consumption is reduced by using energy efficient materials. The "cradle-to-grave" cycle is a criterion for the environmental effects of materials, and minimizing this effect along with energy consumption is of great interest. The goal of the research is to compare different experimental designs and statistical modeling methods to help inform our approach for a multivariate, multi-response green building framework. The results of the experiments are studied by using Treed regression and Multi Adaptive Regression Splines techniques to find influential factors.

2 - Using Approximate Dynamic Programming to Control an Electric Vehicle Charging Station System

Victoria C.P. Chen, University of Texas-Arlington, Industrial, Manufacturing, & Systems Engr., Campus Box 19017, Arlington, TX, 76019-0017, United States, vchen@uta.edu, Ying Chen, Jay Michael Rosenberger, Wei-jen Lee

Electric vehicle charging stations system assumed to locate in Dallas Fort-Worth area integrate wind power, solar power and main electricity grid to supply electricity for the demand from the electric vehicles. Design and analysis of computer experiments based infinite-horizon approximate dynamic programming (ADP) algorithm is used to generate a high-quality policy to control this 31 dimensional system over a continuous-state space. A specified 45-degree line correspondence stopping rule is utilized to identify the high-quality ADP policy at early DP iterations. The results demonstrate with the selected ADP policy, the system has a better control performance than using the greedy policy.

3 - Optimizing Location of Electric Vehicle Charging Stations

Ukesh Chawal, The University of Texas at Arlington, Arlington, TX, United States, ukesh.chawal@mavs.uta.edu, Jay Rosenberger, Victoria Chen, Wei-Jen Chen, Raghavendra Punugu, Mewan Wijemanne

Due to the economic and environmental concerns associated with fossil fuels and the growing need for sustainability, the use of electric vehicles (EVs) is a viable solution. In this paper, a Mixed-Integer Linear Programming (MILP) model and a Design and Analysis of Computer Experiments (DACE) based system design optimization approach have been used to optimize the locations of the EV Charging stations and the number of slots to be opened to maximize the profit, meeting the customers demand.

4 - A Simulation Framework for Police Patrol Deployment: A Decision Support Tool

Khan Md. Ariful Haque, The University of Texas at Arlington, Arlington, TX, United States, khanmdariful.haque@mavs.uta.edu

Evaluating dynamic deployment strategies and determining the best one is a real challenge to a police department without reforming the current practice that costs money and time without any result. A flexible discrete-event simulation framework has been proposed that can facilitate any police department in city level for evaluating possible dynamic policing strategies without spending significant resources. From available data, estimated input parameters considering randomness of Call arrivals and service times of different priority levels are using into the model that will enable police department in decision making based on the output.

Chair: Harshad Rai, University of Illinois at Urbana-Champaign, Champaign, IL, United States, hrrai2@illinois.edu

1 - Looking Inside Your Shopping Bag the use of Retail Data to Capture Health Lifestyles

lichung Jen, National Taiwan University, Taipei, Taiwan, lichung@ntu.edu.tw, YiChun Liu

When a patient goes to a clinic, the doctor can only see the results from all the medical examinations and then infer what is wrong about his/her health without knowing what exactly is the behavior of his/her daily nutrition intake. Due to the recent development of Big Data technology, the transactions data collected by retailers can reveal the details of consumer purchase behavior illustrating their health lifestyle. In this study, we construct an index of calories activity (CAI) of food consumption based on the customer transaction database of a supermarket. Through the index, we are able to identify customers with health risks.

2 - The Optimal Bootstrap and its Applications

Bradley E. Sturt, Massachusetts Institute of Technology, Cambridge, MA, United States, bsturt@mit.edu, Dimitris Bertsimas

The bootstrap is a randomized method for calculating quantities, such as confidence intervals (CI), directly from data. Since the variability from randomization can lead to inaccurate outputs, we take a deterministic approach. In this talk, we present the first efficient deterministic approximation algorithm (FPTAS) for the bootstrap method. In experiments, the algorithm quickly produces CIs that are substantially more accurate and trustworthy than those from traditional methods. Finally, we present several new computational complexity results related to the bootstrap and probability theory.

3 - Internet of Things

Michael Chuang, SUNY New Paltz, 1 Hawk Drive, New Paltz, NY, 12561, United States, mikeychuang@gmail.com

Internet of Things, a global infrastructure enabling services by interconnecting physical and virtual things based on interoperable information and communication technologies, has emerged in business applications in various industrial areas, and will reshape tomorrow's business and technology development.

4 - GPU Supported Large Scale Simulation Models for Influenza Pandemic Outbreaks

Shalome Hanisha Anand Tatapudi, University of South Florida, 4202 E. Fowler Avenue, ENB 118, Tampa, FL, 33620-5350, United States, tatapudi@mail.usf.edu, Walter Silva, Tapas K. Das

Influenza pandemics are a serious concern and researchers are trying to understand its patterns. One such tool to effectively understand the disease characteristics is through an agent-based (AB) simulation model, which is versatile, yet has computational limitations when it comes to simulating larger populations. This study integrates the flexibility of AB simulation with computational efficiency of a graphical processing unit (GPU) to create models for pandemic outbreaks in large areas comprising of hundreds of millions of people.

5 - NYC Traffic Collision Analysis to Mine Patterns in Traffic Fatalities

Harshad Rai, Graduate Student, University of Illinois at Urbana-Champaign, 107, East Springfield Ave., Apt. 317, Champaign, IL, 61820, United States, hrrai2@illinois.edu, Anirudh Madhusudan

This project focuses on the use of Machine Learning algorithms to analyze traffic collisions. In the future, there is likely to be a lot more data about cities. Vehicle-to-vehicle and vehicle-to-infrastructure is likely to provide transformative changes in mobility. Cities are breeding grounds for emergent behavior, so this provides a lot of interesting challenges. The DBSCAN algorithm, a density based clustering method; is used to cluster traffic fatalities to recognize possible danger zones. Spatio-temporal visualization and analysis is carried out to find patterns in traffic collisions. Random forest is used to predict the recurrence of accidents and fatalities.

1 - Simulation Optimization of Risk Measures with Adaptive Risk Levels

Enlu Zhou, Georgia Institute of Technology, 755 Ferst Drive NW, Atlanta, GA, 30332-0205, United States, enlu.zhou@isye.gatech.edu, Helin Zhu, Joshua Hale

Optimizing risk measures such as Value-at-Risk (VaR) and Conditional Value-at-Risk (CVaR) of a general loss distribution is usually difficult, because 1) the loss function might lack structural properties such as convexity or differentiability since it is often generated via black-box simulation of a stochastic system; 2) evaluation of risk measures often requires rare-event simulation, which is computationally expensive. We extend the recently proposed gradient-based adaptive stochastic search (GASS) to the optimization of risk measures VaR and CVaR, and incorporate an adaptive updating scheme on the risk level.

2 - Trust Based Optimization with Adaptive Restart: A Family of Global Optimization Algorithms

Logan Michael Mathesen, Arizona State University, 699 S. Mill Ave, Tempe, AZ, 85281, United States, lmathese@asu.edu, Giulia Pedrielli

The field of simulation optimization has seen many algorithms proposed for local optimization drawing upon locally convergent search methods, and numerous global optimization algorithms with differing strategies to achieve convergence. Globally we look into meta-model based algorithms that stochastically drive global search through an optimal sampling criteria evaluated over a predicted response and its uncertainty. We propose Trust Region Based Optimization with Adaptive Restarts (TBOAR), a family of algorithms that dynamically restarts a trust region based local search method via an optimal sampling criteria derived upon a meta-model based global search approach.

3 - Martingale Search Algorithms for Simulation Optimization

Seksan Kiatsupaibul, Chulalongkorn University, 65 Soi Sukhumvit 7, Bangkok, 10110, Thailand, seksan@cbs.chula.ac.th, Robert L. Smith, Zelda B. Zabinsky

We propose a class of adaptive random search algorithms for simulation optimization that generalizes a number of algorithms in the literature. In the course of the algorithm, design points are sequentially sampled from the design space, according to an adaptive sampling probability function. Objective function values are estimated via shrinking balls, which satisfies a martingale property in a continuous domain. We extend the martingale property to discrete domains, noting that we only make a single observation for each sample point in each iteration, although later returns to the same point will accumulate a collection of observations for the same design point.

Emerging Applications in Network Optimization

Sponsored: Optimization, Network Optimization

Sponsored Session

Chair: Robert Mark Curry, Clemson University, Central, SC, 29630, United States, rmcurry@g.clemson.edu

1 - A Centrality Study of Protein-protein Interaction Networks

Saeid Rasti, North Dakota State University, Fargo, ND, United States, saeid.rasti@ndsu.edu, Chrysafis Vogiatzis

One of the main objectives of Systems biology is to reveal fundamental, architectural principles that provide us with better insight on the underlying structure and functionality at the cellular level. In this talk, we present the state-of-the-art of using centrality indices to analyze and interpret protein-protein interaction networks (PPINs). We then proceed to discuss a series of novel group centrality metrics and their implications for PPINs. Of particular interest to us is a membership centrality index, that builds upon standard centrality metrics. Our results showcase that group centrality enables us with an efficient and effective way to detecting essentiality in the proteome.

2 - Solution Methods for the Interdependent Network Flow Problem

Negin Enayaty Ahangar, Industrial Engineering, University of Arkansas, nenayaty@email.uark.edu, Kelly Sullivan, Sarah G. Nurre

We formulate a multi-layered network flow problem in which the flow of each layer is dependent on the flow of other layers. The formulation can be considered as an extension of the minimum cost flow problem to a multi-layered network. This problem has applications in identifying and mitigating vulnerabilities in interdependent infrastructure systems. We identify valid inequalities to tighten the model's LP relaxation. We propose a solution methods using these valid inequalities to solve this NP-Hard problem. Computational results are presented to compare the proposed solution method with the traditional branch and bound method.

3 - On Routing Unmanned Aerial Vehicles for Surveillance and Reconnaissance Activities

Cai Gao, University at Buffalo, Bell 316, University at Buffalo, Buffalo, NY, 14260, United States, caigao@buffalo.edu, Jose Luis Walteros, Chase Murray

We tackle a variation of the close-enough traveling salesman problem in which the salesman is accounted of visiting a node if he traverses a pre-calculated optimal distance through each circular area surrounding the node. This variation arises in the context of unmanned aerial vehicle routing, where a vehicle must cross an area collecting information form a set of targets, while minimizing the detection risks. We consider two approaches for modeling the tradeoff between the amount of collected information and the observed risk and test them by solving a collection of instances adapted from the literature.

4 - An Augmenting Flow Algorithm for a Class of Node-capacitated Maximum Flow Problems

Robert Mark Curry, Clemson University, 111 Woodside Lane, Central, SC, 29630, United States, rmcurry@g.clemson.edu, Cole Smith

We consider a class of maximum flow problems having node- and arc-capacity constraints, in which each unit of flow on arc (i,j) consumes a non-negative amount of capacity at node i. Rather than solving a linear program for these problems, we present an augmenting flow algorithm. In this algorithm, we augment flows along a path having positive residual capacities among all arcs and nodes along the path. When no such paths exist, we find and augment flow along flow-cycles that increase the residual capacity at an incapacitated node. We prove the optimality and computational complexity of our algorithm and apply it to solve various problems in wireless sensor network settings.

1 - Pickup and Delivery with Synchronized Transfers

Monireh Mahmoudi, Arizona State University, Tempe, AZ, United States, mmahmou2@asu.edu, Xuesong Zhou

In this paper, we consider complex assignment-routing constraints corresponding to the pickup and delivery problem with time windows and synchronized transfers by constructing multi-dimensional networks. More specifically, we introduce a multi-vehicle state-space-time network in which only non-dominated assignment-based hyper paths are examined. Then, we reach optimality for local clusters derived from a large set of passengers on real-world transportation networks. Extensive experiments over the standard instances and real-world data set show the solution optimality, as well as computational efficiency of our developed algorithm.

2 - Solving Stochastic Scheduled Service Network Design Problems

Mike Hewitt, Loyola University Chicago, 370 Grandview Ave, Glen Ellyn, IL, 60137, United States, mhewitt3@luc.edu

Consolidation carriers transport shipments that are small relative to trailer capacity. To be cost-effective, a carrier must consolidate shipments, which requires coordinating shipment paths in both space and time. However, they often must determine these shipment paths before all information (e.g. size, times available and due) regarding a shipment is known. In this talk, we present an extension of an iterative refinement algorithm designed to solve Scheduled Service Network Design Problems to stochastic variants.

3 - Inventory Routing in Continuous Time using Time-Expanded Models

Natashia Boland, Georgia Institute of Technology, Ferst Drive, Atlanta, GA, 30332, United States, natashia.boland@gmail.com, Felipe Lagos, Martin W. P.Savelsbergh

Inventory routing is the problem of routing vehicles in space and time to deliver product to customers whose demand is a function of time, so that customers are never short of product and so that the sum of delivery and/or inventory costs are minimized. To date, research on inventory routing problems has focused on discrete time settings. Here we treat continuous time: customers demand is a continuous function of time. We show how integer programming models based on time discretization can be constructed so as to yield both primal and dual bounds on the value of the continuous-time problem, leading to a solution procedure, for which we present computational results.

Bilevel Optimization

Sponsored: Computing

Sponsored Session

Chair: Juan Borrero, University of Pittsburgh, Pittsburgh, PA, 15260, United States, jsb81@pitt.edu

Co-Chair: Hosein Zare, University of Pittsburgh, Pittsburgh, PA, 15260, United States, moz3@pitt.edu

1 - Solving Facility Location Problem through Robust Bilevel Optimization

Liang Xu, University of Pittsburgh, 3700 O'Hara Street, 1048 Benedum Hall, Pittsburgh, PA, 15261, United States, lix21@pitt.edu, Bo Zeng

We study facility location problem through robust bilevel optimization, a novel model as well as solution procedure is proposed. Computational demonstrations based on practical system will also be discussed in the talk.

2 - Asymmetric Bilevel Linear Programming with Incomplete Information and Learning

Juan Borrero, Oklahoma State University, 322 Engineering N, Stillwater, OK, 74078, United States, jsb81@pitt.edu, Oleg A. Prokopyev, Denis R. Saure

We consider an asymmetric bilevel linear problem where the leader and follower interact repeatedly. At each period the leader implements an upper-level solution after which the follower reacts by solving the lower-level problem. The leader has incomplete information about the cost function of the follower's problem, and learns about it from observing his reaction to her actions. Given that the leader's objective is to find an optimal solution of the full-information bilevel problem, we study a set of greedy and 'best'-case decision policies that are able to find an optimal solution in finite time periods, and can provide a real-time certificate of optimality to the leader.

3 - A New Bilevel Market Based Capacity Expansion

Bo Zeng, University of Pittsburgh, 3700 O'Hara Street, Benedum Hall, Pittsburgh, PA, 15260, United States, bzeng@pitt.edu

Bilevel optimization has been used to build capacity expansion models for power grid. Considering multiple market clearing responses, we build a new model for market based capacity expansion. Numerical results will be reported.

4 - Optimal Strategies in Pediatric Vaccine Pricing Problem

Hosein Zare, University of Pittsburgh, 4200 Fifth Avenue, Pittsburgh, PA, 15260, United States, moz3@pitt.edu, Oleg A. Prokopyev, Osman Yalin Ozaltin

We consider pediatric vaccine pricing problem in an oligopolistic market and explore the optimal pricing approach in a bilevel setting. Given that the customer in the lower-level problem selects a subsets of available vaccines to minimize the cost of vaccination, the vaccine manufacturer in the upper-level problem sets the price of vaccines to compete with other manufacturers and maximize her profit. We study the problem under different assumptions and provide the optimal pricing strategy in each situation.

Algorithms for Structured Optimization Problems I

Sponsored: Optimization, Nonlinear Programming

Sponsored Session

Chair: Shiqian Ma, The Chinese University of Hong Kong, Shatin, Hong Kong, sqma@se.cuhk.edu.hk

1 - Value-function Based Non-cooperative Games

Tianyu Hao, PhD Student, University of Southern California, 3715 McClintock Avenue, GER240, Los Angeles, CA, 90089-0193, United States, tianyuha@usc.edu, Jong-Shi Pang

Inspired by the family of network interdiction games which are proposed by Andrew Liu and his collaborators, we studied a two-stage non-cooperative game. The objective function of each player's optimization problem contains a value function of a second-stage linear program, which is dependent on the first-stage variables in a way that a point-wise linear function upper bounds the second-stage decision variable. We first establish results regarding the existence of solution. Then we show that under Slater's conditions and some other conditions, Lemke's method can compute a solution to such games.

2 - Difference of Convex Approaches to Statistical Learning

Miju Ahn, University of Southern California, Los Angeles, CA, United States, mijuahn@usc.edu

We discuss a difference-of-convex (dc) programming approach to the sparsity representation problem in statistical learning. We present a unified formulation of many existing surrogate sparsity functions that are employed as approximations of the L-0 function, summarize optimality and sparsity results of the resulting dc optimization problem using such sparsity functions, discuss a LASSO based algorithm for solving the latter problem, and present numerical results on two sets of sparse statistical estimation problems: least square regression and logistic classification.

3 - Linear Convergence of Randomized Feasible Descent Methods under the Weak Strong Convexity Assumption

Chenxin Ma, Lehigh University, Bethlehem, PA, United States, chm514@lehigh.edu, Martin Takac, Rachael Tappenden

In this paper we generalize the framework of the Feasible Descent Method (FDM) to a Randomized (R-FDM) and a Randomized Coordinate-wise Feasible Descent Method (RC-FDM) framework. We show that many machine learning algorithms, including the famous SDCA algorithm for optimizing the SVM dual problem, or the stochastic coordinate descent method for the LASSO problem, fits into the framework of RC-FDM.We prove linear convergence for both R-FDM and RC-FDM under the weak strong convexity assumption. Moreover, we show that the duality gap converges linearly for RC-FDM, which implies that the duality gap also converges linearly for SDCA applied to the SVM dual problem.

Advances in General Purpose Cutting Planes

Sponsored: Optimization, Integer and Discrete Optimization

Sponsored Session

Chair: Matthias Koeppe, University of California-Davis, Davis, CA, 95616, United States, mkoeppe@math.ucdavis.edu

1 - Interactive Software for Cut-generating Functions and Beyond

Yuan Zhou, University of California-Davis, 1 Shields Avenue, Department of Mathematics, Davis, CA, 95616, United States, yzh@math.ucdavis.edu, Matthias Koeppe

We present software for investigations with cut-generating functions in the Gomory-Johnson model and extensions, implemented in the computer algebra system SageMath.

2 - V-polyhedral Cuts

Aleksandr M. Kazachkov, Carnegie Mellon University, Pittsburgh, PA, United States, akazachk@cmu.edu, Egon Balas

Generating cutting planes for mixed-integer programs from valid general disjunctions, containing multiple inequalities per term, has been an active topic of inquiry in recent years. We investigate this idea from the V-polyhedral perspective, using a properly selected set of points and rays to generate cuts. Our framework, called V-polyhedral cuts, can be viewed as a strict extension of the generalized intersection cut paradigm, which only applies to generating cuts from convex sets. We discuss theoretical properties of V-polyhedral cuts and the results from an implementation of one variant of the method.

3 - Computer-assisted Discovery and Certification of Next-generation Cutting Planes for Mixed Integer Programming
Matthias Koeppe, University of California-Davis, One Shields Avenue, Dept of Mathematics, Davis, CA, 95616, United States, mkoeppe@math.ucdavis.edu, Yuan Zhou

The revival of Gomory's classic general purpose cutting planes in the mid-1990s enabled the development of powerful branch-and-cut software. Challenging new applications and increased data sizes prompt us to develop next-generation general-purpose cutting plane systems. We revisit Gomory and Johnson's infinite-dimensional relaxations of integer programs. We overcome the difficulties in studying the "facet-defining" valid inequalities of these relaxations by making use of computer-assisted discovery and certification. The goal is to develop a large library of parametric families of such "facets" as the foundation of learning-based cutting-plane systems.

4 - Cutting Planes from Extended Formulations
Sanjeeb Dash, IBM T.J.Watson Research Center, 1101 Kitchawan Road, Yorktown Heights, NY, 10598, United States, sanjeebd@us.ibm.com

We discuss how to use extended formulations of the LP relaxation of a mixed-integer program to obtain stronger split cutting planes than those that can be obtained from the original LP relaxation. We analyze a few different approaches to building extended formulations, and the effectiveness of split cuts in each case. In particular, we consider the Lovasz-Schrijver and Sherali-Adams lift-and-project operator hierarchies, and also discuss extended formulations of mixed-integer programs obtained by replacing integral variables by weighted sums of binary variables.

Dynamic Optimization for Allocation Problems

Sponsored: Optimization, Integer and Discrete Optimization

Sponsored Session

Chair: Viswanath Nagarajan, University of Michigan, Ann Arbor, MI, 48109, United States, viswa@umich.edu

1 - Pricing in Dynamic Two-sided Markets with Service Guarantees
Kamesh Munagala, Professor, Duke University, P.O. Box 90129, Department of Computer Science, Durham, NC, 27708-0129, United States, kamesh@cs.duke.edu, Reza Alijani, Siddhartha Banerjee, Sreenivas Gollapudi, Konstantinos Kollias

We consider dynamic two-sided markets, where buyers and sellers arrive over time following Poisson processes. Each agent has private value and patience level for receiving/providing service, and a known location in an underlying metric space. The platform posts prices and wages at nodes in the metric space, as well as choose agents for matching to simultaneously ensure three orthogonal objectives: 1) maximizing profit; 2) minimizing maximum metric distance of any match; and 3) minimizing abandonment probability of an accepted agent. We consider a natural class of scheduling policies, and develop LP rounding techniques that find approximately optimal policies.

2 - Exact Competitive Ratios for Online Edge-weighted Bipartite Matching with a Known Set of Edge Weights
Will Ma, Massachusetts Institute of Technology, 71 School Street, Cambridge, MA, 02139, United States, willma353@gmail.com, David Simchi-Levi

In this paper we obtain tight competitive ratios for the online edge-weighted bipartite matching problem, as a function of the set of potential edge weights, which is assumed to be given in advance. We obtain corresponding results for the Adwords problem under the small bids assumption, and the stochastic matching setting if each fixed node can be matched a large number of times. Our results are for the adversarial arrival model, and based on our optimal "tradeoff function" for online budgeted allocation in general, when each budget, or resource, could be converted to reward at multiple rates. Our analysis is primal-dual, and uses a randomly-initialized tradeoff function to handle the multiple rates.

3 - Closing the Gaps: An Online Learning Algorithm for the Lost-sales Inventory System with Lead Times
Huanan Zhang, University of Michigan, 2133 Glencoe Hills Drive, Apt 10, Ann Arbor, MI, 48108-1094, United States, zhanghn@umich.edu, Xiuli Chao, Cong Shi

We develop an improved nonparametric learning algorithm for periodic-review lost sales inventory systems with positive lead time, where the firm does not know the demand distribution a priori but makes the replenishment decision in each period based only on the past sales (censored demand) data. It is known that the optimal policy is hard to compute even with full information, hence in this paper we focus on finding the best base-stock policy. We establish a square-root convergence rate of the proposed learning algorithm, which is the best possible rate for this class of problems.

4 - Adaptivity Gaps for Stochastic Probing Problems
Viswanath Nagarajan, University of Michigan, 1205 Beal Avenue, Ann Arbor, MI, 48109, United States, viswa@umich.edu, Anupam Gupta, Sahil Singla

We consider a general class of stochastic probing problems with submodular or subadditive objectives. Each element is active independently with some known probability, but we know the status of an element only after "probing" it. There is also a constraint on the sequence of elements that may be probed. The goal is to find a policy for probing elements so as to maximize the expected function value on the active elements. Such problems arise in many applications, eg. influence maximization, Bayesian mechanism design and path planning. We show that the gap between optimal adaptive and non-adaptive policies is small, which also leads to good approximation algorithms for these stochastic probing problems.

Energy

Contributed Session

Chair: Emre Çelebi, Kadir Has University, Istanbul, Turkey, ecelebi@khas.edu.tr

1 - Efficient Allocation of Benefits in Multinational Transmission Expansion Planning using Cooperative Game Theory
Martin Kristiansen, PhD Student, NTNU, Nedre Mollenberg gate 23A, Trondheim, 7014, Norway, martin.kristiansen@ntnu.no

There are multiple countries involved in, or affected by, multinational grid investments. Although cooperative investment strategies always result in nonnegative aggregate net-benefits, benefits for individual parties can be asymmetric and, in some cases, negative. In this talk, we present a methodology to determine an efficient and fair allocation of benefits using Shapley Value from cooperative game theory. Moreover, we verify numerically that our case study of the North Sea Offshore Grid yields a convex cooperative game, meaning that the computed allocation is in the core and, consequently, provides a higher payoff to all countries than under any other possible subcoalition.

2 - Enhanced Representative Days and System States Modeling for Energy Storage Investment
Diego Alejandro Tejada Arango, Research Assistant, Universidad Pontificia Comillas, C/ Santa Cruz de Marcenado 26, Madrid, 28015, Spain, dtejada@comillas.edu, Sonja Wogrin, Efraim Centeno

In this work, we analyze the impact of different options to represent the operation decisions in the study of energy storage (ES) investment for long-term planning models. We compare the representative days and the system-states approaches for the representation of these operation decisions. We proposed enhanced versions of these approaches to improve the ES investment approximation. An Spanish case study is evaluated and the results are used to identify the potential profits that energy storage investment can obtain.

3 - Investment Plan Against Malicious Attacks on Power Networks: Multilevel Game-theoretic Models with Shared Cognition
Hamzeh Davarikia, PhD Candidate, Research Assistant, University of Arkansas, 2801 S.University Avenue, Little Rock, AR, 72204, United States, hxdavarikia@ualr.edu, Mustafa Alassad, Yupo Chan

We developed a tool for utility transmission planners to protect power network from potential attacks. An extended tri-level mixed-integer linear-programming interdiction-model returns the best protecting strategy. Deception is an integral part of the mathematical model, accomplished by releasing misinformation based on shared cognition theory. In addition, the multi origin-destination model allows the impact of disabled facilities to become transparent. The results from IEEE 24 and 118 Bus Test Systems show the viability of the model, including its capacity to impute the worth of deception.

4 - Nested Decomposition Algorithm for Electric Power Infrastructure Planning
Cristiana Lara, Carnegie Mellon University, 5000 Forbes Avenue, Pittsburgh, PA, 15213, United States, cristianallara@cmu.edu, Ignacio E.Grossmann

We propose a Nested Benders Decomposition algorithm for mixed-integer problems arising in the planning of electric power systems. Our decomposition, which extends previous nested Benders methods by handling integer and continuous state variable, targets large-scale multi-period problems and allows us to investigate the impact of the number of representative days per year in the planning strategy over a long time horizon. The proposed algorithm is applied to a case study in the ERCOT region for a 30 year planning horizon, and demonstrate massive computational savings from our decomposition. Additionally, we compare the results for the different numbers of representative days.

5 - Integrated Models for Transmission/generation Investments and Market-clearing Equilibrium in Electricity Markets

Emre Çelebi, Kadir Has University, Kadir Has Caddesi, Cibali, Istanbul, 34083, Turkey, ecelebi@khas.edu.tr

Investments in transmission/generation assets and market-clearing equilibrium are interrelated and influenced by a variety of factors including strategic behavior of the generation firms and uncertainties in demand and generation assets. Integrated investment/market-clearing models are formed as bi-level programming problems and they are reformulated by using a method for discretely constrained mixed complementarity problems. The proposed models are demonstrated using a realistic 9-node Turkish electricity market model. These models will be useful in planning generation/transmission investments and analyzing the relations among these investments and the market outcomes.

Power System Resilient Design and Optimization

Sponsored: Energy, Natural Res & the Environment Electricity

Sponsored Session

Chair: Amir Mousavian, Clarkson University, amir@clarkson.edu

1 - Closed-loop Distribution Grid Restoration for Natural Disaster Recovery

Jianhui Wang, Southern Methodist University, Dallas, TX, United States, jianhui@smu.edu

We present a closed-loop distribution system restoration decision support model to assist distribution utility operators in making optimal and effective decisions during distribution system restoration under extreme weather events. The modeling framework consists of four modules: data fusion, advanced controls, multi-objective optimization and crew and resource dispatch.

2 - Storage Investment Model Considering Energy and Reserves Markets

Hrvoje Pandzic, Faculty of Electrical Engineering and Computing University of Zagreb, Unska 3, Zagreb, 10000, Croatia, hrvoje.pandzic@fer.hr, Yury Dvorkin, Miguel Carrion

We present an investment model for a merchant storage investor who is trying to maximize its profit in energy and reserves market.

3 - Communication-constrained Resilient Distribution Grid Design

Geunyeong Byeon, University of Michigan, Ann Arbor, MI, United States, gbyeon@umich.edu, Russell Bent, Pascal Van Hentenryck, Harsha Nagarajan

Several extreme weather events have revealed potential risks to electric power grids and motivated the need for upgrades that improve the resilience of grids to these events. Moreover, the increased functional dependencies between a power grid and its associated communication network have also added a new layer of risks to grid reliability. Hence, we consider the problem of designing resilient distribution grids in combination with its dependencies on communication systems. We pose the problem as a two-stage mixed-integer stochastic optimization problem and develop decomposition-based algorithms to analyze practically relevant test cases.

4 - Evaluating the Impact of Renewable Generation on Transmission Expansion Planning

Ebrahim Mortaz, Auburn University, 115 N.debardeleben St. Apt 29, Auburn, AL, 36830, United States, emortaz@auburn.edu, Jorge F. Valenzuela

In this talk, we study the impact of renewable generation on transmission expansion planning (TEP). We solve the TEP problem considering two prominent sources of renewable energy, wind and solar, and assess the effects of harvesting locations and installed capacity on the transmission network expansion plan. In solving the TEP problem, the hourly fluctuations of demand and RES over time are considered. We run all of our simulations on the IEEE 24-bus test system for a planning horizon of ten years. The simulation results provide alternative investment plans for expanding the transmission network that includes high penetration of RES.

Decisions in Energy Markets using Extended Concepts of Equilibrium

Sponsored: Energy, Natural Res & the Environment, Energy

Sponsored Session

Chair: Sauleh Ahmad Siddiqui, Johns Hopkins University, Baltimore, MD, 21218, United States, siddiqui@jhu.edu

1 - Solving Problems with Equilibrium Constraints with an Application to Energy Markets

Sauleh Ahmad Siddiqui, Johns Hopkins University, 3400 N Charles Street, Baltimore, MD, 21218, United States, siddiqui@jhu.edu

We provide a new set of complementarity-based algorithms for solving mathematical programs with equilibrium constraints and extend them to solve equilibrium problems with equilibrium constraints. We apply these algorithms to provide insights into energy markets with hierarchical structures. We conclude with policy insights and recommendations on how this approach can be extended.

2 - Carbon Emissions Forensic in Energy Sector: Is it Necessary?

Yihsu Chen, University of California Santa Cruz, Santa Cruz, CA, 95060, United States, yihsuchen@ucsc.edu

Climate policy has mostly focused on regulating power suppliers. There is a growing interest to explore regulating emissions from the demand side by forcing consumers to reduce their energy consumptions or to purchase power from cleaner sources. One possible approach is to impose a carbon tax on power consumption through network flow tracing. This paper analyzes the market outcomes under supplier- and demand-based approaches. We conclude that both approaches likely lead to the same market outcomes while consumer-based approach is likely to be inferior owing to its significant transaction cost.

3 - Phasing Out the U.S. Federal Helium Reserve: Policy Insights from a World Helium Model

Olivier Massol, IFP School, 228-232 Avenue Napoleon Bonaparte, Rueil-Malmaison, 92852, France, olivier.massol@ifpen.fr, Omer Rifaat

We propose a market equilibrium model to study the effects of the recently decided rapid phase out of the U.S. Federal Helium Reserve (FHR), a strategic stockpile accumulated during the 1960s. The model treats both helium producers and the FHR as profit maximizing players in a dynamic non-cooperative game (formulated as a MCP). Evidences gained from our market simulations indicate that, compared to the currently implemented policy, a slower depletion of the U.S. FHR stockpile would systematically increase the financial return to the U.S. federal budget, lower helium venting into the atmosphere, and would also augment the global welfare.

Advances in Stochastic Optimization

Sponsored: Optimization, Optimization Under Uncertainty

Sponsored Session

Chair: David Brown, Duke University, Durham, NC, 27708, United States, dbbrown@duke.edu

Co-Chair: Santiago Balseiro, Duke University, Durham,NC, United States, santiago.balseiro@duke.edu

1 - Static Routing in Stochastic Scheduling: Performance Guarantees and Asymptotic Optimality

Chen Chen, Duke University, 100 Fuqua Drive, Box 90120, Durham, NC, 27708, United States, cc459@duke.edu, Santiago Balseiro, David Brown

We study stochastic scheduling with the weighted sum of expected completion time objective and processing times that may vary across both jobs and machines. We analyze static routing policies that route each job to a particular machine upfront and then sequence jobs on each machine via the WSEPT rule. A good routing can be found by solving a convex quadratic program that only uses expected job processing times. We provide an additive performance bound on the sub-optimality of this static routing policy that implies asymptotic optimality in the regime of many jobs. The key to this result is a lower bound on the performance of an optimal adaptive scheduling policy via a penalized information relaxation.

2 - Learning Preferences with Side-information: Near Optimal Recovery of Tensors
Andrew A. Li, MIT, Cambridge, MA, 02139, United States, aali@mit.edu, Vivek Farias

Many recent problems in e-commerce can be cast as large-scale problems of tensor recovery. Thus motivated, we study the problem of recovering tensors from their noisy observations. We provide an efficient algorithm to recover structurally 'simple' tensors given noisy observations of their entries; our version of simplicity subsumes low rank tensors for various definitions of tensor rank. Our algorithm is practical for massive datasets and provides a significant performance improvement over incumbent approaches to Tensor recovery. Further, we show a near-optimal recovery guarantee. Experiments on music streaming data demonstrate the performance and scalability of our algorithm.

3 - Stochastic Online Scheduling on Unrelated Machines
Varun Gupta, University of Chicago, guptav@uchicago.edu, Benjamin Moseley, Marc Uetz, Qiaomin Xie

We derive the first performance guarantees for a combinatorial online algorithm that schedules stochastic, nonpreemptive jobs on unrelated machines to minimize the expectation of the total weighted completion time. Prior work on unrelated machine scheduling with stochastic jobs was restricted to the offline case, and required sophisticated linear or convex programming relaxations for the assignment of jobs to machines. Our algorithm is purely combinatorial, and therefore it also works for the online setting.

4 - Robust Markov Decision Processes under Non-rectangular Uncertainty
Julien Grand-Clement, Columbia University, New York, NY, United States, jg3728@columbia.edu, Vineet Goyal

Markov decision processes are a common paradigm for modeling dynamic optimization problems. We consider a robust approach to Markov decision processed where the uncertainty in probability transitions is modeled using an uncertainty set. Most prior works consider the case of uncoupled uncertainty (or rectangular uncertainty) between different states, potentially resulting in highly conservative policies. The general coupled uncertainty set leads to intractable formulations. In this work, we consider a natural low-rank coupled uncertainty between different states and show that this leads to a tractable approach and overcomes the conservativeness of using uncoupled uncertainty sets.

New Directions in Stochastic Inventory Control

Sponsored: Optimization, Optimization Under Uncertainty

Sponsored Session

Chair: Cong Shi, University of Michigan, 1205 Beal Ave., Ann Arbor, MI, 48105, United States, shicong@umich.edu

1 - Inventory Management with Opaque Products
Yeqing Zhou, Columbia University, 550 W. 120th St, New York, NY, 10027, United States, yz2714@columbia.edu, Adam Elmachtoub, David D.Yao

We study the use of opaque products in a multi-item inventory system. An opaque product is defined as a product where some specific attributes are not revealed to customers until after payment. We derive the optimal opaque fulfillment policy which minimizes the long run average inventory costs and show that a simple heuristic is near-optimal for managing opaque products. We also quantify the cost savings achieved by having opaque products (versus not having them) using a connection to the balls-into-bins framework.

2 - Nonparametric Learning Algorithms for Stochastic Inventory Systems with Random Capacities
Weidong Chen, PhD Student, Michigan Engineering, Ann Arbor, MI, 48105, United States, aschenwd@umich.edu

We propose a nonparametric learning algorithm for the single-product, periodic-review, backlogging inventory systems with random production capacities. We assume that the firm has no prior information on the demand distribution nor the capacity distribution and only has access to past demand and supply data (which can be referred to as censored capacity information). We propose a cyclic gradient-descent type of algorithm whose running average cost asymptotically converges to the clairvoyant optimal costWe prove that the rate of convergence guarantee of our algorithm is O(\sqrt{T}), and conduct numerical experiments to demonstrate the effectiveness of our proposed algorithms.

3 - Online Algorithms for Stochastic Inventory Systems
Yuchen Jiang, University of Michigan, Ann Arbor, MI, 48109, United States, ycjiang@umich.edu

We study stochastic inventory systems by designing online algorithms to determine optimal inventory decisions before the realization of any future demands. Our online algorithm uses up-to-date demand information and hence can be carried out in practice. Moreover, our competitive analysis shows that the algorithms we proposed preform well even in the adversarial setting, where the worst case demand realization is considered.

Sequential Decision Making under Uncertainty

Sponsored: Optimization, Optimization Under Uncertainty

Sponsored Session

Chair: Belleh Fontem, University of Mary Washington, Fredericksburg, VA, 22407, United States, bfontem@umw.edu

1 - Multi-objective Sequential Stochastic Assignment Problems
Ge Yu, University of Illinois, Champaign, IL, United States, geyu3@illinois.edu, Sheldon Jacobson

We provide an asymptotic analysis of multi-objective sequential stochastic assignment problems (MOSSAP). In MOSSAP, a fixed number of tasks arrive sequentially, with an n-dimensional value vector revealed upon arrival. Each task is assigned to one of a group of known workers immediately upon arrival, with the reward given by an n-dimensional product-form vector. The objective is to maximize each component of the expected reward vector. We provide expressions for the asymptotic expected reward per task for each component of the reward vector, under three classes of Pareto optimal policies. We also compare the convergence rates of these three classes of Pareto optimal policies.

2 - Concentration Inequality Approach to Variance-Constrained Bivariate Optimal Stopping
Belleh Fontem, University of Mary Washington, Fredericksburg, VA, United States, bfontem@umw.edu

Under a certain payoff structure, we consider the problem of finding an optimal stopping time for a bivariate random walk subject to a constraint on the stopping variance of one of the state variables. The non-linearity of the variance constraint gives rise to time-inconsistency in the sense that traditional Bellman optimality is inapplicable. We employ two concentration inequalities to prove optimality of the first-exit time of the relevant state variable from either a control band, or a half-space (depending on the how we interpret optimality). The motivating application is determining an optimal selling policy for a risk-averse rental car firm that also serves purchasing customers.

The Final Step in the Remarkable Journey of the Isoperimetric Problem: The Completion of Euler's Approach

Plenary

Invited Session

1 - The Final Step in the Remarkable Journey of the Isoperimetric Problem: the Completion of Euler's Approach
Richard Tapia, Rice University

In this presentation we give a brief overview of the remarkable life of the impactful isoperimetric problem. We identify three distinct classes of solution approaches that have been used throughout history: the Cartesian coordinate representation approach of Euler, the synthetic geometry approach of Steiner, and the parametric representation approach of Weierstrass. We say that one of our three classes of approaches has been completed when an appropriately short sufficiency proof for the isoperimetric problem has been constructed that belongs to this class of proofs. In a legendary work from 1744, Euler presented his contribution, establishing neither necessity nor sufficiency for this problem. This failure led Steiner in 1838 to propose his approach that gave only necessity and not sufficiency as he believed. The Steiner path was completed by Lawlor in 1998. Euler's and Steiner's failures led Weierstrass in 1879 to propose his approach, which did indeed lead to sufficiency but required a somewhat elaborate theory. The Weierstrass approach was completed in 1934 by Littlewood, Hardy, and Polya. The major contribution in this presentation is our completion of Euler's approach. Our proof uses elementary tools.

Game Theoretical Models in Strategic Managament

Sponsored: Decision Analysis

Sponsored Session

Chair: Wenxin Xu, University of Illinois at Urbana-Champaign, 1206 S Sixth Street, (217) 503-8779, IL, 61820, United States, wenxin.v.xu@polyu.edu.hk

1 - Uncertain Innovation, Spillovers, and First and Second Mover Advantages

Jovan Grahovac, Purdue University, 403 W State Street, West Lafayette, IN, 47907, United States, jgrahov@purdue.edu, Dharma Kwon, Wenxin Xu

We use a game theoretic duopoly model to examine the impact of spillovers and uncertain R&D expenditures and completion times on firm outcomes. We characterize the Nash equilibrium of the model and we find that spillovers may or may not diminish the profit of the firm that is more capable in R&D. In other words, the technological leader may wish to commit to imitability of its innovation under certain conditions. Moreover, we find that the technological leader does not always invest earlier than the laggard, and we discuss implications of these results for firm strategy and the resource-based view.

2 - Exit Strategy under Uncertainty and Incomplete Information

Dharma Kwon, University of Illinois at U-C, 350 Wohlers Hall, 1206 S Sixth Street Mc-706, Champaign, IL, 61820, United States, dhkwon@illinois.edu

We examine a duopoly exit game between two firms where the the flow profits are stochastic and the exit cost of each firm is private information, and we characterize the Markov perfect Bayesian equilibria.

3 - Innovation Effort, Spillovers and Patent Licensing Strategy

Benoit Chevalier-Roignant, King's College London, London, United Kingdom, benoit.chevalier-roignant@kcl.ac.uk

In this paper, we endogenize the choice between licensing a technology or keep it proprietary. An innovator decides on the innovation effort to achieve a process innovation, on whether (and under which conditions) to license the technology and, when demand is known, on supply. We examine the growth and volatility conditions which drive the choice of licensing contracts and the level of innovation effort.

4 - R & D Competition with Spillovers and Uncertain Completion Times

Wenxin Xu, The Hong Kong Polytechnic University, wenxu@polyu.edu.hk

We examine a game-theoretic model of two firms that are competitively engaged in research and development (R &#38 D) projects. We investigate the impact of imitability on R&D investment strategies when the R &#38 D completion times are uncertain and either firm can receive spillover from the other.

Operations Research Approaches for Building Demand Response

Invited: Tutorial

Invited Session

Chair: Jiming Peng, University of Houston, Houston, TX, !, United States, jopeng@Central.uh.edu

Co-Chair: Rajan Batta, University at Buffalo (SUNY), 410 Bell Hall, University at Buffalo (SUNY), Buffalo, NY, 14260, United States, batta@buffalo.edu

1 - Operations Research Approaches for Building Demand Response in a Smart Grid

Miguel Anjos, Polytechnique Montreal, Montreal, QC, United States, miguel-f.anjos@polymtl.ca, Juan Gómez

Electric power systems need to ensure that production and demand of electricity are continuously in balance. With fundamental changes taking place in the power grids of many countries due to a variety of technological and policy developments, there is a need to obtain additional flexibility to achieve this essential power balance. Demand response refers to the collection of all the means to obtain this flexibility from the demand side of the balance. We present a selection of contributions of operations research to the provision of demand response by the residential, commercial and institutional sectors of the economy. The aspects covered include electricity tariffs, building energy management systems, load estimation, local generation, electric vehicles, energy storage, and building-level aggregation. We conclude with a brief discussion of current opportunities for operations research to support the development and realization of the potential of demand response.

Joint Session RMP/APS: Topics in Revenue Management and Applied Probability

Sponsored: Applied Probability

Sponsored Session

Chair: N. Bora Keskin, Duke University, Durham, NC, 27708-0120, United States, bora.keskin@duke.edu

1 - Revenue Management in Systems of Reusable Resources

David Simchi-Levi, Massachusetts Institute of Technology, Dept of Civil and Environmental Engineering, 77 Massachusetts Avenue Rm 1-171, Cambridge, MA, 02139, United States, dslevi@mit.edu

We first consider personalized assortment optimization in systems of reusable resources. When the manager is not privy to real-time utilization data we show that the optimal policy can be computed efficiently. When real-time utilization data is available, we propose effective heuristic policies. We further consider the joint pricing and assortment problem and show that non-discriminatory policies can be developed in special cases despite theoretical hardness. Motivated by practical considerations we extend these techniques to settings in which demand varies periodically over time.

2 - Less Can be More in Price Experimentation

Divya Singhvi, Massachusetts Institute of Technology, Cambridge, MA, United States, dsinghv@mit.edu, Georgia Perakis

We consider a dynamic pricing problem where a monopolist is selling a single product but has no knowledge of the demand curve. Further, there is a cost on price experimentation. The monopolist seeks to efficiently learn the demand curve and keep the cost of price experimentation low. We propose an approach for price experimenting and learning which is simple and mimics industry practice. We provide bounds on the number of price experimentations needed to achieve a threshold revenue level. We show that with few price experimentations (aka 4) we can be within 18% of the optimal.

3 - Matching or Not Matching: Strategic Pricing in a Competitive Airline Environment
Alexandre Jacquillat, Carnegie Mellon University, Pittsburgh, PA, United States, ajacquil@andrew.cmu.edu, Michael Benborhoum, Maxime Cohen

A common practice in the airline industry involves matching competitors' lead-in fares, which may lead to missed revenue opportunities. This talk presents a complete approach to assess how airlines can strategically react to competitors' pricing decisions. We study a game-theoretic model of capacitated Bertrand competition that identifies conditions under which deliberately deviating from competitors' prices can increase revenues.

4 - On Incomplete Learning and Certainty-equivalence Control
N. Bora Keskin, Duke University, Fuqua School of Business, 100 Fuqua Drive, Durham, NC, 27708-0120, United States, bora.keskin@duke.edu, Assaf Zeevi

Motivated by dynamic pricing applications, we consider a dynamic control-and-estimation problem. The decision-maker sequentially chooses controls and observes responses that depend on both the chosen controls and an unknown parameter. The decision-maker uses a certainty-equivalence policy, and we characterize the asymptotic accuracy performance of this policy.

Grand Ballroom B

Multi-Item and Multi-Location Revenue Management Models

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Candace Arai Yano, University of California-Berkeley, Berkeley, CA, 94720-1777, United States, yano@ieor.berkeley.edu

1 - Dynamic Pricing of Omnichannel Inventories
Joline Uichanco, University of Michigan, Ross School of Business, 701 Tappan St, Room 4418, Ann Arbor, MI, 48109-1234, United States, jolineu@umich.edu, Pavithra Harsha, Shivaram Subramanian

We develop a dynamic pricing model for omnichannel retail which accounts for cross-channel interactions in demand (channel substitution) and supply (cross-channel fulfillment). The model combines ideas from dynamic pricing and capacity control to address the novel features of an omnichannel setting. We propose two computationally tractable pricing policies based on partitioning the channel agnostic inventories. A markdown optimization system based on our models was developed and implemented at a major US retailer. Causal model analysis of the pilot data show 12% improvement due to the new system.

2 - Product Quality, Service and Pricing
Ruxian Wang, The Johns Hopkins Carey Business School, Baltimore, MD, Shiliang Cu

We develop a unified framework to investigate firms' joint decisions on product quality, price and ancillary service, when they offer a line of products to consumers in a variety of monopolistic and competitive environments.

3 - Marginal Estimation+Price Optimization" with Robust Choice Models
Karthik Natarajan, Singapore University of Technology and Design, Singapore University of Technology and Design, 20 Dover Drive, Singapore, 138682, Singapore, karthik_natarajan@yahoo.com, Chung-Piaw Teo, Zhenzhen Zen, Cong Chen

We develop an estimation and optimization framework for the multi-product pricing problem by exploiting properties in a new class of choice models. The pricing problem under this new choice model is a convex optimization problem when the marginal distributions of the utilities are log-concave. We develop a data-driven second order conic/linear program to estimate a robust choice model, and to find the corresponding optimal prices. Mixed Integer Linear Programming models can be used to find the prices when side constraints are present.

Chair: Erica Plambeck, Stanford University, Stanford, CA, 94305-5015, United States, elp@stanford.edu

Co-Chair: Dan Andrei Iancu, Stanford University, Stanford, CA, 94107, United States, daniancu@stanford.edu

1 - Consumer Education and Reverse Logistics in a Social Enterprise
Andre Du Pin Calmon, INSEAD, Boulevard de Constance, Fontainebleau, 77300, France, andre.calmon@insead.edu, Gonzalo Romero

We study the problem faced by a social enterprise that distributes new life-improving technologies in a developing market. Its goal is to profitably increase the adoption of a product that is sold through a small retailer. The retailer sells to budget-constrained consumers that have an uncertain product valuation. The distributor considers two strategies: (i) improve the information accuracy provided to consumers, and (ii) improve its reverse logistics. We show that if the distributor highly values product adoptions, it prefers reverse logistics rather than improving information accuracy.

2 - Pay it Forward: A Sustainability Incentive in Smallholder Commodity Supply Chains
Joann De Zegher, Stanford University, dezegher@stanford.edu, Dan Andrei Iancu, Erica Plambeck

Batched payments in commodity supply chains burdens the cash flow management of small suppliers in developing economies. We formulate a dynamic model of consumption-maximizing, cash-constrained farmers to analyze the supply chain consequences of batched payments. Building on this, we propose a novel incentive and sourcing policy for buyers to achieve their no-deforestation commitments in commodity supply chains of developing economies. Our proposed incentive increases farmer welfare and buyer profits. A one-size-fits-all policy achieves no-deforestation most often, but a tailored policy minimizes deforestation. The palm oil supply chain starting in Indonesia motivates our study.

3 - Off Grid Electricity at the Bottom of the Pyramid
Bhavani Shanker Uppari, INSEAD, 1 Ayer Rajah Avenue, Singapore, 138676, Singapore, BhavaniShanker.Uppari@insead.edu, Manuel Barron, Rowan Clarke, Serguei Netessine, Martine Visser, Ioana Popescu

We report results of a large-scale randomized controlled trial in Rwanda whose goal was to understand off-grid electricity adoption at the bottom of the pyramid. We focus on different business models designed to stimulate transition from kerosene to electric lamps. These experiments demonstrate behavioral barriers to adoption of electricity and ways to overcome them.

4 - Truthful Mechanisms for Medical Surplus Product Allocation
Can Zhang, Georgia Institute of Technology, 499 Northside Circle NW, Apt 315, Atlanta, GA, 30309, United States, czhang2012@gatech.edu, Atalay Atasu, Turgay Ayer, Beril L. Toktay

We analyze resource allocation problems faced by medical surplus recovery organizations (MSROs) that recover reusable medical products to fulfill the healthcare needs of under-served regions/countries. We present strategies to improve MSROs' value provision when recipient needs are private information, and validate our results using historical data from a partner MSRO.

1 - An Examination of Early Transfers to the ICU Based on a Physiologic Risk Score
Wenqi Hu, Columbia Business School, New York, NY, United States, wh2274@columbia.edu, Carri Chan, José R. Zubizarreta, Gabriel J. Escobar

Unplanned transfers of patients from the ward to the Intensive Care Unit (ICU) can occur due to rapid deterioration and may increase the patients' risk of death and lengths of stay in hospital. A new predictive model, the EDIP2, was developed with the intent to identify patients at risk of deterioration, which in some cases could trigger proactive transfers to the ICU. This work examines the potential costs and benefits of preventive ICU admissions based on this new dynamic warning system. We find that preventive ICU admissions have the potential to improve patient outcomes, and physicians' fears of needlessly clogging the ICU may not be as dire as initially feared.

2 - Optimal Timing of Drug Sensitivity Testing for Patients on First-line Tuberculosis Treatment
Sze-chuan Suen, University of Southern California, 3715 McClintock Ave, GER 240, Los Angeles, CA, 90089, United States, ssuen@usc.edu, Margaret L. Brandeau, Jeremy D. Goldhaber-Fiebert

Tuberculosis (TB) patients who are not responsive to first-line treatment should be triaged to appropriate treatment alternatives. Treatment response can be monitored using inexpensive but noisy sputum-smear (SS) tests or expensive but accurate drug sensitivity tests (DST). We use a partially observed Markov decision process (POMDP) to determine whether and when DST should be administered. We apply our model to TB in India to identify patterns of SS test results that should prompt DST. We find an optimal DST policy that would save India approximately $1.9 billion.

3 - Outcomes-based Reimbursement Policies for Chronic Care Pathways
Saša Zorc, INSEAD, Fontainebleau, France, sasa.zorc@insead.edu, Stephen Chick, Sameer Hasija

We develop an outcomes-based model of contracting in care for chronic patients, using data from United Kingdom's NHS. The government contracts with healthcare providers in effort to maximise population health minus the cost. We consider the decision of whether to contract with individual healthcare providers or groups of such providers, as well as which contract type to use. Individual contracts fail to provide the desired incentives if providers under such contracts cooperate (collusion), however so do group contracts if group members fail to coordinate (free-riding). We demonstrate that individual outcomes-adjusted capitation contracts are the most resistant to these adverse effects.

4 - Optimal Risk-based Group Testing in Public Health Screening
Hrayer Y. Aprahamian, Virginia Tech, 1145 Perry Street, Blacksburg, VA, 24060, United States, ahrayer@vt.edu, Douglas R. Bish, Ebru K. Bish

Public health screening so as to classify subjects as positive or negative for a binary characteristic (e.g., an infection) is an essential tool that can save lives and reduce suffering. We study optimal group testing designs, in which multiple subjects are tested with a single test, considering subject-specific risk characteristics, and accuracy- and equity-based objectives, and characterize structural properties of optimal testing designs. These properties allow us to develop efficient algorithms and derive insights on equity versus accuracy trade-off. We demonstrate the value of risk-based testing through a case study on chlamydia screening in the United States.

Drug Shortages

Sponsored: Health Applications

Sponsored Session

Chair: Emily Tucker, University of Michigan, Ann Arbor, MI, 48105, United States, eltuck@umich.edu

1 - Identifying Critical Components of a Multi Agent Drug Supply Chain
Rozhin Doroudi, Northeastern University, 360 Huntington Ave, Boston, MA, 02115, United States, doroudi.r@husky.neu.edu, Ozlem Ergun, Jacqueline Griffin, Rana Azghandi

The growing epidemic of drug shortages in the US indicates the fragility of drug supply chain in the face of disruptions. Identifying most critical components in the supply chain can assist policy makers in mitigating these shortages. In this study we propose a node criticality measure for underlying network of a drug supply chain in which nodes are agents and arcs are material flow between them. Unlike most node criticality measures in network science literature this measure does not abstract away domain-specific functions of network components. Therefore, it can be used in predicting the effect that disruption of one node can have on the overall supply chain performance.

2 - Evaluating Flexible Inventory Policies for Robust Pharmaceutical Supply Chains
Rana Azghandi, Northeastern University, 360 Huntington Avenue, Boston, MA, 02115, United States, rana.azghandi@gmail.com, Jacqueline Griffin

Despite efforts to increase robustness of pharmaceutical supply chains, they remain vulnerable to supply disruptions and, correspondingly, drug shortages continue to be common. Designing a system which is robust for these disruptions is complex and requires adaptive decision process that dynamically changes over time. We use a stochastic optimization model to characterize the effects of the inventory policy parameters (cycle service level) for varying supply disruption profiles. Additionally, we study the effects of flexibly inventory policies via a system dynamics simulation.

3 - Mitigating U.S. Drug Shortages through Supply Contracts
Hui Zhao, The Pennsylvania State University, 419 Business Building, Smeal College of Business, University Park, PA, 16802, United States, huz10@psu.edu, Justin Jia

Drug Shortage is a major challenge facing the US pharmaceutical industry and the government. We propose to mitigate shortage through Pareto-improving supply contracts that consider the manufacturer's and GPO's profits, the government spending, and the hospital's cost. We show that price increases must be paired with strengthened failure-to-supply clauses (IPS) to achieve consistent and significant shortage reduction as well as Pareto improvement. With realistic data, a 30% price increase under IPS can lead to an average of 53% shortage reduction. We also show the impacts of IPS on different parties in the supply chain.

4 - Incentivizing Resilient Pharmaceutical Supply Chains to Prevent Drug Shortages
Emily Tucker, PhD Candidate, University of Michigan, 1205 Beal Ave. Ann Arbor, MI, 48109, United States, eltuck@umich.edu, Mark S. Daskin, Burgunda V. Sweet, Wallace J. Hopp

A substantial portion of drug shortages are caused by manufacturing issues. While these can be mitigated through redundancy and safety stock, many companies choose to maintain lean supply chains for drugs with low profit margins. We present a stochastic programming approach to solving the pharmaceutical supply chain design problem under disruption. We discuss potential policies to incentivize companies to maintain more resilient supply chains and reduce the impact of shortages.

Mehmet Ayvaci, University of Texas at Dallas, Richardson, TX, United States, Mehmet.Ayvaci@utdallas.edu, Oguzhan Alagoz, Mehmet Eren Ahsen, Elizabeth Burnside

Decision models representing the clinical situations where treatment options entail a significant risk of morbidity or mortality should consider the variations in risk preferences of individuals. In this study, we develop a stochastic modeling framework that optimizes risk-sensitive diagnostic decisions after a mammography exam. Using a risk-sensitive finite-horizon MDP model, we provide medical/policy insights. We empirically validate our model and demonstrate that the current medical practice of breast biopsies resemble risk-seeking behavior.

2 - Optimal Fractionation in Radiotherapy with Two Modalities

Sevnaz Nourollahi, University of Washington, 6322 5th Avenue NE, Lower Unit, Seattle, WA, 98115, United States, sevnaz@uw.edu, Minsun Kim, Archis Ghate

We present a formulation and a solution method for the optimal fractionation problem with two modalities using the standard linear-quadratic modelof dose-response. Numerical experiments and sensitivity analyses will be described to provide insight into the resulting dosing decisions.

3 - Optimal Strategies for Monitoring and Prediction of Chronic Kidney Disease Demand-for-care

Zlatana Dobrilova Nenova, University of Denver, 2720 Shady Avenue, Apt 2, Denver, CO, 15217, United States, znenova@katz.pitt.edu, Jennifer S.Shang

Chronic disease monitoring strategies involve understanding patient's overall health state. In this research, we design a framework for optimizing such strategies, which consists of three models: two parameter estimation models (Case-based Reasoning and Survival Analysis) and one optimization model (MDP). We showcase our framework using chronic kidney disease, which is selected due to its complexities, prevalence and cost of care. Furthermore, we demonstrate how the proposed MDP model can be used to predict medium-term appointments' demand, which is important when making staff hiring and patient recruitment decisions.

4 - Optimal Decision Making in a Markov Model with Parameter Uncertainty: the Case of Chronic Kidney Disease

Mohammad Reza Skandari, University of Chicago, 5454 South Shore Drive, 914, Chicago, IL, 60615, United States, skandari@uchicago.edu, Steven Shechter

We investigate a Markov decision process whose unknown transition parameters are revealed partially through state observation. Decisions are made as the state evolves. We use the model to study the optimal time to start preparing a type of vascular access for chronic kidney disease patients who will need dialysis.

Simulation in Healthcare

Sponsored: Health Applications

Sponsored Session

Chair: Michael W. Carter, University of Toronto, Toronto, ON, M5S 3G8, Canada, carter@mie.utoronto.ca

1 - Cost-effectiveness Analysis of Nalmefene to Treat Alcoholism

Greg Zaric, London, ON, Canada, gzaric@ivey.ca, Estefania Ruiz Vargas, Richard Zur

We developed a microsimulation model to estimate the cost-effectiveness of nalmefene plus psychosocial support in an alcohol dependent population with high or very high drinking risk levels. The model simulates a large cohort from age 17 to age 110 in 1-year time steps. In each time step individuals are classified as being in one of three drinking states Among current drinkers, changes in consumption are based on age, sex, and current drinking status. Transition rates were estimated using three large databases, and treatment efficacy was modeled based on clinical trial results.

2 - Modelling Surge Across Emergency Department, Operating Room, and Inpatient Beds with Generic, Data-driven, Discrete Event Simulation Model

Carolyn Busby, University of Toronto, Toronto, ON, L6J.2W5, Canada, carolyn.busby@mail.utoronto.ca, Michael W. Carter

Canadian hospitals routinely operate, at, near or over capacity. To manage beds, and serve patients when full, hospitals have written surge protocols that outline what actions should be taken to alleviate the congestion. However, although these protocols are routinely employed, they have not been fully captured in hospital models. Additionally, as the hospital fills up, capturing the interaction of operating rooms, the emergency department, and inpatient beds become critical. A data-driven, generic, discrete-event-simulation model is presented that captures these interaction and the process changes that occur when in surge.

3 - Coordinated Response of Hospitals in Disaster

Bahar ShahVerdi, George Mason University, Washington, DC, United States, bshahver@masonlive.gmu.edu, Elise Miller-Hooks, Marcedeh TariVerdi

A discrete event simulation framework is presented for assessing the benefits of coordinated response of hospitals in a disaster incident involving area-wide damage and mass casualties. Impacts on critical resources, physical spaces and demand are modeled. Findings from numerical experiments show the potential of joint capacity modification strategies.

Co-Chair: Vibhanshu Abhishek, Carnegie Mellon University, Pittsburgh, PA, 19104, United States, vibs@cmu.edu

1 - Business Models in the Sharing Economy: Manufacturing Durable Goods in the Presence of Peer-to-Peer Rental Markets

Jose A.Guajardo, University of California-Berkeley, Haas School of Business, 545 Student Services Bldg, Berkeley, CA, 94720-1900, United States, jguajardo@berkeley.edu

Business models that focus on providing access to assets rather than on transferring ownership of goods have become an important industry trend. Motivated by this trend, this research analyzes the interaction between a manufacturer of durable goods and a peer-to-peer marketplace, characterizing market outcomes under alternative market structures.

2 - Product Heterogeneity and Externality of Sponsored Search on Online Marketplaces

Siddhartha Sharma, Carnegie Mellon University, 4800 Forbes Avenue, 3024 Hbh, Pittsburgh, PA, 19104, United States, na, Vibhanshu Abhishek, Param Vir Singh

E-commerce marketplaces like Amazon, Ebay and Flipkart have gained significant prominence in the last decade. In this paper, we examine a new phenomenon used by these marketplaces called Product Listing Ads (PLA) which allow third party sellers to promote their listings via an ad. Using a large scale randomized field experiment we measure the impact of PLA on the marketplace and on competing advertisers.

3 - Motivating Effective Mobile App Adoption in Multi-channel Shopping: A Large Field Experiment

Tianshu Sun, University of Southern California, 3670 Trousdale Parkway, Bridge Hall, BR.I.310B, Los Angeles, CA, 90089, United States, tianshus@marshall.usc.edu, Lanfei Shi, Siva Viswanathan, Elena Zheleva

Using a randomized field experiment involving 250,000 customers from a large ecommerce platform, we investigate i) whether and how a firm can motivate customers to adopt mobile apps and ii) the causal effect of induced mobile app adoptions on customers' purchase behaviors. We find that i) both providing information and monetary incentive can lead to significant increase in customers' app adoption; ii) the effect of mobile app adoption varies greatly depending on how customers are motivated. Although providing monetary incentives may lead to larger increase in mobile app adoption, such induced adoption does not result in more purchases in the long run. In contrast, providing information leads to effective mobile adoption that sustainably increases customers' purchases, and overall profits of the firm. We further examine customers' multichannel behavior and explore how induced app adoptions affect customers' purchases.

4 - Putting a Dollar Sign to Retweets – How Startup External Social Capital Improves VC Funding
Fujie Jin, Kelley School of Business, Indiana University, Bloomington, IN, Veeresh Thummadi

This project looks at how startups can leverage external social capital from social media platforms to improve their VC funding outcomes. We focus on firm social media activities, to see whether retweets or mentions from investors and other established firms serve as quality signals to attract VC funding. Our findings suggest that external social capital from social media platforms provide another source of relevant information for venture capitalists funding decisions and that startups should employ social media strategies that enhance their external social capital on these platforms.

1 - Enabling Healthcare Delivery through Vehicle Maintenance
Li Chen, Cornell University, 321 Sage Hall, Ithaca, NY, 14853, United States, li.chen@cornell.edu, Sang-Hyun Kim, Hau Leung Lee

Difficulties in healthcare delivery in developing economies arise from poor road infrastructure of rural communities, where the bulk of the population reside. Riders for Health, a nonprofit social enterprise, has developed specialized capabilities that enable significant enhancements in vehicle maintenance for healthcare delivery. The organization has engaged with the governments and provided its services using different contract schemes. In this paper we develop an analytical model based on reliability theory to compare the outcomes of these contracts, and relate the findings to data collected from a 2.5-year implementation by Riders for Health in Zambia.

2 - A Model of Interplay between Regulation, Time-to-Market, and Quality in New Drug Development
Canan Savaskan, SMU. Cox School of Business, P.O. Box 750333, Dallas, TX, 75275, United States, csavaskan@cox.smu.edu, Vishal Ahuja

In this paper, we study the interplay between Prescription Drug User Fee Act, firm choice of product innovation, FDA's product review quality and the product time to market. While the FDA regulation on PDUFA has had positive impact on product approval times, the effect on final product quality has been mixed. IN this paper, using game theoretic modeling, we capture the impact of improved product review times on drug quality in the market.

3 - Optimizing Local Content Requirements under Technology Gaps
Lauren Xiaoyuan Lu, University of North Carolina at Chapel Hill, Kenan-Flagler Business School, CB #3490, McColl Building, Chapel Hill, NC, 27599, United States, lauren_lu@unc.edu, Shiliang Cui

We study how the government of a developing country optimizes its Local Content Requirement (LCR) policy to maximize social welfare in a setting where foreign OEMs produce and sell final products in the host country and the OEMs' sourcing costs for components are higher from local suppliers than from global suppliers due to technology gaps. We characterize and compare the optimal product-level and component-level LCR policies imposed on multi-component products. Such policies have not been well studied in prior research but are practically relevant given that most real-world LCR policies regulate multi-component products.

4 - The Impact of Category Captainship on the Retail Competition
Alper Nakkas, The University of Texas at Arlington, Arlington, TX, United States, alper.nakkas@novasbe.pt, Mumin Kurtulus

Category captainship is a retailing practice where a retailer relies on a leading manufacturer (referred to as captain) on improving the category performance. This paper studies category captainship in the context of retail competition. We find that category captainship can be beneficial for not only the collaborating retailer but also for the competing retailer.

1 - When do Givers Take and Takers Give? Reciprocity Styles and Student Interaction on MOOCs
Aravinda Garimella, University of Washington, Seattle, WA, United States, aravinda@uw.edu

MOOCs are platforms of collaborative learning that heavily rely on student interaction. We show that students are heterogeneous in their reciprocity styles and identify three distinct styles. We show that incentives have different effects on students based on their intrinsic reciprocity styles. Our analysis is conducted on three years of daily interaction data between students on Khan Academy.

2 - Pricing Strategies under Service Competition and Uncertainty
Vashkar Ghosh, vashkar.ghosh@warrington.ufl.edu, Janice Ellen Carrillo, Kyung Sung Jung, Young Kwark

We analytically examine the service competition between two online retailers in the presence of consumers' uncertainty. We consider the impact of online reviews on the profits of the parties in the channel and show their preferences toward agency and reselling models.

3 - Returns, Rebates and Restocking Fee
Rachel Rong Chen, UC Davis, Davis, CA, United States, rachen@ucdavis.edu, Paolo Roma

Buyers are often uncertain of the product valuation before their purchase. As a result, they might return the product to the retailer. This paper examines the possibility of using product rebates to deter consumer returns, and compare the effectiveness of rebates vs. restocking fee at reducing returns.

4 - Strategic Store Design in a Vertical Channel
Jane Gu, University of Connecticut, Storrs, CT, United States, jane.gu@uconn.edu

We investigate the strategic implications of a big retailer's store organization when the retailer sells competing manufacturers' products. We model consumers' shopping behavior at the big retailer as a dynamic process of consideration set formation, and investigate how consumers' consideration set evolves in the battle between a well-known manufacturer's effort to induce consumers to search for its own product at the retailer's store and the retailer's effort to motivate consumers to search for other product alternatives through its store design. Our results show that the retailer has an incentive to withhold from improving store organization as long as its store is not poorly organized.

5 - Product Upgrades under Innovation Uncertainty
Yiwei Wang, willwangyiwei@gmail.com, Shuya Yin, Vidyanand Choudhary

Firms constantly invest on the development of prospect technologies hoping to improve the performance. However, a potential risk is that the new technologies may be unstable and their performance could be inconsistent from time to time. This project aims to provide conditions under which firms should or should not adopt the prospect technology. These conditions are affected by a number of driving forces, such as the characteristics of the technologies and cost structures.

Sponsored Session

Chair: Itai Ashlagi, Stanford University, Stanford, CA, 94305, United States, iashlagi@stanford.edu

1 - Communication Requirements and Informative Signaling in Matching Markets

Itai Ashlagi, s, Stanford, CA, 94305, United States, iashlagi@stanford.edu, Mark Braverman, Yash Kanoria, Peng Shi

We study how much communication is needed to and a stable matching in a two-sided matching market with private preferences. Segal (2007) and Gonczarowski et al. (2015) showed that in the worst case, any protocol that computes a stable matching requires the communication cost per agent to scale linearly in the total number of agents. In real-world markets with many agents, this communication requirement is implausibly high. This casts doubts on whether stable matchings can arise in large markets. We study markets with realistic structure on the preferences and information of agents, and show that in "typical" markets, a stable matching can be found with much less communication effort. Our protocols have good incentive properties and give insights on how to mediate large matching markets to reduce congestion.

2 - The Reverse Economics of (thin) Centralized Matching Markets

Afshin Nikzad, Stanford University, 741A Homer Ave, Stanford, CA, 94301, United States, afshin.nikzad@gmail.com

We study the monopoly and duopoly equilibria of centralized matching markets where there is externality for thickness. When these markets are "thick", their equilibria are governed by the usual economic laws, e.g. the higher the demand, the higher the price. However, when these markets are "thin", their economics could be very different. In particular, we characterize the Reverse Law of Demand, according to which, the wage paid to workers may go up when the labor supply goes up. We also characterize the Adverse Effect of Competition in the duopoly equilibrium, according to which, customers may face higher price (and therefore lower average welfare) under a duopoly than under a monopoly.

3 - Dynamic Reserve Prices for Repeated Auctions: Learning from Bids

Hamid Nazerzadeh, CA, United States, nazerzad@marshall.usc.edu, Yash Kanoria

A large fraction of online advertisements are sold via repeated second-price auctions. In these auctions, the reserve price is the main tool for the auctioneer to boost revenues. In this work, we investigate the following question: How can the auctioneer optimize the reserve prices by learning from the previous bids, while accounting for the long-term incentives and strategic behavior of the bidders? To this end, we consider a seller who repeatedly sells ex ante identical items via a second-price auction. Buyers' valuations for each item are drawn i.i.d. from a distribution F that is unknown to the seller. We find that if the seller attempts to dynamically update a common reserve price based on the bidding history, this creates an incentive for buyers to shade their bids, which can hurt revenue. When there is more than one buyer, incentive compatibility can be restored by using personalized reserve prices, where the personal reserve price for each buyer is set using the historical bids of other buyers. Such a mechanism asymptotically achieves the expected revenue obtained under the static Myerson optimal auction for F. Further, if valuation distributions differ across bidders, the loss relative to the Myerson benchmark is only quadratic in the size of such differences. If up-front fees are permitted, we show how the seller can determine such payments based on the bids of others to obtain an approximately incentive compatible-mechanism that extracts nearly all the surplus.

Health Care, Strategy and Policy

Contributed Session

Chair: Hamideh Anjomshoa, IBM Research Australia, Carlton, Victoria, Australia, hamideh.a@au.ibm.com

1 - Evaluating the Effects of the Implementation of Variances to the Current Allocation System on the State of Georgia

Monica Gentili, University of Louisville, JB Speed Building, Room 304, Louisville, KY, 40292, United States, monica.gentili@louisville.edu, Shanthi Muthuswamy, Mohsen Mohammadi, Vinod Venkata Naga Sai

The U.S. transplant community has long been concerned about disparities in access to and outcomes of transplantation. One of the alleged causes of disparity is administratively determined organ allocation boundaries that limit organ sharing across regions. To overcome these issues members of the Organ Procurement Transplant Network can propose a modification (i.e., a variance) to the current allocation system to allocate organs differently than the OPTN Policies. In this study, using optimization and simulation, we investigate how the implementation of the Statewide Sharing variance would affect access to and outcomes of transplantation for the state of Georgia over time.

2 - Comparison of Particle Filter Methods for the Estimation of Reproduction Number of Influenza Epidemics

Xi Chen, University of Texas at Austin, 3500 Greystone Drive, Apt 271, Austin, TX, 78731, United States, carol.chen@utexas.edu

Accurately estimating the parameters of the infectious disease progression model can efficiently help organizations determining the progression and severity of the disease and response properly and quickly. We propose a Posterior particle filter and two Single Statistic Posterior particle filters and compare them with Bootstrap Filter and Auxiliary Particle Filter to show their ability of accurately and consistently estimating the parameters in infectious disease progression models which are non-linear in nature. Besides, we show the importance of the re-sampling algorithm in helping improving the consistency of particle filters.

3 - Identifying Temporal Disease Progression Patterns using Electronic Medical Records

Xiaochen Wang, PhD Student, Yale University, 300 George Street, Suite 503, New Haven, CT, 06511, United States, xiaochen.wang@yale.edu, Hongyu Zhao

Wide availability of electronic medical records nowadays allows for a more comprehensive understanding about disease progression patterns and their associations with patients' outcomes. We will describe a multi-layer continuous-time hidden Markov model to learn the hidden states of a disease and their progression on patients receiving different treatment. Our disease progression model can explicitly include demographic information and characterize treatment effects under different treatments. We will show how our model parameters can be estimated using the EM-based algorithms, and illustrate its usefulness through its application to a congestive heart failure patient cohort.

4 - Minimizing Health Compromising Behaviors via School-based Programs: An Application of Linear Programming

Banafsheh Behzad, Assistant Professor, California State University, Long Beach, 1250 Bellflower Blvd., MS.850, CBA 440, Long Beach, CA, 90840, United States, banafsheh.behzad@csulb.edu, Niloofar Bavarian, Sheena Cruz

We aimed to examine the minimum curriculum delivery levels of a school-based social-emotional and character development program needed to observe an impact on youth's internalizing and externalizing behaviors and outcomes, while controlling for known barriers to implementation fidelity by using a linear programming model.

5 - Considering Efficacy-based Objective Functions for Dorfman Style Pooling using a Combo Assay

Evan Mullins, Virginia Tech, 966 Nellie's Cave Road, Blacksburg, VA, 24060, United States, evanm@vt.edu, Ebru Korular Bish, Doug Bish

We derive performance metrics for a two-infection combo assay and develop an optimization model to capture classification accuracy with respect to a testing budget constraint and an optimization model that minimizes total cost to the testing center. We consider performance metrics influenced by the dilution effect and then modify them for the special case of no dilution effect. We propose three hypothetical sensitivity functions to quantify that quantify the dilution effect and analyze their effect on the performance metrics. The methodology is then evaluated by a numerical study based on for four distinct sub-groups.

6 - Optimal Budget Allocation for Infectious Disease Control

Hamideh Anjomshoa, IBM.Research Australia, 204 Lygon Street, Carlton, Victoria, 3124, Australia, hamideh.a@au.ibm.com, Manoj Gambhir, Roslyn Hickson, Olivia Jayne Smith

There are typically multiple possible intervention combinations that can be applied to control infectious disease outbreaks. We simulate the spatiotemporal disease transmission dynamics and subsequent impacts of intervention applications. We identify the optimisation framework to optimally allocate resources given the budgetary constraints which we demonstrate with a case study of dengue fever. The key challenge in this work is the nonlinear dynamics, combined with budget allocations between spatial regions.

1 - Managing Patient Flow Dynamics in Internal Wards

Jing Dong, Northwestern University, 2145 Sheridan Road, Room C210, Evanston, IL, 60208, United States, jing.dong@northwestern.edu, Ohad Perry

We introduce a new class of queueing models that take into account the most salient features of patient flow dynamics in Internal Wards. We also develop efficient approximation techniques for long-run performance analysis, which greatly facilitate evaluating the effect of various operational policies.

2 - Data-driven Appointment-scheduling under Uncertainty: The Case of an Infusion Unit in a Cancer Center

Nikolaos Trichakis, MIT, 100 Main Street, E62-576, Cambridge, MA, 02143, United States, ntrichakis@mit.edu, Avishai Mandelbaum, Petar Momcilovic, Sarah Kadish, Ryan Leib, Craig Bunnell

We consider appointment scheduling under a time-varying number of servers, in a data-rich environment where service durations and punctuality are uncertain. Our data-driven approach, based on infinite-server queues, yields tractable and scalable solutions that accommodate hundreds of jobs and servers. We successfully test our approach against near-optimal algorithms, which exist for merely single-servers. To test for practical performance, we leverage a unique dataset from a cancer center, that combines real-time locations, electronic health records and appointments log. Focusing on one of the center's infusion units (~90 daily appointments, 25+ infusion chairs), we reduce cost by 30%.

3 - Designing Personalized Anticoagulation Therapy

Rouba Ibrahim, University College London, MS& I.department, UCL, Gower Street, London, WC1E 6BT, United Kingdom, rouba.ibrahim@ucl.ac.uk, Vedat Verter, Beste Kucukyazici, Michel Gendreau, Mark Blostein

We develop an analytical framework for personalizing the anticoagulation therapy of patients who are taking warfarin, and present results from a case study using data collected at the anticoagulation clinic of the Jewish General Hospital in Montreal.

4 - Dynamic Server Assignment in a Multiclass Queueing System with Shifts, with Application to Nurse Staffing in Emergency Departments

Vahid Sarhangian, University of Toronto, Toronto, ON, Canada, sarhangian@mie.utoronto.ca, Carri Chan

Nurse staffing decisions in emergency departments (EDs) are typically assigned weeks in advance, which can create staffing imbalances as patient demand fluctuates. In this work, we consider the potential benefits of assigning nurses to different areas within an ED at the beginning of each shift. We study the problem of optimal reassignment of nurses to areas by considering a multiclass queueing model of the system. We analyze an associated fluid control problem and use the solution to develop policies that achieve asymptotically optimal performance under fluid-scaling for the original stochastic system. We find this additional flexibility can substantially reduce waiting times for patients.

1 - Estimating Consumer Preferences for Pooled Transportation

Kashish Arora, INSEAD, Fontaniebleau, France, kashish.arora@insead.edu, Karan Girotra, Fanyin Zheng

Marketplace operators run aggressive incentive schemes to achieve scale, that is key to the efficacy, survival and eventual domination of a marketplace. This study quantifies and compares the effect of incentives given to the "buyer" side and "seller" side using data from a leading ride-hailing market. We build a structural model to accurately capture the driver and passenger response to incentives, and the nature of incentives. Driver effort on the platform is unobserved, for which we devise a novel local matching model based imputation method. We find that in short-term (current week) passenger incentives are more effective while the opposite is true in the long-term (next 3 months).

2 - (DIS)Value of Information in a Supply Chain of Perishable Products

Ming Hu, University of Toronto, Rotman School of Management, 105 St. George Street, Toronto, ON, M5S.3E6, Canada, ming.hu@rotman.utoronto.ca, Peng Luo, Jiahua Wu

Our study is based on a data set from a fast-food restaurant chain. During the observation window, this restaurant chain switched from third-party POS systems to their own system, which allows them to gather real-time sales information from stores. We study store managers' adjustment of operational decisions in response to this change, as well as the resulting impact on customer satisfactions.

3 - Behavioral Drivers of Routing Decisions: Evidence from Restaurant Table Assignment

Fangyun Tan, Southern Methodist University, 6212 Bishop Blvd, Dallas, TX, 75275, United States, ttan@cox.smu.edu, Bradley R. Staats

In many settings, humans make routing decisions dynamically, either because algorithms don't exist, decision support tools have not been implemented, or existing rules are not enforced. Understanding how individuals make decisions creates the opportunity to identify both positive deviances, as well as suboptimal decision making that can be improved. In this paper we theoretically identify the factors that may impact decision making before empirically examining a large operational data set in a casual restaurant setting to research whether and how hosts deviate from their predefined round-robin rule to seat customers to servers.

4 - Empirical Analysis of Supply Network Relationship Concentration, Structure, and Firm Performance

Marcus A. Bellamy, Boston University, Rafik B. Hariri Building, 595 Commonwealth Avenue, Boston, MA, 02215, United States, bellamym@bu.edu, Soumen Ghosh, Manpreet Singh Hora

We examine the concentration and structural configuration of a firm's supply chain as drivers of its performance using supply chain relationship data from the Bloomberg database. We demonstrate how firm performance may be influenced by such drivers and how the industry context within which a firm operates augments their influence.

Inventory Management

Contributed Session

Chair: Mustafa Hekimoglu, Isik University, Istanbul, Turkey, mustafa.hekimoglu@isikun.edu.tr

1 - Joint Replenishment and Transshipment for Three Locations - Asymptotics and Bounds

Weifen Zhuang, Associate Professor, School of Management, Xiamen University, Xiamen, 361005, China, wfzhuang@xmu.edu.cn

We study the problem of joint replenishment and transshipment for a retailer who sells seasonal products through three physical stores. The decisions involve the one-shot stocking at the beginning of the season and the supply/transshipment decision throughout the season. Applying an MDP formulation with compound Poisson demand processes, we identify the optimal policies. We then study two downward transshipment models and develop bounds, which are shown to be asymptotically optimal. We develop effective heuristics by making use of the bound solution. The bounds and heuristics can be extended to deal with the problem of multiple-location.

2 - Ordering and Transshipment Policies for a Healthcare System with Two Hospitals

Erhun Kundakcioglu, Ozyegin University, Faculty of Engineering, Nisantepe mah. Orman sok., Istanbul, 34794, Turkey, erhun@alumni.ufl.edu, Hamed Shourabizadeh

One of the most important challenges in healthcare systems is managing inventory. Depending on available capacity and average expiration dates, hospitals typically determine replenishment cycles without mathematical optimization. Our study focuses on determining optimal inventory levels that minimize the sum of inventory holding, ordering, and transshipment costs for a system of two hospitals. Hospitals can collaborate in the form of stock transfer and joint replenishment. Due to uncertain demand, hospitals are expected to benefit from a collaborative inventory model that increases the quality of care for patients (drug accessibility) and time between consecutive orders.

3 - Warehouse Storage Layout Optimization using Community Detection and Mathematical Modeling

Husam Dauod, PhD Student, Binghamton University, 99 Main Street, Apt 5, Binghamton, NY, 13905, United States, hdauod1@binghamton.edu, Sung Hoon Chung, Sang Won Yoon

This research presents a community detection approach to analyze and optimize warehouse storage layout in order picking environments. Storage layout is a key warehouse management function that greatly affects the overall performance. However, storage layout optimization is challenging because it requires the analysis of large amounts of orders data. To analyze this data efficiently, networks community detection is used to extract association relationships between items. These relationships are then used in a mixed integer programming model to determine optimal inventory locations. Results indicate that the proposed approach provide good results with short computational time.

4 - Dynamic Substitution Policy for Selling Multiple Products with Supply Uncertainty

Chengzhang Li, Purdue University, 2367 Edison Dr, West Lafayette, IN, 47906, United States, li1392@purdue.edu, Qi Feng, J. George Shanthikumar

We study a firm selling multiple substitutable products over a planning horizon of multiple periods. The firm faces replenishment cycles of fixed lengths with uncertain supply. In each period, when the random demands materialize, the firm may substitute one product with another in meeting the demands. Extending the notion of stochastic linearity, we show that the replenishment problem is concave via transformation. We design an efficient algorithm to decide the substitution policy that delivers close-to-optimal performance. We also show that restricting substitutions between products with adjacent characteristics can yield a benefit close to allowing full substitution among all products.

5 - Optimum Pricing and Inventory Control for Spare Parts in Existence of Secondary Markets

Mustafa Hekimoglu, Assistant Professor, Isik University, Sile Campus, Sile, Istanbul, 34980, Turkey, mustafa.hekimoglu@isikun.edu.tr, Rommert Dekker, Erwin Van der Laan

Secondary markets for spare parts are online platforms where Original Equipment Manufacturers (OEMs), distributors, customers can obtain spare parts with short lead times and for cheaper prices or they can dump their excess inventory. From an OEM's perspective, pricing against secondary market while controlling inventory is critical as higher prices may lead customers to secondary markets or even early phase-outs of their capital products. In this study, optimum policy for single period problem of pricing and inventory control is developed under linear demand model assumption. Also, we developed insights for multi-period problem under discounter cost criterion.

Healthcare/Service Systems in Applied Probability

Sponsored: Applied Probability

Sponsored Session

Chair: Song-Hee Kim, University of Southern California, Los Angeles, CA, 90089, United States, songheek@marshall.usc.edu

1 - Dynamic Decision Making in a Queueing System with Secondary Service

Wanyi Chen, wanyic@live.unc.edu

Motivated by operational practices in emergency departments, we consider a queueing model where each job is one of two types. Type 1 jobs need only a primary service given by a single server. Type 2 jobs need an additional secondary service. Secondary service is conducted by infinitely many servers. Primary servers cannot serve a new job until secondary service of a job is over. Jobs incur waiting costs and there is an option of starting primary and secondary services together with an extra cost. The decision is whether or not to use that option for each job given the probability that the job is type 1. We show the optimal policy is of threshold-type and numerically test the performance of heuristic methods.

2 - Improving Itinerary Completion at a Destination Healthcare Institution

Jonathan Helm, Indiana University, Kelley School of Business, 1309 East Tenth Streeet, Bloomington, IN, 47405, United States, helmj@indiana.edu, Mark P.Van Oyen

At a destination hospital, patients travel long distances to receive treatment. For these patients, itinerary completion - defined as the completion of their treatment segment before the weekend - is an important metric. Motivated by itinerary completion, we present a new methodology for modeling and optimizing flows in a network of outpatient clinic visits to minimize flow times of priority patients within a queueing network with hard deadlines for service completion.

3 - A Real-time Risk Prediction and Discharge Optimization Framework for Inpatient Flow and Patient Outcomes

Pengyi Shi, Purdue University, 403 W. State St, Krannert School of Management, Kran 472, West Lafayette, IN, 47907, United States, shi178@purdue.edu, Jonathan Helm, Jivan Romain Deglise-Hawkinson, Julian Pan

Hospital discharge processes are critical to quality and access. Inpatient congestion can be mitigated by early discharge, which, however, carries risks of adverse events for individual patients. In collaboration with a healthcare analytics company, we develop a real time risk prediction model for readmission risk on each day of a patient's hospital stay. We integrate this prediction with a discharge optimization framework that balances the risk of early discharge for individual patients with the risks of inpatient congestion. In this talk, we present our methodology and discuss our joint implementation efforts at a partner hospital.

4 - Analysis of Hospital Networks via Time-Varying Fluid Models with Blocking

Noa Zychlinski, Technion - Israel Institution of Technology, Haifa, 3200003, Israel, noazy@tx.technion.ac.il, Avishai Mandelbaum, Petar Momcilovic, Izack Cohen

This research focuses on modeling, developing and analyzing time-varying fluid networks with blocking. These models are motivated by two applications. The first is patient flow analysis between hospitals and geriatric institutions in order to improve their joint operation. The second application includes analysis of tandem flow lines with blocking and finite waiting rooms before the first station, and between stations. The finite capacity of the first station leads to customer loss, and therefore, requires reflection analysis. We demonstrate that our models yield operational insights on network performance.

1 - Effect of Presorting on the Delay in Multiclass Queues with a Global FCFS Service Discipline

Willem Mélange, Ghent University, Ghent, Belgium, Willem.Melange@UGent.be, Joris Walraevens, Dieter Claeys, Herwig Bruneel

We study the effect of presorting on the delay of a random customer in a continuous-time queueing system with two types of customers and dedicated servers. In this system, all arriving customers are accommodated in a single FCFS queue. All customers, except for the first P are served in a FCFS order, regardless of their types. The first P customers however can overtake customers of the other type in order to be served. The motivation for this work comes from traffic. Our results can be used to determine optimal lengths of filter lanes.

2 - Dynamic Control of Service Systems with Teams

Junqi Hu, Georgia Institute of Technology, Atlanta, GA, 30332, United States, hujunqi1210@gatech.edu, Sigrun Andradottir, Hayriye Ayhan

Consider a Markovian queueing network with two stations in tandem,flexible servers, finite intermediate buffer, and infinite supply of jobs in front of the first station. We assume that the servers always work in teams and allow the team service rates to be general. Our objective is to maximize the long-run average throughput by dynamically assigning servers to teams and teams to stations. We first establish sufficient criteria for eliminating inferior teams, and then we show how to find the optimal policy among the remaining teams. Finally, we investigate special cases with constraints on team formation and with structured team service rates.

3 - Strategic Customers in Systems with Batch Arrivals: On How to Protect Your Party

Olga Bountali, Southern Methodist University, 4210 Fairmount Street, Apartment 3063, Dallas, TX, 75219, United States, obountali@smu.edu, Apostolos Burnetas, Lerzan Ormeci

Customers in batch-arrival systems that are served individually vacillate upon the "join-balk" dilemma: should each member decide under the objective of maximizing his revenue or should they all aim to maximize the batch welfare? We consider a Markovian queue and address the question above under two rules with regards to the decision framework: the 0-1 case, where the whole batch decides to join or balk, and the partial case, where only a fraction of the customers joins. We analyze and compare the equilibrium behavior in both cases and the corresponding implications on the social welfare.

4 - Queueing Processes on a Random Graph
René Bekker, PhD, VU Amsterdam, Netherlands, r.bekker@vu.nl, Nicos Starreveld, Michel Mandjes

During this presentation we attenpt to develop a queueing model on a random graph. The queueing process at each node is following the dynamics of an infinite-server queue. The links between nodes (or the nodes themselves) evolve between up and down states according to some background process. Alternatively, the model can be interpreted as a network of infinite-server queues. The performance measures we study are the number of links that are up and the queue content at the nodes. We explicitly determine their moments, give a functional central limit theorem for the number of nodes that are up, and present more detailed results for fully symmetric random graphs.

1 - Supply Chain Implications of Shock Propagation and Systematic Risk
Jing Wu, City University of Hong Kong, Hong Kong, jing.wu@cityu.edu.hk, John R.Birge

In this talk, by leveraging supply chain data that is unstructured, incomplete, and highly complex, we show empirically the spill-over effects of moderate shocks transmitted to other connected firms in supply chains. We also show the systematic risk implications of the self-organized supply chain structure which cannot be explained by common risk factors.

2 - Stock Market Reaction to the 2015 Volkswagen Diesel Emission Scandal
Brian W. Jacobs, Michigan State University, 632 Bogue Street. Rm N370, East Lansing, MI, 48824, United States, jacobsb@bus.msu.edu, Vinod R. Singhal

Responsible sourcing is of increasing research interest, but what happens if your customer is not socially responsible? We examine the propagation of changes to shareholder value that emanated from the 2015 VW diesel emissions scandal, spread upstream in the supply chain, and horizontally to competitors and the diesel industry.

3 - Supply Chain Contagion in Credit Default Swap Market
Volodymyr O. Babich, Georgetown University, 37th & O.St NW, McDonough School of Business, Washington, DC, 20057, United States, vob2@georgetown.edu, Senay Agca, John R. Birge, Jing Wu

We present evidence for the existence of the supply-chain contagion channel in the Credit Default Swap (CDS) market, using event studies and diff-in-diff regressions, based on CDS, supply chain, and firm data from 2004 to 2014. The CDS spread up- (down-) jump in a supply chain is associated with CDS spread increase (decrease) for the reference firm. Supply-chain contagion extends to higher supply-chain tiers. We identify firm and supply chain attributes that contribute to CDS supply chain contagion. For example, older SC links, and links with stronger financial ties between customers and suppliers amplify contagion. We confirm results with robustness tests, e.g., placebo test with inactive links.

4 - Optimal Term Design for Supply Chain Finance
Xiaobo Ding, Johnson School, Cornell University, Ithaca, NY, United States, xd72@cornell.edu

Small suppliers are often cash-strapped due to long payment collection cycles and high credit rates. Supply chain finance, also known as reverse factoring (RF), is a popular instrument used in practice to address this problem. In this paper, we study the supplier's cash management problem under RF, and also quantify the value of RF to the supplier. We show that the optimal policy for the multi-period cash management problem is a modified (L,U) policy. We explain how RF creats a win-win-win situation for the supplier, the buyer and the bank. Moreover, our model can be used to inform the design of the optimal term for supply chain finance.

Computational Research Methods and Applications in TIMES

Sponsored: Technology, Innovation Management & Entrepreneurship

Sponsored Session

Chair: Hyunwoo Park, Ohio State University, 2100 Neil Ave, Columbus, OH, 43210, United States, park.2706@osu.edu

1 - A Bicentric Diagram Approach to Manage Interdependencies when Designing Complex Systems
Hyunwoo Park, The Ohio State University, Columbus, OH, United States, park.2706@osu.edu, Manuel Sosa, Rahul C. Basole

Complex systems are conceived as network of interconnected components. An important challenge for engineering managers is to identify the components that could potentially be affected if design changes affect two interdependent components. We introduce a novel approach, based on bicentric diagrams, to manage design changes of pairs of interdependent components of complex systems. We illustrate the use of our approach by applying it to the management of various critical technical interfaces during the development of large commercial aircraft engine.

2 - Prediction of Patient Activation During Technology Enabled Continuity of Care Intervention
Nitin Joglekar, Boston University, 595 Commonwealth Ave, Boston, MA, 02215, United States, joglekar@bu.edu, Carolyn Queenan, Kellas Ross Cameron

Patients' skills, knowledge, and motivation to actively engage in their healthcare are assessed with the Patient Activation Measure (PAM). We predict PAM as a function of the strength of information signals associated with telemedicine technology enabled care using a machine learning methodology. Predictions are shown to be subject to under/over estimation biases, consistent with the behavioral concept of system neglect in signal detection theory.

3 - Visual Business Ecosystem Intelligence: A Computer Vision Based Approach
Rahul C.Basole, Georgia Institute of Technology, School of Interactive Computing, 85 5th Street Nw, Atlanta, GA, 30332, United States, basole@gatech.edu

This study presents the application of computer vision, pattern recognition, and data visualization techniques for extracting, analyzing, and understanding image-based data of emerging business ecosystems.

4 - Business Model Innovation Feature Extraction and Application to the Lean Startup Framework
Christophe Pennetier, INSEAD, 6 Marina Boulevard, # 27-15, Singapore, 018985, Singapore, christophe.pennetier@insead.edu, Serguei Netessine, Karan Girotra

Using a new curated dataset with more than half a million startups, we use state-of-the-art text mining and machine learning techniques to identify business model innovations and study their effects on startups' success. We are the first to empirically study the lean startup approach.

Computer Aided Medical Diagnosis

Invited: InvitedHealthcare Systems and Informatics

Invited Session

Chair: Juri Yanase, Complete Decisions, LLC, Baton Rouge, LA, 70810, United States, jurijuriy@aol.com

Co-Chair: Evangelos Triantaphyllou, Louisiana State University, Baton Rouge, LA, 70803, United States, etriantaphyllou@yahoo.com

1 - Translating Prediction to Decision: A Framework to Tackle Risk Identification and Presentation Challenges in Sepsis
Muge Capan, Christiana Care Health System, 902 N. Market Street, Apt 527, Wilmington, DE, 19801-3082, United States, Muge.Capan@ChristianaCare.org, Julie Simmons Ivy, Stephen Hoover, Kristen Miller, Jeanne Marie Huddleston, Ryan Arnold

Rising incidence and mortality rate make sepsis, a spectrum of acute organ dysfunction secondary to an infection, a significant burden on the healthcare system. While predicting sepsis-induced deterioration using electronic health records promises enhanced risk detection, translating findings into decisions is challenging. We present a framework to reengineer the risk presentation associated with sepsis and in-hospital mortality in septic patients.

2 - Computer-Aided Diagnostic Models for Breast Cancer Screening
Oguzhan Alagoz, University of Wisconsin-Madison, 3242 Mechanical Engineering Building, 1513 University Avenue, Madison, WI, 53706, United States, alagoz@engr.wisc.edu

Mammography is used for early breast cancer diagnosis however similarities between early signs of breast cancer and normal structures in images make diagnosis a difficult task. We have developed computer-aided diagnostic models and tested them using real-life mammography data. In this presentation, we describe our experiences, list the limitations of the existing CADx models, and provide possible future research directions.

3 - Constraint Relaxation Extensions for Imbalanced Classification
Talayeh Razzaghi, Assistant Professor, New Mexico State University, MSC 4230, P.O. Box 30001, Department of Industrial Engineering, Las Cruces, NM, 88003-8001, United States, talayehr@nmsu.edu, Onur Seref, Petros Xanthopoulos

In this work, we study several algorithmic modifications of relaxed support vector machines to tackle a number of disease diagnosis problems with imbalanced datasets in the presence of outliers. We provide computational evidence proving better performance for the combined use of cost sensitive learning with constraint relaxation compared to bagging-based algorithms, which treat imbalanced-ness and outliers separately.

4 - Current Trends and Challenges of Computer-Aided Medical Diagnosis
Juri Yanase, Complete Decisions, LLC, 10517 Springbrook Ave., Baton Rouge, LA, 70810, United States, jurijuriy@aol.com, Evangelos Triantaphyllou

Computer-aided diagnosis is already more than 50 years old and has entered a maturity stage. It offers certain advantages for employing information from big data and being consistent. It finds applications in a wide range of areas. However, some serious challenges persist and include the need to analyze ultra large volumes of data, and algorithmic, security, and legal liability issues.

New Problems in Revenue Management

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Georgia Perakis, Massachusetts Institute of Technology, Cambridge, MA, 02142-1347, United States, georgiap@mit.edu

1 - Optimizing Over Tree Based Ensemble Objective Functions
Max R. Biggs, Massachusetts Institute of Technology, 77 Massachusetts Ave NE49-40497, Apartment 2, Cambridge, MA, 02139, United States, maxbiggs@mit.edu

In many real world applications, there is an unknown relationship between decisions and outcomes. For example, we might have data on previous actions taken in different situations, and observe outcomes. Using this data, there are powerful machine learning algorithms which can be used to build a predictive model. However, there has been little attention on how to make decisions if we fit a tree based ensemble model and use it as our objective function. We will show that this optimization problem can be modeled as a MILP, and present tractable decompositions and heuristics. We apply this methodology to a jury selection problem, where there is uncertainty as to how a juror will influence the jury.

2 - Stochastic Probing to Maximize the Value of Diagnostic Information
Mathieu Dahan, MIT, Cambridge, MA, United States, mdahan@mit.edu, Saurabh Amin, Georgia Perakis

We consider an adaptive probing problem to maximize the detection of failures in infrastructure networks. We study a stochastic programming model which accounts for the spatial distribution of alerts, including relative distances between locations and predictive accuracy of failure events within each location. Our result shows how to optimally sequence the probing of locations based on the tradeoff in exploiting a given location versus exploring other locations. We connect our work with recent literature on stochastic orienteering. Finally, we apply our approach to improve the value of diagnostic information for a regulated gas utility who invests in leak surveys to detect network failures.

3 - Submodular Batch Scheduling for Warehouse Picking
Daniel Chen, Massachusetts Institute of Technology, Cambridge, MA, United States, dcchen@mit.edu, Retsef Levi, Georgia Perakis

We describe theoretical and data-driven work in collaboration with an online retailer. In a warehouse, multi-item orders take up capacity on a wall until all items are picked. To avoid exceeding capacity, the retailer must balance picking efficiency with completing orders quickly. Motivated by this, we model an NP-hard batch scheduling problem to minimize average order completion times, where the processing time of each batch is given by a submodular function, generalizing previous problems in the literature. We provide integer programming formulations and approximation algorithms, and testing on a data-driven simulation suggests a potential 15% reduction in the time orders stay at the wall.

New Models in Pricing and Revenue Management

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Sandun Perera, PhD, University of Michigan-Flint, 2200 Riverfront Center, 303 East Kearsley Street, Flint, MI, 48502, United States, sperera@umich.edu

1 - Multi-product Pricing with Stockouts and Satisficing Customers
Varun Gupta, Penn State Erie, The Behrend College, 5101 Jordan Rd, Burke 281, Erie, PA, 16563, United States, vxg15@psu.edu, Metin Cakanyildirim

Stockouts for high inventory turnover products lead to loss of sales as customers may substitute their preferred product (stocked out) with another product (available). We study centralized pricing for a retailer and equilibrium prices for competing retailers selling to satisficing customers with stockout-based substitution under lost sales and backorders.

2 - Dynamic Pricing and Replenishment for Seasonal and Regular Products
Oben Ceryan, LeBow College of Business, Drexel University, 2040 Market St. Apt. 801, Philadelphia, PA, 19103, United States, oceryan@drexel.edu

We consider a firm that offers two substitutable products that differ in how their inventories are managed, a seasonal product with a fixed initial quantity that allows dynamic price adjustments but no replenishments, and a regular product with a static price that can be periodically replenished. We study the impact of these asymmetries on optimal dynamic pricing and replenishment decisions.

3 - Dynamic Pricing to Explore Markets with Customer- and Time-heterogeneity
Meng Li, Rutgers University, 227 Penn Street, Camden, NJ, 08102, United States, meng.li@rutgers.edu, Bora Keskin

Consumers are often heterogeneous in their preferences for product quality, and companies usually face uncertainty about consumer preferences when they sell differentiated products to such heterogeneous consumers. We study this problem in a situation where a company dynamically optimizes its prices.

4 - Optimizing Starvation to Avoid Cannibalization: Retailer's Strategies for Markets in Crisis
Sandun Perera, School of Management, The University of Michigan-Flint, 2200 Riverfront Center, 303 E. Kearsley Street, Flint, MI, 48502-1950, United States, sperera@umich.edu, Syagnik Banerjee, Metin Cakanyildirim

At times of crisis and disaster, donors often pay for necessary commodities distributed via local retailers. Retailers need to set prices that balance the tradeoffs between vulnerable customer needs and their ability to pay. We study this pricing problem under different market conditions.

Pricing and Consumer Experience in Behavioral and Service Settings

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Sami Najafi-Asadolahi, Santa Clara University, Santa Clara, CA, 95053, United States, snajafi@scu.edu

1 - Why Markdown as a Pricing Modality? the Role of Threat of Entry
Elodie Adida, University of California Riverside, Riverside, CA, United States, elodieg@ucr.edu, Ozalp Ozer

Markdown as a pricing modality is ubiquitous in retail. Despite its practical advantages everyday-low-price is rarer. We explore whether and why either of these pricing modalities is an effective defense against a firm that enters the market with the alternative pricing modality when consumers are heterogeneous, strategic and regret-prone.

2 - Patient's Waiting Experience in an Urban Emergency Department
Sina Ansari, Northwestern University, McCormick School of Engineering, 2145 Sheridan Road, Evanston, IL, 60208, United States, sinaansari2013@u.northwestern.edu, Seyed Iravani, Laurens G.Debo

Excessive wait time is the most common reason patients become unsatisfied and leave the emergency department before being treated. In this study, we aim to study the impact of announcing patient's waiting times and operational transparency on patients satisfaction and Left-Without-Being-Seen (LWBS) rate.

3 - How Freemium Gets Consumers to Pay a Premium: The Role of Loss-Aversion
Sami Najafi Asadolahi, Assistant Professor, Santa Clara University, Leavey School of Business, 500 El Camino Real. Lucas Hall, Santa Clara, CA, 95053, United States, snajafi@scu.edu, Nishant Mishra, Sajjad Najafi, Andy A.Tsay

We consider a firm offering two versions of a single product: a basic version for free and a premium version at a positive price. Consumers are heterogeneous and loss-averse with, stochastic and endogenous reference points. Each consumer first uses the free version, which enables him to understand the value of both the free and premium versions; he then decides whether to buy the premium version. The firm maximizes its expected profits by setting the best price for the premium. We show that after using the free version, the consumer is less likely to buy the premium version if the realized free version's value is unexpectedly high but more likely to buy if the realized free version's value is unexpectedly low.

Managing Incentives in Collaborative New Product Development

Invited: New Product Development

Invited Session

Chair: Timofey Shalpegin, University of Auckland, Auckland, 1010, New Zealand, t.shalpegin@auckland.ac.nz

1 - Incentivizing R&D for Neglected Diseases
Rongrong Luo, SUTD, SIngapore, Singapore, rongrong_luo@mymail.sutd.edu.sg

Many developing countries grapple with neglected diseases due to a lack of effective/safe biopharmaceutical treatments. The world health organization calls on non-government organizations (NGOs), and biopharmaceuticals to act in concert to eliminate neglected diseases. We model the interaction between an NGO, an Innovator and a Marketer. First, we characterize the conditions for a disease to be neglected in the absence of incentives. Subsequently, we evaluate the effectiveness of different incentive mechanisms in inducing collaboration to bring products targeting neglected diseases to market.

2 - Rights of First Negotiation and Rights of First Refusal in New Product Development Partnerships
Shantanu Bhattacharya, Singapore Management University, Lee Kong Chian School of Business, 50 Stamford Road, Singapore, 178899, Singapore, shantanub@smu.edu.sg, Guangyu Wan, Sameer Hasija, Niyazi Taneri

This paper considers a new product partnership between a pharmaceutical firm (Pharma) and a biotechnology firm (Biotech). The partnership involves collaboration in the early phase of the R&D process, when uncertainty about valuation makes designing a licensing contract challenging. In practice, right of first negotiation (ROFN) and right of first refusal (ROFR) contracts are used to manage future uncertainty that can be resolved over time. We build a principal-agent model where the Biotech as the principal designs a contract including a possible upfront fixed fee and a ROFN or ROFR clause for the future licensing of the drug candidate, and identify the situations where each clause is appropriate.

3 - Effect of Incentive Design on of Location Decision of Product Development of Teams
Sara Rezaee Vessal, HEC Paris, Paris, 91570, France, sara.rezaee-vessal@hec.edu, Svenja C. Sommer

To successfully compete on an international scale, multinationals increasingly turn towards globally dispersed product development teams, both to draw on a diverse set of expertise and to access more accurate local knowledge. However, dispersion also creates additional challenges for collaboration, which can have negative effects on project performance. In this study, we compare dispersed and co-located teams and address the question how to incentivise them. We show that despite the current trend among firms, geographically dispersed teams are not always the optimal structure, especially when collaboration is in the form of information sharing.

4 - Outsourcing Component Development for New Products to External Suppliers
Timofey Shalpegin, University of Auckland, ISOM, Business School, The University of Auckland, Auckland, 1010, New Zealand, t.shalpegin@auckland.ac.nz

New products sometimes fail due to failure of their key components developed by external suppliers. We find that some common contracts between manufacturer and suppliers cannot provide sufficient incentives for the suppliers to ensure high (first-best) component quality. We propose a contract that creates right incentives for the suppliers.

5 - Risk Taking in Organisations: An Evolutionary Approach
Antoine Feylessoufi, University of Cambridge, Christ's College, Cambridge, CB2 3BU, United Kingdom, af545@cam.ac.uk, Daniel Ralph, Stylianos Kavadias

Through social interactions, the behaviour of an individual is affected by the population but also influences the other members within that population. In a new approach to capture this effect on risk taking in organisations, we incorporate notions of prospect theory into an evolutionary game theoretic model widely used in biological ecosystems. We find that unexpected and extreme levels of risk taking behaviour (or lack thereof) can emerge in organisations through this mechanism. Moreover, it may drive all employees to risk taking behaviour even when this is discouraged through a firm's reward system. We describe how some successful ventures and collapses can be explained by this model.

Stochastic Approaches: Methods and Application

Invited: Data Envelopment Analysis

Invited Session

Chair: Andrew L. Johnson, Texas A&M University, College Station, TX, 77843-3131, United States, ajohnson@tamu.edu

1 - Markup Size, Export Tax Rebates, and Resource Misallocation
Mahmut Yasar, myasar@uta.edu

The paper provides an analysis of the allocation effects of the export tax rebate policy. We first add a tax rebate to the Melitz and Ottaviano (2008) model and examine the impact of this policy on firms' markup size and resource allocation. We then use customs transactions, tax administration, and firm-level data to measure the effect of variation in export tax rebates. We find that an increase in tax rebates shifts production to eligible firms and that "more fully" refunding export VATs increases allocative efficiency.

2 - Models with Ratio Measures & Potential Ratio Inefficiency
Ole Bent Olesen, University of Southern Denmark, Odense, Denmark, ole@sam.sdu.dk, N.C. Petersen, Victor Podinovski

In a recent, the authors developed a methodology that allows the incorporation of ratio inputs and outputs in the variable and constant returns-to-scale DEA models. Practical evaluation of strong and weak efficiency of decision making units (DMUs) in such models generally goes beyond the application of standard linear programming techniques. In this paper we discuss how the DEA models with ratio measures can be solved and introduce a new type of potential ratio (PR) inefficiency. It characterizes DMUs that are strongly efficient in the model of technology with ratio measures but become inefficient if the volume data used to calculate ratio measures become available.

3 - Estimating Firm Specific Efficiency in Stochastic Frontier Models
John Ruggiero, University of Dayton, Dayton, OH, United States, jruggiero1@udayton.edu

Production frontiers are estimated using either maximum likelihood or the method of moments when errors are composed of statistical noise and inefficiency. Firm level efficiency has been estimated using a conditional expectation of inefficiency given observed overall error. In this paper we discuss the limitations of this measure and provide an alternative estimator.

4 - Shape Constrained Estimation of Production Functions
Andrew L. Johnson, Houston, TX, 77030, United States, ajohnson@tamu.edu

Nonparametric estimation methods avoid functional form misspecification. However, the flexibility of nonparametric methods often cause difficulties in interpreting production function estimates. However, microeconomic theory provides additional structure for modeling a production or cost function which can be interpreted as shape constraints. Several nonparametric shape constrained estimators have been proposed that combine the advantage of avoiding functional misspecification with improving the interpretability of estimation results. We will review the recent work by our research team in this area.

Behavioral Analytics

Invited: Social Media Analytics

Invited Session

Chair: Tauhid Zaman, MIT, Cambridge, MA, 02114, United States, zlisto@gmail.com

1 - Building a Location-based Set of Social Media Users

Tauhid Zaman, MIT, 6 Whittier Place, Apt 8M, Boston, MA, 02114, United States, zlisto@gmail.com, Christopher Marks

We introduce a method for producing a set of social media users from a specified location. Building on existing methods for identifying user locations, network search, and community detection, we propose an expand-classify methodology which recursively collects users based on their connections, and then classifies the users according to a factor graph model. This factor graph model accounts for the implications of both observed user profile features and social network connections in inferring location. Using geo-located Twitter data for evaluation, we find that our method typically outperforms Twitter's native user search in producing a location-based set of users.

2 - Determining Group Membership using Social Media Activity Patterns

Matthew Robert Webb, US.Army, 361 Beacon Street, Apt.1, Boston, MA, 02116, United States, mrwebb@mit.edu

We propose a novel classification algorithm to determine a user's group membership based on the time series of his or her social media posts and the user's location. We do this by comparing the user's pattern of activity to that of a known group. We apply our method to the class of Muslim users whose prayer activity is determined by the position of the Sun in relation to the horizon at a location. By assuming Muslim users do not utilize social media during these prayers, we are able to infer the religious affiliation of unknown user accounts.

3 - Predicting Performance under Stressful Conditions using Galvanic Skin Response

Tauhid Zaman, PhD, MIT Sloan, Cambridge, MA, United States, zlisto@mit.edu, Carter Mundell, Juan Pablo Vielma

We show that the biological signal known as galvanic skin response (GSR) allows one to predict a subject's performance under stress. We conduct an experiment where subjects answer arithmetic questions under different stress conditions while having their galvanic skin response monitored. Using only the GSR measured under low stress conditions, we are able to predict which subjects will perform well under high stress conditions, achieving an area under the curve of 0.76. Without using GSR, we do no better than random guessing.

4 - Modeling Dynamic user Engagement for Online Gamers

David Scott Hunter, MIT, dshunter@mit.edu

We propose a new model for user engagement based on online gameplay data. Our model clusters users into varying groups, where each group corresponds to differing gameplay behaviors. Using these clusters, we are able to construct an engagement score that allows us to accurately predict whether or not a user will buy the next version of the game.

Mechanism Design and Applications

Invited: Auctions

Invited Session

Chair: Brian Baisa, Amherst College, Amherst, MA, 01002, United States, bbaisa@amherst.edu

1 - Post Efficient Auctions and English Auctions for Bidders with Non-Quasilinear Preferences

Brian Baisa, Amherst College, Converse Hall, Office 211, Amherst, MA, 01002, United States, bbaisa@amherst.edu

We study efficient auction design for a single indivisible object when bidders have interdependent values and non-quasilinear preferences. When the object being sold is a good, there is an efficient ex post implementable mechanism if there is an efficient ex post implementable mechanism in a corresponding quasilinear setting. This result extends results on efficient ex post equilibria of English auctions with quasilinearity to our non-quasilinear setting. However, in procurement settings there is no mechanism that has an ex post efficient equilibrium if the level of interdependence between bidders is sufficiently strong.

2 - Optimal Quantity Caps in Discriminatory Price Auctions with Resale

Justin Burkett, Wake Forest University, 1834 Wake Forest Road, Department of Economics, Winston-Salem, NC, 27106, United States, burketje@wfu.edu, Brian Baisa

We present a model of a discriminatory price auction in which a large bidder competes against many small bidders, followed by a post-auction resale stage in which the large bidder is endogenously determined to be a buyer or a seller. We extend first-price auction with resale results to this setting and give a tractable characterization of equilibrium behavior. We use this to study the policy of capping the amount that may be won by large bidders in the auction. Despite being used in the US Treasury auction among others, this policy has received little attention in the auction literature.

3 - Optimal Auction Design in the Presence of Competition

Mallesh Pai, Rice University, Department of Economics, MS-22, Rice University P.O. Box 1892, Houston, TX, 77251-1892, United States, mallesh.pai@rice.edu

I study the design of the optimal auctions in the presence of competition. Using the theory of mathematical programs with equilibrium constraints, I study the problem of a seller whose competitors have committed to using second price auctions. I provide necessary conditions on the distribution of buyer values for this seller's optimal auction to be a second price auction with a reserve. The conditions are strict weakenings of Myerson's increasing virtual value condition.

4 - Sample Complexity of Multi-item Profit Maximization

Tuomas W. Sandholm, Carnegie Mellon University, Gates Center for Computer Science, Pittsburgh, PA, 15213, United States, sandholm@cs.cmu.edu, Maria-Florina Balcan, Ellen Vitercik

In multi-item settings, it is typically unrealistic to assume the designer has a prior over buyers' valuations. We analyze revenue-maximizing sales mechanisms when the designer has samples from the prior, introduced by Likhodedov and Sandholm in AAAI-04. We provide generalization guarantees that bound the difference between profit on the sample and profit over the prior. Our overarching theorem uses Rademacher complexity to measure intrinsic complexity of widely-studied single- and multi-item auction classes. It also applies to linear and non-linear single- and multi-item pricing. Furthermore, it enables one to determine the optimal complexity in mechanism hierarchies.

New Methods and Algorithms in Artificial Intelligence

Sponsored: Artificial Intelligence

Sponsored Session

Chair: Bradley Walls, University of Arizona, Tucson, AZ, 8, United States, blwalls@email.arizona.edu

1 - Machine Learning Methods to Tease Out Hidden Patterns in Hierarchical Data

Praveen Pathak, University of Florida, 8325 SW. 16th Place, Gainesville, FL, 32607, United States, praveen@ufl.edu

We use Machine Learning methods to tease out hidden patterns in hierarchical data and forecast an outcome characterized by high dimensionality. Our methods outperform comparable statistical models and are robust in dealing with sparse data. We offer insights on extending the technique problem domains were the outcome is based on a model of effects characterized by high dimensionality.

2 - Optimal Regression Trees

Jack Dunn, Massachusetts Institute of Technology, 24 Hardwick St, Unit 1, Cambridge, MA, 02141, United States, jackdunn@mit.edu, Dimitris Bertsimas

Decision tree methods are widely used for regression problems, but one must choose between methods that are interpretable (such as CART) and those with high accuracy (random forests or boosting). We introduce a new approach for constructing Optimal Regression Trees based on mixed-integer optimization, and develop high-performance heuristics for these problems that offer significant improvements over traditional greedy approaches and run in comparable times. We show in a collection of synthetic and real-world instances that our Optimal Regression Trees improve substantially over CART and related methods such as Random Forests, delivering high-accuracy solutions that are interpretable.

3 - Fuzzification of Sorting for Multiple Combinatorial Optimization Applications

Paul Eugene Coffman, Technical Leader, Ford Motor Company, 6100 Mercury Drive, Dearborn, MI, 48126-2746, United States, gcoffman@ford.com, Stephany Coffman-Wolph

Many efficient heuristics for combinatorial algorithms (e.g., bin packing, knapsack, and queueing) rely on fast sorting algorithms. Using an established three-step framework for the fuzzification of algorithms, sorting algorithms can be converted into fuzzy sort algorithms. These "fuzzy" sort algorithms often provide computational improvements with minimal acceptable trade-offs, yielding "good enough" solutions. Extending selected traditional heuristic algorithms with fuzzy sorting should generate acceptable solutions faster than the base algorithms for these problems types.

Social Media Analytics for Healthcare Improvement I

Invited: Social Media Analytics

Invited Session

Chair: Shu He, University of Illinois at Urbana-Champaign, Urbana, IL, 61802, United States, shuhe2@illinois.edu

1 - Big Data Analytics for Text-based Data in Healthcare: A Review and Research Directions

Priya Nambisan, University of Wisconsin - Milwaukee, Northwest Quadrant Building B, Rm #6410, 2025 East Newport Avenue, Milwaukee, WI, 53201, United States, nambisap@uwm.edu

Many recent studies have focused on developing algorithms for analyzing text based health data such as patient postings on social media, physician notes, etc. However, it is not clear whether these studies are contributing to healthcare research or to research on algorithm development. In this study, 40 papers in this topic were systematically analyzed to evaluate the effectiveness of the algorithms to analyze text based data and to determine the relevance of the findings for the healthcare domain. Based on the analysis, several limitations of these studies are identified and future research directions are discussed.

2 - The Effectiveness of Social Media-enabled Patient Communities on Health Goal Attainment: An Approach of Survival Analysis

Jiahe Song, Assistant Professor, Western Michigan University, Kalamazoo, MI, United States, carrie.song@wmich.edu, Pei Xu

This study explores how social media-enabled patient communities affect health goal attainment. Applying social cognitive theory, we studied the online antecedents of goal attainment from the respects of social support and self-reflection. A survival analysis was applied to a unique dataset of patients' interactions and goal progress. Findings indicate that the two social support factors, informational and emotional support, have opposite effects (direct and buffering) on goal attainment. The two self-reflection factors, verbal and leisure update, also affect the possibility of goal attainment oppositely. The research provides important implications to online disease self-management.

3 - Expanding the Reach of Humanitarian Organizations on Social Media

Eunae Yoo, Arizona State University, Tempe, AZ, United States, eunae.yoo@asu.edu, Elliot Rabinovich, Bin Gu

Humanitarian organizations have been using social media to broadcast important messages to their stakeholders. On social media, a user's follower count typically represents the user's audience size, or reach. We explore the mechanisms that drive follower growth for organizations involved with disaster relief using a large data set from Twitter during the 2016 Ecuador earthquake. Our data capture the dynamic nature of the user network one week before and after the disaster, and we find that the follower bases of the organizations in our sample increase dramatically after the earthquake.

4 - The Nature of Connections on Twitter and its Dynamics

Youngsoo Kim, Singapore Management University, School of Information Systems, 80 Stamford Road, Singapore, 178902, Singapore, yskim@smu.edu.sg

Twitter is one of the leading social network sites (SNS). Prior studies have mainly focused on social networking behavior or information diffusion process on Twitter. By contrast, this study explores (1) the network formation (link connection with the focus on the network structural format), (2) the nature of link (online versus offline relationship) and its impact on communication frequency, and (3) the dynamics of homophily and interaction over time.

1 - Minimizing Multimodular Functions and Allocating Capacity in Bike-sharing Systems

Daniel Freund, Cornell University, 109 Lake St, Ithaca, NY, 14850, United States, df365@cornell.edu

We consider the strategic question of how to (re-)allocate dock-capacity in bike-sharing systems. We develop mathematical formulations for variations of this problem and exhibit discrete convex properties in associated optimization problems. This allows us to design a polynomial-time allocation algorithm that can handle constraints such as a limit on the number of docks moved in the system. We apply our algorithm to data sets from Boston, New York City, and Chicago.

2 - Learning Preferences with Side-information

Andrew A. Li, Massachusetts Institute of Technology-ORC, 77 Massachusetts Avenue, Bldg. E40-149, Cambridge, MA, 02139, United States, aali@mit.edu

Product and content personalization is now ubiquitous in e-commerce. Companies seek to use a variety of information on the interactions between a product and a customer to drive personalization decisions. We formalize this problem as one of recovering a large-scale matrix, with side information in the form of additional matrices of conforming dimension. We provide an efficient algorithm that is practical for massive datasets and demonstrate its performance on data from a music streaming service.

3 - Tight Weight-dependent Competitive Ratios for Online Edge-weighted Matching, with Application to Revenue Management

Will Ma, Massachusetts Institute of Technology, Cambridge, MA, Contact: willma353@gmail.com

Online bipartite matching is a classical problem in the study of online algorithms. These problems can be abstracted as follows: there are fixed resources that must be allocated on-the-fly, without knowledge of future demand. This talk studies the generalizations of these problems when each resource could be sold at multiple, known prices. We show how to generalize the algorithms to accommodate multiple prices, and achieve a tight competitive ratio under the integral or asymptotic settings.

4 - Computationof the Bootstrap: Complexity, Exact Algorithms, and Deterministic Approximations

Bradley E. Sturt, Massachusetts Institute of Technology, Somerville, MA, Contact: bsturt@mit.edu

The bootstrap is a randomized method for calculating quantities, such as confidence intervals, directly from data. Because variability from randomization can lead to inaccurate outputs, we propose a deterministic approach. We present computational complexity results for the bootstrap method and the first FPTAS for the bootstrap method. We demonstrate that the algorithms run fast in practice and produce bootstrap confidence intervals that are more accurate compared to traditional methods.

Drone Delivery Systems - II

Invited: InvitedDrone Delivery Systems (tentative title)

Invited Session

Chair: Chase Murray, University at Buffalo, Amherst, NY, 14260-2050, United States, cmurray3@buffalo.edu

1 - Establishing Energy Efficient Paths for Delivery Drones in Direction Dependent Uniform Wind-Fields

Abhishake Kundu, Texas Tech University, Dept of Ind Eng, Box 43061, Lubbock, TX, 79409-3061, United States, abhishake.kundu@ttu.edu, Tim Matis

The purpose of this research is to propose an efficient minimum-energy path planning algorithm that combines global and local waypoints for parcel delivery using drones. Constraints on turn rate and turn acceleration is considered for the vehicle with limited battery power, flying in a uniform wind-field on the horizontal plane. The minimum energy path of the delivery drone pursues Dijkstra's arcs subject to curvature constraints for transitional headings, in contrast to minimum time traversal route that follows a Dubins path.

2 - The Customer-centric Vehicle Routing Problems with Drones

Mohammad Moshref-Javadi, PhD Candidate, Purdue University, 315 N. Grant St., Room 324E, West Lafayette, IN, 47907, United States, moshref@purdue.edu, Seokcheon Lee

This research proposes a new drone delivery system that focuses on minimizing the total waiting time of recipients. In this delivery system, a single truck takes drones and supplies and follows a route to visit some demand locations or dispatch the drones to customers for package delivery. The truck and drones can work in parallel, that is, the truck does not have to wait for the drones to return to the truck at the same location. We also compare this system with a static system in which the truck has to wait for the drones to return to the truck at the same location. This drone delivery system is specifically useful for disaster relief logistics and customer-oriented commercial systems.

3 - Augmenting a Truck with a Drone for Parcel Delivery

John Gunnar Carlsson, University of Southern California, 3750 McClintock Avenue, Los Angeles, 90089, United States, jcarlsso@usc.edu

Abstract We determine the efficiency of a delivery system in which an unmanned aerial vehicle (UAV) provides service to customers while making return trips to a truck that is itself moving. In other words, a UAV picks up a package from the truck (which continues on its route), and after delivering the package, the UAV returns to the truck to pick up the next package.

4 - Drone Delivery with Time Dependent Travel

Chase Murray, University at Buffalo, Dept of Industrial & Systems Engineering, 309 Bell Hall, Amherst, NY, 14260-2050, United States, cmurray3@buffalo.edu

A new variant of drone delivery problems is presented. In this problem, multiple drones are available to support last-mile delivery of small parcels. The drones coordinate with a single delivery truck. Travel times for the truck are time-of-day dependent. A mathematical programming formulation is described, as well as a heuristic approach for solving this problem.

AAS Best Student Presentation Competition I

Sponsored: Aviation Applications

Sponsored Session

Chair: Virginie Lurkin, Ecole Polytechnique Fédérale de Lausanne, Route Cantonale, Lausanne, 1015, Switzerland, vlurkin@ulg.ac.be

Co-Chair: Peng Wei, Iowa State University, Ames, IA, 50011, United States, pwei@iastate.edu

1 - Predicting Performance of Traffic Management Initiatives

Alexander Estes, University of Maryland, 3802 Calverton Blvd, Apartment 25, Beltsville, MD, 20705, United States, aestes@math.umd.edu

The Federal Aviation Administration uses traffic management initiatives to manage excess demand for resources in the national airspace system. We present methods for estimating the performance that a given traffic management initiative will produce under a given set of weather and traffic conditions. These methods combine a weighting scheme from Geographic Weighted Regression with forest-based regression methods. Estimates of the conditional density can be produced along with standard regression estimates.

2 - Probabilistic Modeling of Airline Network Evolution

Reed Harder, Dartmouth, 14 Engineering Drive, Hanover, NH, 03755, United States, reed.haseltine.harder.TH@dartmouth.edu

Airline networks evolve as airlines enter and exit segments, based on the profitability of the routes related to this segment, competitive considerations, and the function of a given segment in the overall network. However, forecasting such segment entry and exit remains challenging due to the complexity of the air transportation system and the relative sparsity of entry and exit data. We present and compare probabilistic methods for predicting segment entry and exit by an airline, using data on past airline operations, network structure, and regional demographics.

1 - A Sequential Weighted Laplacian Regularized Optimal Design of Experiments for Response Surface Modeling of Expensive Tests

Stanford Martinez, Graduate Research Assistant, University of Texas at San Antonio, San Antonio, TX, United States, ddfe530tx@gmail.com, Adel Alaeddini

In the design of experiments, space-filling methods can be used to reduce the number of tests needed to learn the response surface intrinsic to an experiment. Classical methods include preset designs that only take into account currently measured samples. Laplacian regularization adds a penalty term that will allow the learning of the interconnectivity of both measured and unmeasured data. In addition, further weighting can be applied using weighted regression techniques to mitigate effects of outliers present in an experiment. The effects of these two additions to the classical form of optimal experimental design will be compared to other methods in terms of performance and practicality-of-use.

2 - Critical Nodes in Interconnected Networks

Venkat Venkateswaran, Georgia Institute Of Technology, Room 4143, 800 West Peachtree, NW, Atlanta, GA, 30308, United States, venkat.venkateswaran@scheller.gatech.edu

We consider a system of interconnected networks. Initial damage to nodes can have far-reaching effects through cascading failures. We develop the methodology to identify nodes that may produce various levels of network degradation through such cascading. Computational results from sample test problems are presented.

3 - Queue Inference with Uncertain Observations

Andrew Keith, PhD Student, USAF, Dayton, OH, 45433, United States, andrew.keith@afit.edu, Darryl K. Ahner

Although the effect of various queue types on system performance has been well studied, the internal structure and parameters of a queuing system of interest may be completely unobservable in military and competitive commercial applications. Furthermore, external input and output information may be observable but subject to substantial uncertainty due to measurement error in the adversarial environment. This analysis quantifies the uncertainty in arrival and departure times, which are then used to estimate the number of servers and service rates of an internally unobservable GI/G/c queue.

Supply Chain Management

Contributed Session

Chair: Juhi Bhardwaj Sapra, Rensselaer Polytechnic Institute, Troy, NY, United States, bhardj@rpi.edu

1 - The Interactive Effects of User Generated Contents on the Determinants of Tourist Destinations Strategies

Jinjin Xu, Tianjin University, Tianjin, China, x_jinjin@outlook.com, Liming Zhao

Vigorous development of tourism industry and sharing economy has led to fierce competition among China's tourist destinations, which accelerates tourism organizations to re-evaluate their competitive strategies. This study conducted from a strategy perspective and contributes both theoretically and practically to the tourism literature by validating artificial neural network model to investigate the relationships among user generated content and tourist destinations strategies. The empirical findings reveal four hidden nodes that have a significant impact on tourist destination performance.

2 - A Perspective of Managerial Cognitive Capability on Orchestration of Corporate Brand

Tzu-Hsuan Lin, PhD Student, National Taiwan University, Taipei, Taiwan, D00724004@ntu.edu.tw, Ming-Huei Hsieh

Through the perspective of managerial cognitive capability, this paper contributes to the hanging paradox of corporate branding - continuity versus change. It presents a process model regarding the interplay between the CEO's managerial cognitive capabilities and organizational strategic change based on 21 brands launching in four case studies - Franz Collection, Gloria Hotel, Johnson Health Tech., and Tayohya Home Fashion. The findings underscore the criticality of the CEO's dominant logic on sculpting and leveraging the corporate brand identity in concerto with product brand to achieve evolutionary fit.

3 - Diversification and Diagonal Integration: New Strategies for the Internet-of-things Landscape

Suri Gurumurthi, Hong Kong University of Science and Technology, 10707 Flaxton Street, Culver City, CA, 90230, United States, suri.gurumurthi@gmail.com

The supply chain strategy literature provides terminology and a conceptual framework for firms as they navigate towards positions of greater competitive advantage within their industry, sector, and value chain. However, these frameworks and models for the most part are based on the relationship and network dynamics of the firms within that value chain. New models are needed to guide firms as they make investment and diversification decisions within a network structurally and operationally defined by consumers, and their interactions with other consumers. Conceptual frameworks and strategy models are presented in the context of the so-called Internet-of-things landscape.

4 - Post Entry Mode Performance of Non-equity Based Entry Modes under Exogenous Shock

Johann Schessl, Research Assistant, EBS.Business School University for Business and Law, Rheingaustraße 1, Oestrich-Winkel, 65375, Germany, johann.schessl@ebs.de

This study examines post entry mode performance of non-equity based and equity based entry modes immediately after an exogenous shock. Using a sample of car manufacturers in European markets during the crisis of 2008, we attempt to determine if entry modes have an effect of performance immdiately after an exogenous shock. We theorize tat non-equity based are more responsive to the new business environment after an exogenous shock and therefore outperform equity based entry modes in the short term.

5 - Impact of Managerial Incentives Alignment on Marketing Strategies Evidence from SEO Context

Juhi Bhardwaj Sapra, Rensselaer Polytechnic Institute, 110 8th Street, Troy, NY, 12180, United States, bhardj@rpi.edu, Nithya Shankar

Studies have shown that manager's compensation incentivizes a myopic management behavior which involves cutting of marketing expenses that leads to higher profits in the short term but lower long term firm valuation. Our study explores this phenomenon in the context of seasoned equity offering (SEO) where firms behave myopically. We investigate the moderating effects of the change of compensation post SEO on firm's spending decisions. We contribute to the agency theory where alignment of compensation play an important role in firms performance post SEO. We attempt to explore the implications of SEO and managerial incentives that could mitigate myopic management and improve firm value.

1 - The Structure and Influencing Factors of Trade Network About BRICS

Shaowei Chen, Xi'an University of Finance and Economics, Xi'an, China, 516329356@qq.com

In the past two decades, the emerging countries developed rapidly, became to play important roles in the world. Especially Brazil, Russia, India, China and South Africa, which were called BRICS, made a great contribution to the world economy. Recent years, the development speed of BRICS was lower than before. Based on the bilateral trade data of BRICS during the period 2005~2015, this paper analyzed the characteristics by using the complex network method. It focused on the change about the network statistics of BRICS's trade network, especially after the time that China proposed "One Belt and One Road".

2 - Study on Social Security, Infrastructure and Rural Household Consumption Behavior

Wei Wang, Xi'an University of Finance and Economics, No. 2 Weichang Road, Chang'an District, Xi'an, Shaanxi Province, China, wangwei_871020@126.com

Rural household consumption is affected by factors at different levels. The factor of rural infrastructure is concerned in this paper. Factors influencing rural household consumption are divided into individual ones and organizational ones. The result shows that the causing effect of social insurance to household consumption is significant but small. Other household consumption characteristics factors, such as marital status, income, family size, also have a significant impact. Community-level factors on household expenditure have strong explanatory power, while transportation, water infrastructure has a significant positive impact.

3 - A Study on the Untrue Information Transmission in Subway Emergency

Ting Wang, Tongji University, 1 Zhangwu Road, Shanghai, 200092, China, 787084787@qq.com, Haifeng Zhao

Once in subway emergency , due to its closed, high traffic characteristics, the impact and harm may be amplified. In view of the fact that information dissemination in emergencies has a strong similarity with the spread of infectious diseases. In sudden events in subway, the SI model is established for the dissemination of untrue information by referring to the model of infectious diseases. The law of change in individual passenger groups were analyzed. In controlling the number of passengers who believe untrue information and hesitant person, the optimal control model is derived.Emergency decision-makers can establish the optimal control model and effectively control untrue information.

1 - When Psychology Meets Operations: the Influence of Cognitive and Emotional Loads on the Efficiency of Customer-Service Employees

Daniel Altman, Technion - Israel Institute of Technology, Haifa, Israel, altmand@campus.technion.ac.il, Anat Rafaeli, Galit Tom-Tov

We introduce the concept of Psychological Load, integrating predictions of psychological theories regarding two types of such load: Cognitive and Emotional Loads that customers offer to service agents. We measure both loads and test their effects on agent Response Time and customer Length of Stay using 145,995 service interactions. We find that Cognitive Load increases agent Response Time, and is positively related to Length of Stay. Emotional Load has a U-shaped effect on agent Response Time; high levels of positive or negative emotion relate to high Response Time. Time-based analyses support the causality of the effects. The paper offers novel insights into the study of agent efficiency.

2 - Dynamic Network Revenue Management for a Cloud Provider Hosting Interactive Applications

Hossein Jahandideh, University of California-Los Angeles, Los Angeles, CA, 90034-6473, United States, hs.jahan@gmail.com, Kevin McCardle, Julie Ward, Filippo Balestrieri

We consider a cloud provider which hosts interactive applications such as websites or mobile apps. Depending on the traffic of users for an application, the provider commits a subset of its resources (hardware capacity) to serve the application. The provider uses dynamic pricing to indirectly select the applications hosted and maximize revenue. We model the problem as a large-scale stochastic dynamic program, and decompose it into single-resource sub-problems by exploiting structural properties of optimal Lagrangian variables. We combine the solutions to the sub-problems to define a dynamic pricing policy, and propose novel upper bounds on the optimal revenue to evaluate our pricing mechanism.

3 - Service Design with Acclimation and Non-homogeneous Memory Decay

Yifu Li, Hong Kong University of Science and Technology, Room 3208 , Lift 21, Clear Water Bay, Kowloon, 999077, Hong Kong, ylick@connect.ust.hk, Tinglong Dai, Xiangtong Qi

In today's "experience economy," service providers increasingly emphasize creating memorable, delightful service experiences, a crucial driver of which is the schedule of activities in a service package. Empirical literature shows the most engaging activity should be scheduled neither at the beginning nor the end of the package. Theoretic literature, on the other hand, points to a U-shaped schedule. The paper closes this gap between empirical and theoretic literature and provides a foundation for advanced analytics that is called for in developing next-generation operating models.

Recent Advances in Approximations for Multi-objective Integer Programs

Sponsored: Multiple Criteria Decision Making

Sponsored Session

Chair: Hadi Charkhgard, University of South Florida, USF, Tampa, FL, 33559, United States, hcharkhgard@usf.edu

1 - A Feasibility Pump and Local Search Based Heuristic for Biobjective Pure Integer Linear Programming

Hadi Charkhgard, University of South Florida, Tampa, FL, 33559, United States, hcharkhgard@usf.edu, Aritra Pal

We present a new heuristic algorithm to approximately generate the nondominated frontier of bi-objective pure integer linear programs. The proposed algorithm employs a customized version of several existing algorithms in the literature of both single-objective and bi-objective optimization. Our proposed method has two desirable characteristics: (1) There is no parameter to be tuned by users other than the time limit; (2) It can naturally exploit parallelism. A computational study shows the efficacy of the proposed method and also the value of parallelization on that.

2 - A Feasibility Pump and Local Search Based Heuristic for Solving Multiobjective Mixed Integer Linear Programs

Aritra Pal, University of South Florida, 4202 E. Fowler Avenue, Tampa, FL, 33620, United States, aritra1@mail.usf.edu, Hadi Charkhgard

We present a new heuristic algorithm to approximately generate the nondominated frontier of multiobjective mixed integer linear programs. The proposed algorithm employs a customized version of several existing algorithms in the literature of both single objective and multiobjective optimization. Our proposed method has two desirable characteristics: (1) There is no parameter to be tuned by users other than the time limit; (2) It can naturally exploit parallelism. An extensive computational study shows the efficacy of the proposed method on some existing standard test instances in which the true frontier is known.

3 - A New Algorithm to Optimize a Function Over the Set of Efficient Solutions for Biobjective Mixed Integer Linear Programming

Alvaro Sierra, University of South Florida, 4411 Shady Terrace Lane, Unit A, Tampa, FL, 33613, United States, amsierra@mail.usf.edu, Hadi Charkhgard

We present a new criterion space search algorithm for optimizing a function over the set of efficient solutions of a biobjective mixed integer linear program. The algorithm is easy to implement and because it maintains a lower and an upper bound on the value of the linear function at any point in time, it can be used to quickly generate a provably high-quality approximate solution. An extensive computational study shows that the efficacy of the algorithm.

4 - Goal Programming - A Comparison with Other MCDM Methods

Nilakantan Sundara Raman Narasinganallur, K.J. Somaiya Institute of Management Studies & Research, B.602 Tulip Rachna Garden, Mulund Colony, Mumbai, 400082, India, nilakantan@somaiya.edu

For solving multi-criteria decision problems, different schools of thought have developed around different methodologies. Goal Programming is an elegant multi-objective programming technique using the structure of mathematical programming and extending it beyond its confines of single objective situations. Due to its simplicity and structure, it is much better than other multi-objective, multi-criteria decision-making techniques like Analytical Hierarchy Process, Fuzzy Theory etc. The presentation will discuss a few examples of Goal Programming and evaluate its merits vis-à-vis other MCDM techniques.

1 - Fluid Optimal Control of Polling Systems with Large Switchover Times

Yue Hu, Northwestern University, Evanston, IL, United States, yuehu2017@u.northwestern.edu, Ohad Perry, Jing Dong

We study the optimal-control problem of stochastic polling systems with large switchover times. Under proper scaling, the stochastic system can be approximated by a Hybrid Dynamical System (HDS). For the HDS, we analyze two classes of controls, and prove that any (periodic) stationary behavior can be achieved by one of those controls. We employ this latter result to prove that the exhaustive policy is optimal among all stationary controls with respect to long-run average holding costs.

2 - A Generalized Markov Chain Model to Capture Dynamic Preferences and Choice Overload

Agathe Soret, Columbia University, New York, NY, United States, acs2298@columbia.edu, Vineet Goyal

Modeling preferences is a key problem in many settings. Many random utility based parametric models have been considered, but all suffer from two limitations: failure to capture i) dynamic preferences that depend on the offered assortment, and ii) the choice-overload phenomenon (where the probability of purchase decreases with the number of available options). We propose a generalization of the MNL model that addresses both these limitations. We show that our model can be estimated efficiently and also present a near-optimal algorithm for constrained assortment optimization.

3 - Optimization Strategies to Support Analyses and Decisions to Increase the Coverage of Cervical Cancer Screening Tests in Rural Areas of Cundinamarca, Colombia

Maria Camila Patino Torres, Universidad de los Andes, Bogota, Colombia, mp.patino10@uniandes.edu.co, Ivan Mura, Camilo Gomez

The barriers in the access to diagnosis and treatment of cervical cancer in Colombia are illustrative of the inequalities among population groups in the country. Through data analysis, the implementation of network flow and vehicle routing models, and economic evaluations, we assess the coverage of existing facilities in a large rural area, and propose alternatives to improve it. Our results show that cost-effective alternatives exist to provide access to screening for vulnerable populations.

4 - A Two-Stage Vehicle Routing Algorithm Applied to Disaster Relief Logistics after the 2015 Nepal Earthquake

Stephanie Allen, The State University of New York at Geneseo, New York, NY, United States, stephanie.a.allen95@gmail.com, Caroline Haddad

After the 2015 Nepal Earthquake, the Himalayan Disaster Relief Volunteer Group distributed supplies to affected areas. We model the organization's operations as a vehicle routing problem using Fisher and Jaikumar's two-stage method, which allocates locations to vehicles via an assignment integer program and then uses heuristics to route the vehicles. Our results illustrate the open nature of the VRP and the computational necessity of heuristics.

5 - Contract Tracing Protocol

Chungjae Lee, Georgia Institute of Technology, Atlanta, GA, United States, clee384@gatech.edu, Jason Bermudez, Kevin Desprez, Alex Kehres, Leah Patterson, Suphaphat Petlerkwang, Yuntong Zhu, Pinar Keskinocak, Brian Gurbaxani

Contact tracing is a protocol that prevents disease transmission by identifying disease-carriers. The Center for Disease Control and Prevention (CDC) suspects that the protocol is improperly estimating the number of contacted individuals and incurring excessive cost. Mathematical models and a decision tool are developed to design cost-effective protocols with quantitative justification for respiratory diseases. Through the tool, the CDC can reduce cost at most by $360,000 per protocol.

Health Care, Modeling and Optimization

Contributed Session

Chair: Xiaoli Duan, Northeastern University, Boston, MA, United States, duan.xi@husky.neu.edu

1 - Improving Outpatient Scheduling with Simulation

Michelle Rose Hribar, Oregon Health & Science University, Portland, OR, United States, hribarm@ohsu.edu, Sarah Read-Brown, Leah Reznick, Lorinna Lombardi, Mansi Parikh, Winston Chamberlain, Thomas Yackel, Michael F. Chiang

Clinicians today face increased patient loads, decreased reimbursements and negative productivity impacts from using electronic health records (EHR), but have no guidance on how to improve clinic efficiency. This study evaluates novel scheduling strategies using simulation and EHR data before their implementation in outpatient ophthalmology clinics. Key findings from this study are: 1) EHR timestamp data in simulation models represents clinic workflow, 2) simulations provide critical information for schedule creation and resource allocation, 3) scheduling long appointments last reduces patient waits, and 4) new schedule implementation challenges limit efficiency improvements.

2 - Establishing Staffing Levels and Surge Planning for the Emergency Department of the Children's Hospital of Pittsburgh using Simulation

Kiatikun Louis Luangkesorn, University of Pittsburgh, 1028 Benedum Hall, 3700 Ohara St, Pittsburgh, PA, 15261, United States, lluangkesorn@pitt.edu, Anna Svirsko, Bryan A. Norman, Jayant Rajgopal, John Rossi

An urban hospital emergency department experiences high variability in arrivals over the course of a day, from day to day, and from season to season. To handle this variable demand, Children's Hospital uses both a standard staffing level and a surge team for when the standard staffing level is not able to keep up with the patient demand. We present a simulation model to jointly analyze staffing levels and the surge plan in this environment. This simulation is used to evaluate the effects of staffing on ED length of stay and the need to implement the surge plan over the course of the year.

3 - Ophthalmology Benchmarking using Data Envelopment Analysis

Timothy R.Anderson, Portland State University, Mail Code ETM, P.O. Box 751, Portland, OR, 97201, United States, tim.anderson@pdx.edu, Daria Spatar

A benchmarking study of the electronic medical records adoption and usage by ophthalmology practices was conducted using data envelopment analysis.

4 - Agent-based Models of Opioid Use Spread

Xiaoli Duan, Northeastern University, Boston, MA, United States, duan.xi@husky.neu.edu, James Benneyan, Iulian Ilies

We developed several agent-based models of the spread of opioids abuse to help understand and mitigate this worsening national epidemic. Models varied in stochasticity, scale (individual to region), and topology (geographical to social) and were tested on several sociodemographic populations. Results indicated that different models work better in different settings and can help identify the magnitudes and combinations of interventions and investments (e.g., reduced prescription availability, education initiatives, or increased recovery services) necessary to effectively reduce the epidemic.

Chair: Van-Anh Truong, Columbia University, New York, NY, 10027, United States, vt2196@columbia.edu

1 - A Fluid Model for an Overloaded Bipartite Queueing System with Heterogeneous Matching Utilities

Yichuan Ding, UBC, 2053 Main Mall, Vancouver, BC, V6T1Z2, Canada, daniel.ding@sauder.ubc.ca, S. Thomas McCormick, Mahesh Nagarajan

We consider a bipartite queueing system (BQS) with multiple types of servers and customers, where different customer-server combinations may generate different utilities. Whenever a server is available, it serves the customer with the highest index, which is the sum of a customer's waiting index and the matching index. We develop a fluid model to approximate the behavior of such a BQS system, and show that the fluid limit process can be computed over any finite horizon. We prove that the fluid limit process converges to a unique steady state, which can be efficiently computed. We illustrate the use of our machinery by analyzing the public housing assignment in the city of Pittsburgh using a real data set.

2 - Learning Personalized Treatment Regimes from Observational Data

Nathan Kallus, Cornell University, New York, NY, United States, kallus@cornell.edu

In this talk I will describe several recent advances in learning personalized decision policies from observational data and its application to personalized medicine using electronic health records, including new methods, problems, and applications.

3 - Conspicuous by its Absence: Diagnostic Expert Testing under Uncertainty

Tinglong Dai, Assistant Professor, Johns Hopkins University, Baltimore, MD, 21202, United States, dai@jhu.edu, Shubhranshu Singh

Motivated by prevalent—albeit little explored—under-provision in the US healthcare setting, we study a scenario in which costly diagnostic testing is needed to acquire customers' true conditions and the expert's accuracy of diagnosis is unknown to customers. Our work is the first to formally link diagnostic uncertainty and information asymmetry.

4 - The Zocdoc Effect: How Does Online Information Impact Appointment Availability in Out-patient Care?
Yuqian Xu, University of Illinois at Urbana-Champaign, Champaign, IL, United States, yxu@stern.nyu.edu, Mor Armony

In this paper, we propose a queueing model to study the impact of online healthcare channels. We analyze the impact of in-clinic service time and the number of offered appointments on patient joining decisions. We consider doctor's revenue maximization problem with these two service rates. We show that when the market size is large, the doctor uses partial market coverage strategy; while when the market size is small, the doctor uses full market coverage strategy. We then extend our model into a multiple doctors setting and show that (i) in small markets, each additional doctor induces each doctor to slow down further; (ii) otherwise, the market is large enough that each server acts as a local monopolist.

Chair: Felipe Aros-Vera, Ohio University, Athens, OH, 45701, United States, aros@ohio.edu

1 - A Model for Strategic Facility Location and Tactical Resources Allocation under Uncertainty for Natural Disaster Response
Adan Rodriguez, Universidad Complutense de Madrid, Facultad de CC. Matematicas, Plaza de las Ciencias, 3, Madrid, 28040, Spain, adanro01@ucm.es, Begona Vitoriano, Laureano F. Escudero, Juan F. Monge, M. Teresa Ortuno

A strategic preparedness facility location and tactical preparedness resource allocation model is presented for a multi-period stochastic problem to manage natural disaster's response. That preparedness consists of warehouses location and capacity assignment and extension planning over years, and annual planning for procurement and allocation of commodities to warehouses. Uncertainty is taken into account including different scenarios of natural disasters in each season into a year, affecting operations management and costs. The model is being developed for public managers, but it also could be extended to other type of organisations.

2 - Facility Location and Allocation of Resources in Post-disaster Humanitarian Logistics
Felipe Aros-Vera, Ohio University, 277 Stocker Center, 1 Ohio University, Athens, OH, 45701, United States, aros@ohio.edu, Nick Loree

This presentation introduces a facility location model that explicitly accounts for deprivation costs incurred by survivors in post disaster environments. It provides realistic measures of disaster response logistics by allowing for multiple sourcing, number of facilities as a model output, capacity limitations, and inventory allocation decisions.

3 - Transportation of Hazardous Materials under a Disaster Settings Considering Risk Perception
Ruben Yie, Universidad el Norte, Km 5 Antigua via Puerto Colombia, Barranquilla, Colombia, ryie@uninorte.edu.co, Ana M. Bedoya, Fabian Betancur

This research has two main stages: stage 1 focuses on measure how people perceive risk within a network that transport hazardous materials, and how this perception of risk affects their decision making process. Stage 2 tries to develop a mathematical model to route this hazardous materials in order to minimize risk of the cargo but also the risk perception of the people sharing the network. Both stages are under a natural disaster settings (static or dynamic). Also an evolutive algorithm with learning machine properties (ant controlled genetic algorithm) was created to solve this problem.

4 - Location, Allocation and Prepositioning of Stock and Preparation and Response to Natural Disasters
Pamela Alvarez, Universidad Andres Bello, Manquehue sur 1076, dpto NA 1002, Santiago, AL, Chile, palvarez@unab.cl, Andrés Bronfman

The effects of natural disasters are unpredictable and emergency plans must be adapted to each situation. This work proposes a methodology in stages to address the problem of preparation-response. Phase 1 generates the base response plan with a multiobjective model that determines the location of shelters and warehouses, and assigns the population to this facilities. It seeks to minimize evacuation and supply times, and costs. Phase 2 (post disaster) considers the base plan and, with a new model, locates new shelters and warehouses, and reassigns the population according to the new configuration. The methodology was applied in the city of Iquique, Chile.

5 - A Humanitarian Logistics Inventory Management Model for Post-disaster
Azadeh Sadeghi, 2nd Andover Rd., Apt B11, Athens, OH, 45701, United States, as262914@ohio.edu

This presentation focuses on inventory management and control policies for post disaster humanitarian logistics. A mathematical model is proposed in which both traditional inventory and logistics costs and the cost of human suffering as a consequence of late delivery of the supplies are considered. The proposed model is also applicable to facility location humanitarian logistics problem.

JFIG Panel Discussion: Tips for Writing CAREER Propsals

Sponsored: Junior Faculty JFIG

Sponsored Session

Chair: Jose Luis Walteros, University at Buffalo, SUNY, 413 Bell Hall, Buffalo, NY, 14260, United States, josewalt@buffalo.edu

1 - JFIG Panel Discussion: Tips for Writing CAREER Proposals
Jose Luis Walteros, University at Buffalo, SUNY, 413 Bell Hall, Buffalo, NY, 14260, United States, josewalt@buffalo.edu

The panelists consist of past NSF CAREER awardees. The panelists will share their experience in the process of getting their awards. They will discuss failures, successes and provide some tips on how to properly plan and consolidate a solid proposal. They will also answer questions from the attendees.

2 - Panelist
Changhyun Kwon, University of South Florida, 4202 E. Fowler Ave. ENB118, Tampa, FL, 33620, United States, chkwon@usf.edu

3 - Panelist
Esra Buyuktahtakin, New Jersey Institute of Technology, Industrial and Manufacturing Engineering Dept, Newark, NJ, United States, esratoy@njit.edu

4 - Panelist
Alejandro Toriello, Georgia Institute of Technology, 765 Ferst Drive NW, Atlanta, GA, 30332, United States, atoriello3@isye.gatech.edu

Latest Developments in Scheduling

Invited: Project Management and Scheduling

Invited Session

Chair: Zhi-Long Chen, University of Maryland, College Park, MD, 20742-1815, United States, zchen@rhsmith.umd.edu

1 - Online Scheduling of Ordered Flow Shops
Kangbok Lee, Pohang University of Science and Technology, Pohang, Korea, Republic of, kblee@postech.ac.kr, Feifeng Zheng, Michael L. Pinedo

This work considers online over-list scheduling of ordered flow shops with the makespan as objective. We focus on ordered flow shops, in particular proportionate flow shops with different speeds and proportionate flow shops with different setup times. We derive several results on the worst case performance of the Greedy Algorithm in the online setting.

2 - Subcontracting Operations with Production Costs
George Vairaktarakis, Case Western Reserve University, Dept of OR and OM, 10900 Euclid Avenue, Cleveland, OH, 44106-7235, United States, gxv5@case.edu, Ke Fu, Vernon Hsu

We consider multiple manufacturers subcontracting part of their workload at a third party (3P) production facility with the rest of the work processed in-house. Production costs are customer-specific, both at their own facility as well as at 3P. We explore structural properties of optimal production plans and in propose fast polynomial time algorithms for several cases of the problem.

3 - Parallel Algorithms for Flow Shop Scheduling Subject to Limited Machine Availability

Yumei Huo, City University of New York, Staten Island, NY, United States, Yumei.Huo@csi.cuny.edu

In this paper, various parallel ant colony algorithms (PAC) and parallel tabu search algorithms (PTS) are presented and applied to Permutation Flowshop Scheduling Problem subject to limited machine availability. The objective is to minimize total flowtime criterion. This problem is proved to be NP-complete in a strong sense for more than one machine even when machines are always available. PACs and PTSes are based on the classical ant colony and tabu search algorithms. Various platforms are considered, including Message Passing and shared memory. All parallel algorithms will be compared with monte carlo algorithm and will be compared with each other in terms of both performance and CPU times.

4 - Integrated Production and Two-stage Delivery Scheduling: Offline and Online Algorithms

Zhi-Long Chen, University of Maryland, Robert H. Smith School of Business, Dept of Decision, Operations & Info Tech, College Park, MD, 20742-1815, United States, zchen@rhsmith.umd.edu, Lixin Tang, Feng Li

We study integrated production and distribution scheduling problems that arise in practical make-to-order settings in several industries. In these problems, make-to-order products are first processed in a plant, and then delivered to customer sites through two stages of shipping: first, from the plant to a pool point (e.g., a port, a distribution or a consolidation center), and second, from the pool point to customer sites. We consider both offline and online problems, propose several heuristics, and analyze their worst-case and asymptotic performance ratios. The heuristics are tested computationally using both real data from a company and randomly generated data.

Economics of Digital Channels

Sponsored: EBusiness

Sponsored Session

Chair: Yi-Chun Ho, George Washington University, Washington, DC, 20052, United States, chadho@gwu.edu

1 - The Impact of the Sharing Economy on Household Finance

Tingting Nian, University of California, Irvine, Irvine, CA, United States, tnian@uci.edu

Powered by digital technologies, many peer-to-peer platforms or what is called the sharing economy have emerged in the past decade. While the impact of the sharing economy has received a great deal of attention in the past couple of years, extant research hasn't fully documented the impact of the sharing economy on consumers, workers, industry and the society as a whole. In this study, we exploit the geographic and temporal variation in Uber's entry to examine the impact of Uber's entry on the personal bankruptcy rate as well as other consumer credit default rates.

2 - Reward on User Generated Content

Zixuan Meng, University of Washington, 2021 NE 90th St Apt A501, Seattle, WA, 98115, United States, zxmeng@uw.edu

The value of user-generated content has been heatedly discussed and strongly emphasized in the past few years. However, most of the studies attribute such value to social capital gain and few studies have been conducted on how the value of content could be monetarized. Using a unique setting where readers can voluntarily provide monetary reward to content-generators, we intend to analyze how monetary incentive influences content-generators' behavior. We further analyze how change in rewarding policies would change users' content generation and rewarding behavior.

3 - The Impact of Verification in Online Matching Markets: Evidence from a Randomized Field Experiment

Lanfei Shi, University of Maryland, College Park, MD, United States, lanfeishi@rhsmith.umd.edu, Siva Viswanathan

Online matching markets suffer from significant information asymmetries. Online dating, in particular, has been challenged by fake profiles and scams, and markets have resorted to verification as a mechanism to mitigate such issues. While it is generally believed that verification is beneficial, it is not clear what type of users would choose to verify their credentials given an option, and what are the outcomes of such choices. In collaboration with one of the leading online dating platforms in the US, we design and conduct a randomized field experiment to answer these questions. Our findings provide insights on how to effectively leverage verification.

4 - Crowding-out Effect Mitigation through Intervention Strategies

Shun-Yang Lee, University of Connecticut, Storrs, CT, United States, shun-yang.lee@uconn.edu, Dandan Qiao, Qiang Wei, Andrew Whinston

Monetary incentives are often used to motivate individuals' pro-social behaviors. However, incentives are known to result in the crowding-out effect, which dampens individuals' intrinsic motivation and leads to lower contribution quality, typically exemplified in the form of information bias. In this paper, we conduct randomized experiments to investigate ways to overcome the crowding-out effect of monetary incentives. Our results suggest that monetary incentives, when combined with appropriate intervention strategies such as goal-setting and challenge-seeking, can motivate users to increase their contribution quantity without hurting the quality. Additional experimental results suggest that the moderating effect of these intervention strategies is heterogeneous, with low-altruistic individuals benefiting the most from the intervention. Our research contributes to the study of incentive provision and pro-social behaviors and has significant theoretical and practical implications.

Bringing Behavioral Operations Into the Classroom

Sponsored: Behavioral Operations Management

Sponsored Session

Chair: Ryan Buell, Harvard Business School, Morgan Hall 429, Boston, MA, 02163, United States, rbuell@hbs.edu

1 - Exercise Exploring Behavioral Ideas in Service Ops

Michael Dixon, Utah State University, Logan, UT, United States, mike.dixon@usu.edu

Services are a ripe area to use to teach, apply, and consider multiple behavioral principles. This in-class exercise introduces students to a berth of such principles and challenges students to consider how different service industries apply, or could apply these principles. The exercise allows students to appreciate the importance of behavioral concepts in the management and design of service operations and introduces them to a wide array of ideas in behavioral research. The exercise can be used as an introduction to the importance of behavioral ideas in and operations management or services management course.

2 - Breakfast at the Paramount: A Case Study on Queuing Dynamics

Ryan Buell, Harvard Business School, Morgan Hall 429, Boston, MA, 02163, United States, rbuell@hbs.edu

The Paramount is a 44-seat diner on Charles Street in the Beacon Hill neighborhood of Boston. A frequent "Best of Boston" award winner, the restaurant is a perennial favorite among locals and tourists, particularly for brunch on the weekends, when lines often stretch down the street. The case focuses on the restaurant's interesting seating policy and a recent increase in the popularity of carryout orders, which poses a threat to the service experiences of customers and the sustainability of the operation. The session will introduce the multimedia case study, and how it can be used to teach the analytical and behavioral dynamics of queues in courses on operations management and service operations.

3 - Sharing the Risk: A Classroom Experiment for Teaching About Supply Chain Contracts

Karen L.Donohue, University of Minnesota, SCO.Department, 321 19th Street Avenue S, Minneapolis, MN, 55455, United States, donoh008@umn.edu, Yinghao Zhang

We describe an activity for introducing students to issues that can arise in using risk-sharing contracts (e.g., buyback and revenue sharing). The activity consists of two exercises where students take on the role of a supplier, first choosing what contract to offer, and second setting contract parameters for one of the contract types. In discussing the outcomes, students discover that the profit margin of a product (whether it is high versus low margin) leads to differences in contract preferences and performance. This provides an opportunity to introduce two important behavioral factors, loss aversion and prospective accounting, that help explain these results.

4 - Behavioral Drivers of Learning

Bradley R. Staats, University of North Carolina at Chapel Hill, Campus Box 3490, McColl 4721, Chapel Hill, NC, 27599-3490, United States, bstaats@unc.edu

Pal's Sudden Service is a quick service restaurant that has created a unique operating model that focuses on process control and improvement. The company treats the restaurant business like a manufacturing operation and was the first restaurant to win the Baldrige Quality award. At the same time the company has high employee engagement and together this has lead to excellent operating and financial performance. The case examines how it has architected an organization to learn and grow. This session will introduce the case and how it can be used to teach about behavioral drivers of learning.

Behavioral Collaboration

Invited: InvitedBehavioral Aspects of OR

Invited Session

Chair: Leroy White, Professor, Warwick Business School, Warwick Business School, United Kingdom, Leroy.White@wbs.ac.uk

1 - The Problems of Collaborative Behaviour and Operations Research: An Overview

Leroy White, University of Bristol, School of Eonomics Finance and Accounting, 12 Priory Road, Bristol, BS8 1TU, United Kingdom, leroy.white@bristol.ac.uk

Abstract not available.

2 - Affordances for Collaborative Behavior Operations Research Interventions: A Practice-based View

Katharina Burger, University of Portsmouth, Business School, OSM, Portland Street, Portsmouth, PO1 3DE, United Kingdom, katharina.burger@port.ac.uk

Theorizing from practice-based OR interventions is a critical task for behavioral operations researchers who aim to understand how collaborative performance can be scaffolded. A micro-level lens to realize theory-based empirical studies of affordances is proposed. Drawing on data from a low-tech facilitated modelling workshop, three key dimensions of behavior with OR performance scaffolds are highlighted: trust, entrenchment and sharedness.

3 - Building the Multiplex: An Agent-Based Model of Formal and Informal Network Relations

Duncan Robertson, Loughborough University, SBE, Loughborough, United Kingdom, d.a.robertson@lboro.ac.uk, Leroy White

We present a new agent-based model of group decision making, where links are made in hierarchical organizational structures. Our model presents a trade off between deliberate organizational hierarchical planning and allowing organizational 'short cuts' to form spontaneously. We present results showing when organizations should be planned and when emergent designs can offer higher performance.

Large-scale Data Analytics in Urban Transportation Modeling II

Sponsored: TSL, Urban Transportation

Sponsored Session

Chair: Shanjiang Zhu, George Mason University, Fairfax, VA, 22030, United States, szhu3@gmu.edu

Co-Chair: Zhen Qian, Carnegie Mellon University, Carnegie Mellon University, Pittsburgh, PA, 15213, United States, seanqian@cmu.edu

1 - Statistical Inference of Probabilistic Origin-destination Demand using Day-to-day Traffic Data

Zhen Qian, Carnegie Mellon University, 4800 Forbes Avenue, Pittsburgh, PA, 15213, United States, seanqian@cmu.edu, Wei Ma

Our research develops a novel framework for estimating the mean and variance/covariance of Origin-Destination demands considering the route choice variation and statistical equilibrium simultaneously. The observability and non-uniqueness property of the estimated probabilistic O-D demand are discussed. The framework is evaluated in a small and a large-scale network to provide insights and to demonstrate computational efficiency.

2 - How Does Social Media Infer the Longitudinal Travel Behavior?

Qing He, University at Buffalo, The State University of New York, 313 Bell Hall, Buffalo, NY, 14260, United States, qinghe@buffalo.edu, Zhenhua Zhang, Shanjiang Zhu

This paper proposes a sequential model-based clustering method to group the high-resolution Twitter locations and extract the Twitter displacements. Further, this study compares the displacement-based results from Twitter data with the results from traditional household travel survey. Our study demonstrates the potentials of employing social media to infer longitudinal travel behavior and to support travel demand modeling for a metropolitan area.

3 - Optimizing Paratransit Operations to Serve Demand of Passengers with Disabilities in Urban Areas

Eric Gonzales, University of Massachusetts-Amherst, 130 Natural Resources Way, Civil and Environmental Eng, Amherst, MA, 01003, United States, gonzales@umass.edu, Mahour Rahimi

Demand responsive transit service for people with disabilities is typically provided in the United States with paratransit services managed by transit agencies, as required by the Americans with Disabilities Act (ADA). The cost of operating a dedicated fleet of vans and cars for these customers is rising as more people become eligible for ADA service. Demand and operations data for NJ Transit support models and analysis to optimize zoning strategies, garage locations, and transfer policies. An opportunity now exists to further improve costs and mobility by coordinating ADA service with transportation network companies, which has been piloted by the MBTA in Boston.

4 - Inferring Origin-Destination Demand Matrix and Utility-Based Travel Preferences in Multi-Modal Travel Environment using Automatic Fare Collection Data

Laiyun Wu, SUNY-Buffalo, 326 Bell Hall, Buffalo, NY, 14226, United States, laiyunwu@buffalo.edu

We develop inference methods for understanding and expressing public transit system utilization based on travelers' origins/destination (OD) and ensuing behavior. The presented methodology infers both the preference vector and true OD-pair demand by analyzing Automatic Fare Collection (AFC) data, as travelers make their multi-modal route choice decisions in the time-dependent travel environment.

Digital Advertising

Sponsored: Information Systems

Sponsored Session

Chair: Manmohan Aseri, The University of Texas at Dallas, Richardson, TX, 75080, United States, manmohan.aseri@utdallas.edu

1 - Block the Ad-block Users? Not Always

Manmohan Aseri, University of Texas-Dallas, 2200 Waterview Parkway, Apt 1738, Richardson, TX, 75080, United States, manmohan.aseri@utdallas.edu, Milind Dawande, Ganesh Janakiraman, Vijay S.Mookerjee

Ad-Blockers are the software or the plug-ins which remove ads from the users' browsers when they access a website on the internet. Companies which are heavily dependent on the advertisement revenue dislike the ad-blocker usage due to the loss of the ad revenue. We address the problem from the perspective of those publishers (websites) which rely heavily on the ad revenue and provide insights about how these companies should react to ad-block users. We solve the problem using a game theoretic model. Our results suggest that the network effect plays a critical role in the reaction of a publisher to the ad-block users. These results are consistent with the current practice.

2 - When are Two Machines Better than One? A Model to Reduce Rental Cost in Cloud Computing

Leila Hosseini, Information Systems, The University of Texas at Dallas, Richardson, TX, 75080, United States, leila.hosseini@utdallas.edu, Vijay S.Mookerjee, Chelliah Sriskandarajah

Amazon Web Services (AWS), a major cloud provider in the cloud infrastructure market, offers a diverse set of computing resources called virtual machines (VM). All VMs are priced based on their capabilities such that VMs whose prices are higher perform better than those which have lower prices. In this setting, AWS users receive a lot of flexibility to select their desired VMs. However, it is difficult to encounter to this much flexibility without being confused at the same time. Therefore, it is a must for users to find an efficient solution to transform this confusing market into a beneficial one. We study AWS cloud user's problem of renting VMs to minimize rental cost in the presence of a time constraint.

3 - Measuring Channel Complementarities in an Online Advertising Supply Chain

Changseung Yoo, The University of Texas at Austin, Austin, TX, 78712, United States, csyoo@utexas.edu, Anitesh Barua, Genaro J. Gutierrez

In the empirical literature on testing complementarities, no distinction has been made between the existence of complementarity and recognizing and acting upon such complementarity. To address this gap, we analyze how a decision maker's understanding of complementarities can affect the empirical evidence of complementarities or substitutabilities within a structural model.

4 - CPV vs CPC in Internet Video Advertising

Zhen Sun, Information Systems, The George Washington University, Washington, DC, 20052, United States, zhens@email.gwu.edu, Sameer Mehta, Vijay S. Mookerjee

This study is aim to conduct an economical analysis on the two pricing models in Internet video advertising.

Network Design

Sponsored: TSL, Facility Logistics

Sponsored Session

Chair: Mohammad Marufuzzaman, Mississippi State University, Dept of Industrial & Systems Engineering, P.O. Box 9542, Starkville, MS, 39762, United States, maruf237@gmail.com

1 - Optimizing Electric Vehicle Charging Station Expansion Decisions with an Integration of Renewable Energy and Vehicle-to-grid Sources

MD Abdul Quddus, Mississippi State University, 319 North Jackson Street, Apt 3E, Starkville, MS, 39759, United States, mq90@msstate.edu, Mohannad Kabli, Mohammad Marufuzzaman

This study proposes a novel formulation for designing and managing electric vehicle charging stations, considering both long-term planning decisions and short-term hourly operational decisions over a pre-specified planning horizon and under stochastic power demand. We propose a highly customized hybrid algorithm that combines Sample Average Approximation (SAA) with an enhanced Progressive Hedging Algorithm (PHA). A case study based on a road network around Washington, D.C. is present to visualize and validate the modeling results. Our computational results provide a number of managerial insights to the decision makers while indicating the robustness of the proposed algorithm.

2 - The Location Decision Revisited: Empirical Findings from the Automotive Sector

Ioannis Siskos, Kuhne Logistics University, Grosser Grasbrook 17, Hamburg, 20457, Germany, ioannis.siskos@the-klu.org Ioannis Siskos, Vlerick Business School, Reep 1, Gent, 9000, Belgium, ioannis.siskos@the-klu.org, Ann Vereecke, Luk N. Van Wassenhove, Matthias Holweg

In this paper we empirically test location factors in the automotive context, using de facto location decisions car firms have taken, i.e Vehicle Assembly Plant openings and closures. The main research question here is whether the location factors identified in the literature have the same effect in both openings and closures of Vehicle Assembly Plants.

3 - Optimal Planning of Swapping Station Network with Customer Satisfaction

Fang Guo, Huazhong University of Science and Technology, Hongshan District, 1037 Luoyu Road, WuHan, 430074, China, fang_guo@hust.edu.cn, Jun Yang

Key to the mass adoption of electric vehicles is the establishment of a sufficient battery service infrastructure network on the basis of customer behavior and psychology. Motivated by EV service infrastructure network design under the battery leasing/electric car sharing service business models,we present an electric vehicle battery service network design problem considering a customer's satisfaction related to "range anxiety" and "loss anxiety". The problem is formulated as a linear integer programming model under deterministic and fuzzy scenarios. A Tabu Search heuristic is proposed to solve the problem. Finally, we conduct parametric analysis on real-world road networks.

4 - Strategic and Tactical Planning in Dimension Stone Industry

Gangaraju Vanteddu, Associate Professor, Southeast Missouri State University, Harrison College of Business, One University Plaza, MS.5815, Cape Girardeau, MO, 63701, United States, gvanteddu@semo.edu

Supply Chain network design and tactical planning in dimension stone industry present certain unique challenges, in the presence of highly variable demand and material availability related constraints. In this research, generic linear programming based models are proposed for the strategic and tactical level planning to optimize the cost of developing a supply chain network and for medium term production planning.

Advanced Vehicle Control and Traffic Operations with Connected Vehicles

Contributed Session

Chair: Lili Du, Illinois Institute of Technology, 3201 South Dearborn Street, Chicago, IL, 60616, United States, ldu3@iit.edu

1 - Facilitating the Emergency Response Vehicles' Movement Through a Transportation Network Link in the Connected Vehicle Environment

Gaby Joe Hannoun, Graduate Student, Virginia Polytechnic Institute and State University, 7054 Haycock Rd, Falls Church, VA, 22043, United States, gabyjoe@vt.edu, Pamela Murray-Tuite, Kevin Heaslip

Due to the increased traffic especially in urban areas and the risky maneuvers that Emergency Response Vehicles (ERVs) are forced to perform, a new mathematical program leveraging the vehicle to vehicle communications is proposed to facilitate the movement of the ERVs. The integer linear program finds the fastest passage for the ERV along a transportation link while avoiding conflict with nearby vehicles. It can be adapted to different road types, ERV characteristics, and surrounding conditions. When compared to current practices, the proposed formulation offers the same or faster ERV passage along with increased safety since it limits confusion and unexpected incidents caused by human factors.

2 - Multi Vehicle Coordination Strategy for Vehicles Approaching Signalized Intersection to Reduce Emissions using Connected Vehicles Technology

Vaibhav Rungta, Graduate Assistant, Rochester Institute of Technology, Rochester Institute of Technology, James E. Gleason Building, 81 Lomb Memorial Drive, Rochester, NY, 14623, United States, vr2002@g.rit.edu, Katie McConky

The connected vehicles technology allows vehicles and traffic infrastructure to exchange information. This information can be used to provide vehicles with optimal speed profiles which reduce emissions and fuel consumption. However for vehicles with different characteristics a single speed may not be optimal for all the vehicles while maintaining the traffic flow. This research aims to generate speed profiles which may be sub-optimal for a single vehicle, but result in lower emissions and fuel consumption at the system level for a group of vehicles.

3 - Non-Connected Vehicle Detection using Connected Vehicles

Yong Hoon Kim, Purdue University, 2335 Hokins Dr., West Lafayette, IN, 47907, United States, kim523@purdue.edu, Lin Liu, Srinivas Peeta

This study proposes a hidden Markov model, which is a probabilistic inference approach, to identify non-connected vehicle location/trajectory using connected vehicle trajectories under mixed traffic streams of connected vehicles. This methodology is integrated with a cooperative-situation awareness framework. The proposed model is analyzed using real-world vehicle trajectory data to aid the situational awareness of connected vehicles under low market penetration rates.

4 - Constrained Model Predictive Control and Distributed Computation based Car-Following Control for a Platoon mixed with CAVs and Human-Drive Vehicles

Siyuan Gong, Illinois Institute of Technology, Chicago, IL, 60616, United States, sgong1@hawk.iit.edu, Lili Du

The study developed a car-following control mechanism for a platoon mixed with human-drive vehicles and CAVs on a straight highway. Specifically, the movement of human-drive vehicles is modeled by the Newell car-following model and the aggregated response delay anticipated by a machine learning algorithm. By utilizing the connectivity between CAVs, a constrained MPC combined a distributed computation approach is developed to generate optimal control law for individual CAVs so that the desired traffic smoothness and stability are ensured in the system level. Last, the performance of our approaches is validated by simulation experiments.

Models for the Management of Agriculture Industry

Invited: Agricultural Analytics

Invited Session

Chair: Foad Iravani, University of Washington, Foster School of Business, Seattle, WA, 98195, United States, firavani@uw.edu

1 - Transfer Price and Yield Risk-sharing Contracts for Cotton Supply Chains

Guang Xiao, Hong Kong Polytechnic University, Hong Kong, guang.xiao@polyu.edu.hk, Panos Kouvelis, Li Jian

Motivated by the practices from cotton supply chains, we propose a stylized model to study the contracting interactions among a ginner and its farmers with the presence of crop diversification and side selling. We propose a yield risk-sharing contract to better align the yield and price risks in the supply chain.

2 - Farmland Allocation with Crop Rotation Benefits

Javad Nasiry, Hong Kong University of Science and Technology-HKUST, Hong Kong Uni. of Sci. and Tech., ISOM.Dept.,, Lee Shau Kee Business Building, Room 4079, Hong Kong, nasiry@ust.hk, Onur Boyabatli, Yangfang Zhou

We examine a farmer's decision on how to allocate the available farmland between two crops when the crops have rotation benefits across growing seasons. The allocation decision is subject to revenue uncertainty in commodity markets. We characterize the optimal dynamic allocation policy. We then calibrate our model using the data from the United States Department of Agriculture to represent a typical Iowa farmer growing corn and soybean.

3 - Pulses Supply Chains in India: Issues and Solutions

Bin Hu, UNC Chapel Hill, McColl Building CB3490, Kenan-Flagler Business School, Chapel Hill, NC, 27599, United States, bin_hu@unc.edu, Liying Mu, Srinagesh Gavirneni

Pulses are a vital source of plant-based protein for the large number of vegetarians in India. Unpredictable domestic yields and limited import availability in times of need have recently caused crises for India. Many solutions (e.g., export restrictions, minimum support prices, long-term contracts) have been proposed to address the issues inherent to pulses supply chains and there is widespread debate on which to pursue. We evaluate the role of long-term contracts in resolving these supply chain problems and specifically evaluate the impact of contract timing, uncertainty, budget constraints, and salvage value.

4 - An Analysis of Price vs. Revenue Protection Government Subsidies in the Agriculture Industry

Foad Iravani, University of Washington, Foster School of Business, ISOM.Department, Box 353226, Seattle, WA, 98195-3226, United States, firavani@uw.edu, Saed Alizamir, Hamed Mamani

We develop models to analyze the effects of government subsidy programs in the agriculture industry on consumers, farmers, and the government. We provide insights about the impacts of crop and market characteristics on the relative performance of subsidies.

Statistics and Probability in Finance

Sponsored: Financial Services

Sponsored Session

Chair: Agostino Capponi, Columbia University, Columbia University, New York, NY, 10027, United States, ac3827@columbia.edu

1 - The Optional Sampling Theorem

Philip Ernst, Rice University, Houston, TX, United States, philip.ernst@rice.edu

Suppose you have one unit of stock, currently worth 1, which you must sell before time T. The Optional Sampling Theorem tells us that whatever stopping time we choose to sell, the expected discounted value we get when we sell will be 1. Suppose however that we are able to see a units of time into the future, and base our stopping rule on that; we should be able to do better than expected value 1. But how much better can we do? And how would we exploit the additional information? The optimal solution to this problem will never be found, but in this paper we establish remarkably close bounds on the value of the problem, and we derive a fairly simple exercise rule that manages to extract most of the value of foresight.

2 - Risk-sensitive Cooperative Games for Human-Machine Systems

Matthew Stern, Columbia University, New York, NY, United States, mns2141@columbia.edu

Autonomous systems can substantially enhance a human's efficiency and effectiveness in complex environments. Machines, however, are often unable to observe the preferences of the humans that they serve. Though the human's and machine's objectives are aligned, asymmetric information, along with heterogeneous sensitivities to risk by the human and machine, make their joint optimization process a game with strategic interactions. We propose a framework based on risk-sensitive dynamic games to model applications including self-driving taxis and robo-financial advising.

3 - Strategic Dynamic Pricing with Network Effects

Ali Makhdoumi, MIT, 77 Massachusetts Ave. , 32D-640, Cambridge, MA, 02139, United States, makhdoum@mit.edu, Azarakhsh Malekian, Asu Ozdaglar

We study the optimal pricing policy of a committed monopolist selling durable goods in a dynamic pricing game with multiple rounds. Customers are forward-looking and experience a (positive) network effect. The monopolist announces and commits to a price sequence and strategic buyers decide on when (if ever) to buy the good in a perfect Bayesian equilibrium. We explicitly find the optimal pricing policy and show that it is linearly increasing in time, where the slope of the price path is described by a single network measure: sum of the entries of the inverse of network effects matrix.

4 - Reducing Bias in Event Time Simulation VIA Measure Changes

Alexander Shkolnik, University of California-Berkeley, Berkeley, CA, 94720, United States, ads2@berkeley.edu

Stochastic point process models of event timing are common in many areas, including finance, insurance and reliability. Monte Carlo simulation is often used to perform computations in these models. The standard sampling algorithm, which is based on a time-scaling argument, is widely applicable but generates biased simulation estimators. This article develops a measure change technique for reducing the bias and accelerating the algorithm. We prove the existence of a broad class of measure changes that yields martingales of independent interest. The result ensures that our algorithm has the same scope as the standard time-scaling scheme. Numerical results illustrate our approach.

Applications of Location Analysis

Sponsored: Location Analysis

Sponsored Session

Chair: Sibel Alumur Alev, University of Waterloo, University of Waterloo, Waterloo, ON, N2L 3G1, Canada, sibel.alumur@uwaterloo.ca

1 - Risk Aware Capacitated Facility Location Problems

Stefan Nickel, Karlsruhe Insitute of Technology, Institute for Operations Research, Karlsruhe, 76131, Germany, stefan.nickel@kit.edu, Tanya Gonser, Iris Heckmann, Francisco Saldanha-da-Gama

In this talk we present a new exact algorithmic framework for solving multi-stage stochastic mixed 0-1 problems based on a branch-and-bound approach. The approach can be applied to multi-stage problems with mixed-integer variables and uncertainty in each time stage.We describe the underlying scenario tree with a unique set of indices that enables an easy reformulation of the deterministic equivalent model.Computational results are presented for risk-aware capacitated facility location problems with multiple stages as well as uncertain demand and capacities. The results show that the presented method leads to the optimal solution for all considered instances with a good performance.

2 - A Mathematical Model for Point-to-point Based Airline Network Design Problems

Mihiro Sasaki, Nanzan University, 18 Yamazato, Showa, Nagoya, 466-8673, Japan, mihiro@nanzan-u.ac.jp, Takehiro Furuta

We consider an airline network design model for passenger transportation based on point-to-point services in which hubs are not necessarily required. We formulate the problem as an integer programming problem and propose a dynamic programming heuristic method to solve large-sized problems. We report some analytical results from passengers' perspectives.

3 - Shipment Scheduling in Hub Location Problems

James H. Bookbinder, University of Waterloo, 421 Richview Avenue, Toronto, ON, M5P.3G7, Canada, jbookbinder@uwaterloo.ca, Mobina Masaeli, Sibel Alumur Alev

We incorporate shipment scheduling decisions into hub location problems. We determine optimal hub locations, hub network structure, the number of vehicles to operate in the network, and the time period of dispatching each vehicle from a hub. We develop three MIP models for different problem versions, depending on whether holding costs are incorporated and whether the vehicles are of different types. We investigate the impact of shipment scheduling on hub network configurations, routing decisions, and total network costs. We solve the models on instances from a new dataset with real data.

4 - Heuristic Solutions for a Class of Stochastic Uncapacitated p-hub Median Problems

Francisco Saldanha-da-Gama, University of Lisbon, Deio-Fcul, Bloco C6, Lisbon, 1749016, Portugal, fsgama@ciencias.ulisboa.pt, Ángel Corberán, Rafael Marti, Juanjo Peiró

We extend the r-allocation p-hub median problem by including fixed allocation costs, non-stop services and uncertainty in traffic and costs. However, even for small instances of the problem, a compact optimization model for the new problem becomes too large for being tackled by a general solver. This fact motivates the development of an approximate procedure whose starting point is the determination of a feasible solution to every (deterministic) single-scenario problem. Such solutions are then embedded into an iterative process rendering feasible solutions for the overall problem. We discuss the results of the numerical experiments performed using instances build from well-known data sets.

Advances in Stochastic Simulation

Sponsored: Simulation

Sponsored Session

Chair: Henry Lam, khlam@umich.edu

1 - Efficient Rare-event Simulation for Heavy-tailed Processes VIA Principle of Multiple Big Jumps

Chang-Han Rhee, Centrum Wiskunde & Informatica, Jakoba Mulderplein 164, Amsterdam, 1098 XG, Netherlands, rhee@cwi.nl, Jose Blanchet, Jose Blanchet, Bohan Chen, Bert Zwart, Bert Zwart

We propose a new class of strongly efficient rare event simulation estimators for heavy-tailed random walks and compound Poisson processes. The new estimators are straightforward to implement, has bounded relative errors, and are "universal" in the sense that a single importance sampling scheme applies to a very general class of rare events. In particular, our estimators can deal with rare events that are provoked by multiple big jumps (hence, beyond the usual principle of a single big jump) as well as multidimensional processes such as the buffer content process of a queueing network. We illustrate our new method with examples in mathematical finance, simulation optimization, and queueing theory.

2 - Input Model Averaging

Barry L. Nelson, Northwestern University, Dept of Industrial Eng and Mgmt Sciences, 2145 Sheridan Road, Room C216, Evanston, IL, 60208-3119, United States, nelsonb@northwestern.edu, Alan T. Wan

Input uncertainty is an aspect of simulation model risk that arises when the input distributions are derived or "fit" to real-world, historical data. While there has been significant progress on quantifying and protecting against input uncertainty, there have been few direct attempts to reduce it. We show that frequentist model averaging can be a provably effective way to create input models that better represent the true, unknown input distributions, thereby reducing model risk. We provide theoretical and empirical support for our approach.

3 - Ranking and Selection with Covariates

Haihui Shen, City University of Hong Kong, Kowloon, Hong Kong, haihui.shen@my.cityu.edu.hk, Jeff Hong, Xiaowei Zhang

We consider a new ranking and selection problem in which the performance of each alternative depends on some observable random covariates. The best alternative is thus not fixed but depends on the values of the covariates. Assuming a linear model that relates the mean performance of an alternative and the covariates, we design selection procedures producing policies that represent the best alternative as a function in the covariates. We prove that the selection procedures can provide certain statistical guarantee, which is defined via a nontrivial generalization of the concept of probability of correct selection that is widely used in the conventional ranking and selection setting.

4 - Bagging-based Estimation of Simulation Input Uncertainty

Huajie Qian, University of Michigan, Ann Arbor, MI, United States, hqian@umich.edu, Henry Lam

We study resampling-based methods for estimating input-induced variance in stochastic simulation as a means to construct output confidence intervals under nonparametric input uncertainty. We revisit two unbiased bootstrap estimators and investigate their efficiencies. We then investigate an infinitesimal jackknife estimator on a bagging prediction that closely connects to the input uncertainty problem. We demonstrate that the bagging-based approach is more efficient for single-run simulation experiments. We also present a subsampling technique that significantly reduces the simulation effort required by the methods.

1 - Facility Location and Item Prepositioning under Demand Uncertainty and Road-Facility Vulnerabilities

Melih Celik, Middle East Technical University, ODTU. Endustri Muh. Bolumu, Universiteler Mh. Dumlupinar Bl. No: 1, Ankara, 06800, Turkey, cmelih@metu.edu.tr, Ece Aslan

This study proposes a multi-echelon humanitarian supply chain network design by incorporation of demand uncertainty and road-facility vulnerabilities. In the frame of the study, a two-stage stochastic programming model is formulated to make decisions on warehouse locations and item prepositioning in the first stage, and relief distribution in the second stage. As an extension, concurrent road repair decisions are also considered. A sample average approximation scheme is developed for the solution of the proposed model, which is executed under efficiency- and equity-based objectives.

2 - Network Operations Against Attacks: A Tri-Level Model in Oil & Gas Production and Distribution

Mustafa Alassad, University of Arkansas, Little Rock, AR, United States, mmalassad@ualr.edu, Yupo Chan, Hamzeh Davarikia

Oil and gas are distributed via pumps and pipelines that are exposed to threats. Hardening strategies against malicious attacks are needed. A tri-level leader-follower-operator game determines the optimal fortification tactics to protect the critical assets. There exist dimensions of gaming beyond outright fortification, including tactics often adapted in the "fog of war," such as deception. This is modeled mathematically under the shared cognition concept. Our computational results show that the deception concept is much more effective than fortification, where the cost of attacker's damages diminished significantly without substantial resource commitment on the part of the defender.

3 - A Spectral Risk Measure in Hazardous Materials Transportation

Liu Su, University of South Florida, ENG 302, Tampa, FL, 33620, United States, liusu@mail.usf.edu, Longsheng Sun, Mark Henry Karwan, Changhyun Kwon

Due to catastrophic consequences of accidents by hazardous materials (hazmat) transportation, risk-averse approach for routing is needed. In this paper, we consider spectral risk measures, which are coherent and more general than existing approaches such as conditional value-at-risk. We develop a mixed integer programming model in hazmat routing to minimize a special class of spectral risks and propose an efficient algorithm to solve the problem. For general spectral risk measures, we approximate the spectrum function using step functions. By applying spectral risk measures to hazmat routing, we protect the road network from undesirable route choices that may lead to severe consequences.

4 - Optimizing Disaster Resilience of the Built Infrastructure

Elise Miller-Hooks, Professor, George Mason University, 208 Rosalie Cove Ct, Silver Spring, MD, 20905, United States, miller@gmu.edu, Mersedeh Tariverdi, Hossein Fotouhi, Seksun Moryadee

A multi-stage stochastic, mixed integer program is presented for quantifying and maximizing disaster resilience of the built infrastructure to multiple probabilistic hazard events. Dependencies on interdependent societal lifelines, including transportation, water and power, which are themselves subject to failure, are explicitly modeled. The model is applied on a case study.

Joint Session RAS/Practice: Education Programs in OR/MS for Railways

Sponsored: ORinformed Healthcare Policies

Sponsored Session

Chair: Steven Harrod, Technical University of Denmark, Technical University of Denmark, Kgs. Lyngby, 2800, Denmark, stehar@dtu.dk

1 - Railway Education Programs at the Technical University of Denmark and Other European Universities, and Related Careers

Steven Harrod, Technical University of Denmark, Room 132, Building 424, Kgs. Lyngby, 2800, Denmark, stehar@dtu.dk

Railway agencies, infrastructure managers, and operators nearly all desire formal university education today. This presentation summarizes the education programs available in Europe and some of the typical career paths available at European railways.

2 - OR/MS Education in Railways in China

Xy Yin, Beijing Jiaotong University, Beijing, China, xyyin@bjtu.edu.cn

This paper introduces the development process of the theory of Operations Research and Management Science in the education of the railway transportation in Beijing Jiaotong University. Beijing Jiaotong University has been established for 120 years. The major of railway transportation management is the earliest major in the school, and the theory of Operations Research and Management Science has been adopted in the major-related courses, including the organization of train operation and the organization of railway freight transportation. Such theory makes teaching level improved, helps to train a large number of qualified staffs in the fields of China railway transportation management.

3 - Railway Operations Education at the University of Illinois at Urbana-champaign

C. Tyler Dick, University of Illinois at Urbana-Champaign, Urbana, IL, 61801, United States, ctdick@illinois.edu

The Rail Transportation and Engineering Center (RailTEC) at the University of Illinois at Urbana-Champaign is home to the strongest academic program in railroad engineering of any university in North America, complimented by the largest and most diverse program of research on the topic. After many years of decline, railways have reemerged as an area of interest to North American academicians. This presentation will describe how RailTEC uses a combination of coursework, research, industry internships and international collaboration to meet the challenge of educating the next generation of railway operations and engineering professionals.

4 - OR Careers in Railways at BNSF

Pooja Dewan, Chief Data Scientist, BNSF Railway, 2650 Lou Menk Drive, #2, Fort Worth, TX, 76131, United States, pooja.dewan@bnsf.com

As one of the largest freight railroads in North America, BNSF moves goods and commodities that feed and clothe millions of people; help build roads and buildings; and provide a critical link that connects consumers with the global marketplace. Railroads carry more than 40 percent of freight in the U.S. by volume and provide the most fuel-and cost-efficient means for moving freight over land. Behind the scenes helping equip BNSF leaders with the research necessary to make decisions on is the company's Operations Research team. The team's mission is to leverage advanced analytics to provide innovative tools and insights that help support and enhance the decisions made by company's leaders.

1 - Choice-based Optimization in Transport, Mobility and Logistics

Shadi Sharif Azadeh, Erasmus University Rotterdam, Rotterdam, Netherlands. Contact: sharifazadeh@ese.eur.nl

Combining customer behaviour models in optimization provides a better understanding of the preferences of clients to policy makers while planning for their systems. These preferences are formalized with discrete choice models. However, their complexity leads to mathematical formulations that are highly non-linear and non convex in the variables of interest. On the other hand, we are also interested in discrete optimization models where supply and demand closely interact, which is typically the case in transportation. Such models are associated with (mixed) integer optimization problems, whose discrete variables are used to design and configure the supply. The goal of this research is to develop a general methodology which integrates both supply and demand under the framework of discrete choice models whose associated mixed integer linear problems are scalable and solvable within reasonable time.

2 - Integrated Computational and Theoretical Scheme for Linking Quality Control and Stochastic Modeling in Bioenergy Supply Chain Network Design

Krystel Castillo, University of Texas-San Antonio, San Antonio, TX, Contact: Krystel.Castillo@utsa.edu

In recent years, industry has seen the advent of highly complex, large-scale supply chains (SCs), whichhave become increasingly difficult to analyze and optimize using conventional modeling techniques and solutionprocedures. A particularly relevant example is found in the emerging second-generation biofuel industry, whichfaces unique, unaddressed challenges such as: (1) understanding the biomass quality/availability and quantifying howthese variables impact the design of technologies, and (2) assessing the impact of uncertainties related to thebiomass quality/availability on the supply chain design and planning. This presentation will include a discussion on a unified computational and theoretical scheme that links qualitycontrol, twostage stochastic modeling and tractable optimization algorithms to (1) enable the conversion of largequantities of biomass into marketable products, (2) better represent the random nature of the biomass quality, and (3)assess the impact of these uncertainties on the system's design. These computational tools are being integrated into science-as-service platform. This alpha version of a cloud-based Decision Support System aims to facilitate the adoption of experimental and field data as well as computational models..

1 - Price Formation with an Evolving Resource Mix

Congcong Wang, MISO, 720 City Center Dr, Carmel, IN, 46032, United States, cwang@misoenergy.org

With an evolving resource mix including increasing renewable penetration and demand-side participation, pricing needs have changed and will continue to change as resources are operated to balance variations and uncertainties in net demands throughout the day. This talk tries to provide a holistic view of the price formation challenges and how MISO is preparing for the low-carbon future. Numerical examples will be presented to illustrate the pricing challenges and potential solutions, including but not limited to sustainability of traditional resources facing prices driven down by low-marginal costs renewables and flexibility of resources that must be maintained for reliability needs.

2 - Pricing Methods in ISO Day-ahead and Real-time Auction Markets

Richard O'Neill, Chief Economist, Federal Energy Regulatory Commission, 12601 Meadowood Drive, Silver Spring, MD, 20904, United States, richard.oneill@ferc.gov

We examine four pricing methods for non-convex auctions markets comparing the properties of each including transparency, make-whole payments, entry price signals, price signals for price-responsive demand.

3 - A Market Design Integrating the View of Stochastic Producers

Antonio J. Conejo, The Ohio State University, Department of Integrated Systems Engineering, 210 Baker Systems Building, Columbus, OH, 43210, United States, conejonavarro.1@osu.edu, Ramteen Sioshansi

The goal of this presentation is to reexamine the design of electricity markets in light of the fundamental changes that electric power systems are undergoing, while account for the two decades of experience we have with restructured electricity markets. This includes increasing use of non-dispatchable, uncertain, and variable weather-dependent renewable energy, the use of distributed energy resources, and novel uses of electricity by end consumers.

1 - Wasserstein Distributional Robustness and Regularization in Statistical Learning

Rui Gao, Georgia Institute of Technology, 755 Ferst Drive NW, ISyE Main Building, Atlanta, GA, 30332-0205, United States, rgao32@gmail.com

A central problem in statistical learning is to design algorithms that not only perform well on training data, but also generalize to new and unseen data. In this paper, we tackle this problem by formulating a distributionally robust stochastic optimization problem, which minimizes the worst-case expected loss over a family of distributions that are close to the empirical distribution in Wasserstein distances. We establish a relation between such Wasserstein distributionally robust stochastic optimization and the gradient-norm regularization. In particular, we identify a broad class of loss functions, for which the worst-case expected loss is upper and lower bounded by some gradient-norm regularization problems. Moreover, we show that the gap between the upper and lower bounds is asymptotically zero with probability one. The relation between Wasserstein distributional robustness and regularization has the following important implications: (i) It provides new interpretations for problems involving regularization, including a great number of statistical learning problems, and several discrete choice models such as the multinomial logit. (ii) It enables a new method to derive generalization error bounds for statistical learning problems, by leveraging tools from distributionally robust optimization. For example, we derive an optimal generalization error bound for linear prediction with Lipschitz loss. (iii) It suggests a novel and systematic way to regularize problems in deep learning. As an example, we demonstrate superior performance on training generative adversarial networks (GANs) using our new regularization scheme.

2 - A Cluster Fusion Penalty for Grouping Response Variables in Multivariate Regression Models

Brad Price, West Virginia University, College of Business and Economics, P.O. Box 6025, Morgantown, WV, 26506, United States, brad.price@mail.wvu.edu

We propose a method for estimating coefficients in multivariate regression when there is a clustering structure to the response variables. The proposed method includes a fusion penalty, to shrink the difference in

fitted values from responses in the same cluster, and an L1 penalty for simultaneous variable selection and estimation. The method can be used when the grouping structure of the response variables is known or unknown. When the clustering structure is unknown the method will simultaneously estimate the clusters of the response and the regression coe cients. Theoretical results are presented for the penalized least squares case, including asymptotic results allowing for p n. We extend our method to the setting where the responses are binomial variables. A coordinate descent algorithm is proposed for both the normal and binomial likelihood, which can easily be extended to other glm settings. Simulations and data examples from business operations and genomics are presented to show the merits of both the least squares and binomial methods.

3 - Statistical Degradation Modeling and Prognostics of Multiple Sensor Signals via Data Fusion: A Composite Health Index Approach

Changyue Song, University of Wisconsin-Madison, Rm 3221, Mechanical Engineering Building, 1513 University Ave, Madison, WI, 53715, United States, csong39@wisc.edu

Nowadays multiple sensors have been widely used to monitor the degradation status of a unit simultaneously. As those sensor signals are often correlated and measure different characteristics of the same unit, effective fusion of such diverse "gene pool" is important to better understand the degradation process and produce more accurate prediction of the remaining useful life (RUL). This is a challenging task as the true degradation status cannot be directly observed, and the degradation process has to comply with the engineering principles governing the underlying failure mechanism. To address this issue, this article proposes a novel data fusion method that constructs a composite health index (HI) via the combination of multiple sensor signals for better characterizing the degradation process. In particular, we formulate this problem as an indirect supervised learning problem and leverage the quantile regression to derive the optimal fusion coefficient. In this way, the prognostic performance of the proposed method is theoretically guaranteed. To the best of our knowledge, this is the first paper that provides the theoretical analysis of the data fusion method for degradation modeling and prognostics. Simulation studies are conducted to evaluate the proposed method in different scenarios. A case study on the degradation of aircraft engines is also performed, which shows the superior performance of our method over the existing HI-based methods.

4 - Frequentist Consistency of Variational Bayes

Yixin Wang, Columbia University, New York, NY, United States, yixin.wang.sh@gmail.com

A key challenge for modern Bayesian statistics is how to perform scalable inference of posterior distributions. To address this challenge, variational Bayes (VB) methods have emerged as a popular alternative to the classical Markov chain Monte Carlo (MCMC) methods. VB methods tend to be faster while achieving comparable predictive performance. However, there are few theoretical results around!". In this paper, we establish frequentist consistency and asymptotic normality of VB methods. Specifically, we connect VB methods to point estimates based on variational approximations, called frequentist variational approximations, and we use the connection to prove a variational Bernstein-von-Mises theorem. The theorem leverages the theoretical characterizations of frequentist variational approximations to understand asymptotic properties of VB. In summary, we prove that (1) the VB posterior converges to the Kullback-Leibler (%&) minimizer of a normal distribution, centered at the truth and (2) the corresponding variational expectation of the parameter is consistent and asymptotically normal. As applications of the theorem, we derive asymptotic properties of VB posteriors in Bayesian mixture models, Bayesian generalized linear mixed models, and Bayesian stochastic block models. We conduct a simulation study to illustrate these theoretical results.

1 - A High Dimensional State Transition Development Framework for Deicing Activities at Dallas Fort Worth International Airport

Ashkan Aliabadi Farahani, University of Texas, Arlington, TX, United States, ashkan.aliabadifarahani@mavs.uta.edu

In complex systems, the system state is often high-dimensional and state transitions are unknown. When system data are available, it may be possible to empirically estimate state transitions to enable simulation and/or optimization of the system. This paper presents a data-driven framework for state transition estimation and development.

2 - TK-MARS: An Efficient Approach for Black-Box Optimization

Hadis Anahideh, University of Texas at Arlington, Arlington, TX, United States, hadis.anahideh@mavs.uta.edu, Jay Rosenberger, Hadis Anahideh

In this study, a modified version of MARS, TK-MARS (Tree Knot MARS), is developed to improve the use of MARS within the surrogate optimization context. TK-MARS is genuinely able to identify peaks and valleys where optimization needs to know. More importantly, due to the limitations of existing optimization test problems, a novel construction of representative surrogate-optimization test problems are presented to overcome the real world noisy black-box function with a set of important variables.

3 - Inverse Probability of Treatment Weighting in Adaptive Pain Management with Correlated Treatments

Nilabh Ohol, University of Texas-Arlington, 900 Greek Row Drive, Apt 201, Arlington, TX, 76013, United States, nilabh.ohol@mavs.uta.edu, Aera Kim LeBoulluec, Victoria C. P. Chen, Li Zeng, Jay Michael Rosenberger, Robert J.Gatchel

Interdisciplinary pain management combines biological and psychosocial factors causing patient's pain and administers best treatments. To improve pain outcomes, our framework employs state transition and outcome models using data from Eugene McDermott Center for Pain at the University of Texas Southwestern Medical Center at Dallas. The sequential treatment structure of the data leads to a form of endogeneity. This research develops a process based on the inverse probability of treatment weighted method to address endogeneity and presents a framework to develop a general approach for correlated treatments.

4 - Machine Learning Approaches to Modeling Category Sales: Implications for Optimal Store-level Pricing and Promotions

Durai Sundaramoorthi, Washington University in Saint Louis, 10352 Conway Road, Saint Louis, MO, 63131, United States, dsundaramoorthi@gmail.com, Seethu Seetharaman

We discuss and propose five machine learning models as candidate models of product category sales as functions of marketing variables (price, display, feature, price promotion), both within and across categories at the same retail store. Using store-level weekly scanner data from 24 product categories in each of 9 stores of a supermarket chain over a period of 5 years, we estimate the five proposed machine learning models and compare their empirical performance to those of three commonly used statistical models. Taking the overall best-performing machine learning, we optimize the profit made by the chain.

1 - Data-driven Modeling and Analysis of Urban Congestion Caused by Demand for Parking

Chase Patrick Dowling, PhD Student, University of Washington, Seattle, WA, 98105, United States, cdowling@uw.edu, Tanner Fiez, Lillian Ratliff, Baosen Zhang

Congestion caused by drivers searching for parking has been limited to theoretical modeling and empirical study; yet, pervasive installation of digital parking meters providing troves of data on parking transactions. These data can be used to estimate occupancy, but are not amenable to canonical theoretical models.We present a new model, amenable to transaction data, using a network of finite capacity queues. We estimate demand for parking across time and location and the subsequent volume of traffic generated. Combined with travel time data, the impact of this congestion can be estimated.

2 - A Data Driven Study on the Relation Between Parking Garage Occupancy and Traffic Speeds in Urban Areas

Rui Ma, University of California, Davis, 2041 Academic Surge, University of California, One Shields Avenue, Davis, CA, 95616, United States, drma@ucdavis.edu, Shenyang Chen, Michael Zhang

Theoretical studies have suggested that parking and traffic conditions in cities are related, yet few empirical studies are conducted to quantify this relationship. We develop a data processing procedure to extract and fuse the time-varying parking garage occupancy and traffic speed data at the street or city blocks levels via APIs, and study their relationship. It is found that during the morning and evening commute periods, the relationship between the average speed and the parking occupancy are distinct and both can be modeled by a reversed logistic function. Such a macroscopic relationship can be exploited to evaluate the effectiveness of downtown access control or congestion charging.

3 - A Spatial-temporal Flexible Parking Reservation System

Xin Wang, University of Wisconsin-Madison, 8916 Red Beryl Drive, Middleton, WI, 53562-4278, United States, xin.wang@wisc.edu, Xiaotian Wang

In a reservation-based parking system, customers departing late cause service failure for subsequent customers. To guarantee the service level, the parking system needs to run at a low utilization, which is a huge waste of parking resources, especially in congested urban area. We propose a flexible reservation system with spatial-temporal flexibility to address the issue. A game-theoretical model is used to capture the customers' utility over the flexibility.

Condition-Based Maintenance and Support Operations

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Chiel Van Oosterom, vanoosterom@ese.eur.nl

1 - Optimally Replacing Multiple Systems in a Shared Environment

David Tarek Abdul-Malak, University of Pittsburgh, 1702 Jancey Street, Pittsburgh, PA, 15206-1146, United States, dta10@pitt.edu, Jeffrey P. Kharoufeh

In this talk we will present a model for replacing multiple stochastically degrading systems using condition-based maintenance. Systems are assumed to degrade in a shared, exogenous, Markov modulated environment. Continuous state variables and a high dimensional state space cause the problem to be computationally intractable. To overcome these complications, structural results are proven and a novel reinforcement learning (RL) approach is employed.

2 - Maintenance Optimization for Partially Observable Multi-component Systems

Ayse Sena Eruguz, Postdoctoral Researcher, Eindhoven University of Technology, P.O. Box 513, Eindhoven, 5600 MB, Netherlands, a.s.eruguz@tue.nl, Rob Basten, Lisa M.Maillart

We consider a multi-component system in which a condition parameter (e.g., vibration or temperature) is monitored. The outcome of monitoring indicates whether the system is functioning properly, is defective, or has failed. However, the condition signal does not reveal which component in the system is defective or has failed. The decision maker needs to infer the exact state of the system from the current condition signal and the past data, in order to decide when to intervene for maintenance. We model this problem as a partially observable Markov decision process.

3 - Joint Planning of Multiaction Maintenance with Complex Effects

Yisha Xiang, Lamar University, 2626 Cherry Engineering Building, Beaumont, TX, United States, yxiang@lamar.edu, Yue Shi, David W. Coit

Existing maintenance literature mainly focus on a single type of preventive maintenance action (e.g., replacement) and often make simple assumptions regarding the effects of maintenance activities. Many important maintenance effects are overlooked in these models, for example, deterioration suppression after maintenance interventions, deterioration rate reduction under maintenance effect, and the random duration of the effective maintenance period. In this research, we consider joint planning for multiple maintenance actions with complex effects, and formulate the problem as Markovian decision process. Structural properties of optimal policies are investigated.

4 - Condition-based Repair Prioritization in Repairable Inventory Supply Chains

Chiel van Oosterom, Eindhoven University of Technology, PO Box 513, Eindhoven, 5600MB, Netherlands, c.d.v.oosterom@tue.nl, Joachim Jacob Arts, Geert-Jan Van Houtum

We propose a model for exploiting information collected via condition monitoring of components operating in the field to dynamically prioritize repairs in a capacitated repair shop. Specifically, we consider a repair shop that supports a serial system with a number of different repairable components, which all deteriorate over time according to continuous-time Markov chains. The system is down whenever a component fails and no ready-for-use spare part is available for that component. The objective in prioritizing repairs is to maximize the long-run availability of the system.

QSR Best Refereed Paper Competition

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Kaibo Wang, Tsinghua University, Beijing, 100084, China, kbwang@tsinghua.edu.cn

Co-Chair: Prahalada Rao, PhD, University of Nebraska-Lincoln, Lincoln, NE, 68588, United States, rao@unl.edu

1 - QSR Competition

Kaibo Wang, Tsinghua University, Department of Industrial Engineering, Beijing, 100084, China, kbwang@tsinghua.edu.cn

The QSR Best Paper Competition intends to promote outstanding research papers on the state-of-the-art methodological development and applications in the area of Quality, Reliability, Statistics, and Data Sciences. Four finalists will be selected to present their work in this session, and a winner will be identify by a panel.

2 - Effective Model Calibration via Sensible Variable Identification and Adjustment, with Application to Composite Fuselage Simulation

Yan Wang, Xiaowei Yue, Rui Tuo, Jeffrey H. Hunt and Jianjun Shi

We introduce a new concept of sensible variables for calibration and propose an effective calibration method to identify and adjust sensible variables with limited physical experimental data. With a skillful integration of engineering design knowledge, this method can overcome the curse of dimensionality in the calibration of composite fuselage computer model.

3 - An Integrated Manifold Learning Approach for Online Process Monitoring of Additive Manufacturing Processes

Chenang Liu, Grado Department of Industrial and Systems Engineering, Virginia Tech, Zhenyu (James) Kong

This paper is to implement a new online process monitoring method for additive manufacturing using online sensing data. To achieve this objective, an integrated manifold learning algorithm termed multi-kernel learning embedded isometric mapping (MKL-ISOMAP) is proposed. In the case studies, this method demonstrates excellent performance in data compression and prediction.

4 - Direct Learning to Rank and Rerank

Cynthia Rudin and Yining Wang

Learning-to-rank is directly relevant for predictive maintenance applications, where equipment needs to be prioritized for inspection or repair. This work exposes a serious problem with the state of learning-to-rank algorithms, which is that they are based on convex proxies that lead to poor approximations. We then discuss the possibility of "exact" reranking algorithms based on mathematical programming. We prove that that a relaxed version of the "exact" problem has the same optimal solution, and provide an empirical analysis.

5 - A Functional Covariate Degradation Model with Application to Degradation Analysis of Dual-phase Steel by Utilizing Its Microstructure Images

Wujun Si, Department of Industrial and Systems Engineering, Wayne State University, Detroit, MI 48202, USA Qingyu Yang, Xin Wu

As the first time, this article conducts degradation analysis utilizing material microstructure image information. A novel functional covariate degradation model is proposed. A penalized least squares estimation method is developed for model parameter estimation. Analytical inferences are developed. Both simulation studies and physical experiments are conducted for validation.

Environmental impacts and the Energy-water-Food Nexus

Sponsored: Energy, Natural Res & the Environment Environment & Sustainability

Sponsored Session

Chair: Daniel Huppmann, International Institute for Applied Systems Analysis (IIASA), International Institute for Applied Systems Analys, Vienna, n, Austria, huppmann@iiasa.ac.at

1 - Bridging the Resolution Gap to Improve the Assessment of Sustainable Development Pathways

Nils Johnson, Research Scholar, International Institute for Applied Systems Analysis, Laxenburg, Austria, johnsonn@iiasa.ac.at, Edward Byers

The broad scope of global energy-economic models has required a trade-off in terms of spatial and temporal resolution with most models employing 5-10 year temporal intervals and large, often continental-scale, regions. This coarse resolution poses a challenge for exploring how fine resolution phenomena, such as water constraints and climate change, may influence energy transitions. A novel nexus assessment platform is introduced that seeks to bridge this "resolution gap", enable linkages among global change models, and facilitate interdisciplinary research to better understand how land-energy-water interactions influence sustainable development pathways.

2 - Linking Electricity Production Cost Models with Climate and Hydrological Models: Lessons Learned from Multiple Approaches and Scenarios

Jordan Macknick, National Renewable Energy Laboratory, Golden, CO, United States, Jordan.Macknick@nrel.gov, Gregory Brinkman, Matthew O'Connell

Water availability and temperature can affect thermal power plants' heat rate, capacity, and ability to operate, due to physical- and policy-related constraints. The degree to which a generator is affected by water is determined by its fuel, prime mover, and cooling system type. Here we link an electricity production cost model with different climate and hydrologic models to examine how water resource characteristics can affect power system costs and performance characteristics, as well as sensitivities from different scenarios of water availability and temperature. The Eastern Interconnection and Western Interconnection are modeled under alternative infrastructure and climate scenarios.

3 - National and Regional Implications of Water Resource Variability and Climate Change on the Evolution of the United States Power Sector

Stuart Cohen, National Renewable Energy Laboratory, Golden, CO, United States, Stuart.Cohen@nrel.gov

Water resource variability can influence U.S. power sector evolution, including technology selection, siting, and system operation. In addition, temperature rise due to climate change can affect seasonal loads, generator efficiency, and transmission capacity. We use the Regional Energy Deployment System (ReEDS) electric sector capacity expansion model of the United States to explore how myriad climate and policy scenarios could affect the structure and operations of the U.S. power sector, from present day to 2050. We explore electric sector capacity and generation along with environmental and economic impacts.

4 - Energy-water-land Nexus: An Integrated Assessment Modeling Perspective

Mohamad I. Hejazi, PNNL/JGCRI, College Park, MD, United States, mohamad.hejazi@pnnl.gov

Energy, water, and land systems are increasingly interconnected. In this study, we use the Global Change Assessment Model (GCAM), where interactions between population, economic growth, energy, land and water resources interact simultaneously in a dynamically evolving system, to investigate: 1) how water scarcity affects energy and land use decisions; 2) the effects of climate impacts; 3) how these impacts evolve under different policies in the context of the shared socioeconomic pathways; 4) the effects of different adaptation measures and their associate investment costs; and 4) the relative contributions of climate and human systems on water scarcity regionally and globally.

5 - Regional SDG Implications of the Energy-water-land Nexus

Daniel Huppmann, International Institute for Applied Systems Analysis (IIASA), Matthaeusgasse 8, Vienna, Austria, huppmann@iiasa.ac.at

We discuss regional impacts of the energy-water-land nexus on the Sustainable Development Goals using the MESSAGE Integrated Assessment Model.

Big Data

Contributed Session

Chair: Xinbo Geng, Texas A&M University, College Station, TX, United States, gengxbtamu@email.tamu.edu

1 - Internet of Things, Big Data, and New Business Models: A Literature Review

Régis Delafenestre, Professor, SKEMA Business School, Av. Willy Brandt, Lille, 59777, France, regis.delafenestre@skema.edu, Xavier Brusset

With the advent of Big Data and the Internet of Things, e-commerce supply chains require substantial upheavals to remain competitive. New business models will be invented to take advantage of the enormous flow of consumer and Internet of Things data. These business models will remodel supply chains into demand chains which generate the possibility of inventing new ways of creating value for consumers. As a first step, we present the result of a systematic literature review and qualitative content analysis. We leverage the existing knowledge on big data and business models to identify the dimensions of demand-supply alignment and map the drivers, enablers necessary to invent such business models.

2 - An Empirical Study on Workload and Service Lead Times in the Aviation Maintenance Repair Overhaul Industry

Busra Keles, University of Miami, 1251 Memorial Drive, Coral Gables, FL, 33146, United States, bkeles@miami.edu, Murat Erkoc, Nazrul Islam Shaikh

Maintenance-Repair-Overhaul (MRO) service industries are constantly subject to internal and external factors that result in unsteady workload such as, unanticipated and/or irregular complex tasks, unexpected customer requirements, supplier related delays, and resource variations. To predict service time of an upcoming order and negotiate due dates, one should consider the current and future workload that capture complex scheduling, planning, queuing, and costing parameters through processing big data. For this purpose, we develop a model to identify the factors that influence workload and capture their mappings to service performance, capacity requirements, and budget.

3 - Understanding Patients' Purchasing Decisions for Online Healthcare Services an Empirical Study Considering Text Form Interaction Data

Tong Liu, Phd Candidate, Shanghai Jiao Tong University, No 1954 , Hua Shan Road, Xu Hui District, Shanghai, 200030, China, liutong3231@163.com

Now it is of great value to take a look at how patients make purchase decisions for online healthcare services. Some platforms allow patients to interact with physicians in several free chances before they make an order for a paid remote service, so we want to test whether the interaction information contained in those free trails will influence patients' purchasing decision. We use Bayesian updating process to describe the formulation of patients' perceived choice utility when they received the feedbacks from the physicians during interaction, where the prior beliefs come from static information contained on webpages and the updating samples are extracted through text mining methods.

4 - Real-time Segmentation of Consumers for Optimized Targeting

Chandra Devarkonda, Executive Consultant, IBM, Potomac, MD, United States, chandra.devarkonda@us.ibm.com

This paper addresses the issues of providing insightful guidance to retail customer-facing agents be it machine agents (bots) or human agents using data captured in near real time. It considers inherent human decision biases because of brand perceptions, recent buying behavior and influence of networks in buying decisions. Additionally, the solution demonstrates how to capture, ingest, process consumer information almost as it happens and use the outputs to update the understanding of value the consumer brings to the firm. The resulting output demonstrates classification of customers that incorporate both transactional value as well as social value.

5 - A Hybrid Algorithm for Bayesian Network Structure Learning Based on Wrapper Approach

Yi Luo, University of Michigan, 3585 Green Brier Blvd., Apt. 95B, Ann Arbor, MI, 48105, United States, Luo1@email.arizona.edu, Daniel L.McShan, Randall K.Ten Haken, Issam El Naqa

Bayesian Network (BN) allows for understanding hierarchical relationship between variables and predicting outcome, and it also achieves competitive performance compared to other statistical learning methods. But learning the structure of BNs without restrictive assumption is NP-hard. We developed a novel hybrid learning algorithm to seek stable BNs structures from high dimensional dataset based on wrapper method, and it was used to explore biophysical relationship behind radiotherapy outcome. In addition to having a high prediction performance based on the cross validation, our method can be easily extended to build multi-objective dynamic BNs for personalized adaptive decision support.

6 - Learning the LMP-load Coupling from Data: A Support Vector Machine Based Approach

Xinbo Geng, Texas A&M.University, 053E Wisenbaker Building, College Station, TX, 77840, United States, gengxbtamu@email.tamu.edu, Le Xie

We investigate the fundamental coupling between loads and locational marginal prices (LMPs) in security-constrained economic dispatch (SCED). Theoretical analysis based on multi-parametric programming theory points out the unique one-to-one mapping between load and LMP vectors. Such mapping is depicted by the concept of system pattern region (SPR) and identifying SPRs is the key to understanding the LMP-load coupling. The SPR identification problem is modeled as a classification problem and a SVM based data-driven approach is proposed. It is shown that even without the knowledge of system topology and parameters, the SPRs can be estimated by learning from historical load and price data.

Recent Progress in Global Optimization

Sponsored: Optimization, Global Optimization

Sponsored Session

Chair: Guanglin Xu, University of Iowa, Iowa City, IA, 52242, United States, guanglin-xu@uiowa.edu

1 - A Data-driven Distributionally Robust Bound on the Expected Optimal Value of Uncertain Mixed 0-1 Linear Programming

Guanglin Xu, The University of Iowa, 108 Pappajohn Business Building, Iowa City, IA, 52242, United States, guanglin-xu@uiowa.edu

We study the expected optimal value of a mixed 0-1 linear program with uncertain objective coefficients following a joint distribution. We assume that the true distribution is not known exactly, but a set of independent samples can be observed. Using the Wasserstein metric, we construct an ambiguity set centered at the empirical distribution from the observed samples. The problem of interest is to investigate the bound on the expected optimal value over the Wasserstein ambiguity set. We compare our approach with a moment-based approach from the literature for two applications. Numerical results illustrate the effectiveness of our approach.

2 - Semidefinite Programming for Nash Equilibria in Bimatrix Games

Jeffrey Zhang, Princeton University, 206 Lakeside Road, Princeton, NJ, 08540, United States, jeffz@princeton.edu, Amir Ali Ahmadi

We are interested in exploring the power of SDP relaxations for the problem of finding an additive -approximate Nash equilibrium for bimatrix games. We show that for zero-sum games our SDP is guaranteed to return a rank-1 solution. Furthermore, we prove that if a rank-2 to our SDP solution is found, then a 5/11-NE can be recovered for any game, or a 1/3-NE for a symmetric game. We propose algorithms based on iterative linearization procedure of smooth nonconvex objective functions which empirically often recover solutions of rank at most two and close to zero. We then show how our SDP approach can address two (NP-hard) problems of economic interest. Finally, we relate our SDP to the Lasserre hierarchy.

3 - Globally Solving Non-convex Quadratic Programs via Linear Integer Programming Techniques

Wei Xia, Lehigh University, Bethlehem, PA, 18015, United States, wex213@lehigh.edu, Juan Vera, Luis F.Zuluaga

A quadratic program (QP) is a well-studied fundamental NP-hard optimization problem which optimizes a quadratic objective over a set of linear constraints. We reformulate QP as a mixed-integer linear problem (MILP). This is done via the reformulation of QP as a linear complementary problem, and the use of binary variables together with some fundamental results on the solution of perturbed linear systems, to model the complementary constraints. Reformulating non-convex QPs as MILPs provides an advantageous way to obtain global solutions. To illustrate, we compare the performance of our solution approach with the current benchmark global QP solver quadprogBB on a large variety of QP test instances.

4 - Rank Minimization Problem

Xin Shen, Rensselaer Polytechnic Institute, 2000 6th Avenue, Apt A801, Troy, NY, 12180, United States, shenxinhust@gmail.com, John E.Mitchell

The problem of minimizing the rank of a matrix subject to constraints can be formulated equivalently as a semidefinite programwith complementarity constraints (SDCMPCC). We investigate calmness of locally optimal solutions to the SDCMPCC formulation and hence show that any locally optimal solution is a KKT point, under an assumption on the original set of constraints. We develop a penalty formulation of the problem. We present calmness results for locally optimal solutions to the penalty formulation. We also develop a proximal alternating linearized minimization (PALM) scheme for the penalty formulation, and investigate the incorporation of a momentum term into the algorithm.

Mechanism Design and Network Pricing

Sponsored: Optimization, Network Optimization

Sponsored Session

Chair: Evdokia Velinova Nikolova, University of Texas at Austin, 400 E Monroe Street, Austin, TX, 78704, United States, nikolova2009@gmail.com

1 - Aversion to Uncertainty and its Implications for Revenue Maximization

Emmanouil Pountourakis, University of Texas at Austin, 16 Bristol Street, Unit 3, Cambridge, MA, 02141, United States, malgor21@gmail.com

Mechanism design often assumes that buyers are risk neutral, or exhibit risk aversion due to a non-linear utility for money. Yet behavioral studies show that real agents exhibit various risk attitudes, which, cannot be captured by any expected utility model. We adopt a model from prospect theory, where an event which occurs with probability x<1 is worth strictly less than x times the value of the event when it occurs with certainty. We characterize optimal mechanisms in the static setting as menus of binary lotteries and we show that under a reasonable assumption, posted pricing obtains a constant approximation. Third, we show that constant approximation is impossible in dynamic settings.

2 - Pricing: How to Induce Optimal Flows under Strategic Link Operators

Thanasis Lianeas, Univeristy of Texas at Austin, Austin, TX, 78704, United States, tlianeas@mail.ntua.gr, Evdokia Velinova Nikolova

Our main result is to observe that a slight regulation on the network owners market solves all three issues above. Specifically, if the authority could set appropriate caps (upper bounds) on the tolls (prices) operators can charge then: the game among the link operators has a unique strong Nash equilibrium and the users' game results in a Wardrop equilibrium that achieves the optimal total delay. We call any price vector with these properties a great set of tolls. We then ask, can we compute great tolls that minimize total users' payments? We show that this optimization problem reduces to a linear program in the case of single-commodity series-parallel networks. Starting from the same linear program, we obtain multiplicative approximation results for arbitrary networks with polynomial latencies of bounded degree, while in the single-commodity case we obtain a surprising bound, which only depends on the topology of the network.

3 - Bifurcation Mechanism Design – From Optimal Flat Taxes to Improved Cancer Treatments

Ger Yang, University of Texas at Austin, Austin, TX, United States, geryang@utexas.edu, Georgios Piliouras, David Basanta

Small changes to the parameters of a system can lead to abrupt qualitative changes of its behavior, a phenomenon known as bifurcation. Such instabilities are typically considered problematic, however, we show that their power can be leveraged to design novel types of mechanisms. Hysteresis mechanisms use transient changes of system parameters to induce a permanent improvement to its performance via optimal equilibrium selection. Optimal control mechanisms induce convergence to states whose performance is better than even the best equilibrium. We apply these mechanisms in two different settings that illustrate the versatility of bifurcation mechanism design. In the first one we explore how introducing flat taxation can improve social welfare, despite decreasing agent "rationality", by destabilizing inefficient equilibria. From there we move on to consider a well known game of tumor metabolism and use our approach to derive novel cancer treatment strategies.

Using Deep Neural Networks for Solving Combinatorial Optimization Problems

Sponsored: Computing

Sponsored Session

Chair: Mohammadreza Nazari, Lehigh University, Bethlehem, PA, 18015, United States, mon314@lehigh.edu

Co-Chair: Afshin OroojlooyJadid, Lehigh University, Bethlehem, PA, 18015, United States, afo214@lehigh.edu

1 - Neural Combinatorial Optimization with Reinforcement Learning

Irwan Bello, Google Brain, Mountain View, CA, United States, ibello@google.com

We present a framework to tackle combinatorial optimization problems using neural networks and reinforcement learning. We focus on the traveling salesman problem (TSP) and train a recurrent neural network that predicts a distribution over city permutations. Using negative tour length as the reward signal, we optimize the parameters of the recurrent neural network using a policy gradient method. With minimal engineering and without heuristic designing, Neural Combinatorial Optimization achieves close to optimal results on 2D Euclidean graphs with up to 100 nodes. Applied to the KnapSack, another NP-hard problem, the same method obtains optimal solutions for instances with up to 200 items.

2 - Learning Combinatorial Optimization Algorithms over Graphs

Le Song, Georgia Institute of Technology, 266 Ferst Drive, Atlanta, GA, 30332, United States, lsong@cc.gatech.edu, Hanjun Dai, Elias B. Khalil, Yuyu Zhang, Bistra Dilkina

Significant expertise is required to design good heuristics for hard graph optimization problems. In many applications, it is typically the case that the same optimization model is solved again and again on a regular basis, maintaining the same problem structure but differing in the data. This provides an opportunity for learning heuristics that exploit the structure of such recurring problems. We propose a unique combination of reinforcement learning and graph embedding to address this challenge, and demonstrate competitive performance for Minimum Vertex Cover, Max Cut, TSP and Set Covering.

3 - Controlling Stochastic VRP Systems by using Deep Reinforcement Learning

Mohammadreza Nazari, Lehigh University, Murray H.Goodman Campus, Bethlehem, PA, 18015, United States, mon314@lehigh.edu, Afshin Oroojlooy Jadid, Lawrence V. Snyder, Martin Takac

We present a deep learning scheme for the VRP problem with stochastic demands. Demands arrive randomly at different locations, and at each time step a vehicle chooses its next destination according to a policy learned by deep reinforcement learning in order to maximize its reward over a time horizon. This problem has applications in distribution networks and real-time taxi allotment and has been widely studied in the stochastic optimization, but most studies assume that the demand distribution is known. A major complexity arises when the demands are non-stationary or from an unknown distribution. In this talk, we address this issue by using deep recurrent Q-networks.

4 - Financial Evaluation of Large Cap Companies on the Stock Market; Artificial Neural Networks Approach to Stock Picking

Alireza Moghimi, New Mexico State University, 1132 E.Mesa Apt.15, Las Cruces, NM, 88001, United States, moghimi@nmsu.edu

The current research proposes an Artificial Neural Network based forecasting model to evaluate the relative financial performance of a group of firms. The model employs company's historical financial data and classifies firms based on their future financial performance. The study attempts to generate portfolios that could outperform the market and shift the distribution of the returns earned by an investor. The model employs the financial statements of the companies on S&P-500 index for 2006 to 2014 period. A portfolio based on the proposed model is compared to several benchmarks by bootstrapping and statistical analysis. The model is significantly outperforming the market.

1 - Upper and Lower Bounding Procedures for Snow Plow Optimization

Joris Kinable, Carnegie Mellon University, 5000 Forbes Avenue, Pittsburgh, PA, 15213, United States, jkinable@cs.cmu.edu, Willem-Jan Van Hoeve, Stephen F.Smith

Snow plow optimization is a complex process in which routes for a fleet of vehicles have to be determined, while adhering to vehicle operating restrictions, and resource utilization and replenishment constraints. We present upper and lower bounding techniques for a real-world snow plow optimization problem. Feasible routes and schedules are calculated using heuristics and a Constraint Programming approach. To study the quality of our solutions, a bounding procedure is developed based on a Mixed Integer Programming model for Capacitated Arc Routing with Intermediate Replenishment Facilities. Computational experiments are conducted on data from the city of Pittsburgh (USA).

2 - Consistency vs. Flexibility in Multi Objective Vehicle Routing Problems

Mohsen Emadikhiav, University of Connecticut, Storrs, CT, United States, Mohsen.Emadikhiav@business.uconn.edu, David Bergman, David Bergman, Robert Day

In this talk, we discuss a branch-and-price algorithm for a multi-objective consistent VRP with simultaneous pickups and deliveries, and analyze the tradeoffs between several classical VRP objectives. Our experimental results indicate that for short-term planning, enforcing consistency only marginally affects other objectives, but for real-time planning, particularly when there is high variability in order release times, enforcing consistency can significantly impact other objectives.

3 - A Branch-and-price Algorithm for a Vehicle Routing-allocation Problem

Mohammad Reihaneh, University of Massachusetts, 277 Riverglade Dr, Apt 2, Amherst, MA, 01002, United States, mo.reihaneh@gmail.com, Ahmed Ghoniem

We investigate a vehicle routing-allocation problem (VRAP) where the decision-maker jointly optimizes the location of delivery sites, the assignment of customers to (preferably convenient) delivery sites, and the routing of vehicles operated from a central depot to serve customers at their designated sites. We propose an effective dynamic programming-based branch-and-price (B&P) algorithm that is demonstrated to greatly outperform the use of commercial branch-and-bound/cut solvers such as CPLEX. Our computational study demonstrates the efficacy of the proposed approach using a test-bed of 60 challenging problem instances.

4 - Vehicle Routing with Drones

Amro El-Adle, Isenberg School of Management, UMass-Amherst, Amherst, MA, United States, aeladle@umass.edu, Ahmed Ghoniem, Mohamed Haouari

We investigate a vehicle routing problem with drones in which customers may be served either by the vehicle or by a portable drone that is launched from the vehicle. A key consideration in this setting is to synchronize vehicle and drone operations. Models and optimization approaches are presented, along with a computational study.

Chair: Ermin Wei, Northwestern University, Evanston, IL, 60208, United States, ermin.wei@northwestern.edu

1 - Asynchronous Distributed Newton Method

Ermin Wei, Northwestern University, 2145 Sheridan Rd, Tech L310, Evanston, IL, 60208, United States, ermin.wei@northwestern.edu

The problem of minimizing a sum of local convex objective functions over a networked system captures many important applications and has received much attention in the distributed optimization field. Most of existing work focuses on development of distributed algorithms under the presence of a central clock. The only known algorithms with convergence guarantees in asynchronous setup could achieve linear rate. In this work, we built upon existing literature to develop and analyze an asynchronous Newton method. We show that this algorithm converges almost surely and has superlinear rate in expectation. Numerical studies confirm superior performance against other existing asynchronous methods.

2 - Object-parallel Augmented Lagrangian Solution of Continuous Stochastic Programs

Gyorgy Matyasfalvi, Rutgers University, 100 Rockafeller Road, Piscataway, NJ, 08854, United States, matyasfalvi@gmail.com, Jonathan Eckstein

We describe an "object-parallel' C++ approach to implementing iterative optimization methods, with the goal of coding the algorithms in a readable, MATLAB-like style, but with efficient parallel implementation of underlying low-level linear algebra operations. Recent advances in augmented Lagrangian algorithms and mathematical modeling environments, combined with our "object-parallel' software development techniques suggest efficiently scalable solver implementations for stochastic programming problems, without employing decomposition methods.

3 - Accelerated Distributed Nesterov Gradient Descent

Guannan Qu, Harvard University, Cambridge, MA, 02138, United States, guannan.q@gmail.com, Na Li

This paper considers the distributed optimization problem over a network, where the objective is to optimize a global function formed by a sum of local functions. We develop an Accelerated Distributed Nesterov Gradient Descent (Acc-DNGD) method. When the objective function is convex and smooth, we show that it achieves a $O(\frac{1}{t^{1.4-\epsilon}})$ convergence rate for all $\epsilon\in(0,1.4)$. We also show the convergence rate can be improved to $O(\frac{1}{t^2})$ if the objective function belongs to a special class. When the objective function is μ-strongly convex and L-smooth, we show that it achieves a linear convergence rate of $O([1 - O((\frac{\mu}{L})^{5/7})]^t)$.

4 - Variable Partitioning for Distributed Optimization

Richard Zheng, PhD Student, Georgia Institute of Technology, 6228 Mount Vernon Oaks Dr, Atlanta, GA, United States, richardzyc@gatech.edu

Solving a large-scale optimization problem sequentially can be computational challenging. We focus on one of the most popular distributed approaches, dual decomposition and distributed sub-gradient methods. We explain that a partition of variables can critically affect the speed of convergence and highlight the importance of the number of dualized constraints. Then, we introduce a novel approach to find a partition that reduces the number of dualized constraints by utilizing a community detection algorithm from physics literature. Empirical experiments on a real application show that the proposed method significantly accelerates the convergence of the distributed sub-gradient method.

Advances in Integer Programming

Sponsored: Optimization, Integer and Discrete Optimization

Sponsored Session

Chair: Akshay Gupte, Clemson University, Clemson University, Clemson, SC, 29634-0975, United States, agupte@clemson.edu

1 - Optimal Group Cuts

Amitabh Basu, Johns Hopkins University, Department of Applied Mathematics and Statist, 100 Whitehead Hall, Baltimore, MD, 21218, United States, basu.amitabh@jhu.edu, Michele Conforti, Marco Di Summa

We investigate natural measures of the quality of cutting planes such as depth of cut, volume cut off, and the so-called "merit index" introduced by Gomory and Johnson. We find the optimal cutting planes according to these measures for the infinite and finite group relaxations introduced by Gomory-Johnson. Interestingly, when the volume cut off is used as the measure, the optimal cuts turn out to be automorphisms of the well-known Gomory mixed-integer cut. The proofs uncover interesting connections with rearrangement inequalities in functional analysis and generalizations of the Brunn-Minkowski theorem to topological groups.

2 - Small and Strong Formulations for Unions of Convex Sets from the Cayley Embedding

Juan Pablo Vielma, Massachusetts Institute of Technology, 77 Massachusetts Avenue, E62-561, Cambridge, MA, 02139, United States, jvielma@mit.edu

There is often a significant trade-off between formulation strength and size in mixed integer programming. When modelling convex disjunctive constraints (e.g. unions of convex sets) this trade-off can be resolved by adding auxiliary continuous variables. However, adding these variables can result in a deterioration of the computational effectiveness of the formulation. We introduce a technique to construct formulations without these detrimental continuous auxiliary variables. We then show it can recover and generalize all known strong formulations without continuous auxiliary variables.

3 - Nonconvex Piecewise Linear Functions: Advanced Formulations and Simple Modeling Tools

Joseph A.Huchette, MIT, 77 Massachusetts Avenue, Cambridge, MA, 02139, United States, huchette@mit.edu

Piecewise linear functions are a central modeling primitive throughout optimization. In this work, we present novel mixed-integer programming (MIP) formulations for (nonconvex) piecewise linear functions. Leveraging recent advances in the systematic construction of MIP formulations for disjunctive sets, we derive new formulations for univariate functions using a geometric approach, and for bivariate functions using a combinatorial approach. All formulations derived are small (logarithmic in the number of piecewise segments of the function domain) and strong, and we present extensive computational experiments in which they offer substantial computational performance gains over existing approaches.

4 - Approximating Integer Programs using the Lexicographic Order

Akshay Gupte, Clemson University, Clemson University, Clemson, SC, United States, agupte@clemson.edu, Michael Eldredge

The convex hull of integer points in a box that are bounded lexicographically above or below a threshold have a useful polyhedral structure. We attempt to solve integer optimization problems over a polytope by enforcing a split in the lexicographical order of the integer points in the polytope. We compare the cuts generated by this disjunction with cuts generated by elementary disjunctions. Here, we present our results.

11:00 - 11:45 GAMS/ 11:45 - 12:30 Optimization Direct, Inc.

Invited: Vendor Tutorial

Invited Session

1 - GAMS - An Introduction

Steven P. Dirkse, GAMS.Development Corporation, DC, WA, United States, sdirkse@gams.com

We'll introduce the key concepts of the GAMS language (e.g. sets, data, variables, equations) as we show how to build an optimization-based decision support application. Along the way, we'll show how GAMS supports an easy growth path to larger and more sophisticated models and provides access to the most powerful large-scale solver packages. We will also look at some of the data management tools included in the GAMS system and show how to analyze and debug large problems using the various tools available within GAMS. Finally, we'll show how our latest release supports integrating GAMS with object-oriented programming languages like C#, Python, and Java.

2 - DSx and CPLEX: Overview of Datascience Experience for Advanced Modeling and Optimization and LatestDevelopments/Results in CPLEX and ODh+CPLEX

Alkis Vazacopoulos, Optimization Direct, Inc., 202 Parkway, Harrington Park, NJ, 07640, United States, alkis@optimizationdirect.com

Organizations are increasingly hiring Data Scientists with Open Source skills. Leverage the capabilities of Data Science Experience DSx to work with Open Source tools like R, Python, Spark, as well as integration with CPLEX and Weather Company data. Come learn how DSx integrates with Open Source tools to enable clients to get the best of both worlds (Open Source programming and the Modeler GUI for those who prefer not to code). Furthermore we will review the latest developments/results in CPLEX Optimization Studio and the new ODh+CPLEX.

Addressing Variability and Uncertainty in Power Systems Operations with Alternative Approaches

Sponsored: Energy, Natural Res & the Environment Electricity

Sponsored Session

Chair: Alberto J. Lamadrid, Lehigh University, Bethlehem, PA, 18015-3120, United States, ajl259@cornell.edu

1 - The Role of Stochastic Optimization in the Electric Power Sector

Kory W. Hedman, Arizona State University, P.O. Box 875706, GWC206 School Of ECEE, Tempe, AZ, 85287-5706, United States, kwh@myuw.net

The electric power sector is seeing an increase in stochastic resources, in the form of non-dispatchable or semi-dispatchable renewable resources as well as distributed energy resources. This talk will begin with a discussion on existing industry practices to manage uncertainty and recently proposed changes within the electric power sector. The presentation will cover how stochastic optimization techniques are already being used to help manage uncertainties and the presentation will cover how recent advanced in two-stage stochastic programming can further assist the electric power sector in the management of stochastic resources.

2 - Evaluating Electric Power Systems

Miguel Ortega-Vazquez, Electric Power Research Institute, 3420 Hillview Avenue, Palo Alto, CA, 94304, United States, mortegavazquez@epri.com, Erik Ela

This presentation will provide an update on research evaluating electric power system operating reserve methods and their comparison with advanced optimization methods for improved reliability and economic efficiency.

3 - Dynamic Electric Vehicle Travel Management in Coupled Power and Transportation Networks

Hao Zhu, University of Illinois Urbana-Champaign, 306 N.Wright Street, 4056 ECE Building, Urbana, IL, 61801, United States, haozhu@illinois.edu

This talk presents a framework to integrate the variable loads due to the changing of electrical vehicles into the operations of power systems.

4 - Multi-stage and Multi-timescale Robust Co-optimization Planning for Reliable and Sustainable Power Systems

Lei Wu, Clarkson University, 8 Clarkson Avenue, P.O. Box 5720, Potsdam, NY, 13676, United States, lwu@clarkson.edu, Bo Zeng

We will develop a decision-support tool Multi-stage and Multi-timescale robust Co-Optimization Planning (MMCOP) that augments existing power utility capabilities to support collaborative planning, analysis, and implementation of emerging variable and distributed power systems and help effectively mitigate risks and uncertainties in both short-term operation and long-term policy/technology changes. This tool will assist power market participants, utilities and regulatory agencies in analyzing economic, reliability, and sustainability issues when considering options for planning new and upgraded transmission facilities to accommodate existing and emerging generation sources.

Bayesian Approach

Contributed Session

Chair: Thomas G. Yeung, IMT-Atlantique, Nantes, France

1 - Valuing Demand Sample Information Prior to its Collection

Adam Jason Fleischhacker, Associate Professor of Operations Management, University of Delaware, 222 Alfred Lerner Hall, Newark, DE, 19716, United States, ajf@udel.edu, Pak-Wing Fok, Mokshay Madiman

We present both closed-form and computational approaches to valuing sample information prior to its collection. In particular, we look at the value of collecting demand data and its relationship to improving forecasts. Closed form approaches extend the existing literature on preposterior analysis and computational approaches leverage the probabilistic programming language Stan.

2 - Tuning a Bayesian Framework for B2b Pricing

Fang Liang, SAS.Institute, Inc., 100 SAS.Campus Drive, Cary, NC, 27513, United States, fang.liang@sas.com, Maarten Oosten

As in many other B2B markets, rail cargo companies negotiate prices with customers in the form of special agreements that are renewed on a regular basis. We propose a framework for optimizing the agreement prices that includes assessment of existing agreements, estimating the relationship between prices and performance of the agreements, leveraging this relationship to optimize agreement under various scenarios, and utilizing the scenario analysis to support negotiation. This approach needs to respond to changes in the business environment by learning quickly from the latest relevant observations. Bayesian approach is applied to accomplish this and the sensitivity of this approach is tuned.

3 - Evidential Reasoning Rule for Probabilistic Inference & Machine Learning with Ambiguous Data

Dong-Ling Xu, Professor, Manchester University, Manchester Business School, F37 MBS.East, Manchester, M13 9SS, United Kingdom, L.Xu@Manchester.ac.uk, jian-bo yang

The Evidential Reasoning (ER) rule extends Bayes rule for inference with ambiguous data, unknown prior & data with various degrees of reliability. We explain its relationship with Bayes rule & Dempster rule for evidence combination, what assumptions are behind each rule & where the extensions are. We show how to obtain evidence from data (big or small) with ambiguity so that the inference using the ER rule constitutes a maximum likelihood probabilistic inference process, & how to use it in machine learning to build transparent models with maximum likelihood predictions.

4- Representing Markov Process as Dynamic Copula Bayesian Networks

Thomas G.Yeung, Associate Professor, IMT-Atlantique, 4 rue Alfred Kastler BP.20722, La Chantrerie, Nantes, 44307, France, thomas.yeung@imt-atlantique.fr, Alex Kosgodagan-Dalle Torre

In multivariate/high-dimensional statistics, recent attractive approaches include copula-based graphical models such as pair-copula Bayesian networks. Their attractiveness is largely due to the flexibility of copulae to capture dependence. However, very little attention has been given for these models to fit within a full probabilistic framework and for which inference could be performed efficiently. We prove that any k-th order Markov process can be represented as a dynamic pair copula-based Bayesian network. We also show the requirements in order to perform analytical conditioning. We motivate this work through a bridge degradation application and an example focused on Brownian motion.

Recent Advances in AC Optimal Power Flow

Sponsored: Energy, Natural Res & the Environment Electricity

Sponsored Session

Chair: Andy Sun, Georgia Institute of Technology, Atlanta, GA, 30312, United States, andy.sun@isye.gatech.edu

1 - Optimal Power Flow of Radial Networks and its Variations: A Sequential Convex Optimization Approach

Na Li, Harvard University, 33 Oxford St, Cambridge, MA, 02138, United States, nali@seas.harvard.edu, Wei Wei, Jianhui Wang, Shengwei Mei

A sequential convex optimization method is proposed to solve broader classes of optimal power flow (OPF) problems over radial networks. The non-convex branch power flow equation is decomposed as a second-order cone inequality and a non-convex constraint involving the difference of two convex functions. This approach solves a sequence of convexified penalization problems, where concave terms are approximated by linear functions and updated in each iteration. It could recover a feasible power flow solution, which usually appears to be very close, if not equal, to the global optimal one. Two variations of the OPF problem whose convex relaxation is generally inexact, are elaborated in detail.

2 - Characterizing Non-convexities in the Feasible Spaces of AC OPF Problems

Daniel K.Molzahn, Argonne National Laboratory, 1111 S. Wabash Ave., Apt 1507, Chicago, IL, 60605, United States, dan.molzahn@gmail.com

Optimal power flow (OPF) is one of the key power system optimization problems. OPF problems that use an AC power flow model can have non-convex feasible spaces. As part of an effort to characterize the difficulty associated with solving different AC OPF problems, this presentation discusses approaches for identifying non-convexities in AC OPF feasible spaces. These approaches include a method for computing the entire feasible space for small AC OPF problems and an algorithm for identifying pairs of points which certify the existence of a non-convex region of the feasible space.

3 - Some Techniques for Strengthening the SOCP Relaxations for Solving AC OPF

Andy Sun, Georgia Institute of Technology, 755 Ferst Drive, Atlanta, GA, 30312, United States, andy.sun@isye.gatech.edu

In this talk, we will discuss some techniques to strengthen the SOCP relaxations of ACOPF both single-phase and multi-phase, including minor reformulation of rank one constraints, bound tightening, and some linear transformation techniques.

4 - Convex Relaxation of Optimal Power Flow in Multiphase Radial Networks with Delta Connections

Changhong Zhao, National Renewable Energy Laboratory, 15013 Denver West Pkwy, Golden, CO, 80401, United States, changhong.zhao@nrel.gov, Emiliano Dall'Anese, Steven Low

We proposes a semidefinite relaxation of the AC optimal power flow (OPF) problem in multiphase radial networks with wye and delta connections. Two multiphase power flow models are developed to facilitate the integration of delta-connected loads or generation resources in the OPF problem. The first model is called the extended branch flow model. The second model leverages a linear relationship between phase-to-ground power injections and delta connections under a balanced voltage approximation. Based on these models, pertinent OPF problems are formulated and relaxed to semidefinite programs. Numerical studies on IEEE test feeders show efficiency and exactness of the proposed relaxations.

1 - Simulation-based Optimization Models for Electricity Generation Expansion Planning Problems Considering Human Health Externalities

Mark Rodgers, PhD, Rutgers University, Newark, NJ, United States, markrodgersphd@gmail.com

Generation expansion planning models determine capacity investment decisions that minimize market costs. Such models are often dominated with fossil fuel investments. While they are economical sources of electricity, fossil fuels create by-products that have harmful health effects. To mitigate this, we leverage an EPA screening tool along with simulation methods to create a closed-form relationship between expansion decisions and health damages to be included in the objective function of the expansion planning model. This yields minimized societal costs and health damages from emissions in the electricity sector.

2 - Microgrid Formation Approach for Resilient Electricity Networks

Alberto J. Lamadrid, Lehigh University, 621 Taylor Street, R451, Bethlehem, PA, 18015-3120, United States, ajl259@cornell.edu

We propose a program for microgrid formation in the electricity system after a disruption, considering a system with high penetration of renewables and where flows are expected to be undirected. We compare our extended formulation to results presented in the literature. Additionally, we allow for possible mobile and fixed Distributed Generation technologies, Distributed Energy Resources, and demand responsive loads with a minimum satisfiability constraint. The extended mixed-integer linear program (MILP) can be used as an operations and a short term planning tool for DG scenario-based location. The MILP is applied to the IEEE 37-bus, 30-bus and 118-bus systems.

3 - Designing Hydro Supply Chains for Energy Food and Flood

Kwon Gi Mun, Fairleigh Dickinson University, Fort Lee, NJ, United States, kgmun@fdu.edu, Yao Zhao, Razi Ali Rafique

In this research, we apply SCM concepts to water resource development and provide the end-to-end and dynamic perspectives. We found that the development of hydropower has the potential to address all these issues such as water, food, and energy. Our results demonstrate the value of the supply chain perspective on hydro network expansion, and provide insights on the optimal development strategies regarding location, sequence and mix of hydro projects.

Joint Session OPT/Practice: Applications of Stochastic and Robust Optimization

Sponsored: Optimization, Optimization Under Uncertainty

Sponsored Session

Chair: Sebastian Maier, Imperial College London, Imperial College Road, Skempton Building, London, SW7 2AZ, United Kingdom, s.maier13@imperial.ac.uk

1 - Valuing Portfolios of Real Options under Both Exogenous and Endogenous Uncertainties

Sebastian Maier, Imperial College London, Imperial College Road, Skempton Building, London, SW7 2AZ, United Kingdom, s.maier13@imperial.ac.uk, Georg Pflug, David Gann, John Polak

We extend our existing approach for modeling and approximating the value of portfolios of real options to include endogenous, decision- and state-dependent uncertainties. The options are to defer investment, to stage investment, to temporarily halt expansion, to temporarily mothball the operation, and to abandon the project. Two of the underlying uncertainties, decision-dependent cost to completion and state-dependent salvage value, are endogenous, the other two, annual operating revenues and their growth rate, are exogenous. Using a simulation and regression approach we present an efficient valuation algorithm. Its applicability is illustrated by valuing an infrastructure investment.

2 - Integrating Decisions with Advance Supply Information in Assemble-to-order Systems

Jie Chu, McMaster University, 1280 Main St, W. Hamilton, ON, L8S.4M4, Canada, chuj6@mcmaster.ca, Kai Huang

In this paper, we consider a periodic review Assemble-To-Order (ATO) system, where each component follows an independent base stock policy. We first consider the ATO system with lead time and demand uncertainties in which the decision maker has advanced knowledge of uncertain lead times. Then we advance the methodology by considering a situation where the decision maker only has full distributional knowledge of uncertain lead times. The stochastic programming models are proposed and solved by the sample-average-approximation (SAA) algorithm.

3 - On Robust Solutions to Uncertain Hierarchical Transmission Expansion Problems

Shisheng Cui, Pennsylvania State University, University Park, PA, United States, cuishisheng05@gmail.com, Uday Shanbhag

We consider a robust formulation for proactive planning of transmission with imperfect long-run transmission pricing based on a MW-km charging system. The deterministic model is described by a mixed-binary mathematical program with equilibrium constraints (MPEC), a challenging optimization problem. Then, leveraging techniques from robust solutions to uncertain complementary problems, we incorporate robustness into the transmission expansion problem and obtain global solutions via a branching procedure. Preliminary numerics will be provided.

4 - The Value of Flexibility in Robust Location -Transportation Problems

Amir Ardestani-Jaafari, McGill University, Montreal, QC, Canada, amir.ardestanijaafari@mail.mcgill.ca, Erick Delage

We study a robust location-transportation problem in which, while the location and capacity of each facility need to be determined immediately, the determination of final production and distribution of products can be delayed until actual orders are received. It is a computationally challenging task to make wait-and-see decisions adaptable to data while the problem remains practically attractive. To overcome this difficulty, we propose a tractable conservative approximation to the problem that provides a promising trade-off between tractability and wait-and-see decisions flexibility.

New Directions in Stochastic Programming

Sponsored: Optimization, Optimization Under Uncertainty

Sponsored Session

Chair: Suvrajeet Sen, University of Southern California, University of Southern California, Los Angeles, CA, 90089-0193, United States, s.sen@usc.edu

1 - Algebraic Topics for Stochastic Programming

Ruediger Schultz, University of Duisburg Essen, Department of Mathematics, Thea-Leymann-Str. 9, Essen, D-45127, Germany, ruediger.schultz@uni-due.de

In the talk, selected topics from stochastic programming are discussed, where structural and algorithmic findings benefit from an algebraic point-of-view. In particular, augmentation algorithms for two-stage stochastic integer programs and polynomial optimization models for stationary flows in gas pipelines are forming the departure points for our considerations.

2 - Multistage Stochastic Programming with Parametric Cost Function Approximations

Raymond Perkins, Princeton University, Princeton, NJ, United States, raymondp@princeton.edu, Warren Powell

A widely used heuristic for solving stochastic optimization problems is to use a deterministic rolling horizon procedure which has been modified to handle uncertainty (e.g. buffer stocks, schedule slack). We formalize this approach by proposing these parameterizations as a powerful strategy to hedge against uncertainty, and present a stochastic gradient algorithm for optimizing the parameters in a fully sequential, stochastic base model. This base model, implemented as a simulator, does not require any of the standard assumptions that are widely used in stochastic programming such as two-stage models or intertemporal independence. We derive the gradients and test the algorithm on several parameterizations, demonstrating significant improvements over a vanilla deterministic lookahead.

3 - On the Asymptotical Result of Two-stage Stochastic Quadratic Programming

Junyi Liu, University of Southern California, Los Angeles, CA, United States, junyiliu@usc.edu

We consider a class of two-stage stochastic quadratic programming (STQP) problems with continuous random variables. To accommodate the above structure, Stochastic Decomposition (SD) algorithm constructs affine/quadratic minorants and approaches a statistically acceptable solution. On the convergence side, we present the contraction property of stochastic proximal mapping and show the linear convergence to the neighborhood of the optimum wp1.

4 - An Extension to the Network Flow Optimization Problem

Gerrit Slevogt, Universität Duisburg-Essen, Duisburg, Germany, gerrit.slevogt@uni-due.de

A transient gas network model with the highlight of active elements being modelled multiplicatively at the nodes is extended to stochastic demand and its structure is presented. Going beyond existing literature the modeling of active components is not restricted to compressor stations but includes all common active gas network elements.

Sponsored Session

Chair: Sam Davanloo Tajbakhsh, davanloo-tajbakhsh.1@osu.edu

1 - Symmetry, Saddle Points, and Global Geometry of Non-convex Matrix Factorization

Xingguo Li, University of Minnesota, Minneapolis, MN, 30318, United States, lixx1661@umn.edu

We propose a general theory for the geometry of nonconvex objectives by characterizing stationary points and the null space of the associated Hessian via invariant groups. Moreover, we characterize the global geometry of low-rank matrix factorization and illustrate how the rotational symmetry group raises infinite strict saddle and global minima. We divide the parameter space into the regions: (R1) containing strict saddle with negative curvature; (R2) containing global minima with restricted strong convexity; and (R3) with large gradient. We further extend our result to matrix sensing. This allows us to show global convergence for popular iterative algorithms with random initialization.

2 - Convex Optimization Problems with Misspecified Vector of Parameters: Solution Framework and Rate Analysis

Hesamoddin Ahmadi, Innovative Scheduling DBA Optym, 5333 SW. 75th street Apt L71, Gainesville, FL, 32608, United States, hesamoddin.ahmadi@optym.com
Hesamoddin Ahmadi, Pennsylvania State University, University Park, PA, United States, hesamoddin.ahmadi@optym.com

In this talk, we consider a misspecied optimization problem that requires minimizing a function f over a closed and convex set X with an unknown vector of parameters. The source of misspecification is a deterministic vector that can be obtained by solving another suitably defined optimization problem in parallel, referred to as the learning problem. We develop joint first-order schemes for computation and learning and provide rate statements.

3 - Sample Average Approximation with Sparsity-inducing Penalty for High-dimensional Stochastic Programming

Hongcheng Liu, Stanford University, Stanford, CA, 94085, United States, hql5143@stanford.edu, Xue Wang, Tao Yao, Runze Li, Yinyu Ye

Traditional sample average approximation (SAA) scheme for stochastic programming requires that the number of samples should be polynomial in the number of problem dimensions in order to ensure proper optimization accuracy. We study a modification to SAA in the scenario where the global minimizer is either sparse. By making use of a regularization penalty referred to as the folded concave penalty, we show that the required number of samples can be significantly reduced: the sample size is only required to be poly-logarithmic in the number of dimensions.

4 - On Statistical Learning Problems with Nonconvex L0-Norm Penalty Formulated by Complementarity Constraints

Sam Davanloo Tajbakhsh, The Ohio State University, 210 Baker Systems Building, 1971 Neil Ave, Columbus, OH, 43210, United States, davanloo-tajbakhsh.1@osu.edu

Imposing sparsity in high-dimensional statistical learning could be performed by imposing nonconvex l0 norm penalty. From the statistical perspective, some local solutions to nonconvex problems could be superior to global solutions of convex counterparts. In this talk, we propose our findings to solve the original nonconvex problem formulated by complementarity constraints.

1 - A Methodology for Optimized Oil Well Location During Operational Drilling in Presence of Geological Uncertainty

D. Echeverría Ciaurri, IBM.Researcch, Yorktown Heights, NY, United States, decheve@us.ibm.com, V.M. Babin, A.M. Vashevnik, O.S. Ushmaev, A.P. Gruzdev, A.V. Pozdneev, D. Echeverría Ciaurri

We propose a novel methodology for the construction of an oil field development strategy that leverages decision trees and takes into account geological uncertainties of a reservoir. The approach is designed to dynamically decide on the drilling location of the next wells and on the need for appraisal wells. The strategy can be delivered to the drilling operator in the form of a pre-computed manual. The methodology was applied to a new oil field and 15% improvement in expected net present value was obtained with respect to an optimized development strategy with predetermined wells placement.

2 - How to Improve Educational Programs for Underprivileged Children? the Impacts of Value-focused Decision Analysis

Valentina Ferretti, London School of Economics and Political Science, Houghton Streetl London | WC2A 2AE, London, United Kingdom, V.Ferretti@lse.ac.uk, Gabriella Csányi

This project develops a value-focused Decision Analysis intervention designed and deployed to support the Csányi Foundation in selecting underprivileged children to enter the Foundation's Educational program. To minimize dropout rates, the Foundation expressed the need to improve the selection process, by better identifying the selection criteria that will allow the Foundation to meet its objectives and by fostering consensus among the board members. To achieve these targets, we combined a use of Multi Attribute Value Theory and Value Focused Thinking within a facilitated mode of engagement.

3 - Decision Analytics for Reducing Surgical-site Infections: Application to Coronary Artery Bypass Graft Patients

Eva Lee, Georgia Tech, Industrial & Systems Engineering, Ctr for Operations Research in Medicine, Atlanta, GA, 30332-0205, United States, evakylee@isye.gatech.edu

This study focuses on reducing SSI for coronary artery bypass graft(CABG) patients at a large hospital. A system-approach - using decision trees, machine learning, simulation and multi-objective optimization - was employed to account for the interdependency of preoperative, intraoperative and postoperative processes. A number of intervention and process changes were initiated. The site zero percentage within six months and sustained that rate for over 24 months.

1 - The Effectiveness of Trimmed Opinion Pools in Time Series Forecasting Involving Structural Breaks

Shijith Kumar Payyadakkath Meethale, PhD Candidate, IE Business School, Madrid, Spain, shijith.pm@Student.ie.edu, Matthias Seifert, Yun Shin Lee

We introduce simple trimming approaches to aggregate judgmental time series forecasts involving structural breaks. While the extant literature explores trimming rules for aggregating forecasts in stable environments, we focus on relatively unstable environments characterized by fundamental regime shifts. In an empirical study, we find that forecasters are relatively under confident and sensitive to regime shifts and fluctuations in time series, making static trimming approaches less applicable. We further propose asymmetric trimming approaches to aggregate opinion pools under such unstable environments.

2 - Risky Choice Following Near Miss Events in Sequential Tasks under Ambiguity

Florian Mathis Federspiel, Assistant Professor, INCAE Business School, Alajuela, Costa Rica, florian.federspiel@incae.edu, Matthias Seifert, Robin Dillon-Merrill

Studies have shown that near miss events can lead to inconsistent risk perceptions. Yet near misses are often clouded in ambiguity, allowing for hubris and misattribution of what caused success or prevented failure. We provide an analytical model of near misses and investigate the experience of such an event on risk taking in a real options task. Over two experiments, we show that increases in risk taking following a near miss occur mainly under ambiguity. We further find that this effect depends on the decision maker's prior expectation. Only those with an expectation of failure fall prey to the near miss bias.

3 - Group Decision Making with Multiple Conflicting Performance Targets

Matthias Seifert, IE Business School, Maria de Molina 12, 5, Madrid, 28006, Spain, matthias.seifert@ie.edu, Enrico Diecidue, Anshdha Ria

In many multi-stakeholder decision contexts, it is of crucial importance to aggregate preferences in a way that rewards the diversity of targets met. Extending Tsetlin & Winkler's (2007) work on multiattribute performance targets, we study the properties of a novel group-weighting rule, which draws on the dis-/similarity of preferences held by individuals and assigns higher values to those alternatives that maximize the diversity of targets achieved. We then benchmark the performance of this rule against classic approaches based on equal weighting (e.g. average winner, majority voting).

4 - Dynamic Pricing under Habit Formation and Satiation

Wen Chen, Providence College, United States, wchen@providence.edu, Ying He

we study the dynamic pricing problem when consumer forms habit and/or satiation from their past consumptions in this paper. Our analysis is based on utility model under habit formation and satiation that are proposed and axiomatized in the decision theory literature recently, which provides a solid behavioral foundation for our model. Based on this utility model, we derive an inter-temporal dependent demand function to model how demand in each period depends on the prices in the current period and previous periods through habit formation and satiation. Our analysis shows that "U-shaped", or "Inverse-U-shaped" policy may become optimal.

1 - Easy Affine Markov Decision Processes: Properties and Applications

Matthew J.Sobel, Case Western Reserve University - Retired, Department of Operations, 10900 Euclid Avenue, Cleveland, OH, 44106-7235, United States, matthew.sobel@case.edu, Jie Ning

This tutorial introduces a class of decomposable affine Markov decision processes (MDPs) that have continuous multi-dimensional endogenous states and actions, and an exogenous state that follows an exogenous Markov chain. We show that, unlike most MDPs with continuous state and actions, decomposable affine MDPs are free of the curse of dimensionality and can be solved easily and exactly. A decomposable affine MDP has a value function that is affine in the endogenous state, and has an extremal optimal policy. We illustrate the potential applicability of decomposable affine MDPs using examples of fishery management and dynamic capacity portfolio management.

1 - Pricing and Optimization in Shared Vehicle Systems: An Approximation Framework

Daniel Freund, Cornell University, 109 Lake St, Ithaca, NY, 14850, United States, df365@cornell.edu, Thodoris Lykouris

Pricing in shared vehicle systems is challenging due to complex network externalities: altering prices in any location affects future supply throughout the system within short timescales. Such externalities are well captured by steady-state Markov chain models, which are widely used in this context. However, optimizing these models is computationally difficult since the resulting problems are high-dimensional and non-convex. We develop a framework for designing pricing policies in such systems, based on a novel convex relaxation which we term elevated flow relaxation, coupled with a new infinite projection and pullback technique for proving approximation bounds. Our approach provides the first efficient algorithms with finite-system guarantees for pricing as well as other demand-supply balancing controls used in shared vehicle systems. In the process, we recover recently discovered asymptotic optimality results via elementary arguments.

2 - On the Euler Discretization Error of Brownian Motion about Random Times

Guido Lagos, University of Chile, Santiago, Chile, guido.lagos.barrios@gmail.com

In this talk we study the simulation of barrier-hitting events and extreme events of Brownian motion, when using a discretization on an equidistant time mesh. Specifically, we study the times and position of the discretized Brownian motion in these events and compare it to the ones for the "real" Brownian motion. We establish new results on weak convergence of the (normalized) errors of time and position in all these cases, and give explicit analytic expressions for the limiting distributions. In doing this we derive new results on diffusion approximations of Gaussian random walks by Brownian motions. More importantly, our results give new insight on the connection between several works in the literature dating back to the 60's where the constant $-\zeta(1/2)/\sqrt{2\pi}$ has appeared, where ζ is the Riemann zeta function.

3 - Multi-Agent Online Learning under Imperfect Information: Algorithms, Theory and Applications

Zhengyuan Zhou, Stanford University, 160 Comstock Circle - Unit 106002, Stanford, CA, 94305, United States, zyzhou@stanford.edu

We consider a model of multi-agent online learning under imperfect information, where the reward structures of agents are given by a general continuous game. After introducing a general equilibrium stability notion for continuous games, called variational stability, we examine the well-known online mirror descent (OMD) learning algorithm and show that the "last iterate" (that is, the actual sequence of actions) of OMD converges to variationally stable Nash equilibria provided that the feedback delays faced by the agents are synchronous and bounded. We then extend the result to almost sure convergence to variationally stable Nash equilibria under both unbiased noise and synchronous and bounded delays. Subsequently, to tackle fully decentralized, asynchronous environments with unbounded feedback delays, we propose a variant of OMD which we call delayed mirror descent (DMD), and which relies on the repeated leveraging of past information. With this modification, the algorithm converges to variationally stable Nash equilibria, with no feedback synchronicity assumptions, and even when the delays grow super-linearly relative to the game's horizon. We then again extend it to the case where there are both delays and noise.

4 - Learning Preferences with Side-Information: Near Optimal Recovery of Tensors

Andrew A. Li, Massachusetts Institute of Technology-ORC, 77 Massachusetts Avenue, Bldg. E40-149, Cambridge, MA, 02139, United States, aali@mit.edu

Many recent problems in e-commerce can be cast as large-scale problems of tensor recovery. Thus motivated, we study the problem of recovering tensors from their noisy observations. We provide an efficient algorithm to recover structurally 'simple' tensors given noisy observations of their entries; our version of simplicity subsumes low rank tensors for various definitions of tensor rank. Our algorithm is practical for massive datasets and provides a significant performance improvement over incumbent approaches to Tensor recovery. Further, we show a near-optimal recovery guarantee. Experiments on music streaming data demonstrate the performance and scalability of our algorithm.

1 - Managing Social Responsibility in Multitier Supply Chains

Robert Swinney, Associate Professor, Duke University, 100 Fuqua Dr, Box 90120, Durham, NC, 27708, United States, robert.swinney@duke.edu, Jing-Sheng Jeannette Song

We study the management of social responsibility in a three-tier supply chain in which a Tier 2 supplier sells to a Tier 1 supplier, which in turn sells to a Tier 0 buyer. The Tier 2 supplier potentially violates social and environmental standards, resulting in harm to the Tier 0 and 1 firms. Each member of the supply chain can exert effort to improve the responsibility in Tier 2, and the efforts of Tiers 0 and 1 are substitutable with one another and complementary to the efforts of Tier 2. We determine when it is optimal for the Tier 0 buyer to delegate management of Tier 2 to the intermediate Tier 1 supplier, and when it is optimal for Tier 0 to assume direct control of Tier 2.

2 - Transparency as a Supplier Social and Environmental Responsibility Screening Mechanism

Basak Kalkanci, Georgia Institute of Technology, 3151 Stillhouse Creek Dr SE, Apt 25517, Atlanta, GA, 30339, United States, basak.kalkanci@scheller.gatech.edu, Shi Chen, Erica Plambeck

Some buying firms, facing scrutiny regarding negative social and environmental impacts in their suppliers' operations, have recently made transparency commitments to disclose their audit reports and/or the identities of their suppliers. In this paper, we study the trade-offs faced by a buyer firm in deciding whether or not to make such transparency commitments.

3 - Improving Supplier Social Responsibility under Incomplete Visibility

Leon Matias Valdes, MIT.Sloan School of Management, 77 Massachusetts Avenue, E62 - 459, Cambridge, MA, 02139, United States, lvaldes@mit.edu, Tim Kraft, Yanchong Zheng

We study a manufacturer's decisions when the social responsibility (SR) performance of her supplier cannot be perfectly observed. Only the supplier can directly impact SR; the manufacturer can: (i) invest in the supplier's capabilities to improve SR; and (ii) disclose SR information (true or not) to consumers. In addition, a third party may disclose the true level of SR, which can lead to a penalty for the manufacturer. Our results provide insights into the impact of supply chain visibility on the supplier's and manufacturer's strategies. While greater visibility and third-party scrutiny typically increase SR in the supply chain, we identify situations where this is not the case.

4 - Product Line Design for Greener Products

Iva Petrova Rashkova, Washington University in St Louis, Washington University in St Louis, St Louis, MO, 63130, United States, irashkova@wustl.edu, Lingxiu Dong, Weiqing Zhang

The purpose of this project is to explain why some food manufacturers are adopting local sourcing while others position themselves as organic; while some abandon their traditional products while others expand their product line with the greener versions. We build a model which incorporates two quality valuations - traditional and green - and two market segments - low and high green valuation. We characterize explicitly how the interplay between green-valuation uncertainty, production cost and the size of the green segment affect the manufacturer's optimal product line design.

HIV-Related Applications

Sponsored: Health Applications

Sponsored Session

Chair: Evin U. Jacobson, CDC, Atlanta, GA, 30332, United States, wqm4@cdc.gov

1 - Allocation of HIV Prevention and Treatment Resources in the United States

Evin U. Jacobson, CDC, Atlanta, GA, United States, wqm4@cdc.gov, Katherine A.Hicks, Justin Carrico, Stephanie L.Sansom

To better provide guidance on how HIV prevention resources in the United States could be focused to prevent the most cases of HIV, we explored the optimal allocation of a treatment and prevention budget. The optimal allocation resulted in more than a 40% decrease in new cases over 10 years compared to the estimated current allocation. Coordination of HIV prevention activities could substantially reduce HIV incidence. The optimal allocation is associated with lower overall treatment budget, freeing up additional resources for prevention.

2 - Impact of Enhanced HIV Care and Treatment and Delivering PrEP in the United States

Nidhi Khurana, CDC, Atlanta, GA, United States, Emine Yaylali, Paul Farnham, Katherine Hicks, Benjamin T. Allaire, Evin Jacobson, Stephanie L.Sansom

We used a dynamic, compartmental model of HIV transmission and disease progression to estimate the number of HIV infections prevented in the United States from 2016 to 2020 when pre-exposure prophylaxis (PrEP) was implemented for populations at high risk of acquiring HIV under either the current continuum of care or under an improved continuum that results in the achievement of national HIV prevention goals.

3 - Examining Businesses that Provide Products and Services to Gay and Transgender Individuals Living with HIV

Guruprasad Gadgil, University of North Texas, 1115 Collier Street, #2, Denton, TX, 76201, United States, guruprasad.gadgil@unt.edu, Gayle Prybutok, Victor Prybutok

This mixed method study examines the transference of impression management, the theory of planned behavior, and technology enabled anonymity to develop a model for a HIV-positive population in terms of individuals that run small online businesses that serve the gay and transgender population living with HIV. This work examines why individuals make their data available and why online businesses are motivated to provide practices, products, and services to this community.

Dynamic Decision Making with Application to Major Health Challenges

Sponsored: Health Applications

Sponsored Session

Chair: Shan Liu, University of Washington, Seattle, WA, 98195-2650, United States, liushan@uw.edu

1 - Cost-effectiveness Analysis for Prognostic-based Depression Monitoring

Ying Lin, University of Houston, Houston, TX, United States, ylin58@uh.edu, Shuai Huang, Shan Liu

Inadequate monitoring has been identified as a major challenge in depression treatment follow-up. Prognostic-based monitoring which adaptively allocates monitoring resource to high-risk individuals is promising to improve efficiency and reduce cost. We developed a decision support framework to integrate individual prognostic, monitoring strategy design and cost-effectiveness analysis. We compared several prediction algorithms to monitor high-risk patients for major depression (rule-based, logistic regression, collaborative model, lazy learning, etc.) using a dataset of depression population and identified five cost-effective monitoring strategies.

2 - Dynamic Treatment Selection and Modification for Personalized Blood Pressure Therapy

Margaret L.Brandeau, Stanford University, Management Science and Engineering, 475 Via Ortega, Stanford, CA, 94305-4026, United States, brandeau@stanford.edu

Personalized treatment of disease - identifying which treatments work, for whom, and in what context - can significantly improve patient outcomes compared to treatment based on clinical guidelines. We developed and tested a generalizable computational strategy to help personalize treatment when multiple treatment options, benefits, and risks must be considered, using a Markov Decision Process model informed by high-quality meta-analytic data. We applied the strategy to the selection of blood pressure treatments for a simulated US population, and compared overall benefits and risks to those achieved from application of current blood pressure treatment guidelines.

3 - Adaptive Strategies for Personalized Treatment Selection of Depression in a Heterogeneous Population

Jue Gong, University of Washington, Industrial and Systems Engineering, MEB B14 Box 352650, Seattle, WA, 98115, United States, gongjue@uw.edu, Shan Liu

We established a framework for characterizing personal dynamics in disease progression and making a series of adaptive treatment decisions based on the estimated dynamics. The objective is to select between two treatments of depression to maximize health outcome. Depression progression is assumed to be a POMDP. An extension of the collaborative model and its solution algorithm are developed to estimate the model parameters. The optimal treatment policy is obtained by solving a rolling horizon POMDP. This research has wide applications in chronic disease treatment problems in the era of personalized medicine.

4 - Resource Allocation for Hepatitis C Elimination

Qiushi Chen, Massachusetts General Hospital, 101 Merrimac St., 10th FL, Boston, MA, 02114, United States, qchen@mgh-ita.org, Turgay Ayer, Jagpreet Chhatwal

The burden of hepatitis C virus (HCV) infection continues to rise globally. The advent of highly effective HCV treatment in the last few years enables effective epidemic control and even elimination of the disease. However, high drug cost and unawareness of infection are challenges for achieving this goal. In this study, we develop a hepatitis C transmission model, and identify the optimal allocation for HCV screening and treatment to achieve the disease control target at the minimum cost. We present the allocation policies in different health care settings and target population profiles.

5 - Dynamics of Drug Resistance: Optimal Control of an Infectious Disease

Naveed Chehrazi, McCombs School of Business, Austin, TX, United States, chehrazi@utexas.edu

We study the optimal treatment policy for an SIS-type infectious disease with drug resistance. We prove that the optimal policy is bang-bang with a single switching time and we find that the value function is not Lipshitz continuous. Using numerical analysis, we demonstrate that the optimal policy changes form when the disease transmission rate is a function of disease prevalence (e.g., as a result of social distancing). Our solution approach can be generalized to other control problems.

Modeling and Optimization in Healthcare Decision Applications

Sponsored: Health Applications

Sponsored Session

Chair: Ruichen Sun, University of Pittsburgh, Pittsburgh, PA, 15261, United States, rus19@pitt.edu

1 - Screening for Breast Cancer: the Role of Supplemental Tests and Breast Density Information

Burhaneddin Sandikci, University of Chicago, Booth School of Business, 5807 South Woodlawn Avenue, Chicago, IL, 60637, United States, burhan@chicagobooth.edu, Mucahit Cevik

Mammography screening is the gold standard for breast cancer screening in the US, but it is known to be less accurate for women with dense breasts. Supplemental screening methods such as Magnetic Resonance Imaging (MRI) and ultrasound have been recently introduced to improve detection accuracy. We incorporate the breast density information using a partially observable Markov decision process model, and study the impact of supplemental tests in detecting breast cancer.

2 - Optimizing Vaccine Distribution in Low and Middle Income Countries

Yuwen Yang, University of Pittsburgh, Department of Industrial Engineering, Pittsburgh, PA, 15261, United States, yuy49@pitt.edu, Jayant Rajgopal, Hoda Bidkhori

The WHO Expanded Programme on Immunization aims to provide universal access to a recommended suite of vaccines, with a special focus on underserved low and middle income countries. Despite significant economic, geographical and demographic differences, the structure of the vaccine distribution network is almost identical across all these countries, when there is no compelling reason for this to be so. We present a mixed integer programming formulation to optimize the cold chain network, along with the consideration of cold storage and transportation. We study the structure of the model and examine several options to improve its computational performance with data derived from the real world.

3 - Optimal Pooling, Batching and Pasteurizing of Donor Human Milk

Ruichen Sun, University of Pittsburgh, 3700 O'Hara Street, 1048 Benedum Hall, Pittsburgh, PA, 15261, United States, rus19@pitt.edu, Lisa M.Maillart, Andrew J.Schaefer

Donor human milk - collected and dispensed via milk banks - is the standard of care for NICU and outpatient infants whose mother's own milk is not a viable option. It undergoes complex processes at milk banks. We formulate integer programs to optimize the daily milk processing decisions, including the pooling of milk from different donors to meet macronutrient requirements across different product types, and the batching of pooled milk for efficient pasteurization. The numerical study shows an increase of approximately 25% for the overall utility.

4 - Robust Inverse Optimization with Application to Dietary Recommendation

Taewoo Lee, University of Houston, E209 Engineering Bldg 2, 4722 Calhoun Rd, Houston, TX, 77204-4008, United States, tlee20@central.uh.edu, Kimia Ghobadi, Houra Mahmoudzadeh, Daria Terekhov

In this talk, we explore the robustification of inverse optimization. Our work is motivated by problems in which the observation of the solution is partial, noisy, or uncertain. We build an uncertainty set around the observation and derive an inverse model that finds a cost vector that protects against the worst case scenario in the given uncertainty set. Our model generalizes previous work on single-observation inverse models. It can also be seen as more general than inverse optimization with multiple points, since the points can be thought of as a sample from the uncertainty set.

Stochastic and Simulation Modeling in Healthcare Management

Sponsored: Health Applications

Sponsored Session

Chair: Xiang Zhong, Univ. of Florida, 380 Weil Hall, Gainesville, FL, 32611, United States, xiang.zhong@ise.ufl.edu

1 - Modeling of Cost-effective Interventions to Reduce Total Joint Replacement Read Missions

Hyo Kyung Lee, University of Wisconsin-Madison, Madison, WI, United States, hlee555@wisc.edu, Rebecca Jin, Yuan Feng, Philip A. Bain, Jo Goffinet, Jingshan Li

More than a million total joint replacements are performed in the US each year, where hip and knee replacements are the most common ones. Complications can occur in some replacements which lead to unplanned hospital readmissions. To reduce readmissions, prevalent studies focus on finding the risk factors without considering the intervention processes that are carried out post-discharge. Thus, we present a quantitative intervention process model that incorporates patients' identified risk levels to provide patient-centered interventions. By investigating cost-effectiveness of various intervention policies on hospital readmissions, we seek to provide clinical guidelines.

2 - Achieving Optimal Patient-centered Interventions to Reduce Readmission for COPD Patients

Sujee Lee, University of Wisconsin - Madison, Madison, WI, United States, slee776@wisc.edu, Philip Bain, Chris Baker, Jingshan Li

Staring from 2014, the Centers for Medicare and Medicaid Services have penalized hospitals with high risk-adjusted, 30day unplanned readmission rates of the patients admitted for an acute exacerbation chronic obstructive pulmonary disease. In response, hospitals struggle to develop efficient interventions for COPD patient. To support decision making for the hospitals, this study introduces an optimization model to introduce an incentive based postdischarge intervention policy for COPD patients. Based on predicted risk of readmissions, optimal strategies to minimize readmission rate are presented to distribute incentive budget to encourage COPD patients complying with interventions.

3 - Drug Dispensing Data Driven Modeling of Anticholinergic Drug Prescription Behavior

Nan Kong, Purdue University, 206 South Marting Jischke Drive, Biomedical Engineering, West Lafayette, IN, 47906-2032, United States, nkong@purdue.edu

Anticholinergic drug overdose is common among older adults in the U.S. The overdose leads to increased cognitive impairment and contributes to higher care spending. We develop an individually based state-transition simulation to characterize prescription behavior with incorporation of the variations among patients and pharmacists. We test various semi-Markov models to fit the continuous prescription pattern based on drug dispensing data from a metropolitan area. The simulation can help us conduct research on assessing various prescription behavior interventions.

4 - On the Effect of Electronic Patient Portal on Primary Care Delivery

Xiang Zhong, Univ. of Florida, 380 Weil Hall, Gainesville, FL, 32611, United States, xiang.zhong@ise.ufl.edu, Aditya M. Prakash

Electronic visit (e-visit), which allows patients and primary care providers communicating through secure messages, has enabled virtual care delivery as an alternative to traditional office visits. To help identify the conditions that e-visits lead to improved care delivery efficiency and patient access, we modeled the dynamics of appointment backlog using a Markov Modulated Poisson Process (MMPP), and developed numerical methods for computing system performance metrics. The insights obtained from the models provide guidance to care providers who are engaged in facilitating e-visits to apprehend the influence of the novel care delivery channel on their established practices.

5 - A Simulation Optimisation on the Hierarchical Health Care Delivery System Patient Flow Based on Multi-fidelity Models

Yunzhe Qiu, PhD Candidate, Olin Business School, Haidian District, University City, MO, 63130, United States, qiuyunzhe@wustl.edu, Jie Song, Zekun Lu

The imbalanced development among different levels of healthcare facilities in China's urban healthcare system has raised the uneven patient flow distribution. We develop a method integrating the simulation, the multi-objective optimization and the simulation budget allocation together to comprehensively improve the overall system performances by finding the approximate Pareto patient flow distribution in the hierarchical healthcare system. A case study based on the real data shows the recommended Pareto optimal patient flow distribution can improve the overall hierarchical system performances and our methodology is qualified as a quantitative decision tool for decision makers

MSOM Energy and Sustainability

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Yangfang Zhou, Singapore Management University, Singapore, 178899, Singapore, helenzhou@smu.edu.sg

1 - Promoting Solar Panel Investments: Feed-in-tariff Versus Tax-rebate Policies

Safak Yucel, Georgetown University, Georgetown University, 3700 O. St. NW, 523 Hariri Building, Washington, DC, 20057, United States, safak.yucel@georgetown.edu, Volodymyr O. Babich, Ruben Lobel

We compare two policies governments use to promote investment in solar panels by households: feed-in tariff and tax rebate. The feed-in tariff provides a guaranteed stream of payments to the households. The tax-rebate policy reduces the initial investment cost. We investigate the main economic forces that tilt the government's preference towards one of the policies. One such force is the strategic waiting by forward-looking households in the face of uncertainty and irreversible investments. We model uncertainties in prices and investment costs, the percentage of myopic households in the economy, the heterogeneity in generating efficiencies, and the environmental benefits.

2 - Dynamics of Capacity Investment in Renewable Energy Projects

Nur Sunar, UNC, 1604 Village Crossing Drive, Chapel Hill, NC, 27517, United States, nur_sunar@kenan-flagler.unc.edu, John R.Birge

Using a continuous time model, we analyze the dynamics of capacity investment in renewable power. In this context, we explicitly identify the optimal policy. We also present some numerical examples to explain the structure of the optimal strategy.

3 - Optimal Size of a Combined Heat and Power Generator for an Industrial Firm

Wenbin Wang, Shanghai University of Finance and Economics, Shanghai, China, wang.wenbin@mail.shufe.edu.cn, Gilvan Souza, Owen Wu

We consider a manufacturer who uses both steam and electricity in its primary production process makes investment on a Combined Heat and Power (CHP) system. We provide a decision model and find the optimal capacity and operating policy for a CHP system that reduce the total investment and energy costs.

4 - Is Electricity Storage Green? A Study on the Commercial Sector

Yangfang Zhou, Singapore Management University, 50 Stamford Road, Singapore, 178899, Singapore, helenzhou@smu.edu.sg

Electricity storage facilities, such as industrial batteries, are considered the "game changer" in de-carbonizing the electrical grid. They are being widely installed in the commercial sector, e.g., retail stores and corporate offices. We model the problem of managing electricity storage in a commercial building for both the cases with and without a solar photovoltaic system. Our numerical results, based on models calibrated to electricity load data for more than 70 commercial buildings in the U.S., show that for all these buildings, optimal storage operations may increase carbon emissions. We also study the case when commercial buildings are equipped with solar photovoltaic systems.

Value Chain Innovations:Doing Good by Doing Well

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Ravi Anupindi, University of Michigan, Ann Arbor, MI, 48109, United States, anupindi@umich.edu

1 - Giving it Away to Increase Profits: Price Discrimination and the Effect of Free Goods

Jacob Chestnut, University of Michigan, Ann Arbor, MI, United States, jacobpc@umich.edu, Ravi Anupindi, Hyun-Soo Ahn

Conventional wisdom suggests that a service provider must charge a customer in some form to generate profit. However, a handful of providers do not follow this and give away services to some customers for free. Dr. Devi Shetty, called the "Henry Ford of Cardiac Surgery," is the founder of India's Narayana Health, which performs 40% of surgeries for free. India's Aravind Eye Hospital (AEH) is another well-known example. Though nominally non-profit, with a net surplus of 50% while serving 60% of their consumers for free, AEH's performance suggests that offering partially free service may be more than charity; it may actually increase a provider's total profit.

2 - Assessing the Impact of Telemedicine-Equipped Service Channels on Patient Access

Kamalini Ramdas, London Business School, London, United Kingdom, kramdas@london.edu, Sarang Deo, Kraig Delana, Ganesh Babu, Sri Harinath

We use data from the Aravind Eye Care System in India to examine how the introduction of rural vision centers equipped with telemedicine impacts patient visit volumes, patient mix, revenues and outcomes. Using a difference-in-differences model, we find that the introduction of vision centers substantially increases network volumes, largely through new patients. We also find that patients switch to care closer to home when feasible. Our findings suggest that telemedicine can successfully catalyse care seeking behavior and can enable a pull model of care in rural areas.

3 - Optimal Subsidies for Solar Lanterns in Haiti

Chris Tang, UCLA Anderson School, CA, United States, chris.tang@anderson.ucla.edu, ManMohan Sodhi, James Knuckles

Development supply chains focus on the economic sustainability of poor families. To understand these better, we conducted a field study of such supply chains for solar lanterns in Haiti during 2014-2016. Upon interviewing donor organizations such as the World Bank, we found that the answer to which particular echelon in the supply chain should the donor subsidize differed from one donor to the other and even within donor organizations. Using stylized models, we seek to find the best way to subsidize a multi- echelon supply chain when the donor's budget is limited.

Data-driven Decision Making in Healthcare and Service Operations

Sponsored: Manufacturing & Service Oper Mgmt, Service Operations

Sponsored Session

Chair: Pengyi Shi, Purdue University, West Lafayette, IN, 47907, United States, shi178@purdue.edu

Chair: Nan Liu, Columbia University, Columbia University, New York, NY, 10032, United States, nl2320@columbia.edu

1 - Real-time Outpatient Scheduling Algorithms

Kimia Ghobadi, MIT, 100 Main Street, E62-459, Cambridge, MA, 02142, United States, kimiag@mit.edu, Michael Hu, Retsef Levi, Adam Marshall, Wendi Rieb, Bethany Daily, Inga Lennes, John Stone, Ana Cecilia Zenteno

We developed real-time (online) intra- and inter-day algorithms to schedule outpatient infusion appointments while respecting patient choices. Each appointment is scheduled upon arrival without prior knowledge of future appointments or patient preferences. The goal of the algorithms is to minimize the number of required resources. We analyze the algorithms' performance and provide competitive ratio bounds. The algorithms are tested on two large infusion centers in an academic medical center and the results illustrate up to 34% improvement compared to the centers' historical data.

2 - Improving the use of Operating Rooms using Surgeon Input

Brian Han, Marshall School of Business, University of Southern California, Los Angeles, CA, United States, rongqing.han.2019@marshall.usc.edu, Song-Hee Kim

When allocating operating room times to surgery cases, hospitals need to know how long the surgeries will take. Although the estimation of surgery case duration has been extensively studied, accurately predicting surgery case duration remains a challenge. We examine ways to systematically combine surgeons' forecasts with a model based on observed attributes to improve the accuracy of surgery case duration predictions, and hence the use of operating rooms.

3 - Dynamic Appointment Scheduling of Elective Surgeries under Bed Capacity Constraint

Chengyu Wu, Duke University, 877 Louise Circle, Durham, NC, 27705, United States, chengyu.wu@duke.edu, Li Chen, Jing-Sheng Jeannette Song

We study the problem of scheduling elective surgeries that aims to provide patients with specific surgery dates at the time when they call in, taking into account the ICU capacity and occupancy. In doing so, we develop a heuristic and then validate it using real hospital data.

4 - Managing Appointment-based Services in the Presence of Walk-in Customers

Nan Liu, Columbia University, New York, NY, 10032, United States, nan.liu@columbia.edu, Shan Wang, Guohua Wan

Walk-in customers are accepted in many service industries and especially in healthcare. Motivated by practice in two large community health care networks in NYC, we study how to schedule patients in a clinic session in anticipation for random walk-ins. We use a Poisson regression framework to analyze the temporal pattern of walk-ins based on 3-year data, and propose data-driven optimization models to identify the optimal appointment schedule. We show that the objective function is multimodular, and this elegant structural property allows us to develop efficient solution algorithms. Our models can be applied to general appointment-based services in the presence of random walk-in customers.

1 - Carta: A Course Exploration Platform for Undergraduates

Ramesh Johari, Stanford University, Huang Engineering Center Rm 311, 475 Via Ortega, Stanford, CA, 94305-4121, United States, ramesh.johari@stanford.edu, Tum Chaturapruek, Michael Bernstein, Mitchell Stevens

Students' course choices made early in the college career can largely shape academic options and occupational opportunities later on, but pathways and course selection decision making that leads to these choices are mostly invisible. To address these limitations, we introduce Carta, a web application that provides students with information to inform how they navigate their undergraduate careers. It deploys complete data on enrollments, outcomes, and course evaluations. In this talk we describe the platform, as well as some initial research findings from its deployment.

2 - Non-monetary Dynamic Allocation to Agents with Unit Demand

Peng Shi, USC Marshall School of Business, Los Angeles, CA, United States, pengshi46@gmail.com, Nicholas A.Arnosti

We consider a setting in which agents and items match dynamically over time and monetary transfers are limited. Applications include the allocation of subsidized housing and of discounted tickets. We compare five mechanisms: waitlist with rejection, waitlist without rejection, repeated lottery with infinite entry, single-entry lottery, and ticket-saving lottery. We show that each mechanism is equivalent to one of the two versions of the waitlist. (Equivalence means that for each agent, the distribution of match values are the same in either mechanism.) We compare the utilitarian welfare between these two classes of mechanisms based on the tail of the outside option distribution.

3 - Iterative Local Voting for Collective Decision-making in Continuous Spaces

Vijay Kamble, University of Illinois Chicago, Chicago, IL, United States, vijaykamble.iitkgp@gmail.com

Many societal decision problems lie in high-dimensional continuous spaces not amenable to the voting techniques common for their discrete or single-dimensional counterparts. These problems are typically discretized before running an election or decided upon through negotiation by representatives. We propose a meta-algorithm called Iterative Local Voting for collective decision-making in this setting, in which voters are sequentially sampled and asked to modify a candidate solution within some local neighborhood of its current value. We explore the convergence of such a scheme and test our algorithm for the decision of the U.S. Federal Budget on Mechanical Turk with over 4,000 workers.

4 - Dynamic Matching in School Choice: Efficient Seat Reassignment After Late Cancellations

Irene Yuan Lo, Columbia University, New York, NY, 10025, United States, iyl2104@columbia.edu, Itai Feigenbaum, Yash Kanoria, Jay Sethuraman

We consider the problem in centralized school admissions of reassigning seats after students obtain better outside options. We introduce the Permuted Lottery Deferred Acceptance (PLDA) mechanisms, which assign seats using two rounds of the standard Deferred Acceptance mechanism where the second-round tie-breaking lottery is a permutation of the first-round lottery. We show that a mechanism that reverses the lottery order performs best among all PLDA mechanisms, and characterize PLDA mechanisms as the class of truthful mechanisms satisfying natural efficiency and fairness properties. Empirical investigations based on NYC high school admissions data support our theoretical findings.

Health Care, Strategy and Policy

Contributed Session

Chair: George Miller, Altarum Institute, Ann Arbor, MI, United States, george.miller@altarum.org

1 - The Impact of Provider Consolidation on the Balance of Quality and Process Improvement Efforts in Health Services

Aaron H.Ratcliffe, Assistant Professor, University of North Carolina at Greensboro, 438 Bryan Building, Greensboro, NC, 27402-6165, United States, aaron.ratcliffe@uncg.edu

We develop a competitive queueing model to study how health service providers balance investments in quality which increase patient service valuation against investments in process improvements which increase service efficiency. Our analytical derivations measure the impact of provider consolidation on equilibrium quality effort, service delay and financial performance.

2 - Impact of Structural Quality and Patient Centeredness on Hospitals' Sustainable Operations: An Empirical Evidence from U.S. Hospitals

Yue Zhang, University of Toledo, 2801 W. Bancroft St., Stranahan Hall, Toledo, OH, 43606-3390, United States, yue.zhang@utoledo.edu, Aber Elsaleiby, P.S. Sundararaghavan

The Centers for Medicare & Medicaid Services (CMS) defined sets of quality dimensions as structure, process, outcome, and patient centeredness. This study investigates the role played by these quality measures in impacting hospitals' sustainable operations, which were captured through both reduced unplanned readmission and mortality rates. The analysis was conducted based on data from 571 U.S. acute care hospitals.

3 - Simulations for Evidence Based Interventions

Zhongyuan Yu, Research Assistant Professor, Stevens Institute of Technology, 221 Clinton St, Apt. 4R, Hoboken, NJ, 07030, United States, zyu7@stevens.edu, Michael Pennock

When health providers consider whether or not to implement a new intervention, they are sometimes skeptical of results from randomize clinical trials (RCTs). This is because RCTs are performed under controlled circumstances. Once the intervention is implemented, local factors such as socio-economic status and geographic dispersion of the patient population, as well as organizational culture of the provider can affect realized results. We use an interactive visualization based simulation to rerun the RCT systematically under alterative conditions, which allows decision makers to be better engaged in the discussion, and facilitates adoption of evidence based health care approaches.

4 - CPOE: Is Meaningful Use, Meaningful?

Neset Hikmet, Professor, University of South Carolina, 1301 Gervais St, Suite 1010, Columbia, SC, 29208, United States, nhikmet@sc.edu, Jeffrey S. Puckett, Benjamin Schooley

This study explores the relationship between governmental regulations and the proliferation of Computerized Physician Order Entry (CPOE) between the years 2008-2010 across federally sponsored or administered Health Delivery Organizations within the U.S. We found that a dramatic increase of CPOE installations occurred in tandem with the Medicare Improvements for Patients and Providers Act (MIPPA) of 2008, The American Reinvestment and Recovery Act (ARRA), Health Information Technology for Economic and Clinical Health (HITECH) of 2009 and Stage 1 Meaningful Use objectives (2010-2014).These incentives and mandates appear to have had a strong effect on HDO investments in CPOE technologies.

5 - "Pay for Success" Financing and Home-based Multicomponent Childhood Asthma Interventions: Modeling Results from the Detroit Medicaid Population

George Miller, Institute Fellow, Altarum Institute, 3520 Green Court, Suite 300, Ann Arbor, MI, 48105, United States, george.miller@altarum.org

Pay for Success (PFS) is a mechanism for funding public sector programs with financing from private investors who receive a payout from the public sector only if metrics identified in a performance-based contract are met. To help understand the economics of a PFS intervention in a Medicaid population, we modeled the potential impact of a childhood asthma intervention that targets children enrolled in Medicaid in Detroit. We found that such an intervention has significant potential in a PFS financing scheme if the intervention targets the most severely-affected children.

1 - Contracts for Healthcare Referral Services

Fernanda Bravo, UCLA Anderson School of Management, 110 Westwood Plaza, B4.11, Los Angeles, CA, 90024, United States, fernanda.bravo@anderson.ucla.edu, Elodie Adida

This work focuses on the B2B interaction between a service requester and a service provider in a healthcare environment. The requester is responsible for managing the health of a population of patients, and refers the patient to a provider for advanced care needs. The requester may exert effort to reduce the volume of referrals and the provider may exert effort to reduce the chance of treatment failure. We analyze a variety of payment systems between the two firms and study how to coordinate the effort decisions with either the system optimum or the social optimum.

2 - Longer Quality-adjusted Life Years with Less Cost? – Yes, the Mobile Clinic Operation Can Help

Fang Liu, Nanyang Technological University, S3-B2a-13, 50 Nanyang Avenue, Singapore, 639798, Singapore, liu_fang@ntu.edu.sg, Yulan Wang, Pengfei Guo

In this paper, we consider a discrete-time mobile clinic (MC) delivery model and study the optimal MC implementation from the viewpoint of the government. Specifically, we consider the following three objectives: (1) cost reduction, (2) improving the quality of the adjusted life years (QALYs) of the remote population, and (3) a bi-objective optimization defined as a weighted average of the above two performance measures. We then characterize the corresponding optimal MC delivery policy under each objective, and investigate how disease characteristics affect the MC operation.

3 - Empirical Queues for Health Policy Evaluation

Donald Lee, Yale School of Management, 165 Whitney Ave, Box 208200, New Haven, CT, 06520, United States, donald.lee@yale.edu

A range of health policy questions, from end-of-life care initiation to organ transplant allocation, can be modelled as stochastic networks. The transition dynamics of customers in these networks may depend not only on the network node, but also on the customer's characteristics which may be time-varying. We introduce a new approach for estimating such transition dynamics from data, in order to facilitate the simulation of high resolution counterfactuals. We use the approach to revisit a question concerning the impact of workload on service speed in emergency departments. Based partly on joint works with Ningyuan Chen and with Edieal Pinker.

4 - Reference Pricing for Healthcare Services

Shima Nassiri, University of Michigan - Ross School of Business, Ann Arbor, MI, United States, snassiri@umich.edu, Hamed Mamani, Elodie Adida

The traditional payment system between an insurer and hospitals does not incentivize hospitals to limit their prices and patients to choose less expensive providers, hence contributing to high insurer costs. Reference pricing (RP) has been proposed as a way to better align incentives and control costs. Under RP, the patient may be responsible for part of the cost if they select a high-price hospital. We propose a model to analyze the RP payment scheme that incorporates an insurer, competing hospitals, and patients with the goal of understanding how RP compares with the current payment system.

Retail Supply Chains

Sponsored: Manufacturing & Service Oper Mgmt, Supply Chain

Sponsored Session

Chair: Hao-Wei Chen, University of Toledo, Toledo, OH, 43606, United States, hao-wei.chen@sjsu.edu

1 - Supplier Encroachment with Private Selling Cost Information

Haresh B. Gurnani, Wake Forest University, 319 Farrell Hall, School of Business, 1834 Wake Forest Road, Winston Salem, NC, 27106, United States, gurnanih@wfu.edu, Huiqi Guan, Zhibin (Ben) Yang

We study channel encroachment by a supplier privately informed of its cost of direct selling. The supplier's direct selling capability may positively or negatively affect the supplier's and buyer's profits due to signaling. Both firms and consumers may be worse off from the buyer's acquisition of private cost information.

2 - Managing Opportunistic Consumer Returns in Retail Operations

Mehmet Sekip Altug, George Washington University, 2201 G.Street NW, Funger 415, Washington, DC, 20052, United States, maltug@gwu.edu, Tolga Aydinliyim, Aditya Jain

Although lenient return policies are prominently used in retail, such policies may induce opportunistic return behavior, i.e., short-term purchases with no intention to keep the product, which essentially creates two distinct market segments. In this study, we investigate three state-of-the-art retail strategies: i) Uniform ii) Targeted (enabled by data analytics) iii) Menu of choice return policies. We consider a price-setting newsvendor who also chooses an optimal refund to study the three aforementioned settings and provide insights on when retailers can justify investing in analytics-driven decision making and when they can afford to use traditional approaches to return management.

3 - Improving Supply Quality using Retailer-initiated Returns

Hao-Wei Chen, University of Toledo, Toledo, OH, United States, haowei.chen@utoledo.edu, Wen-Ya Wang

With retailer-initiated returns, customers are encouraged to return purchased items for refunds regardless of their satisfaction level. We investigate how such a strategy affects the supply chain partners' profits and the quality of the product from the supplier through stochastic models. We also discuss the timing for initiating the returns.

Inventory Management

Contributed Session

Chair: Qiang Wang, University of Science and Technology of China, Hefei, China, qiangwan@mail.ustc.edu.cn

1 - Self-reservation Policy to Deal with Fixed and Variable Stockout Costs

Boray Huang, Eindhoven University of Technology, P.O. Box 513, School of Industrial Engineering, Eindhoven, 5600MB, Netherlands, b.huang@tue.nl, Andy Wu

We consider a make-to-stock system to satisfy bulk demand with an exponential inter-arrival time. A key issue in this system is the non-convex shortage cost consisting of fixed and variable expenditures when the demand is not fully satisfied. We propose a type of self-reservation policy by a Markov Decision Process. Our numerical examples indicate the optimal policy may reduce the total average cost by 47% on average.

2 - Simple Modeling Techniques for Base-stock Inventory Systems with State Dependent Demand Rates

Fredrik Olsson, Dr., Lund University, Ole Römers väg 1, Lund, 221 00, Sweden, fredrik.olsson@iml.lth.se

In this paper new modeling techniques of (S-1,S) inventory systems with state dependent demand rates are proposed. Examples of single-location (S-1,S) inventory systems where the demand, experienced by the system, varies due to the state of the system are, e.g., inventory models with partial backorders, lost sales, perishable items, emergency replenishments etc. Instead of, as in the related literature, using partial differential equations we suggest considerably simpler techniques which are based on elementary theory of queueing and renewal processes.

3 - Inventory Models with Service Differentiation Through Response Time Guarantees

Adriana Gabor, Assistant Professor, United Arab Emirates University, Al Ain, United Arab Emirates, adriana.gabor@uaeu.ac.ae, Lars van Vianen, Guangyuan Yang, Sven B.Axsater

Service providers often differentiate their customers through their response time guarantee. Most of the inventory models however, use the fill rate as measure of differentiation. In this paper we incorporate response time guarantees into a (S-1,S,K) model with two customer classes, in which low priority customers are served only if the inventory level is above K. We employ lattice paths combinatorics to derive the exact distribution of the response time for the lower priority class and provide a simple approximation for the response time of the high priority class. We study the impact of response time guarantee on inventory levels as opposed to fill rates.

4 - Effects of Inventory Efficiency, Productivity and Responsiveness on Operational Performance

Gulsah Hancerliogullari, Istanbul Technical University, Macka Campus Faculty of Management, Department of Industrial Engineering, Istanbul, 34367, Turkey, gulsah_2207@hotmail.com, Emra H. Koksalmis

Inventory management has been a well-studied area of research in operations management. The purpose of this study is to examine the relationship between inventory management performance including inventory efficiency, inventory productivity and inventory responsiveness, and firm operational performance. We use financial data for publicly listed various U.S. industries available at Standard & Poor's Compustat database using Wharton Research Data Services (WRDS).

5 - Dual-index Policies for Two-echelon Inventory Systems with Dual Delivery Modes and Batch Orders

Qiang Wang, University of Science and Technology of China, Hefei, China, qiangwan@mail.ustc.edu.cn, Jie Wu, Chaolin Yang, Xiang Ji

In this paper, we consider a periodic-review, infinite horizon two-echelon inventory system with dual delivery modes. These two modes provide different lead times and incur different costs. The downstream stage faces random customer demands. The objective is to find inventory policies that minimize the expected long-run average cost of the system over an infinite planning horizon. Due to the complex system structure, the optimal inventory policy is unknown. In this article, we study a class of simple inventory policies, called dual-index echelon-base-stock policy, which has been proved to be near-optimal for the single-echelon inventory system with dual-sourcing.

Operations Management and Learning in Applied Probability

Sponsored: Applied Probability

Sponsored Session

Chair: Kuang Xu, Stanford University, 655 Knight Way, Stanford, CA, 94305, United States, kuangxu@gmail.com

1 - Dynamic Resource Allocation under Information Loss

Yuan Zhong, University of Chicago / Booth School of Business, 5807 S.Woodlawn Avenue, Chicago, IL, 60637, United States, Yuan.Zhong@chicagobooth.edu, Kuang Xu

We consider the problem of efficient dynamic resource allocation under information loss, in general stochastic processing systems. Information loss is modeled as an information channel. We characterize the capacity region under various channel models, and analyze the role of memory in policy design.

2 - Spectrum Estimation from a Few Entries

Ashish Kumar Khetan, University of Illinois, 104 South Matthews Avenue, Urbana, IL, 61820, United States, khetan2@illinois.edu, Sewoong Oh

Singular values of a data provide insights on the structure of the data. However, in many applications, we only get a partial observation. Under such scenarios, we consider the fundamental problem of recovering spectral properties of the underlying matrix from a sampling of its entries. We are particularly interested in recovering the spectrum, which is the set of singular values, and also in recovering a spectral sum function, which is an aggregate sum of a function applied to each of the singular values. We propose first estimating the Schatten k-norms of a matrix, and then applying Chebyshev approximation to the spectral sum function or applying moment matching to recover the spectrum.

3 - On the Performance of the M/coxian-2/n System with Preemption

Xin Liu, Arizona State University, Tempe, AZ, United States, liuxincell@gmail.com

This presentation discusses the performance of the M/Coxian-2/N system, where the mean service time in the second phase is longer than that in the first phase. The preemption policy assigns the priority to jobs in the first phase. When there are phase-1 jobs in the queue, the policy terminates phase-2 jobs in service and allocates freed servers to phase-1 jobs. The terminated phase-2 jobs are put back to the queue. We use the fluid solution to approximate the number of phase-1 jobs and the number of phase-2 jobs in the system; and use Stein's method to quantify the approximation error. We will discuss the implications of these bounds on the performance of the M/Coxian-2/N system with preemption.

4 - A Lower Bound on the Queueing Delay in Resource Constrained Load Balancing

Martin Zubeldia, MIT, Cambridge, MA, United States, mar.zubeldia@gmail.com, David Famarnik, John Tsitsiklis

We consider a distributed service model where jobs with unit mean, but general distribution, arrive and are immediately dispatched to one of several queues associated with n servers. We assume that the dispatching decisions are made by a central dispatcher endowed with a finite memory, and with the ability to exchange messages with the servers. We develop a novel approach to show that every symmetric dispatching policy with a message rate proportional to n, and with a memory of the order of log(n) bits, results in an expected queueing delay which is bounded away from zero, uniformly in n.

Sponsored Session

Chair: Alessandro Arlotto, Duke University, Durham, NC, 27708, United States, aa249@duke.edu

1 - Process Flexibility for Multiperiod Production Systems

Yuan Zhong, University of Chicago / Booth School of Business, 5807 S.Woodlawn Avenue, Chicago, IL, 60637, United States, yz2561@columbia.edu, Cong Shi, Yehua Wei

We consider process flexibility in a multi-period make-to-order production (MTO) system. First, using a new chaining notion, termed the Generalized Chaining Gap (GCG), we prove that in a general system with high utilization, a sparse flexibility structure with m+n arcs is needed to achieve similar performance as full flexibility, where m and n are the number of plants and of products, respectively. We also provide a simple and efficient algorithm for finding such sparse structures. Moreover, we show that the requirement of m+n arcs is necessary, as for some systems, even the best flexibility structure with m+n-1 arcs cannot achieve the same asymptotic performance as full flexibility.

2 - Robust Data-driven Stochastic Programming from a Bayesian Perspective

Harsha Honnappa, Purdue University, 315 N. Grant Street, West Lafayette, IN, 47906, United States, honnappa@purdue.edu, Prateek Jaiswal, Vinayak Rao

We study the problem of solving a two stage stochastic program with recourse, where the expectation is with respect to a Bayes predictive distribution. We consider two settings: first, a 'classical' Bayesian setting identifying the optimal decision when the likelihood is assumed to be known precisely. Second, an 'expert' posits a likelihood and her uncertainty about this assessment as a Kullback-Liebler ball centered at the likelihood. We then perform a minimax optimization to identify the the set of optimal decisions that are robust against the experts uncertainty. In either case, we provide large sample analysis of the effect of learning the predictive distribution on the value of the program.

3 - Escaping the Local Minima via Simulated Annealing: Optimization of Approximately Convex Functions

Tengyuan Liang, University of Chicago, Chicago, IL, United States, Tengyuan.Liang@chicagobooth.edu, Alexandre Belloni, Alexander Rakhlin, Hariharan Narayanan

We consider the problem of optimizing an approximately convex function over a bounded convex set using only function evaluations. The problem is reduced to sampling from an approximately log-concave distribution using the Hit-and-Run method, which is shown to have the same complexity as sampling from log-concave distributions. In addition to extend the analysis for log-concave distributions to approximate log-concave distributions, the implementation of the 1-dimensional sampler of the Hit-and-Run walk requires new methods and analysis. The algorithm then is based on simulated annealing which does not relies on first order conditions which makes it essentially immune to local minima.

4 - A O(log N)-optimal Policy for the Dynamic and Stochastic Knapsack Problem with Equal Values

Xinchang Xie, Duke University, xinchang.xie@duke.edu, Alessandro Arlotto

We study a dynamic and stochastic knapsack problem in which a decision maker is sequentially presented with n items and needs to select which items to include in a knapsack with fixed capacity. Arriving items have non-negative, independent sizes with common continuous distribution, and every decision is terminal upon arrival. The goal is to maximize the expected number of selections under capacity constraint. An adaptive online policy is proposed and proved to be within O (log n) of the optimal, under mild regularity conditions on the distribution. We also discuss how the distribution of the number of selections under this adaptive policy compares with the number of selections under the optimal policy.

1 - The Freak Out Factor: Retail Investor Behavior in Response to the Global Financial Crisis

Andrew W. Lo, Massachusetts Institute of Technology, Sloan School of Management, Charles E. & Susan T. Harris Professor, Cambridge, MA, 02142, United States, alo@mit.edu

This paper represents the first look at a novel and comprehensive historical brokerage trading dataset that is unique in its breadth of coverage, with over 700k U.S. accounts, and longevity, containing monthly snapshots spanning January 2005 to December 2015. By synthesizing this data with daily asset price series, we are able to observe the dynamics of retail households' investment portfolios at daily frequency before, during, and after the 2008 Global Financial Crisis. We identify canonical empirical behaviors such as the propensity to sell securities and/or portfolios when experiencing extreme positive or negative returns in the recent past, known in the psychology literature as the "disposition" and "loss aversion" effects. We use modern machine learning methods to develop performant predictive models of trading and liquidation, and assess the sensitivity of these models to their key factors including past returns, past trading, balances, allocations, and demographic characteristics. We also document liquidation behavior during the crisis, defined as the reallocation of holdings in risky assets to cash for prolonged periods of time, both for investors facing different drawdowns in their portfolios and those from different demographic segments. We find that investors with the worst historical experiences during the crisis were more likely to liquidate, maintained less aggressive allocations in risky assets for longer periods of time, and experienced worse risk-adjusted returns during the post-crisis recovery period.

1 - Text Based Positioning of Firms Along the Supply Chain

Dimitry Slavin, Ross School of Business, University of Michigan, Ann Arbor, MI, United States, dslavin@umich.edu

An objective method of identifying a firm's economic position based on the content of its annual financial disclosures is proposed. The method's key components include (i) the creation of a consumption-risk related lexicon, (ii) several natural language processing techniques (keyword-extraction, part-of-speech tagging, named-entity recognition, etc.), and (iii) an iterative clustering procedure. The proposed method reveals previously-unknown interdependencies between firms, and is expected to serve as a new, unbiased measure of a firm's supply-chain-related risk.

2 - R&D Spending: Dynamic or Persistent?

Christophe Pennetier, INSEAD, 6 Marina Boulevard, # 27-15, Singapore, 018985, Singapore, christophe.pennetier@insead.edu, Karan Girotra, Jurgen Mihm

We study how a given amount of R&D spending is best allocated over time to optimize R&D performance. Using a sample of US public companies, we estimate the interaction between R&D investment and types of innovation strategy.

Sourcing Innovation Using Contests

Sponsored: Technology, Innovation Management & Entrepreneurship

Sponsored Session

Chair: Lakshminarayana Nittala, Rady School of Management, lakshmi.nittala@rady.ucsd.edu

1 - Innovation Tournaments with Multiple Contributors

Ersin Korpeoglu, University College London, Flat 27 Kingfisher Heights Waterside Way, London, N17 9GL, United Kingdom, e.korpeoglu@ucl.ac.uk, Laurence Ales, Soo-Haeng Cho

In an innovation tournament, an organizer seeks innovative solutions from multiple agents. Agents exert efforts to improve solutions, whose performance is uncertain. We analyze a general model of uncertainty and consider a case in which the organizer seeks multiple solutions. We show that contrary to existing theories, increased competition in a tournament can increase agents' efforts when agents expect good outcomes with high likelihood, and a free-entry open tournament should be encouraged only when agent uncertainty is high or the organizer seeks many diverse solutions.

2 - Motivating Participation and Effort in Innovation Contests

Konstantinos Stouras, Postdoctoral Research Fellow, The Darden School, University of Virginia, 100 Darden Boulevard, Charlottesville, VA, 22903, United States, kostas@virginia.edu, Jeremy Hutchison-Krupat, Raul Chao

An innovation contest is a business process through which a firm crowdsources innovation to a large pool of solvers. Solvers are ex ante heterogeneous and decide whether to participate and how much effort to exert to enhance their performance. We characterize how firm's choice of reward allocation affect solver voluntary participation and effort behavior in equilibrium. We show that multiple awards are beneficial to balance the tension between how many solvers to attract and of what type, and how much effort they would exert towards maximizing the top performance of the participating solvers.

3 - Simultaneous vs. Sequential Crowd Sourcing Contests

Lu Wang, University of Toronto, Rotman School of Management, 105 St George Street, Toronto, ON, M5S.3E6, Canada, lu.wang12@rotman.utoronto.ca, Ming Hu

In a crowdsourcing contest, innovation is outsourced to an open crowd. We consider two alternative mechanisms for an innovative project involving multiple attributes. One is a simultaneous contest, where the best solution is chosen from the aggregate solutions simultaneously submitted by all contestants. The other is multiple sequential sub-contests, with each dedicated to one attribute and the contestants asked to build upon the best work in progress from previous sub-contests. While both mechanisms have their own advantages, either could win over depending on situations.

4 - Designing Internal Innovation Contests

Lakshminarayana Nittala, University of California-San Diego, Rady School of Management, 9500 Gilman Drive, La Jolla, CA, 92093, United States, lnittala@ucsd.edu, Sanjiv Erat, Viswanathan Krishnan

Firms can use contests to engage employees in finding solutions to its problems related to innovation and product development. We present an analytical model inspired by field work to highlight the unique aspects associated with such internal contests and discuss design recommendations.

Data Analytics Models for Healthcare

Invited: InvitedHealthcare Systems and Informatics

Invited Session

Chair: Kai Yang, Wayne State University, Detroit, MI, 48201, United States, kai.yang@wayne.edu

1 - Integration of Multiple Health Information Systems for Quality Improvement of Radiologic Care:

Jing Li, Ph.D, Arizona State University, AZ, United States, jing.li.8@asu.edu

In radiology, several electronic Health Information Systems (HISs) are used: EHR, RIS, and PACS. Each HIS records partial and complementary information about the radiologic care process. We developed a novel technology called Department Data Depot (DDD) that integrates multiple HISs in radiology. We propose nine Quality of Care (QoC) metrics defined upon the data from DDD that measure various dimensions of care quality such as timeliness, efficiency, patient satisfaction, and workload distribution. To demonstrate the clinical utility of DDD, we developed and deployed a web application system, the Radiology Quality Dashboard (RQD), at Mayo Clinic in Arizona (MCA). Use cases will be presented.

2 - Mining Major Patterns of Disease Progression in Patients with Multiple Chronic Conditions

Adel Alaeddini, Assistant Professor, University of Texas at San Antonio (UTSA), San Antonio, TX, United States, Adel.Alaeddini@utsa.edu

Approximately one in four Americans and 75% of citizens aged 65+ years are burdened with MCC. Treatment for people living with MCC currently accounts for an estimated 66% of the Nation's health care costs; a number that is only expected to grow. However, it is still not known precisely how MCC emerged among individuals or in the general population. Using a dataset of more than half million patients being monitored over 10 years, this study investigates major patterns of MCC progression in a diverse population of patients and identifies the risk factors affecting the patterns.

3 - The Vector Representation of Medical Codes using Latent Semantic Mapping

Liwen Cui, Tsinghua University, Shunde Building, Room 615, Beijing, 100084, China, cuiliwen0512@126.com, Xiaolei Xie, Zuo-Jun Max Shen, Zuo-Jun Max Shen, Haibo Wang, Rui Lu

Nowadays, modern machine learning techniques are widely applied in healthcare fields, a tremendous challenge faced by previous research is how to deal with the huge amount of different medical codes that represent diagnosis or surgical operations. We propose a framework that transforms medical codes to vector representations using latent semantic mapping in natural language processing. Our method significantly outperforms various traditional dimensionality reduction methods in healthcare resources prediction, which demonstrate its application potentiality in healthcare predictive analytics.

4 - Hospital Time-to-Readmission Risk Modeling with Latent Heterogeneity

Suiyao Chen, University of South Florida, 5017 Patricia Court, Apt 237, Tampa, FL, 33617, United States, suiyaochen@mail.usf.edu, Nan Kong, Xuxue Sun, Hongdao Meng, Mingyang Li

Hospital readmission risk modeling is of great interest to reduce preventable readmissions and advance care quality. A readmission risk model is preferable if it exhibits superior prediction performance, identifies risk factors and constructs composite metrics to evaluate multiple hospitals. To simultaneously address these features, this paper proposes the models with incorporation of level-specific latent heterogeneity, leveraging the larger scale and less fragmented administrative claims data. To demonstrate the prediction performances of the proposed models, a real case study is considered on a state-wide heart failure patient cohort.

Revenue Management with Choice Models

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Zizhuo Wang, University of Minnesota, Minneapolis, MN, 55414, United States, zwang@umn.edu

1 - Assortment Optimization under a Single Transition Model

Zizhuo Wang, University of Minnesota, 1009 5th Street SE, Minneapolis, MN, 55414, United States, zwang@umn.edu, Kameng Nip, Zhenbo Wang

We consider a Markov chain choice model with single transition. In this model, customers arrive at each product with a certain probability. If the arrived product is unavailable, the seller can recommend a subset of products and the customer will purchase one of the recommended products or choose not to purchase with certain transition probabilities. We study the assortment optimization problem under this model. We show that this problem is NP-Hard while proposing polynomial time algorithms for several special cases and a compact mixed integer program formulation that can solve this problem of large size. We also provide a tight performance bound for revenue-ordered assortments.

2 - Assortment Optimization under Paired Combinatorial Logit Model

Heng Zhang, University of Southern California, Los Angeles, CA, 90007, United States, hengz@usc.edu, Paat Rusmevichientong, Huseyin Topaloglu

We study uncapacitated and capacitated assortment optimization under the paired combinatorial logit model, where the goal is to find a set of products to maximize the expected revenue. We show that even the unconstrained problem is strongly NP-hard. We cast both problems as one of finding the fixed point of a function, whose evaluation requires solving a non-linear integer program. Relaxing this integer program provides a framework for approximation algorithms. We use LP and SDP relaxations with randomized rounding to give 0.6 and 0.79 performance guarantees for the un-capacitated problem, and use LP relaxation with iterated rounding to give a 0.25 performance ratio for the capacitated problem.

3 - Multi-stage Assortment Problems under the Multinomial Logit Model

Yuhang Ma, Cornell University, Ithaca, NY, United States, ym367@cornell.edu, Huseyin Topaloglu

We consider an assortment problem where we offer sets of products in multiple stages and the choice process at each stage is driven by the multinomial logit model. In particular, we have K stages. At each stage, we offer a distinct set of products. If the customer makes a purchase at a certain stage, then her choice process terminates. If the customer does not make a purchase at a certain stage, then she observes the set of products offered at the next stage. The goal is to find a set of products to offer at each stage to maximize the expected revenue obtained from a customer. We show that the problem is NP-hard and develop an FPTAS.

4 - Data Driven Assortment Optimization

Velibor Misic, UCLA Anderson School of Management, Los Angeles, CA, 90095, United States, velibor.misic@anderson.ucla.edu, Dimitris Bertsimas

We present a procedure for transforming data into assortment decisions through a nonparametric, ranking-based choice model. Our procedure consists of an estimation step, which involves solving a large-scale linear optimization problem using column generation to obtain a ranking-based model, and an optimization step, which involves solving a mixed-integer optimization model to obtain the assortment. We provide theoretical results on the tractability of our formulations. We evaluate the effectiveness of our method numerically with real and synthetic data and show that it outperforms alternative parametric and nonparametric proposals.

1 - Quantile Regression - Another Option to Calculate Elasticity for Market Response Models

Justin Ji, Consultant, Operations Research, Revenue Analytics, Atlanta, GA, United States, jj@revenueanalytics.com, Pratik Mital

Quantile regression was first introduced by Roger Koenker and Gilbert Bassett in 1978. It offers more complete statistical model than traditional least squares regression. Quantile regression targets at estimating the conditional median or quantiles of the response variable via investigating the relative level of influences for predictor variables. In addition, quantile regression method is more robust against outliers. In this study, the authors will use traditional least square regression model and quantile regression model to calculate elasticity for market response model.

2 - Emerging Topics in Revenue Management for the Cruise Industry

Greg Vogel, Holland America, Seattle, WA, United States, gvogel@hollandamerica.com

Much research has been done in traditional travel and hospitality industries such as Airlines, Hotels, Resorts, Casinos etc. Very little has been done in regards to the specific problem that are cruise lines. In this talk we discuss similarities and differences between traditional OR research into these industries and the cruise industry and then delve into the problems that the industry is most interested in solving along with an overview of problems that are currently being investigated.

3 - Dynamic and Static Airline Overbooking for Network

Wei Wang, Ph.D, PROS, Houston, TX, United States, weiwang@pros.com

Overbooking and cancellation are important aspects of revenue management, and much research including dynamic programming-based solutions is available in the literature. However, in practice airlines today are still applying static approaches. As an extension to our previous work for single leg, we present a simulation-based comparison of different models under both dynamic and static policies on the network, in particular we allow both no-show refund and cancellations refund to be class dependent.

4 - Maximizing Impact of Customer Reviews & Ratings Sentiment Analysis for Hoteliers

Vinodh Balaraman, ZS Associates, NJ, United States, vinodh.balaraman@zs.com

Maximizing Impact of Customer Reviews & Ratings Sentiment Analysis for Hoteliers Customers' choices seemingly are limitless and so too are their outlets for sharing experiences & opinions. This leaves hotels struggling to influence the customer decision journey, protect their brand and win business. As the volume of social media content explodes, how can hotels leverage data from customers' online activity to deliver a truly unique experience and capture greater market share? In this session, actionable steps will be offered to: 1. Select and process the right customer data from the vast amounts available. 2. Build a strategic roadmap to drive incremental ROI.3. Create greater customer loyalty.

1 - Dynamic Two-Side Platform Pricing in C2C Online Sharing Ecosystems

Peter Angerer, University of Innsbruck, Innsbruck, Austria, peter.angerer@uibk.ac.at, Daniel Provin, Steffen Zimmermann, Barrie R.Nault

Sharing platforms facilitate the sharing of goods between lenders and borrowers. Using an analytical model, we found that sharing platforms have to dynamically adjust platform fees to both consumer groups (dynamic two-sided platform pricing) in order to be profit maximizing. However, the impact of dynamic two-sided platform pricing on consumer's perception of fairness remains unclear. Using a laboratory experiment, we find that fee changes over time have only a moderate effect on perception of fairness while fee differences between lenders and borrowers have a strong negative effect on perception of fairness and intention to share. Thus, sharing platforms need to be aware of those effects on perception of fairness when applying dynamic two-sided platform pricing.

2 - Hitting too Close to Home?: Impact of Airbnb on Hotel Entry

Uttara Madurai Ananthakrishnan, Carnegie Mellon University, 3 Bayard Road, Apt B3, Pittsburgh, PA, 15213, United States, umadurai@andrew.cmu.edu

Participation in sharing economy has been increasing in the past few years. In this paper, we study how entry of sharing economy firms impacts the entry of incumbent hotels in the context of Airbnb. To understand the impact on entry, we exploit the temporal and geographical variability in Airbnb's entry into a market and employ a difference-in-differences specification. Further, we build an entry-model to estimate the business stealing effect of Airbnb. Our results indicate that 10% increase in Airbnb properties leads to a decrease in hotel entries of about 0.4%. Based on this, we perform simulations and provide policy recommendations to city governments to plan for an increasing number of Airbnb entrants.

3 - The Tragedy of your Upstairs Neighbors: When is the Home-Sharing Externality Internalized?

Apostolos Filippas, New York University-Stern, New York University-Stern, New York, NY, 10012, United States, apostolosfilippas@gmail.com, John Joseph Horton

A common critique of home-sharing platforms is that they enable hosts to impose costs on their neighbors. We consider four potential public policy responses that differ in whether the decision right to host is allocated to: (1) individual tenants, (2) building owners, (3) cities, and (4) a social planner. We find that (2) and (4) are equivalent, with (3) leading to too little hosting, and (1) to too much hosting. The efficiency of (2) depends on building owners being indifferent between allowing and banning home-sharing in their buildings. To assess this "no policy arbitrage" prediction, we constructed a dataset of NYC rental apartments listings. Although we do not observe building home-sharing policies, there are several "policy" attributes captured in the data, such as whether buildings allow subletting. Consistent with our prediction, we find that policy choices have no detectable effect on rental prices. Despite the attractiveness of the equilibrium of policy (2), tenants must "sort" across buildings, potentially at substantial cost. We explore this sorting with an agent-based model, and show how individual preferences and moving costs affect the equilibrium.

4 - The Welfare Effects of Peer Entry in the Accommodations Market: the Case of Airbnb

Andrey Fradkin, Massachusetts Institute of Technology, 179 Prospect Street, Cambridge, MA, 02139, United States, Afradkin@gmail.com

I will present one of two projects on the effects of peer-to-peer marketplaces on the economy. Either a project about the accommodations industry or a project about the local services industry. These will include analysis of data from digital platforms.

Managing Information and License in Technology Industries

Invited: New Product Development

Invited Session

Chair: Hyoduk Shin, UC-San Diego, La Jolla, CA, 92093, United States, hdshin@ucsd.edu

Co-Chair: Jingqi Wang, jingqi@hku.hk

1 - Perils of Bargaining Power in Biotechnology R&D Licensing

Niyazi Taneri, National University of Singapore, Singapore, niyazi@nus.edu.sg, Arnoud De Meyer

Both the fate of a product and future payments to the innovator (licensor) in R&D license agreements depend on go/no go decisions. This presents a tradeoff between enhanced outcomes due to partner expertise and terminations purely due to a partner's economic concerns even when clinical prospects are good. We find support for the argument that a larger deal value creates a higher hurdle to clear, thereby increasing the likelihood of a termination. Further investigation reveals that this is due to endogeneity: Underlying drivers of deal value determine whether its effect is positive or negative.

2 - Managing Technology and Licensing in Supply Chains

Jingqi Wang, The University of Hong Kong, Room 806, K.K. Leung Building, The University of Hong Kong, Hong Kong, jingqi@hku.hk

We study how a supplier should manage the technology and license in a supply chain with competing manufacturers. Should the supplier implement cross-licensing policy? Our research shows that it depends. We also investigate the impacts of such cross-licensing policies on manufacturers, and consumers.

3 - Information Exchange in Parallel Search

Ni Fang, University of Cologne, Cologne, Germany, fang@wiso.uni-koeln.de, Fabian J. Sting

How should organizations share and use information in parallel innovation, from an internal and external competitive perspective? Using a framework of co-evolutionary search on a technology landscape, we demonstrate how firms can strike a balance for the fundamental trade-off: the efficiency of channeled search vs. the breadth of autonomous search.

350C

Economics of IS and Operations-Marketing?? Interface

Invited: Social Media Analytics

Invited Session

Chair: Soohyun Cho, Rutgers University, Newark, NJ, 07102, United States, scho@business.rutgers.edu

1 - Designing Electronic Markets for Transportation

Arim Park, Rutgers University, Newark, NJ, United States, arim.park@rutgers.edu, Yao Zhao

There are many trucker strikes since 2002 in Korea which brought significant losses on the nation's economy. We would like to design a fair and efficient mechanism for an electronic market of transportation services in Korea. To this end, we would first identify preferences for both customers and carriers, then develop a two-sided matching model for transportation services to facilitate transaction between customers and carriers. Our objective is to design efficient and fair market mechanism which can serve as the engine of the electronic market.

2 - Beauty Contest and Fintech Revolution

Anurag Garg, Graduate Assistant, University of Florida, Warrington College of Business, Bryan Hall 100. PO Box 117150, Gainesville, FL, 32603, United States, anurag.garg@warrington.ufl.edu, Liangfei Qiu, Subhajyoti Bandyopadhyay

Following the insight of Keynes (1936) on beauty contest, we develop a model that formalizes higher order beliefs and speculative trading in financial markets. We look into the effects of higher order beliefs (and precision of private and public information) on price drift, trading volume - price volatility relationship and on social welfare.

4 - Corporate Prediction Market with Over-Optimistic Participants
Jingchuan Pu, University of Florida, 2300 SW 43rd Str, R1, Gainesville, FL, 32607, United States, jingchuan@ufl.edu, Liangfei Qiu

Recently, corporate prediction market has been growingly popular for the decision making. Even though it has an important role to integrate participates' information, the corporate prediction market is inevitably affected by the participates' irrational thinking. Over-optimism is one of well-known irrationality in the corporation. In this study, we investigate the effect of the information precision and social interactions on the prediction market performance, when there is systematical over-optimism among the market participants.

5 - Quantifying the Effect of Social Media On Crowdfunding Campaigns
Mahdi Moqri, University of Florida, 725 NW. 13th St. 3410, Gainesville, FL, 32601, United States, mahdi.moqri@warrington.ufl.edu

Using a unique dataset from 590 crowdfunding campaigns observed over 4 months, we examine to what extent, and how quickly online WOM affect the rate of contributions. In addition, we explore the effect of different phases of fundraising and of the coverage of the campaigns in online news websites.

Auction Applications

Invited: Auctions

Invited Session

Chair: Robert Day, University of Connecticut, Storrs, CT, 06269-1041, United States, Bob.Day@business.uconn.edu

1 - The Role of Optimization in the Incentive Auction
Karla L. Hoffman, George Mason University, System Eng and Operations Research Dept, 4400 University Drive Mailstop 4a6, Fairfax, VA, 22030, United States, khoffman@gmu.edu, Brian Smith, James Andrew Costa, Rudy K.Sultana, Anthony Coudert

The FCC completed the Broadcast Incentive Auction on March 29, 2017. This auction reassigned television stations onto fewer channels in the United States and Canada and repurposed a significant amount of spectrum for wireless use. Optimization played a vital role in the success of the auction. This talk will reflect on the OR activities that took place before, during and after the auction. We will highlight some of the results from the auction and some of the lessons learned.

2 - Watershed Market Design: the Case of the Central Platte Groundwater Exchange
David McAdams, Duke University, 100 Fuqua Drive, Durham, NC, 27708, United States, david.mcadams@duke.edu

Groundwater and surface water are connected hydrologically, but limited options are available for groundwater and surface water users to contract on water use. I propose a relatively simple watershed-market design that generates location-specific water prices and respects regulatory constraints on water flows and water use. This market design was adopted by farmers in the Central Platte Natural Resources District in Nebraska in 2016.

3 - Bidding and Learning in Repeated Auctions
Karti Puranam, LaSalle University, Philadelphia, PA, 19141, United States, kartys.here@gmail.com, Michael Katehakis

We consider the problem of a firm that procures substitutable items in a sequence of auctions by bidding against the "market." The firm and the "market" learn from each winning bid. We study bidding strategies for the firm when the objective of the firm is to maximize long run discounted profit.

4 - Supplier Versus Supply Base Development
Karca Duru Aral, Syracuse University, 721 University Avenue, Syracuse, NY, 13244, United States, kdaralwa@syr.edu

A buyer may choose to sign a long-term contract with an incumbent to encourage cost reduction (which consequently strengthens the incumbent's monopoly). The buyer can instead choose to invest in developing entrants to challenge the incumbent in a competitive-bid procurement auction - both of which are risky options. We analyze when the buyer should break the incumbent's monopoly and characterize how this decision changes with the buyer's business environment.

350E

Analyzing Social Networks and Social Media for Healthcare

Sponsored: Artificial Intelligence

Sponsored Session

Chair: Xi Wang, University of Iowa, Iowa City, IA, 52246, United States, xi-wang-1@uiowa.edu

1 - Mining User-generated Data in OHC for Drug Related Information
Zhao Mengnan, PhD Candidate, Drexel University, Philadelphia, PA, United States, mz438@drexel.edu

A variety of data resources has been used to identify healthcare-related information, mainly including biomedical database, medical literature, electronic health record (EHR), and clinical note. While these data sources are informative, they are mainly contributed by healthcare professionals. None of them capture the information offered by health consumers. Meanwhile, the popularity of Web 2.0 not only breeds the various online social media sites like Facebook and Twitter, but also fosters online health communities (OHCs). OHCs have been widely used for exchanging health information between health consumers. We focus on detecting drug-related information from OHC data.

2 - Impact of Social Media on Copycat Suicides
Jie Mein Goh, Simon Fraser University, 8888 University Drive, Burnaby, BC, V5A 1S6, Canada, jmgoh@sfu.ca, Srabana Dasgupta, Nilesh Saraf, Dianne Cyr

Prior studies have suggested that widely publicized celebrity suicides often lead to an increase in copy-cat suicides. This is also known as the Werther effect. Given the prevalent use of social media, social-media based conversations after the suicide of a celebrity create significant buzz and generate publicity. However, whether the Werther effect can be caused by social-media conversations on celebrity suicides remains an empirical question. In this study, we test this effect by examining whether and how social media impacts copy-cat suicides using a data set collected from Twitter.

3 - The Impact of Social Capital on Users' Future Contributions in an Online Health Community
Xi Wang, University of Iowa, 810 W. Benton St B213, Iowa City, IA, 52246, United States, xi-wang-1@uiowa.edu
Xi Wang, Central University of Finance and Economics, Beijing, China, xi-wang-1@uiowa.edu, Yuanyang Liu, Kang Zhao, Gautam Pant

Online health communities are increasingly popular sources of information and support for people with health concerns. Encouraging users to make contributions on these platforms, however, is a challenge. Using an online health community for cancer survivors, this study examined if a user's social capital could impact the user's level of future contributions. The outcome reveals that different types of social capital may trigger a user's future contributions in one or more ways.

350F

Social Media and Analytics – A Spectrum of Ideas from Diverse Industries

Invited: Social Media Analytics

Invited Session

Chair: Fay Cobb Payton, North Carolina State University, Raleigh, NC, 27695, United States, fay_payton@ncsu.edu

1 - The Value of Social Media Data in Color Trends Forecasting and Inventory Decisions
Youran Fu, University of Pennsylvania, 3730 Walnut Street, Room 532, Philadelphia, PA, 19104, United States, youranfu@wharton.upenn.edu, Marshall L.Fisher

We partnered with 3 leading apparel retailers to investigate how to use social media data to improve fashion color trend forecasting. We find that using fine-grained Twitter data and the Google search volume index to predict product-color sales three months out can significantly reduce forecast error compared to conventional methods.

2 - Social Sharing and Emerging Infectious Disease Contexts
Bridget Kelley, RTI International, Research Triangle Park, NC, United States, Sarah Ray, Brian Southwell, Linda Squiers, Molly Lynch

Social media may amplify information sharing, but their role during infectious disease outbreaks is unclear empirically. Our content analysis of Twitter posts (n=400) during the 2014 Ebola outbreak suggests most (61%) shared news articles whereas almost none shared government or public health websites, which holds implications for communication efforts.

3 - Brainwave Data Analytics
Kyla McMullen, University of Florida, Gainesville, FL, United States, dr.kyla.mcmullen@gmail.com

Brain-computer interface (BCI) involves the collaboration between a brain and a hardware device, which enables signals from the brain to direct some external activity. BCI data contains the recordings of brain activity through a number of channels over time. Using an Electroencephalography (EEG) device to record brainwave data, a channel can be defined as the electrical potential between a recording electrode and a reference electrode, on the scalp. To control a BCI, the user must produce different brain activity patterns that are identified by a system and translated into commands. The present work uses pattern recognition to create an adaptive brainwave classification system for contexts in which portions of the brainwave signals are missing or otherwise deteriorated.

4 - Does Government Surveillance Give Twitter the Chills?
Uttara Ananthakrishnan, Carnegie Mellon University, 1 Bayard Road, # 28, Pittsburgh, PA, 15213, United States, uttara@cmu.edu

Since Edward Snowden's revelations regarding mass surveillance programs implemented by the NSA, the research community has attempted to estimate what many refer to as "chilling effects" of surveillance, or the tendency to self-censor in order to cope with mass monitoring systems. We propose a new method in order to test for chilling effects in online social media platforms. We use a unique, large dataset of Tweets and propose the use of new statistical machine learning techniques in order to detect anomalous trends in user behavior (use of predetermined, sensitive sets of keywords) after Snowden's revelations made users aware of existing surveillance programs.

Drone Delivery Systems – III

Invited: InvitedDrone Delivery Systems (tentative title)

Invited Session

Chair: Jaeyoung Cho, Lamar University, Beaumont, TX, 77710, United States, jcho@lamar.edu

1 - Optimizing a Drone Network to Deliver Automated External Defibrillators
Justin James Boutilier, University of Toronto, 532 Palmerston Boulevard, Apartment 6, Toronto, ON, M6G 2P5, Canada, j.boutilier@mail.utoronto.ca, Timothy Chan

Public access defibrillation programs can improve survival after out-of-hospital cardiac arrest (OHCA), but automated external defibrillators (AEDs) are rarely available for bystander use at the scene. In this paper, we develop a framework that combines both location and queueing models to optimize the deployment of drone resources. In particular, we use a CVaR-based response time model that accounts for the historical 911 response time distribution and models the efficiency-equity trade-off between urban and rural areas. We applied our framework to 50,000 historical OHCAs in a large area composed of rural and urban regions surrounding Toronto, Canada.

2 - A Real-time Drone Reroute Planning under Uncertain Flight Duration
Seonjin Kim, University of Houston, 529 Barker Clodine, 17101, Houston, TX, 77094, United States, sonjin64@gmail.com, Gino J.Lim

A real-time drone reroute planning method is proposed to handle the issue of uncertain flight duration. Such undesired situations can arise due to unexpected external events such as strong winds and moving obstacles on the flight path. A rerouting algorithm is designed to utilize alternative routes in real-time. A solution approach is also developed to improve the computational performance of the proposed optimization model. In a numerical example, feasibility and effectiveness of the proposed method are illustrated using a case study.

3 - Strategic Network Design for Parcel Delivery with Drones
Fatma Gzara, University of Waterloo, 200 University Avenue W, Waterloo, ON, N2L.3G1, Canada, fgzara@uwaterloo.ca

We study the effects of drone delivery on network design for e-retailers. We develop a nonlinear optimization model that locates warehouses and decides on services offered where one of the services is delivery by drones within a short time window. Customer demand is modeled using interaction model. We develop a novel Logic based Benders decomposition algorithm to solve the nonlinear formulation and perform numerical testing on the NYC case.

4 - Utilization of Unmanned Aerial Vehicles in Port Operations
Jaeyoung Cho, Lamar University, P.O. Box 10024, Beaumont, TX, 77710, United States, jcho@lamar.edu, Maryam Hamidi, Berna Tokgoz

The purpose of this study is to lay the foundation for the development of future port system using unmanned aerial system. We propose a new mathematical optimization model of chemical tankers routing which are performing their respective loading / unloading operations by the support of unmanned aerial vehicles (UAVs). This problem is modeled as a two-echelon vehicle routing problem as the route of the vessels and the path of UAVs must be optimized at the same time.

AAS Best Student Presentation Competition II

Sponsored: Aviation Applications

Sponsored Session

Chair: Virginie Lurkin, Ecole Polytechnique Fédérale de Lausanne, Route Cantonale, Lausanne, 1015, Switzerland, vlurkin@ulg.ac.be

Co-Chair: Peng Wei, Iowa State University, Iowa State University, Ames, IA, 50011, United States, pwei@iastate.edu

1 - A Static Model in Single Leg Flight Airline Revenue Management
Behrooz Pourghannad, University of Minnesota, 1007 29th Avenue SE, Apt B, Minneapolis, MN, 55414, United States, behrooz@umn.edu

Static models on single leg airline revenue management generally consider booking limits or protection limits as the main decision variables to control reservation requests. In the current paper, we provide an alternative framework in which the decision variables are the closing times of fare classes. In a continuous time model with nonhomogeneous Poisson arrivals, cancellations, and noshows, we study the problem of finding optimal closing times to maximize the expected net revenue from a given flight. We analyze the value function, point out some easy cases, and bring an easily implementable dynamic programming based solution method. We also illustrate this method on some numerical examples.

2 - An Optimization Approach for Airport Slot Allocation under the IATA Guidelines
Nuno Ribeiro, cmu, Portugal, Coimbra, Portugal, nribeiro@andrew.cmu.edu

We present a novel modeling and computational approach to optimize slot allocation decisions at schedule-coordinated airports. The model minimizes the displacement from airlines' slot requests, while complying with the "primary criteria" of the IATA guidelines and airport declared capacities. We introduce a strong formulation that provides exact solutions in short computation times at medium-size airports for a full season of operations. Results from Madeira (FNC) and Porto (OPO) airports suggest that the model can improve the slot allocation outcomes, as compared to historical decisions.

3 - The Airline Schedule Recovery Problem

Navid Rashedi, Dartmouth College, Dartmouth, NH, United States, Navid.Rashedi.TH@Dartmouth.edu

The Airline Schedule Recovery problem attempts to repair a schedule of flights to handle disruption events. However, obtaining an online and near-optimal solution for this problem is often challenging. In this research, a Machine Learning based method is developed to achieve a near-optimal solution within a short runtime. Using binary classification techniques, a set of aircraft routings that are more likely to be in the solution will be generated. Then, based on a randomized greedy procedure, the best possible set of feasible aircraft routings is constructed.

Operations Research and Security

Sponsored: Military Applications

Sponsored Session

Chair: Andrew Oscar Hall, PhD, United States Military Academy, 86 B Patridge Pl, West Point, NY, 10996, United States, andrew.hall@usma.edu

1 - Simulation Based Multi-mission Cutter Scheduling for the Coast Guard

Sercan Demir, PhD Candidate, University of Miami, 1251 Memorial Drive #268, Department of Industrial Engineering, Coral Gables, FL, 33146, United States, s.demir@umiami.edu, Gregory E.Higgins, Nurcin Celik

The United States Coast Guard (USCG) plans the world-wide operations of its ships, referred to as cutters. Scheduling is executed manually and focused on large-scale strategic priorities. Yet, this is problematic as stochastic events are increasingly costly and priorities have and will continue to shift. In 2013, USCG cutters lost four times the amount of operational days lost due to unplanned events. We propose a comprehensive multi-mission schedule evaluation mechanism which utilizes historical data to forecast productivity output at the tactical level, given limited resources across a spectrum of current and future scenarios.

2 - Coordinated Defender Strategies for Border Patrols

Víctor Bucarey, PhD Student, Universidad de Chile, Beauchef 851 of 506, Santiago, Chile, vbucarey@ing.uchile.cl

Security is a worldwide concern that in many situations requires the coordinated use of diverse types of resources. In particular the task of patrolling a border requires the coordinated use of may resources to monitor of vast stretches of land 24/7. We formulate a Security Stackelberg game as an integer programming problem that globally combines police precincts and location to be proctected in a border patrol context. We present tight formulations based on the matching polytope and present two sampling methods to provide implementable patrolling strategies.

3 - Valuation of Jumboization for Military Transportation Ships a Real Options Approach

Fikri Kucuksayacigil, Iowa State University, 610 Squaw Creek Drive, Unit 18, Ames, IA, 50010, United States, fksayaci@iastate.edu, K.Jo Min

When transportation requirements increase in the navy, some of the practical solutions involve jumboization. Jumboization is defined as increasing the capacity of an existing ship by extending its length at a future date. The choice of the ship design has future ramifications: With fixed design (the ship is not designed initially envisioning future jumboization investment), jumboization later will be costly. With flexible design, jumboization later will be less costly, however the initial cost may be more because of initially strengthened hull of the ship. We analyze both cases, and determine conditions under which one design is superior to another by using stochastic optimal control approach.

Supply Chain Management

Contributed Session

Chair: Wenting Pan, Saint Mary's College of California, Moraga, CA, United States, wp3@stmarys-ca.edu

1 - Decision-maker's Preferences Modeling within Ambidextrous Supply Chain

Belaid Aouni, Associate Dean, Qatar University, College of Business and Economics, Al Jamiaa Street, Doha, 2713, Qatar, belaid.aouni@qu.edu.qa

The aim of this paper is to utilize the concept of satisfaction function and Goal Programming model to explicitly incorporate the Decision-Maker's preferences for selecting the best supply chain that aggregates simultaneously exploitation and exploration capabilities.

2 - Information Leakage and Sharing in a Two-period Decentralized Supply Chain

Weixin Shang, Associate Professor, Lingnan University, Hong Kong, Hong Kong, shangwx@ln.edu.hk

We consider a supply chain with one manufacturer selling to one retailer who processes private demand information over two selling periods. We examine the retailer's information sharing decisions with and without side payment, and firms' subsequent pricing decisions. Without information sharing, in period 2 the manufacturer will infer the retailer's private information via period-1 order quantity. We find that the retailer does not share the information voluntarily due to harmful double marginalization. However, the retailer shares the information to the manufacturer with side payments when demand uncertainty is high.

3 - Investment Decisions for Improving Quality Along Supply Chains

Yi Man, Shanghai Jiaotong University, Antai College of Economics and Management, 1954 Huashan Rd, Shanghai, 200030, China, iamdiyer@sjtu.edu.cn

In this paper, we consider a supply chain with one supplier and one retailer who jointly make their efforts to improve product quality along supply chains. Investment decisions of the retailer and the supplier as well as order quantity of the retailer are made consequently in order to maximize each party's own profit. From analytical results, we find that the retailer only places the order if the joint investment exceeds certain threshold. The region in which the supplier and retailer make joint efforts in the investment is provided when the demand is exponentially distributed. Numerical studies are given to reveal the effect of the parameters.

4 - The Influence of Supply Network on the Innovation Capability of Firms

Shubhobrata Palit, Student, Georgia Institute of Technology, Atlanta, GA, 30308, United States, shubhobrata.palit@scheller.gatech.edu

We explore the role of a firm's supply network in driving innovation in firms. Using secondary data, we examine how the diversity and the intensity of the knowledge and expertise of suppliers enable firms to drive their own innovation. We also examine the moderating effects of the structural position of the firm in its supply network and the ability of the firm to assimilate external knowledge, in driving its innovation. We find significant associations of innovation characteristics of supply network with the innovation output of the firm. The results have valuable managerial implications to help firms better manage their supply network.

5 - Location and Capacity Optimization for Electron Beam Facilities for Phytosanitary Treatment of Mexican Import Commodities

Yiwei Huang, Pennsylvania State University - Shenango, Sharon, PA, United States, yuh201@psu.edu

We develop a generalizable decision support system for determining the optimum number of eBeam facilities to treat fruits and vegetables imported from Mexico to the U.S., their capacities, and their locations. This system also selects the optimal assignment for each truckload of fresh fruit from Mexican growing regions to the eBeam facilities, and then to the U.S. hubs for distribution. In addition to the standard components of a cost function (transportation, operations, capacity, and building), our nonlinear mathematical model takes into account the time spent waiting at the border crossing and the time lost because of congestion at the eBeam facilities by using queuing approximations.

6 - Impact Supplier's Lead Time has on Assembler's Strategic Decisions

Wenting Pan, Associate Professor, Saint Mary's College of California, 1928 Saint Mary's Road, Moraga, CA, 94556, United States, wp3@stmarys-ca.edu, Yuhong He

This paper examines the impact the supplier's lead time has on the assembler's strategic choice of partnership. Specifically, we study when the assembler would buy components from the suppliers and when the assembler would have a vendor-managed consignment contract with the suppliers. Furthermore, we also explore the conditions under which a supplier would be selected by the assembler as a sub-assembler to manage other suppliers.

Service Science in the IT Industry

Sponsored: Service Science

Sponsored Session

Chair: Aly Megahed, IBM Research - Almaden, San Jose, CA, 95123, United States, aly@gatech.edu

1 - Data Analytics for Pricing Highly-Valued IT Service Contracts

Aly Megahed, IBM.Research - Almaden, 150 Palm Valley Blvd APT.2066, San Jose, CA, 95123, United States, aly@gatech.edu, Taiga Nakamura, Kugamoorthy Gajananan, Mark Smith, Gregory R.Heim

Service providers in B2B (e.g., consulting, outsourcing, healthcare, logistics) often must prepare bids to win service outsourcing contracts. The contracting process can be expensive and highly uncertain as to whether a provider that bids will win a contract. This study presents a data analytics approach for pricing and winning service contracts in the IT industry. We propose a base model and model enhancements, using historical and market data. We show how our tools enhance insights and provide better visibility for contract managers of a real IT outsourcing service provider.

2 - Analytics Driven Business Travel Management Solution

Pawan Chowdhary, IBM.Research, 650 Harry Road, E3-238, San Jose, CA, 95120, United States, chowdhar@us.ibm.com

Business travel is essential to meet customers and for the company to grow. Mid to large enterprise has business travel as one of the largest spend items but still not managed efficiently. IBM Travel Manager is a solution that is catered for the Travel Program Manager to effectively manage travel spend and leverage analytics to get spend insights and savings opportunities. In the presentation we will go few such analytics and touch over cognitive aspect that will drive the travel manager to act upon opportunities pro-actively.

3 - Cognitive & Optimal Solution Composition for it Service Contracts

Ahmed Nazeem, IBM.Research - Almaden, San Jose, CA, 95120, United States, ahmed.nazeem@ibm.com, Aly Megahed, Hamid Motahari, Taiga Nakamura, Hung N.(Nam) Ho-Nguyen

For Information Technology (IT) service providers, composing a customized solution for a given request for proposal (RFP) is a tedious and time-consuming task. It requires a lot of expertise in reading and compiling the client's requirements. Furthermore, composing a solution from existing services to meet the client's requirement has a significant influence on the pricing of the deal, and hence, on the likelihood to win the deal.

Given the complexity of the IT services, their range of attributes, and their inter-dependencies, their a need to develop an automated framework that provides an end-to-end efficient solution for technical solution managers. The project has two 2 main components: (i) a natural language processing components for parsing and compiling the RFP document, and (ii) an optimization component for composing the existing IT services in a way that increases the likelihood of winning the deal. To enable online solution composition, we develop efficient heuristic approaches using business insights and the domain knowledge.

Chair: Robin Qiu, Penn State (The Pennsylvania State University), Penn State (The Pennsylvania State University), Malvern, PA, 19355, United States, robinqiu@psu.edu

1 - Proactive Inpatient Bed Reservations from ED to Reduce Patient Boarding

Seung Yup Lee, Wayne State University, 673 Prentis Street, Detroit, MI, 48201, United States, seung.lee@wayne.edu, Ratna Chinnamm, Evrim Dalkiran, Seth Krupp, Michael Nauss

We explore the benefits of early task initiation for the service network spanning the ED and inpatient units within a hospital. In particular, we investigate the value of proactive bed reservation signals based on future state information of ED patients to reduce ED patient boarding using a fork-join queueing system. Model accounts for the performance of the predictive analytics model for disposition decision. Our results show that proactive bed reservations can lead to significant reductions in ED patient boarding. The insights gained from our models should encourage hospital managers to embrace proactive coordination and adaptive work flow technologies enabled by modern health IT systems.

2 - Outcomes-based Reimbursement Policies for Chronic Care Pathways

Sasa Zorc, INSEAD, 1 Ayer Rajah Avenue, PhD Office, Singapore, 138676, Singapore, sasa.zorc@insead.edu, Stephen Chick, Sameer Hasija

We develop an outcomes-based model of contracting in care of chronic patients, using data from United Kingdom's NHS. The government contracts with healthcare providers in effort to maximise population health minus the cost. We consider the decision of whether to contract with individual healthcare providers or groups of such providers, as well as which contract type to use. Individual contracts fail to provide the desired incentives if providers under such contracts cooperate (collusion), however so do group contracts if group members fail to coordinate (free-riding). We demonstrate that individual outcomes-adjusted capitation contracts are the most resistant to these adverse effects.

3 - Directed Disease Networks based Multiple-Disease Risk Prediction Modeling

Tingyan Wang, Tsinghua University, RM.519, Shunde Building, Beijing, 100084, China, wangty14@mails.tsinghua.edu.cn, Ming Yu, Runtong Zhang

In this study, we propose a novel framework that combines directed disease network and collaborative filtering techniques to enhance multiple disease risk predictive modeling. Firstly, a directed disease network considering temporal information will be developed. Then based on this directed disease network, we investigate different disease risk score computing approaches. We validate the proposed methods with real-world datasets. The results demonstrate the potential value of the proposed modeling framework, e.g., a reference for medical experts to offer effective healthcare guidance for patients, or a tool that helps individuals create and maintain a better healthcare plan over time.

1 - Dominance Analysis of Conflict Amongst Bodies of Evidence for DST using DRSA

Lucimario Gois de Oliveira Silva, Universidade Federal de Pernambuco, 1350 Av Cons Agiar, Boa Viagem 404 Flores, Recife-PE, 51011030, Brazil, lucio_gois@hotmail.com, Adiel Teixeira De Almeida Filho, Roman Slowinski, Salvatore Greco

One of the main problems encountered in Evidence Theory concerns with the identification when two bodies of evidence are high degree of conflict. Thus, different approaches have been developed in the literature without success. To circumvent such problems, this article develops the notion of consistency in conflict where it is possible formally to define when a metric or reduce set of metrics is consistent to classify the conflict. In addition, to obtain this set, the technique known as DRSA is used. In relation to conflict identification, it is possible to use DRSA to generate decision rules on classifying conflict which avoids using subjective thresholds that can be difficult to elicit.

2 - A TOPSIS with Intuitionistic Fuzzy Sets and DEA Approach to Evaluate Retail Industry Performance Ability

Babek Erdebilli, Atılım University, Ankara, 06854, Turkey, babekd@atilim.edu.tr

This research paper discusses a decision-making algorithm with hierarchical structure to find performance efficiencies in order to develop the performance evaluation process in RI in Turkey. The offer presents an Intuitionistic Fuzzy TOPSIS and DEA to utilize both qualitative and quantitative criteria. Firstly, IFTOPSIS can be used to handle more complex problems. At this stage, all qualitative values are weighted by IFTOPSIS; then, the alternatives are formulated by DEAs. It is shown that using the IFTOPSIS value as the only output into DEA classification is more accurate than just using the entire quantitative variables.

3 - Interactive Evolutionary Multiobjective Optimization Driven by Decision Rules

Roman Slowinski, Professor, Poznan University of Technology, Pl. Marii Sklodowskiej-Curie 5, NIP: 777-00-03-699, Pozna , 60-965, Poland, roman.slowinski@cs.put.poznan.pl, Salvatore Corrente, Salvatore Greco, Salvatore Greco, Benedetto Matarazzo

Evolutionary multiobjective optimization can lead more quickly to a small subset of most preferred non-dominated solutions if the search of the solution space is driven by a preference model constructed simultaneously with the search. Here we propose a preference model in terms of "if , then " decision rules induced from rough approximations of preference information given by the user every k generations in terms of classification of a small sample of solutions into "promising" and "to-be-avoided". We present results of very encouraging experiments with this method performed on some well-known benchmark problems.

4 - A Multicriteria Approach to Support the Performance Evaluation Process for Tariff Revisions in Brazil

Adiel Teixeira De Almeida Filho, Universidade Federal de Pernambuco, Caixa Postal 7471, Cx Postal 7471, Av. General San Martin,1083, Recife-PE, 50.630-971, Brazil, atalmeidafilho@yahoo.com.br, Danielle Morais, Luanna T. da Silva Lira, José R.Figueira, Ana Paula C. Costa

Electrical power tariffs in Brazil may be revised according to recent changes introduced by a law approved in 2013. The agency that regulates the Brazilian electric system considers a decision model that includes a benchmark evaluation based on a DEA model to estimate operating costs, followed by public hearings to decide upon a tariff revision for each electricity company. Such decision process is relevant once it affects the profitability of electricity companies as well as final customers' electricity bill. This work presents the ongoing research about this subject and how a multicriteria decision-making technique may contribute to this decision process, which is currently based only on DEA.

1 - Microservice Architecture for Delivering Analytic Models

Jon A.Higbie, Revenue Analytics, 3100 Cumberland Blvd., Suite 1000, Atlanta, GA, 30339, United States, jhigbie@revenueanalytics.com

Since 2011 Micro Service Architecture (MSA) has been gaining favor as an architecture and method for developing software, particularly in the cloud. MSA breaks an application down to small components that perform a single function. These microservices then communicate with each other via web services. If done correctly, the resulting application has high reliability and the microservices are easily reusable. Learn how this approach is changing the way complex analytic solutions are delivered.

2 - Hetergenous Quantum Computing

Gideon Bass, Booz Allen Hamilton, Washington, DC, United States, tb

Quantum computing offers the possibility of producing significant speed-up and improved solution quality when compared to traditional computing. There are now commercially available quantum annealing (QA) devices that are designed to solve difficult optimization problems. We present a heterogeneous computing stack that combines QA with traditional hardware and allows usage of QA on problems larger than existing quantum hardware could solve in isolation, and, as a representative problem, we discuss a sample satellite constellation assignment problem, and the exciting results of this research.

Health Care, Modeling and Optimization

Contributed Session

Chair: Shanshan Wang, Beijing Institute of Technology, Beijing, China, shshwang_bit@163.com

1 - Risk-averse Inpatient Discharge Planning

Maryam Khatami, Texas A&M.University, 4050 ETB, College Station, TX, 77840, United States, maryam.khatami@tamu.edu, Lewis Ntaimo, Mark Alan Lawley

We study the inpatient discharge planning (IDP) problem on a daily basis. Discharge delay deteriorates patient satisfaction, incurs extra costs to the hospital and additional stress to the staff, and causes admission delay for patients in upstream units. We formulate the IDP problem as a risk-averse two-stage stochastic program. Our model captures two sources of uncertainty: inpatient discharge processing time and bed request time. To the best of our knowledge, we are the first to apply the stochastic decomposition algorithm to solve a risk-averse stochastic model. We solve our model for several instances of the IDP problem generated using data from a Texas hospital.

2 - Modelling Delay Dissatisfactions in Appointment Scheduling Problems

Shuming Wang, Associate Professor, University of Chinese Academy of Sciences, No. 80 Zhong-Guan-Cun East Rd, Beijing, 100190, China, wangshuming@ucas.ac.cn, Marcus Teck Meng Ang, Tsan Sheng NG

We consider a problem of appointment sequencing with uncertain service times and no-shows. A Tolerance Aware Delay (TAD) index is proposed to quantify the user's dissatisfaction by incorporating their delay tolerance level. We develop two appointment optimization models using the TAD index, one based on sample average approximation, and the other based on the limited distributional information of the service times. The corresponding optimization models are shown to be in the formats of a mixed-integer LP and mixed-integer SOCP, respectively, which can be evaluated efficiently using off-the-shelf solvers. Numerical experiments demonstrate the performance and insights of using our TAD models.

3 - Real Time Scheduling of Regular and Emergency Patients with Waiting Time Targets

Jing Wen, Shanghai Jiao Tong University, Shanghai, China, janewen@sjtu.edu.cn, Na Geng, Xiaolan Xie

To reduce the waiting time of appointed patients without affecting the treatment quality of emergency patients, this paper studies the real-time scheduling between regular and emergency patients with waiting time targets. A Markov Decision Process model is proposed to minimize the total waiting cost and structural properties of the optimal control policies are established. Several heuristic policies are proposed to solve the large size problem. Numerical experiments are performed to show the influence of parameters and compare the performances of heuristic policies. Key words: emergency patients; waiting time target; regular patients; Markov decision process; heuristic policies

4 - Two-stage Stochastic Surgery Downstream Capacity Planning with Chance Constraint and Equity Metric

Shanshan Wang, PhD Candidate, Beijing Institute of Technology, 5 Southstreet Zhongguancun, Haidian District, Beijing, 100081, China, shshwang_bit@163.com, Jinlin Li

This paper investigates surgery planning on a given planning period, taking downstream resources (e.g. beds in surgical intensive care unit) into consideration. Surgery durations and length of stay are uncertain. The equity of access which can be thought of as a match between patients and providers is defined as constraint of the same access levels among different types of patients. Overtime for ORs captured by chance constraint to guarantee the probability of overtime is no more than a given risk parameter. We propose a two-stage stochastic model with recourse decision, and design an enhanced decomposition scheme. Finally, a practical case study is performed by real data to test our model.

Chair: Li Zeng, Texas A&M University, College Station, TX, 77843, United States, lizeng@tamu.edu

Co-Chair: Qiang Zhou, The University of Arizona, Tucson, AZ, 85721, United States, q.zhou@arizona.edu

1 - Modeling of Hydrogel Swelling in 3D Printing of Artificial Meniscus

Qian Wu, Texas A&M.University, 1501 Harvey Road, Apt 839, College Station, TX, 77840, United States, hi_qianwu@tamu.edu

Hydrogel is a class of biomaterials that has great potential as materials in 3D printing of artificial meniscus (3DPAM). Swelling of hydrogel is critical to geometric fidelity and long-term stability of 3D printed meniscus. On the other hand, hydrogel designed for the 3DPAM application has complex structure and its swelling property is unknown. This study proposes a data-driven modeling framework for hydrogel swelling based on an integration of varying-coefficients models and engineering knowledge. In the case study, the proposed method is applied to data from a novel 3DPAM process and insight that helps understand the underlying swelling mechanism is obtained.

2 - In-situ Monitoring and Modeling of Melt Pools for Porosity Prediction of Laser Based Additive Manufacturing Processes

Mojtaba Khanzadehdaghalian, Mississippi State University, Mississippi State, MS, United States, mk1349@msstate.edu

LBAM is still not widely accepted and is often considered inconsistent and unreliable for many industrial applications. The objective of this research is to characterize and use the underlying thermo-physical dynamics of LBAM captured by melt pool signals to predict porosity during the build. Herein, we propose a novel porosity prediction method on morphological features and the temperature distribution of the top surface of the melt pool as the LBAM part is being built. Self-organizing maps are then used to further analyze the 2D melt pool dataset to identify similar and dissimilar melt pools. To experimentally locate porosity within the Ti-6Al-4V thin wall specimen X-Ray tomography is used.

3 - High Dimensional Functional Regression for a Manufacturing Process

Mostafa Reisi Gahrooei, Georgia Institute of Technology, Atlanta, GA, United States, mrg9@gatech.edu

Many of manufacturing processes involve a set of process variables measured over time or space that directly affect the geometric shape of the output. Understanding the effects of the input variables on the output shape requires a model that combines the functional inputs to predict a surface. The main goal of this paper is to develop a high dimensional regression model that efficiently estimates a high dimensional output based on a set of functional inputs. To enable the proposed method for fast implementation, we exploit regularized high-dimensional regression, to decompose the output surface. With several simulation and case studies, we evaluate the performance of the proposed method.

4 - A Vision-based Approach for Real-time Quality Monitoring for Cyber-manufacturing Processes

Zimo Wang, Texas A&M.University, College Station, TX, 77843, United States, zimowang@tamu.edu, Ashif S.Iquebal, Satish Bukkapatnam

Laser kirigami processes that use sheet precursors offer considerable advantages over traditional powder based additive manufacturing for fast realization of functional complex shapes for custom manufacturing. An in-process monitoring tool that captures shape transformation and process thermomechanics in real time is necessary to assure cost and quality parity with mass production. We present a spatial regression model to combine information from multiple low resolution cameras for real-time monitoring of core kirigami processes. Experimental investigations on our test bed suggest that the present approach can provide fast (fps~5) and accurate (2% error) geometric feature estimates.

Community-based Operations Research

Sponsored: Public Sector OR

Sponsored Session

Chair: Michael Johnson, University of Massachusetts-Boston, University of Massachusetts-Boston, Boston, MA, United States, michael.johnson@umb.edu

1 - Improving Decision-making Skills of Nonprofit Professionals

Michael P.Johnson, University of Massachusetts-Boston, Department of Public Policy & Public Aff, 100 Morrissey Boulevard, Boston, MA, 02125-3393, United States, michael.johnson@umb.edu, Jason Wright

Nonprofits face gaps in organizational capacity, including program design and evaluation, but previous research suggests that capacity building exercises have a positive effect. We describe a data analytics training workshop with staff from Boston-area nonprofits reflecting a wide range of sectors. Through analysis of participant work on case studies provided by the instructor, we examine how participants made sense of training materials, the various strategies employed by participants to solve three case study problems, and participant feedback about the session. Our findings provide a basis for novel interventions in community-based operations research.

2 - Refugee Resettlement via Integer Programming

Andrew C.Trapp, Worcester Polytechnic Institute, Foisie Business School, 100 Institute Rd., Worcester, MA, 01609, United States, atrapp@wpi.edu, Alex Teytelboym

Hundreds of thousands of refugees are resettled yearly from refugee camps to host countries. Local areas that host refugees are reluctant to open capacity, and most impose tight restrictions on the refugee family types they accept. We model this matching challenge as a 0-1 knapsack variant and explore various objectives in the search toward an optimal allocation. We tackle several new theoretical and computational obstacles, and using actual historical resettlement data to simulate realistic scenarios, we address fairness and welfare criteria that play an important role in the current process.

3 - Considering Practical Ethics in Community Based Operations Research (CBOR)

David T. Hunt, Oliver Wyman, One University Square, Princeton, NJ, 08540, United States, david.hunt@oliverwyman.com

We like to think that CBOR involves the application of analytical methods to "do good" locally; and, most will agree these efforts are "doing good." However, what is meant by "doing good" and how do we know when our models are not "doing good" and may in fact be causing harm? Some philosophers consider happiness as the only good, and utilitarianism is based on maximizing happiness. But maximizing happiness can create winners and losers, and are we really "doing good" as long as the pluses outweigh the minuses? This presentation will explore these topics using examples drawn from CBOR.

4 - A Multi-methodology Approach for Community-based Operations Research in a New World Heritage Site

Valentina Ferretti, London School of Economics and Political Science, Houghton Streetl London I WC2A 2AE, London, United Kingdom, V.Ferretti@lse.ac.uk

This study develops a participatory multi-methodology intervention designed and deployed to support planning in a new World Heritage site, i.e. the vineyard landscape of Langhe, Roero and Monferrato in Northern Italy. The proposed framework uses Spatial SWOT Analysis and Multicriteria Decision Aiding (MCDA) in Phase 1 (problem identification - knowledge phase), Stakeholders' Analysis and Spatial MCDA in Phase 2 (problem formulation - planning phase), and Choice Experiments during Phase 3 (problem solving - design). This talk focuses on the results and impacts associated with each phase of the process, by discussing the respective levels of community engagement and methodological innovation.

Healthcare Analytics Applications

Sponsored: Public Sector OR

Sponsored Session

Chair: Andres Garcia-Arce, Geisinger Health Systems, Danville, PA, 17822, United States, garciampu@gmail.com

1 - Stacking Machine Learning Models for the Prediction of No-shows in Outpatient Neurological Appointments

Andres Garcia-Arce, Geisinger Health Systems, 100 North Academy Avenue, MC 30-65, Danville, PA, 17822, United States, garciampu@gmail.com

Patients not showing for their appointments hurt the access and quality of care for other patients. This study aims to improve predictive models for no-shows using machine learning algorithms, including ensembles of models. A novel aspect is that we consider cancelation within 7 days as a no-show. We use data from neurological outpatient appointments made in clinics from Geisinger Health Systems. This contribution will help improve the existing efforts in the reduction of no-shows, increase the access to care, and therefore, improve quality of care and patient satisfaction.

2 - Scenario-based Ambulance Deployment with Two Types of Servers

Soovin Yoon, University of Wisconsin–Madison, 1415 Engineering Drive, Room 3261, Madison, WI, 53706, United States, yoon57@wisc.edu

Ambulance deployment problem with multiple server types is challenging to solve due to inherent uncertainties in emergency calls as well as dependencies between servers. We propose a scenario-based ambulance deployment model with two types of servers, where the objective involves not only the response times but also the match between the server type and patient priority. The problem is formulated as a stochastic integer program with data-driven scenarios. Decomposition algorithms are applied to solve large size instances.

3 - Discovering Patterns in Self-reported Care Experience Data and Clinical Outcome Data to Improve Patient Experience

Qianyu Hu, Penn State University, 126 E.Nittany Avenue, Apt 12, State College, PA, 16801, United States, qianyuhu312@gmail.com

Over past 25 years, patient satisfaction has gained increasing attention. Research has shown that patient experience is critical to improving clinical outcomes and should be measured in addition to standard quality and safety metrics. Therefore, providing a better patient experience, measuring and reporting is regulatory. However, literature is divided on this. We study and analyze the relationship between patient satisfaction and clinical outcomes using statistical and graphical techniques. We use HCAHPS survey data to examine the relationship between patient perspective and clinical outcomes, to provide quality care.

4 - A Predictive Model to Estimate Post Acute Care Needs: A Cohort Study of Patients with Coronary Artery Bypass Graft or Valve Replacement

Ineen Sultana, Graduate Research Assistan, Texas A&M.University, College Station, TX, 77843, United States, ineensultana@tamu.edu

Predicting Discharge Location (DL) for patients is essential for better care coordination with post-acute care (PAC) facilities; it not only aid in efficient discharge planning but also help the PAC facilities project the evolving demands. In this study, a retrospective cohort analysis of patients with coronary artery bypass graft or valve replacement is conducted, and a predictive model is developed using multinomial logistic regression to estimate the potential DL for a patient. Our analysis identified the hospital location, characteristics, and stay in hospitals as well as the characteristics and comorbidity of patients to be the most significant influential factors for the DL estimation.

5 - Real-Time Asset Distribution System: Deploying Machine-learning Solutions in the Emergency Department

Diego Martinez, Johns Hopkins University, Baltimore, MD, United States, dmart101@jhmi.edu, Jeffrey Appelbaum

Hospitals are challenged to provide timely patient care while maintaining high resource utilization. Real-time asset management is one of such initiative whereby clinical staff convenes each morning to forecast low- to high-demand hospital units and ensure that the necessary equipment, such as IV pumps, are available for providing patient care. We designed and deployed a real-time asset distribution system that leverages on machine learning, electronic medical records, and real-time location system to guide clinical staff in recovering under-utilized equipment and relocate them where they are (or will be) needed.

Operations Analytics and Optimization for Manufacturing, Logistics and Energy Systems

Invited: Project Management and Scheduling

Invited Session

Chair: Lixin Tang, Northeastern University, Northeastern University, Shenyang, 110004, China, lixintang@mail.neu.edu.cn

1 - Enterprise Wide Optimization for Refinery Planning with Coordination of Energy Consumption and Product Quality

Lijie Su, Institute of Industrial & Systems Engineering, Northeastern University, Shenyang, China, sulijie@ise.neu.edu.cn, Lixin Tang, Ignacio E.Grossmann

This paper focuses on the Enterprise-wide Optimization(EWO) of planning for refinery plant. The process models of refinery units are integrated in the production planning. The properties of material flow are controlled in order to satisfy the international standard for product oils and environmental demand. The energy consumption with the refining process is taken into account, and coordinated with the properties of final oil products. We present a new mathematical formulation for the EWO of planning to maximize the net profit of refinery. We also analyze the net profit of refinery under different variation conditions, like properties of crude oil, energy consumption and standard of product oil.

2 - A Learning-based Differential Evolution Algorithm for Open-order Coil Allocation Problem in the Steel Industry

Fei Zou, Institute of Industrial & Systems Engineering, Northeastern University, Shenyang, China, zfhelen6@163.com, Lixin Tang

Open-order coil allocation problem is to allocate open-order coils to unfulfilled customer orders for reducing surplus inventory and improving the material utilization. Since the problem is NP-hard, an improved differential evolution algorithm called DEANS is proposed to achieve the near optimal solutions. In the algorithm, construction heuristics are designed to obtain initial solutions and some greedy strategies are proposed to repair infeasible solutions. Mod mutation operators and learning-based mechanisms are adopted to describe and generate the population. Computational experiments on different scale instances verify the effectiveness of the proposed model and algorithm.

3 - Data Analytics-based for Temperature Prediction in Blast Furnace Top System

Xiangman Song, Institute of Industrial & Systems Engineering, Northeastern University, NO. 3-11, Wenhua Road, Heping District, Shenyang, 110004, China, sxmars.cloud@gmail.com, Lixin Tang

Iron-making process is the biggest environmental loader with the largest energy consumption. From the perspective of data analytics, the relationship between the temperature distribution of furnace burden in the top of blast furnace and the corresponding charge level shape is studied and the linear regression model is proposed. In addition, a space-time Kalman method is proposed to predict the temperature distribution. Utilizing the relationship model and the predicted temperature, the burden charging operations can be obtained to reduce the energy consumption. Furthermore, the real iron-making data are used to test the performance. Experimental results show that the method is effective.

4 - A Multi-stage Modeling Method for Converter Steel Making Process

Chang Liu, Institute of Industrial & Systems Engineering, Northeastern University, Shenyang, China, lc1987328@126.com, Lixin Tang

This study concerns with dynamic basic oxygen furnace (BOF) steelmaking process and proposes a data-analytics prediction method. According to the analysis of actual field data, a multi-stage modeling method is proposed for BOF steelmaking process. The key idea of the proposed method is to solve the dynamic prediction in the whole BOF steelmaking process. In order to predict temperature and carbon content more accurately in BOF steelmaking process, IPSO-LSSVM is utilized to establish multi-stage prediction models. In addition, the real industrial data are used for testing. Experimental results show that the data analytics prediction method has a better prediction performance.

5 - Integrated Scheduling of Rolling Section in Steel Production with Demand-side Management

Shengnan Zhao, Institute of Industrial & Systems Engineering, Northeastern University, Shenyang, China, shengna1@andrew.cmu.edu, Ignacio E.Grossmann, Lixin Tang

Electric grid is now using time-of-use pricing strategy on industry customer, which has great impact on the profit of demand side. Involving energy-intensive process, the steel companies can take advantage of processing flexibility to make better use of electric power, and thus reduce energy cost. In this work, we address a new integrated scheduling problem derived from rolling section of steel production, with consideration of batching decision and demand-side management. The problem is formulated as a mixed integer nonlinear optimization model and then reformulated to a MILP model. Numerical experiments are conducted and results show the model is efficient.

1 - Incentivize Ride Matching via Repeated Games

Shumin Ma, Chinese University of Hong Kong, Shatin, NT, Hong Kong, smma@se.cuhk.edu.hk, Qi Wu

Subsidizing drivers generates a supply multiplier effect at the cost of a firm. It contrasts with surge pricing policies, where excessive demand is accommodated at the cost of riders through price hikes, threatening a firm's market share. Supply-side incentives thus provide an alternative for a firm to respond to demand surges when increasing fare price is not an option. We take a game approach and model the spatial matching problem as a repeated Stackelberg game. We show that through driver-targeted loyalty programs, the optimal throughput in equilibrium is attained at the optimal amount of incentives. Incentivize excessively, however, would be disruptive as matching ratios will decline.

2 - Comparing Two Solution Seeking Mechanisms in the Online Labor Market

Jiahui Mo, Nanyang Technological University, 19251 Preston Road, Apt 2520, Dallas, TX, 75252, United States, jhmo@ntu.edu.sg

In the online labor market, firms can seek project solutions via two auction mechanisms: procurement auction and tournament. It is unclear for firms which mechanism to use when they look for better solutions with the same budget. This research compares these two mechanisms and provides some empirical evidences on the effectiveness of these mechanisms. Our findings can provide insights for firms to choose the proper mechanism in the online labor market.

3 - Hotel Strategies to Influence Sales: Incumbents Reaction to Competition from Airbnb

Cheng Nie, University of Texas-Dallas, Richardson, TX, United States, cxn123430@utdallas.edu, Eric Zheng, Sumit Sarkar

The emergence of Airbnb provides an untapped wealth of supplies to the accommodation market, posing a threat to the incumbent hotels. What should hotels do to improve market performance in face of Airbnb? We consider four strategies that hotels could use to improve their sales: manipulate review, improve quality, reduce price, respond to review. We empirically investigate the effectiveness of these strategies by combining data from Airbnb, Expedia, TripAdvisor, the Texas Comptroller office, and Smith Travel Research.

1 - Shared Medical Appointments: An Innovative Approach to Healthcare Delivery

Nazl I. Sonmez, PhD Student, London Business School, London, NW1 4SA, United Kingdom, nsonmez@london.edu, Ryan Buell, Kamalini Ramdas

In this paper, we examine shared medical appointments (SMAs) as a substitute for one-on-one appointments. Under this innovative approach, a group of patients with similar chronic conditions meet with a doctor simultaneously. We conduct a randomized controlled trial at the Aravind Eye Hospital's Glaucoma Clinic to assess the effectiveness of shared medical appointments. Preliminary results obtained with the data we have so far suggest that the knowledge and satisfaction level of patients who attend shared medical appointments is significantly higher than that of patients who attend one-on-one appointments.

2 - Seeking to Belong: How Beneficiaries Influence Performance
Bradley R.Staats, University of North Carolina at Chapel Hill, Campus Box 3490, McColl 4721, Chapel Hill, NC, 27599-3490, United States, bstaats@unc.edu, Paul Green, Francesca Gino

We examine how connecting to beneficiaries of one's work increases performance. In a field experiment of harvesters, we find that beneficiary contact with the end customer did not improve productivity, contact with an internal beneficiary yielded a persistent increase in productivity. We validate this effect in the laboratory.

3 - Speed-quality Trade offs in Home Health: the Effects of Time Spent with Patients on Hospital Readmission
Hummy Song, The Wharton School, University of Pennsylvania, 560 Jon M. Huntsman Hall, 3730 Walnut Street, Philadelphia, PA, 19104, United States, hummy@wharton.upenn.edu, Elena Andreyeva, Guy David

Using a novel dataset on home health care episodes, this study quantifies the effects of reduced time spent with patients during a post-acute nursing visit on hospital readmissions. Since both visit length and readmission are likely to be correlated with unobserved illness severity, we use the daily sequence of nurse visits as an instrument for visit length. As the day progresses, visit length significantly shortens. Omitted variable bias leads to a positive correlation between visit length and readmissions. Using our instrument and controlling for patient, visit, and nurse characteristics, we examine how an increase in visit length affects the likelihood of hospital readmission.

4 - An Econometric Analysis of How Facility Layout Impacts Care Provision in the Emergency Department
Lesley Meng, The Wharton School, University of Pennsylvania, 3730 Walnut Street, Suite 500 JMHH, Philadelphia, PA, 19104, United States, lmeng@wharton.upenn.edu, Robert Batt, Christian Terwiesch

We study how the facility layout of ED patient rooms impacts nurse workflow decisions. Specifically, linking our infrared nurse location tracking data to room occupancy patient data, we are able to investigate potential facility layout variables, such as distance from the nurses' station, that impacts the patient's length of stay in the ED.

1 - Optimizing Counter-propaganda Strategies to Prevent the Spread of Extreme Ideologies Online
Chaitanya Kaligotla, PhD, Argonne National Laboratory, Chicago, IL, 60439, United States, ckaligotla@anl.gov

This talk presents a mathematical model of opinion dynamics at an individual and group level, to characterize the spread of extreme ideologies on internet discussion platforms. Assuming the existence of some prevalent 'red' agents spreading extreme ideologies to other agents, an optimization problem is formulated to develop strategy for the delivery of counter-propaganda messages, by a group of 'blue' agents, to counter the spread of such extreme ideologies in a time and cost effective manner, a problem of increasing relevance to national security. This talk also extends existing research on opinion dynamics and behavioral modeling of internet users.

2 - Behavioral Considerations in Detection Dynamics: Interlacing Human Judgment, Outcome Decomposition, and Threshold Setting
Ignacio J.Martinez-Moyano, Argonne National Laboratory, 9700 South Cass Avenue, Argonne, IL, 60439, United States, imartinez@anl.gov

Detection-selection mechanisms are at the core of security processes in complex systems. Security procedures are designed to protect systems from ill-intentioned individuals and other risks. Detection processes precede defensive action as the identification of threats is needed to determine adequate protective action. In order to identify threats in complex dynamic systems, the coupling of human judgment (many times aided by technology) and outcome understanding is essential to setting adequate thresholds for protective action. Understanding the interaction of human judgment, outcome decomposition, and threshold setting is a promising approach to improving security systems.

Modeling and Analysis of Emerging Mobility Services I

Sponsored: TSL, Urban Transportation

Sponsored Session

Chair: Yu Nie, Northwestern University, Evanston, IL, 60208, United States, y-nie@northwestern.edu

1 - Optimization-based Strategies for Autonomous Vehicle Fleet Operations
Michael Hyland, Northwestern University, 600 Foster St, Evanston, IL, 60208, United States, mhyland@u.northwestern.edu, Hani S.Mahmassani

We consider the problem of operating a fully autonomous vehicle fleet in real-time to serve passenger demand. The problem's twin objectives include minimizing operational costs and maximizing quality of service. Given the highly dynamic and stochastic nature of the problem, we employ a rolling-horizon, optimization-based solution approach. We develop a simulation framework to model the dynamic, stochastic problem, and to test operational strategies. Lastly, we seek to generalize the computational results via empirical relationships between problem parameters (e.g. service area, average trip distance, etc.) and their impact on the problem's objectives.

2 - Analyzing Regional Mobility Impact of Zero Occupancy Vehicles (ZOVs) in Presence of Connected and Automated Vehicles (CAVs)
Omer Verbas, PhD, Argonne National Laboratory, Lemont, IL, 60439, United States, omer@northwestern.edu

The deployment of CAVs in significant numbers is imminent. However, due to novelty of the technology, predicting their impact is challenging. In this study, we investigate the effect on regional mobility of ZOV travel enabled by CAVs. An optimization algorithm has been developed, to minimize the number of cars and travel cost of households, while optimizing individual daily activity-travel schedule, considering their simulated flexibility. The algorithm has been implemented in an advanced integrated activity-based travel demand simulator and scenarios were evaluated for the Chicago region.

3 - An Advanced Parking Navigation System for Downtown Parking
Zhibin Chen, University of Michigan, Ann Arbor, MI, United States, chipin@umich.edu

This paper develops a novel parking navigation system for downtown parking that aims to mitigate parking competition by guiding drivers to appropriate vacant parking spaces. Given drivers' real-time locations and their parking preferences, a two-sided matching algorithm is adopted to achieve a stable driver-optimal matching, under which drivers will be guided to their most appropriate parking spaces (if any), and have no incentive to misreport their private information. Simulation experiments are conducted to demonstrate the ability of the proposed navigation system on reducing driving time and the times of changed assignment compared with other navigation systems.

4 - Fair Versus Optimum On-demand Ride-sharing Plan
Jane Lin, University of Illinois-Chicago, 842 W. Taylor Street (M/C 246), Chicago, IL, 60607, United States, janelin@uic.edu, Luca Foti, Ouri Wolfson

Ride sourcing companies such as Uber and Lyft are offering ride sharing service. When matching passengers, these services attempt to optimize savings at a global level. But it may result in a passenger A matched to passenger B, while if matched to passenger C both A and C would have saved more money. This introduces the concept of "fairness" in ride sharing, which consists of finding the Nash equilibrium in a ridesharing plan. We compare the optimum and the fair plan in different contexts. We show that the gap between the two is not significant when fares are computed on distance traveled and, as a result, the fair plan can be issued without significant losses.

5 - Taxi Market Competition under Spatial Equilibrium
Zhoutong Jiang, Master Student, University of Illinois at Urbana-Champaign, Champaign, IL, Champaign, United States, zjiang30@illinois.edu

The taxi market is complex to model when competition between different companies is considered. A Stackelberg game model based on continuum approximation is proposed to help taxi companies select best driver dispatching and pricing strategies under competition. Properties of market competition are demonstrated using numerical examples.

Digital Marketplaces and Platforms

Sponsored: Information Systems

Sponsored Session

Chair: Jing Gong, Temple University, Philadelphia, PA, 19103, United States, gong@temple.edu

1 - Large Scale Cross Category Analysis of Consumer Review Content on Sales Conversion Leveraging Deep Learning

Xiao Liu, New York University, Stern School of Business, 44 W. 4th Street, New York, NY, 10013, United States, xliu@stern.nyu.edu

Using a dataset that tracks individual-level review reading and purchase behaviors, we quantify the causal impact of content information in the "read" reviews on sales. To extract content information, we apply deep learning natural language processing models and identify six dimensions of content. The comparative advantage of deep learning model is that it sifts category-specific content features across a wide range of product categories without human intervention or domain knowledge. We find that aesthetics and price content significantly affect conversions. Counterfactual simulation suggests that re-ordering reviews can have the same effect as a 1.6% price cut for boosting conversion.

2 - From Automobile to Autonomous: Does Self-driving Improve Traffic Conditions?

Yingjie Zhang, 401 Shady Ave, Apt C-704, Pittsburgh, PA, 15206, United States, yingjie2@andrew.cmu.edu, Jinyang Zheng, Yong Tan

Recently, Uber launched its autonomous car service. While debate has surrounded its impact, limited empirical work has been devoted to investigating the effects of this adoption on the society. This paper makes the first step to exploit this entry effect, using a DID approach applied on a unique accident dataset. We find a significant decrease in traffic accident volumes after the entry of Uber autonomous car service. A mechanism analysis suggests that this effect is mainly driven by the change in public reaction to the adoption. This pilot study contributes to the understanding of values in the adoption of autonomous car technology, as well as its social effects from the transportation perspective.

3 - Uber Might Buy Me a Mercedes Benz: An Empirical Investigation of the Sharing Economy and Durable Goods Purchase

Jing Gong, Assistant Professor, Temple University, 1810 North 13th Street, 201C Speakman Hall, Philadelphia, PA, 19122, United States, gong@temple.edu, Brad N.Greenwood, Yiping Song

In this work, we examine how the introduction of sharing platforms affects durable goods purchase. In particular, we use a unique dataset of new vehicle registrations in China and exploit a natural experiment, the variation in timing of Uber entry across different locations, to estimate the effect on vehicle purchase. Findings suggest that Uber entry is associated with a considerable increase (8%) in new vehicle ownership, suggesting that consumers are actively changing their stock of held resources in order to capture excess rents offered by these platforms. Further, results indicate that the effect of Uber entry varies considerably across gender, age, and vehicle types.

4 - Revenue Management in Crowdfunding

Jiding Zhang, University of Pennsylvania, Philadelphia, PA, United States, jiding@wharton.upenn.edu, Senthil Veeraraghavan, Sergei Savin

Crowdfunding, a mechanism in which funds are raised online using small donations from a large number of individual donors, has recently emerged as a popular approach to funding new ideas. In our paper, we model a setting where a creator of a crowdfunding project selects the amount of contribution it requests from donors and the duration of crowdfunding campaign with the goal of maximizing the raised amount. Our analysis provides project creators with detailed, practical, and intuitive guidelines on how to successfully manage the revenue generation process in a crowdfunding campaign.

Warehousing and Distribution

Sponsored: TSL, Facility Logistics

Sponsored Session

Chair: Debjit Roy, Indian Institute of Management Ahmedabad, Ahmedabad, 560078, India, debzitt@gmail.com

1 - Hyperconnected Urban Deployment and Delivery of Large-items

Nayeon Kim, Georgia Institute of Technology, Atlanta, GA, 30332-0205, United States, nkim97@gatech.edu, Benoit Montreuil

In this paper, we contrast a Physical Internet based hyperconnected deployment and last-mile delivery of large-items over an openly shared logistics network with a current dedicated logistics scheme in an urban environment. We use an agent-based simulation to compare distinct scenarios distinguished by network structure, connectivity, inventory positioning strategy and delivery routing. The potential economic, environmental, and social impact of such hyperconnected logistics on last-mile operations is described.

2 - Synthetic Demand Data to Drive Warehouse Design

Leon McGinnis, Georgia Institute of Technology, Isye Dept, 755 Ferst Drive, Atlanta, GA, 30332-0205, United States, leon.mcginnis@isye.gatech.edu, Di Liu

Suppose you are designing a new automated order fulfillment center to serve many local stores with daily deliveries. How do you model the "demand" from these stores? This talk describes a bootstrap approach to creating synthetic demand data streams. The method enables structural modifications to the demand stream to reflect a wide range of possible changes in the demand pattern, allowing proposed system designs to be "stress tested" prior to installation.

3 - On-demand Warehousing Models

Jennifer A.Pazour, Rensselaer Polytechnic Institute, 110 8th street, CI I.5217, Troy, NY, 12180, United States, pazouj@rpi.edu, Kaan Unnu

On-demand warehousing matches independent operators who have extra space to ones who need warehouse space on-demand. We develop optimization models to determine which warehousing options (construction, long-term lease, or on-demand) is best to fulfill distributed demand requests over multiple periods. The models capture varying commitment and capacity granularity of the different options and are used to quantify the benefits of on-demand options in different customer environments.

4 - Modeling Parallel Process Flows in Intra-logistics Systems

Debjit Roy, Indian Institute of Management, House Number 308, IIM.Ahmedabad, Vastrapur, Ahmedabad, 560078, India, debjit@iima.ac.in, Govind Kumawat

We present an exact two-phase server based stochastic modeling approach for analyzing performance of parallel process flows found in several intra-logistics systems. In comparison to the existing sequential modeling approach, the proposed modeling approach gives substantially better throughput estimates for automated warehousing systems.

5 - Dynamic Slotting using Predictive Analytics

Parvaneh Jahani, University of Louisville, 781 Theodore Burnett Court, Apt 2, Louisville, KY, 40217, United States, parvaneh.jahani@louisville.edu, Kevin Gue

Dynamic slotting continuously adjusts the current state of the forward area with real-time decisions in conjunction with demand predictive analytics. Therefore, the layout of the fast picking area is updated over time with replenishment of the appropriate SKUs, as opposed to traditional methods that periodically reslot the forward area to reach a predefined target map. We explored the methods for demand pattern detection and demand forecasting as well as proposed MIP mathematical model for the dynamic forward-reserve problem for the first time. This model relaxes the major implicit assumptions of the static model and quantifies the effects of the static strategy versus the dynamic strategy.

Emerging Data Sources and Travel Demand Modeling I

Invited: TSL, Intelligent Transportation Systems (ITS)

Invited Session

Chair: Alireza Khani, University of Minnesota, 136 Civil Engineering Building, 500 Pillsbury Drive S.E., MInneapolis, MN, 55455, United States, akhani@umn.edu

1 - Time-Dependent Origin Destination Matrix Calibration for Transit Network Modeling

Jacqueline Nowak, University of Minnesota, Twin Cities, MN, 56267, United States, nowak123@umn.edu, Alireza Khani

Outdated transit demand data presents a challenge for transit network modeling. This work aims to use Automated Passenger Count (APC) data to update an existing origin destination matrix to a time-dependent OD matrix for application in dynamic transit assignment. Results from the Twin Cities transit network are presented.

2 - Special Event Transit Demand Estimation using AFC Data
Pramesh Kumar, University of Minnesota, Minneapolis, MN, 55414, United States, kumar372@umn.edu, Alireza Khani

An improved trip chaining algorithm is proposed for transit origin-destination matrix estimation using Automatic Fare Collection (AFC) data. An optimization model is proposed to decompose the OD matrix ta regular and irregular demand, to capture the effect of special events on transit demand. Results from the Twin Cities transit network are presented.

3 - Observability Quantification of Dynamic Transit Systems with Multi-source Sensor Data
Jiangtao Liu, Arizona State University, 2026 S.Hammond Drive, Apt 205, Tempe, AZ, 85252, United States, jliu215@asu.edu, Xuesong Zhou

A transit network with low observability creates barriers for effective and reliable transit service supply. By incorporating the passenger-based trip time from smart card and flow count data from surveillance system, we propose an agent-based arc-based mixed integer programming (MIP) to estimate the whole transit system state in a time-discretized space-time network. Further, an agent-based path-based binary integer programming (IP) model is offered to quantify the flow range of targeted paths to evaluate the system observability under the estimated transit state before.

Operations Research in Agriculture

Invited: Agricultural Analytics

Invited Session

Chair: Shrikant Jarugumilli, Monsanto, 12447 Bennett Springs Ct, St. Louis, MO, 63146, United States, shrikant.jarugumilli@monsanto.com

1 - Field Production Planning Based on Operational
Rogerio Lenza, Monsanto Company, Rua Joaquim Nabuco, 163 ap 1501, Maringa, Brazil, rogerio.p.lenza@monsanto.com

This project has made use of analytics through operational research built with a novel technology in order to deliver a Crop Placement solution for the corn business in Brazil. This solution allows the generation of multiple what-if scenarios focused on minimizing production cost considering the entire supply chain. Additionally, it has transformed the overall crop planning process, improved the quality of the production plan and increased the productivity of the planning team for all corn plants.

2 - Integrated Supply Chain Optimization at Monsanto Utilizing Advanced Analytics
Barry Surber, Monsanto, Creve Coeru, MT, United States, barry.l.surber@monsanto.com

The flow of material through the production and distribution processes within a Supply Chain is far too often managed through a series of individual decisions that are analyzed independently of the processes that proceed or follow them. In order to efficiently manage these processes in an optimal manner a series of user interfaces, processes, algorithms and an optimization engine was developed to integrate the decision making processes into one system that considers the costs and constraints from these individual decisions in one integrated solution. This solution was developed in-house and has met with outstanding acceptance due to its ease of use and logical process flow for creating scenarios.

3 - Machine Learning Based Simulation and Optimization of Soybean Variety Selection
Durai Sundaramoorthi, Washington University in Saint Louis, 10352 Conway Road, Saint Louis, MO, 63131, United States, dsundaramoorthi@gmail.com, Lingxiu Dong, Yu Li, Xiao Tan, Piruthiviraj Sivaraj

Humanity is facing the greatest challenge of feeding itself. The World Food Programme estimates that about 795 million people do not have adequate food to have a healthy life. About 3.1 million children die every year because of poor nutrition. As a small part of addressing this great humanitarian challenge, this research proposes an analytics framework for growing the optimal soybean varieties. Selecting soybean varieties for planting is an important decision that has significant implications for the yield of the farm. We formulated and solved a simulation-based optimization problem to determine the optimal soybean-mix to minimize the risk associated with the yield.

4 - Application of Vehicle Routing with Time Windows and Split Deliveries in Agriculture
Hadi Panahi, Monsanto, St, Louis, MO, United States, hadi.panahi@monsanto.com, Naveen Singla

Every year Monsanto's testing pipeline tests new seeds for their yield and traits. Seeds are planted in the fields, and harvested for data collection. Advancement decisions can be made once data is collected throughout the harvest season. However, the timing of harvest has a direct effect on the quality of the data. To collect the highest data quality to enable making reliable advancement decisions, first the optimal harvest time is determined via predictive modeling and next harvesters (combines) are deployed from hubs to fields within the recommended harvest time window. In the literature, this problem is studied as Vehicle Routing Problem with time windows and split deliveries (VRPTWSD) as multiple combines can visit the same field. A mixed-integer programming model (MIP) along with a heuristic providing feasible solutions to the MIP as warm start are developed for this problem. Agricultural business rules and objectives are also captured by the MIP model and the heuristic algorithm. This model has been used to provide operational routes during harvest season and to determine the fleet size.

Stochastic Systems in Finance

Sponsored: Financial Services

Sponsored Session

Chair: Alexandra Chronopoulou, achronop@illinois.edu

1 - Indifference Pricing of XVA in Stochastic Volatility Models
Stephan Sturm, WPI, Department of Mathematical Sciences, 100 Institute Road, Worcester, MA, 01609, United States, ssturm@wpi.edu

We consider the pricing of XVA in markets with stochastic volatility. Assuming that the hedger's risk preferences are given by a convex dynamic risk measure, we study the hedger's indifference price for entering the underlying contract with value adjustments due to credit risk, collateralization and differential rates.

2 - Trading Illiquid Goods: Market Making as a Sequence of Sealed-Bid Auctions
Andrew Papanicolaou, NYU, Tandon, Brooklyn, NY, United States, ap1345@nyu.edu

We provide analytic results for the optimal control problem faced by a market maker who can only obtain and dispose of inventory via a sequence of sealed-bid auctions. Under the assumption that the best competing response is exponentially distributed around a commonly discerned fair market price we examine properties of the market maker's optimal behavior. We show that simple adjustments to skew and width accommodate customer arrival imbalance. We derive a straightforward relationship between the market marker's fill probability and direct holding costs.

3 - A Financial Market of a Stochastic Delay Equation
Kiseop Lee, Purdue University, kiseop@purdue.edu

We propose a stochastic delay financial model which describes influences driven by uncertain historical events. The underlying is modeled by stochastic delay differential equation (SDDE).

4 - Designing Clearinghouse Default Funds: the Role of Risk-taking Incentives
Agostino Capponi, Columbia University, 500 W. 120th Street, New York, NY, 10027, United States, ac3827@columbia.edu, Jessie Wang, Hongzhong Zhang

Central counterparties (CCPs) are mandated to reduce counterparty risk in the over-the-counter derivatives markets. We study the optimal design of the default fund contributions, serving the purpose of mutualizing losses of defaulted clearing members. While the default funds allow members to effectively share counterparty risk ex post, we highlight a novel mechanism related to loss mutualization and inducing members to take excess risk ex ante due to an inherent externality among them. We show that the CCPs can mitigate such an inefficiency by optimally choosing a default fund level, balancing the ex post risk-sharing and ex ante risk-taking.

Continuous Facility Location

Sponsored: Location Analysis

Sponsored Session

Chair: Atsuo Suzuki, PhD, Nanzan University, 18 Yamazato-cho, Nagoya, 466-8673, Japan, atsuo@nanzan-u.ac.jp

1 - Multi-range Sensor Location Problem

Daisuke Watanabe, Tokyo University of Marine Science and Technology, 2-1-6 Etchujima, Koto-ku, Tokyo, 135-8533, Japan, daisuke@kaiyodai.ac.jp, Richard Church

In this study, we formulate the optimal location model for surveillance platform with multi-range sensor based on the Maximum covering location model. The objective is to maximize the probability of detecting a historical set of piracy attacks. Using this model, we solve the optimal location of the Counter-Piracy Surveillance System in Somalia.

2 - The Big Triangle Small Triangle Method for the Weber Problem with Line Barriers

Atsuo Suzuki, Nanzan University, Dept of Systems and Mathematical Sciences, 18 Yamazato-cho, Nagoya, 466-8673, Japan, atsuo@nanzan-u.ac.jp, Zvi Drezner, Tammy Drezner

We apply the Big Triangle Small Triangle (BTST) method to the Weber problem with line barrier on the plane. We assume that there are demand points on the plane, and a line barrier with several passing points separates the demand points into two groups. It is a simple model of the situation where a river with bridges prohibits the direct access for the users to the facility on the other side of the river. The objective function of the problem is not convex because it is represented as the minimum of the convex functions. While a naive descent method fails to obtain the exact solution, the BTST algorithm obtains the exact solution.

Aviation Applications in Simulation

Sponsored: Simulation

Sponsored Session

Chair: John Shortle, George Mason University, George Mason University, Fairfax, VA, 22030-4444, United States, jshortle@gmu.edu

1 - A Distance-based Network Simulation for Airport Runway and Priority Scheduling

Haluk Damgacioglu, PhD Candidate, University of Miami, 1251 Memorial Drive McArthur Engr Bldg Room 280, Coral Gables, FL, 33146, United States, haluk.damgacioglu@miami.edu, Alyssa Guller, Nurcin Celik

Runways are the main bottlenecks in airport ground networks leading to extended flight delays and hindering with its throughput. Here, we develop a distance-based network simulation for runway and flight scheduling to minimize the total delay time of all flights and maximize overall runway throughput. The proposed model incorporates both the technical and regulatory constraints for safety, and system uncertainties. The capabilities of the model are demonstrated in San Diego and Ft. Lauderdale airport runways under various scenarios of different priority logics for queueing, and runway layouts.

2 - Measuring Fuel and Travel Time Benefits for Oceanic Flights through Computer Simulation

Arman Izadi, Virginia Institute of Technology, Blacksburg, VA, 24061, United States, armaniz@vt.edu, Antonio Trani

Advanced technologies such as Automatic Dependent Surveillance-Broadcast (ADS-B) have significantly improved situational awareness and communication between pilots and controllers in remote oceanic areas. Reducing oceanic separation minima and proposing novel concepts for the Organized Track System could improve oceanic operations. This talk presents a discrete-time model that simulates all phases of flight from takeoff to landing in order to evaluate these concepts in terms of fuel consumption, travel time, controller workload and safety.

3 - OTP Maximizer: Robust Scheduling with Optimal Block and Ground Times

Zeynep Sargut, Optym, 7600 NW. 5th Place, Sakarya Caddesi No:156, Gainesville, FL, 32607, United States, zeynepsargut@gmail.com, Pranav Gupta, Revindra K. Ahuja, Nomesh Bolia

An airline company usually solves its schedule planning problem considering a little or no stochasticity to maximize its profitability. Highly optimized schedules show an opposite trend in terms of operational metrics such as On Time Performance (OTP). We develop a simulation-based approach to measure the operability of a given schedule under various uncertainties. We aim to optimize the schedules by allocating the available time among the turn and block times so that OTP is maximized at minimal cost using a mixed integer programming formulation.

4 - Simulationof Collision Risk for Alternate Airspace Architectures

John Shortle, George Mason University, Dept of Systems Engineering & OR, 4400 University Drive MS.4A6, Fairfax, VA, 22030-4444, United States, jshortle@gmu.edu

Future airspace architectures will need to handle a wide diversity of aircraft operating in a semi-autonomous fashion. This talks presents a simulation of an airspace architecture in which the core requirement is maintaining a target level of collision risk in all regions of the airspace. Aircraft with better collision avoidance capabilities are thus able to fly in denser airspace. The talk presents a simulation of the concept and discusses implications to capacity, delay and collision risk.

Data Collection and Mining on Traffic Networks

Sponsored: Transportation Science & Logistics

Sponsored Session

Chair: Seyedbehzad Aghdashi, North Carolina State University, 112 Gwinnett Pl, Cary, NC, 27518, United States, saghdas@ncsu.edu

1 - Travel Time Estimation in the Age of Big Data

Arthur J. Delarue, Massachusetts Institute of Technology, 77 Massachusetts Ave, Cambridge, MA, 02139, United States, adelarue@mit.edu, Dimitris Bertsimas, Patrick Jaillet, Sebastien Martin

In this talk, we show that we can leverage network optimization insights to tractably extract accurate travel time estimations from taxi travel time data, with the additional ability to take advantage of many other sources of traffic information. Using synthetic data, we establish the robustness of our algorithm to uncertainty, and display its ability to significantly reduce input variance. We show on real data that our algorithm can leverage any avail- able amount of data, even in a high-variance environment, to provide accurate insights about urban traffic patterns on different scales.

2 - Understanding City Dynamics from Taxis Trajectory Data

Shirin Najafabadi, PhD Student and Research Assistant, The City University of New York (CCNY), 160 Convent Ave, Steinman Hall - Room T-117, New York, NY, 10031, United States, snajafabadi@ccny.cuny.edu, Mahdieh Allahviranloo

This study focuses on trajectories obtained from GPS-enabled taxis and their applications for mining urban commuting patterns. A case study with a taxi trajectory data-set in New York, USA is presented to demonstrate and evaluate spatial distribution of taxi ridership and reveal facts about city dynamics. Using grid cell decomposition method, taxi data dis-aggregated into uniform size units and a radiation model was applied to model spatial correlations of factors associated with urban density to taxi ridership. Also, this paper presents a novel approach using temporal attractiveness of POIs (Point of Interests) to identify activity-locations as well as duration from raw GPS trajectory.

3 - An Optimization Approach to Install License Plate Recognition Sensors in a Traffic Network for Full Road Flow Monitoring Considering the Measurement Errors

Mostafa Salari, Research Assistant, University of Calgary, 312 3420 50th St., NW, Calgary, AB, T3A 2E1, Canada, Mostafa.salari2@ucalgary.ca, Lina Kattan

This work addresses the network sensor location problem (NSLP) to install the minimum number of license plate recognition (LPR) sensors on roads in a traffic network to meet full road flow monitoring. The objective function of the model also aims at minimizing the total measurement errors of sensors while meeting the budget constraint. The Monte Carlo simulation is then applied to consider the randomness of the measurement errors in finding the optimum location set of sensors. Eventually, the concept of backup sensors is developed to maintain the full road flow monitoring regarding the possibility of sensors failures in monitoring the flows.

4 - Reliable Sensor Deployment under Probabilistic Disruptions
Siyang Xie, U. of Illinois at Urbana-Champaign, 205 N.Mathews Avenue, B156 Newmark Lab, Urbana, IL, 61801, United States, sxie13@illinois.edu, Zhoutong Jiang, Yanfeng Ouyang

Many location-aware systems use multiple sensors for geographical positioning and surveillance. The accuracies depend on how the sensors are deployed and used, and may suffer from sensor disruptions when sensors are subject to failures. To optimize the sensor locations and maximize the positioning/surveillance accuracy under disruption risks, we first study the optimal layout of sensor locations on an infinite homogeneous plane. Then we develop a continuum approximation model to formulate the reliable sensor location problem under homogeneous/heterogeneous settings. Numerical examples are presented to illustrate how the proposed model can be applied for sensor deployment optimization.

5 - Predictive Models for Driver Aggressiveness on Arterial Streets using Unsupervised Learning
Nabaruna Karmakar, Graduate Research Assistant, NC State University, Raleigh, NC, United States, nkarmak@ncsu.edu, Seyedbehzad Aghdashi, Masoureh Jeihani, Celeste Chavis, Zohreh Rashidi Moghaddam

Predictive models have been developed to determine drivers' aggressiveness in response to change in arterial road Level of Service (LOS) through data mining of large amount of trajectory and probe vehicle data. K-means clustering has been used to recognize patterns in trajectory data. A Neural Network model is proposed to generate predictive models. Models developed in this research will help decision makers to determine safety impacts of arterial streets treatments.

Analytics Curricula in OR/IE Programs

Sponsored: INFORMEd

Sponsored Session

Chair: Joel Sokol, Georgia Institute of Technology, Georgia Institute of Technology, Atlanta, GA, 30332-0205, United States, jsokol@isye.gatech.edu

1 - MS in Data Science and MS in Business Analytics at ColumbiaUniversity
Adam Elmachtoub, Columbia University, Columbia University, New York, NY, 10027, United States, adam@ieor.columbia.edu, Garud N.Iyengar

The MS in Data Science is offered by the Data Science Institute at Columbia University. Our networked world is generating a extremely large amounts of data that has the potential to transform business, government, engineering and the applied sciences. A new discipline of data science is focused on the tools required to generate information from this data. This MS program is focused on developing new methodologies and applying them to innovative applications.

2 - Master of Science in Analytics at Northwestern: The Importance of Agility
Barry L. Nelson, Northwestern University, Dept of Industrial Eng and Mgmt Sciences, 2145 Sheridan Road, Room C216, Evanston, IL, 60208-3119, United States, nelsonb@northwestern.edu, Diego Klabjan

Analytics is a quickly evolving field and thus education programs must be adaptable and agile. We will discuss how the Master of Science in Analytics program at Northwestern University copes with these challenges.

3 - The Cornell M.Eng. Program – Data Analytics and Beyond
David B. Shmoys, Cornell University, 231 Rhodes Hall, 136 Hoy Road, Ithaca, NY, 14853-3801, United States, david.shmoys@cornell.edu

The Cornell M.Eng. Operations Research program provides a number of concentrations, & the fastest growing is in Data Analytics, blending coursework in OR, data science, & computing, with a client-based project where a team of students work with a faculty member to address a real-world problem. This is complemented by a new program at Cornell Tech in NYC, which combines traditional academic rigor with the energy & opportunity that come with studying in the heart of NYC's tech startup community, & includes an immersive Studio experience, that develops team-building and leadership skills as well as new product ideas in response to the strategic needs of a real organization, & create your own startup.

4 - Georgia Tech's Interdisciplinary MS inAnalytics: On-campus, Online, and International
Joel Sokol, Director, Master of Science in Analytics, Georgia Institute of Technology, School of ISYE, 765 Ferst Drive, Atlanta, GA, 30332-0205, United States, jsokol@isye.gatech.edu

Georgia Tech's Master of Science in Analytics degree is co-owned and co-administered by the College of Engineering, College of Computing, and Scheller College of Business. With an interdisciplinary core, three tracks, 60+ elective choices, and an applied practicum requirement, the degree allows students to specialize and personalize their learning to fit their individual interests and career goals. We offer a premium on-campus option with a variety of perqs, a high-quality MOOC-style online delivery, and a combined MS/MBA option. In this talk, we'll show how it all works.

Sponsored Session

Chair: Emmett J Lodree, University of Alabama, Tuscaloosa, AL, 35487-0226, United States, ejlodree@cba.ua.edu

1 - Managing Volunteer Convergence at Disaster Relief Centers
Hussain Abualkhair, North Carolina A&T.State University, Greensboro, NC, United States, hfabualk@aggies.ncat.edu, Lauren Davis

Disaster Relief center managers face uncertainty in both the timing and quantity of donations, as well as the number of spontaneous volunteers. Volunteer convergence is one of the biggest challenges for relief center managers. To better understand this phenomenon and find effective management strategies, we develop an agent-based simulation model consisting of donors providing relief items, beneficiaries in need of relief items and random arrivals and departures of volunteers. We investigate volunteer assignment policies that reduce donor beneficiary waiting time under given changes in volunteer capacity, available inventory, and beneficiary's arrival rates.

2 - The Optimal Assignment of Spontaneous Volunteers to Parallel Queues with Stochastic Demand
Kyle Paret, North Carolina State University, Raleigh, NC, United States, keparet@ncsu.edu, Maria Esther Mayorga

Immediately following a disaster people converge to assist the affected community. Spontaneous volunteers (SVs) are in a unique position to provide valuable aid at a crucial point in the disaster cycle. Oftentimes these volunteers are ineffectively used or refused all together. Improved methods to integrate spontaneous volunteers are required. In this paper, a multi-server queuing model is formulated to represent the dynamics of assigning SVs to tasks in a post-disaster setting. An optimal assignment policy is generated using a Markov Decision Process. Finally, we use simulation to compare the optimal policy against several heuristic policies and discuss real world implications.

3 - Ambulance Service Region Design under Uncertainty
Shakiba Enayati, State University of New York, Plattsburgh, NY, United States, senayat@ncsu.edu, Osman Ozaltin, Maria Esther Mayorga

Limiting response area for each ambulance may lead to shorter response times to emergency scenes and more evenly distributed workload for ambulances. We propose a two-stage stochastic mixed-integer programming model to address the service region design problem under uncertainty. The output of this model is to locate ambulances at the potential stations in the service area and to assign a set of demand zones to each station at different backup levels. The objective function of our model is to maximize the expected number of covered calls while the assigned workload to each ambulance is restricted. The proposed model can be optimized offline similar to the idea of "patrol-beats" used in policing models.

4 - Approximate Dynamic Programming-based Policies for Donation Collection and Distribution

Robert Alexander Cook, University of Alabama, Tuscaloosa, AL, 35487, United States, Racook1@crimson.ua.edu

This study introduces Approximate Dynamic Programming (ADP) techniques for solving a Markov Decision Problem (MDP) in which we distribute stochastically-arriving donations to disaster survivors. Donations accumulate over time at collection sites and are periodically transported to relief centers where they are distributed to beneficiaries. The MDP model minimizes expected unsatisfied demand during a finite horizon.

Capacity and Inventory Logistics

Sponsored: TSL, Freight Transportation & Logistics

Sponsored Session

Chair: Satya Sarvani Malladi, Georgia Institute of Technology, Atlanta, GA, 30329, United States, mss@gatech.edu

1 - SKU Rationalization with Substitutable Demands in a Packaged Gas Supply Chain

Ethan Malinowski, University at Buffalo (SUNY), 2014 Delaware Avenue, Apt 5, Buffalo, NY, 14216, United States, ejmalino@buffalo.edu, Mark Henry Karwan, Lei Sun, Jose M. Pinto

Effective SKU rationalization is advantageous when applied to businesses with high variance and a variety of potentially substitutable product offerings. Advantages include lower production costs, reduced inventory, and system-wide reductions in transportation costs. We develop two MILP formulations for an industrial gas business with over ten thousand SKU's. One model considers maintaining current customers' product choices and the other introduces notions of swapping and equivalence among SKU's. Both models minimize production and transportation costs while simultaneously reducing SKU variance throughout the system. Computational results and policy implications are presented.

2 - Looking Upstream: Optimal Policies for a Class of Capacitated Multi-stage Inventory Systems

Alexandar Angelus, The University of Texas at Dallas, Jindal School of Management, 800 West Campbell Road SM.30, Richardson, TX, 75080, United States, alexandar.angelus@gmail.com, Wanshan Zhu

We consider a multi-stage, multi-period inventory system with stochastic demand and capacity constraints at each stage. For a class of such systems characterized by having the smallest capacity at the most downstream stage and system utilization above a certain threshold utilization, we identify the structure of the optimal policy. We find the explicit functional form of the order-up-to levels, and show that they depend (only) on upstream echelon inventories. We establish that, above the threshold utilization, this form of the optimal policy achieves the decomposition of the multidimensional objective cost function for the system into single-dimensional convex optimization subproblems.

3 - Exploration of Flexibility Schemes for Time Window Management in E-fulfillment

Charlotte Köhler, Viadrina University Frankfurt (Oder), Frankfurt (Oder), Germany, koehler@europa-uni.de, Jan Fabian Ehmke, Ann Melissa Campbell

When accepting customer requests, online retailers can build tentative delivery routes and check if each customer can be accommodated feasibly with the remaining delivery capacity. Extending customer acceptance mechanisms from the literature, we consider the remaining logistics capacity, the time of the request relative to the booking horizon, and the customer location in the decision of how many different time windows and what time window widths to offer to the customer. We investigate the impact of these ideas on the number of served customers given the demand structure of order data from an e-grocer in Berlin, Germany.

4 - Dynamic Mobile Capacity Logistics and Multi-location Inventory Control

Satya Sarvani Malladi, Georgia Institute of Technology, 2209 Briarcliff Rd NE, Apt 17, Atlanta, GA, 30329, United States, mss@gatech.edu, Alan Erera, Chelsea C. White

We investigate the logistics of distributed production-inventory systems that allow mobile production capacity to be shared dynamically. We establish the value addition over fixed systems and present well-performing heuristics to solve the problem efficiently.

Energy and Climate 3

Invited: Energy and Climate

Invited Session

Chair: Yongyang Cai, Ohio State University, Ohio State University, cai.619@osu.edu

1 - Adding Quantity Certainty to a Carbon Tax: the Role of a Tax Adjustment Mechanism for Policy Pre-Commitment

Hafstead Marc, Hafstead@rff.org

2 - External Impacts of Local Energy Policy: the Case of Renewable Portfolio Standards

Alex Hollingsworth, Indiana University, Bloomington, IN, United States, hollinal@indiana.edu, Ivan Rudik

Renewable portfolio standards are state policies that require in state electricity providers to procure a minimum percentage of electricity sales from renewable sources. We show how RPSs induce out of state emissions reductions through state trade of the credits used for RPS compliance. When one state passes an RPS, it increases demand for credits sold by firms in other states. We find evidence that increasing a state's RPS decreases coal and increases wind generation in outside states. We perform a welfare simulation to evaluate benefits of reductions in local coal fired pollutants, a 1 percentage point increase a state's RPS results in up to $100 million in benefits towards the United States.

3 - Build Today, Regret Tomorrow? Infrastructure and Climate Policy

Yongyang Cai, Ohio State University, Columbus, OH, United States, cai.619@osu.edu, Elizabeth Baldwin, Elizabeth Baldwin, Karlygash Kuralbayeva

The timing of optimal policy to combat climate change is controversial. We consider this question in the light of irreversible "dirty" and "clean" investments. This leads to a "Reverse Green Paradox": the knowledge of an increasing carbon tax will reduce investments in assets that pollute, and so reduce emissions in the short term. This contrasts with the well-known effects of such policy on the suppliers of fossil fuels. So stranded assets play opposing roles, depending on whether these assets supply or demand fossil fuels. Additionally, we show that it is optimal to begin deployment of clean technologies early, if their cost decreases with their cumulative deployment.

4 - Optimal Clean Energy R&D Investments under Uncertainty

Giacomo Marangoni, FEEM, Corso Magenta 63, Milano, 20123, Italy, giacomo.marangoni@feem.it, Gauthier de Maere d'Aertrycke, Valentina Bosetti

The improvement of clean energy technologies asks for risky efforts in research and development (R&D). When evaluating optimal R&D portfolios, accounting for uncertainty while maintaining the rich set of information produced by complex climate-economy models can lead to intractable problems. We avoid succumbing to computation complexity thanks to Approximate Dynamic Programming. We exemplify the methodology by computing the optimal allocation of near-term innovation investments in four key clean energy technologies. We employ an integrated assessment model (WITCH) with a fairly rich description of the energy-economy nexus, and experts' beliefs on future costs to quantify uncertainty.

5 - Promoting Clean Technologies Through Consumption and Production Subsidies

Soheil Shayegh, Fondazione Eni Enrico Mattei (FEEM), 149 Madison Avenue, Midland Park, NJ, 07432, United States, soheilsh@gmail.com

New clean energy technologies typically cost more than established technologies. In order to help clean technologies compete in energy markets, governments can provide two classes of deployment subsidies to different recipients: production subsidies, which lower production costs, or consumption subsidies, which reduce the final price to consumers. Here, we use demand curves to quantify the impacts of these classes of subsidies on technology deployment, social welfare, and market structure. We identify a critical market share in which social welfare is equal under both subsidy schemes. At market shares smaller than the critical value, the benefits of competition favor production subsidies.

Data Analytics & Modeling in Medical Imaging Analysis & Decision Making

Sponsored: Data Mining

Sponsored Session

Chair: Shouyi Wang, University of Texas at Arlington, Arlington, TX, 76013, United States, shouyiw@uta.edu

1 - Supervised Discriminative EEG Brain Source Imaging with GraphRegularization

Feng Liu, University of Texas at Arlington, 1020 W. Abram Street, Apt 172, Arlington, TX, 76013, United States, feng.liu@mavs.uta.edu

The advances in computing and advanced data analytics techniques have led to powerful and promising data-driven tools to solve complex healthcare and medical decision making problems based on increasingly large amounts of data. This session provides a collection of talks in the field to present several most recent research studies that develop data-driven approaches and machine learning techniques for comprehensive decision modeling in medical imaging analysis and decision making.

2 - Discriminative Spectral Pattern Analysis for Prostate Cancer Detection using Light Reflectance Spectroscopy

Rahil Hosseini, University of Texas-Arlington, Arlington, TX, United States, rahilsadat.hosseini@mavs.uta.edu

This talk presents an effective classification procedure that detects the positive margin in prostate cancer by application of data mining techniques. We developed a data-driven method to process and extract features from the Light Reflectance Spectroscopy (LRS) spectrum data, and developed support vector machine and ensemble trees approach for binary and multi-class classification for prostate cancer detection.

3 - A Supervised Learning Model for Predicting Tibia Soft Tissue Insertions using Multi-response Support Vector Regression

Kin Ming Puk, University of Texas at Arlington, 711 Linda Vista Ave, Apt 112A, Arlington, TX, 76013, United States, pukkinming@gmail.com

It has been an ongoing research to precisely identify the location of knee injury without affecting adjacent tissues during the surgical operation, subject to difficulties in locating ligament and related soft tissues and high inter-person morphological variability between patients. This work presents a new prediction framework which is capable of achieving personalized identification of cruciate ligament and optimal position of soft tissue insertions. It is made possible because tibia outline can be accurately and reliably measured from computed tomography imaging and features can thus be extracted for model building with L2,1-regularized multi-response support vector regression.

4 - A Network Modeling and Prediction Framework for Better Epilepsy Surgical Decisions

Shouyi Wang, University of Texas-Arlington, 2029 Randy Snow Road, # 1310, Arlington, TX, 76011, United States, shouyiw@uta.edu

Resective surgery is currently the most effective overall treatment for patients with epilepsy. However, there is still considerable risk of surgical failures for lacking of priori knowledge of seizure spread network. This talk will present a novel network modeling framework using cortico-cortical evoked potentials (CCEP) to understand network mechanisms of epileptogenesis and render clinicians better epilepsy surgical decisions in the future.

1:30 - 2:15 Arundo/ 2:15 - 3:00 Tableau

Invited: Vendor Tutorial

Invited Session

1 - IIOT and Data-Driven Modeling in Asset Heavy Industry

Tailai Wen, Arundo, Houston, TX, United States, tailai.wen@arundo.com, Roy Keyes

The traditional industries start moving towards big data in recent years. While most acknowledge it may bring efficiency improvement and cost reduction to those asset-heavy sectors, to deploy data modeling infrastructure in an enterprise to industrial scale still faces challenges that were not seen in align and less complex modern industries before. In this talk, we will introduce the opportunities and obstacles in this field using real examples that Arundo works on, and demonstrate our solutions to these challenges.

2 - Experience Visual Analytics with Tableau

Ali Kherani, Tableau Software, Seattle, WA, United States, kherani@tableausoftware.com

Get ready to learn how to inform and inspire others when presenting data with Tableau's business intelligence platform. Join us for this tutorial to discover how to turn data into actionable insights and find out why Forbes recently ranked Tableau as the technical skill with the third biggest rise in demand. We'll provide an overview of Tableau and demo the key features and functionality of our visual analytics platform. This overview will excite you to explore your data in a different way!

Autonomous Vehicles

Sponsored: Transportation Science & Logistics

Sponsored Session

Chair: Yiwen Xu, North Dakota State University, P.O. Box 6050, Industrial & Manufacturing Engineering, Fargo, ND, 58108-6050, United States, yiwen.xu6@gmail.com

1 - Recasting Interseciton Automation as a CAV Scheduling Problem within the Mixed Traffic Environment

Pengfei (Taylor) Li, Assistant Professor, Mississippi State University, P.O. Box 9546, 501 Hardy Road, 235 Walker Hall, Mississippi State, MS, 39762, United States, pengfei.li@cee.msstate.edu, Xuesong Zhou

Within the mixed traffic environment, connected-automated vehicles (CAV) are both part of traffic flow and green light request senders. We propose a new vehicle-centered traffic representation and a phase-time-traffic (PTR) hypernetwork model to optimize intersection automation policy (IAP). The new vehicle-centered traffic representation can reflect new features of CAVs in traffic flows. The PTR hypernetwork is to model the integration of mixed traffic with traffic signal operations. We also develop exact algorithms to reduce search space and search the exact optimal solution based on branch-and-bound framework. Algorithms are further enhanced with parallel computing technique.

2 - UAV Delivery Planning Considering Mission Failure Probability

Yiwen Xu, Assistant Professor, North Dakota State University, PO Box 6050, Industrial & Manufacturing Engineering, Fargo, ND, 58108-6050, United States, yiwen.xu@ndsu.edu

Commercialization of Unmanned aerial vehicles (UAVs) is more and more popular. As an emerging application, UAV delivery has attracted considerable attentions. Most previous research on the UAV delivery planning, however, did not consider the mission failure probability and the corresponding hazards. In this talk, we consider such factors and formulate the models to mixed integer programming (MIP) problems. The objective function is set to minimize the expected cost (including expected hazard costs) under given total mission time for all deliveries. We consider both deterministic demands and distributed demands. The models are solved by MIP solvers and numerical examples are included.

Machine Learning for Manufacturing Informatics

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Hao Yan, yanhao@gatech.edu

Co-Chair: Jianjun Shi, Georgia Institute of Technology, Atlanta, GA, 30332-0205, United States, jianjun.shi@isye.gatech.edu

1 - Machine Learning via Nonconvex Model Based Optimization

Tuo Zhao, Georgia Tech, 755 Ferst Dr. NW, Atlanta, GA, 30332, United States, tourzhao@gatech.edu, Han Liu, Tong Zhang

Nonconvex optimization arises in many machine learning problems. Although classical optimization theory has shown that nonconvex optimization is computationally intractable, practitioners have proposed numerous heuristic algorithms, which achieve outstanding performance in real-world applications. To bridge this gap between practice and theory, we propose a new generation of model-based optimization algorithms and theory, which incorporate the statistical thinking into modern optimization. We exploit hidden geometric structures behind nonconvex optimization problems, and obtain global optima with desired statistics properties in polynomial time with high probability.

2 - Machine Learning for in SITU Quality Monitoring of Manufacturing Processes

Bianca Maria Colosimo, Politecnico di Milano, Via La Masa, 1, Milan, I-20156, Italy, biancamaria.colosimo@polimi.it, Marco Grasso

In-situ monitoring of advanced manufacturing processes requires monitoring signal and image data with time. The contribution describes how machine learning approaches can be usefully included in the SPC procedure to detect unnatural process conditions.

3 - Modeling the Distribution of Nonlinear Profile with Application for Process Monitoring and Denoising

Hao Yan, 3525 Highgrove Way NE, Atlanta, GA, 30319, United States, yanhao@gatech.edu

Unsupervised learning of nonlinear profiles has attracted increasing attention among researchers as well as practitioners because of its applications in process monitoring and diagnostics. However, existing unsupervised learning techniques for profile monitoring are typically based on linear models such as Principal Component Analysis, which fails to model the distribution of nonlinear profiles. We present a unified framework for nonlinear profile modeling framework based on variational inference, which a testing statistics can be naturally derived. We then demonstrate how this framework can be used for denoising and profile monitoring with various simulations and case studies.

QSR Student Interaction Session

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Chiwoo Park, Florida State University, Tallahassee, FL, 32310-6046, United States, cpark5@fsu.edu

Co-Chair: Linkan Bian, Mississippi State University, MS, 39762, United States, bian@ise.msstate.edu

1 - QSR Student Interaction

Linkan Bian, Mississippi State University, MS, 39762, United States, bian@ise.msstate.edu

The Student Introduction and Interaction Session is designed for QSR student members to get acquainted with each other, promote themselves in front of our community, and learn from invited guests. In this session, each student will be given two minutes to deliver an elevator speech about his/her research interests and accomplishments; senior QSR members and guests will be invited to interaction with all attendees. A parallel Best Student Poster Competition will be hold at the same room. Students are encouraged to prepare poster presentations to have better exposure. All posters will enter the competition automatically. A winner will be selected by a panel of judges, announced at the QSR business meeting, and awarded a certificate.

Food-Energy-Water and Sustainability

Sponsored: Energy, Natural Res & The Environment Environment & Sustainability

Sponsored Session

Chair: Urmila Diwekar, Vishwanathan Research Institute, urmila@vri-custom.org

1 - Stochastic mixed-integer Programming (MIP) to the Competition of Biofuel and Food Production

Esra Buyuktahtakin, New Jersey Institute of Technology, Newark, NJ, United States, esratoy@njit.edu, Halil Cobuloglu

We present a two-stage stochastic MIP model that maximizes the economic and environmental benefits of food and biofuel production under yield and price uncertainty. The first-stage variables define binary decisions for allocating various land types to food and energy crops, while the second-stage variables are operational decisions related to harvesting, budget allocation, and amounts of different yield types. Results indicate the significant benefit of using the stochastic yield-level information in an optimization model that is solved by a Benders' decomposition algorithm.

2 - Optimizing Spatiotemporal Sensors Placement for Nutrient Monitoring: An Algorithmic Framework

Urmila Diwekar, Vishwamitra Research Institute, 2714 Crystal Way, Crystal Lake, IL, 60012-2224, United States, urmila@vri-custom.org, Rajib Mukherjee

Nutrient monitoring is very important for the area of food-energy-water nexus. In this work, we have proposed a methodology to optimize a dynamic sensor network which can address the spatiotemporal aspect of nutrient movement in a water shed. This is a first paper in the series where an algorithmic and methodological framework for spatiotemporal sensor placement problem is proposed. This framework is based on a novel stochastic optimization algorithm called Better Optimization of Uncertain Systems (BONUS) and is very efficient. A small case study of the dynamic sensor placement problem is presented to illustrate the approach.

3 - Limits to Growth and Global Sustainability of Food-energy-water Nexus

Urmila Diwekar, Vishwamitra Research Institute, Crystal lake, IL, United States, urmila@vri-custom.org, Heriberto Cabezas

A mathematical representation of World dynamics has been constructed inspired by the Limits to Growth. It includes an ecosystem, human population, industry, energy generation, water and the food-energy-water nexus, macro-economy, and rudiments of a legal system with private property, taxation, and regulation. The model provides the conceptual machinery for "steering" the system towards sustainability using socio-economic policies. Optimal control theory is used to forecast policies for three versions of the model. Analysis of sustainability with various scenarios is discussed, and controllability and socio-economic policies to bring the system towards sustainability are described.

Big Data

Contributed Session

Chair: Anurag Agarwal, University of South Florida, Sarasota, FL, United States, agarwala@usf.edu

1 - Real Time Detection of Acute Hypotensive Episode in Intensive Care Unit to Reduce Mortality Rate

Rupesh Agrawal, Research Assistant, Oklahoma State University, 700 N. Greenwood Ave., Tulsa, OK, 74106, United States, rupesh.agrawal@okstate.edu, Surya B. Ayyalasomayajula, Dursun Delen, Ramesh Sharda, Bruce Benjamin

Acute Hypotensive Events (AHE) requires timely attention for intensive care unit (ICU) patients to keep mortality rate low. Timely detection and trend of AHE from "normal" state to "not-normal" state can help ICU medical staff for timely intervention. This study uses rule-based "Complex Event Process" (CEP) detection method to calculate real-time state (normal/not-normal) of "Arterial Blood Pressure" (ABP) signal in real-time. ABP signal streaming at the rate of 125 Hz is used for this study to calculate AHE per second vs per minute, allowing medical professionals between 10-30 mins to provide timely intervention.

2 - Microarray Data Analysis in the Prognosis of Cancer

Sharmin Nahar Mithy, Doctoral Candidate, University of South Florida, 2208 Fitness Club Way, Apt 204, Apt: 204, Tampa, FL, 33612, United States, sharminmithy@mail.usf.edu, Grisselle Centeno

More than one million people get affected by colorectal cancer yearly. The best estimation of prognosis in colorectal cancer is related to the anatomic extent of disease determined on pathologic examination of the resection specimen. Development of statistical models to help the clinicians who will estimate the probability of developing cancer is of great interest in today's research. In this research a neuro-fuzzy approach will be considered in the areas of classification of microarray data analysis. By combining the advantages of both Neural Network and Fuzzy Inference System, Nuero-Fuzzy approaches will be able to achieve a higher accuracy within a relatively shorter training time.

3 - Insights into the Data Mining Cost Model

David Perkins, Associate Professor of Business, Grand Canyon University, 717 East Country Plaza North, Gilbert, AZ, 85234, United States, david.perkins@cox.net

The Data Mining Cost Model (DoCoMo) attempts to provide a robust parametric approach for estimating the cost of a data mining project. This presentation will provide a review of important literature associated with the DoCoMo, will suggest how the DoCoMo can be applied in today's analytics organizations, and will recommend further areas of application and research.

4 - Real-time Data-driven Decision-support Toolkit for the Incentivization and Guidance of Shared Electrified and Automated Vehicles

Chenfeng Xiong, Assistant Research Professor, University of Maryland, 1173 Glenn Martin Hall, College Park, MD, 20770, United States, cxiong@umd.edu, Lei Zhang, Ya Ji

We develop an integrated, personalized, real-time traveler information and incentive technology to incentivize energy-efficient travel, such as the adoption of Shared, Electrified, and Automated Vehicles. Based on machine learning and artificial intelligence, a behaviorally sound and computationally efficient agent-based model is developed to simulate the transportation systems in real-time. The online training of the AI models is based on real-time big-data streams leveraging the biggest transportation data warehouse in the U.S., the Regional Integrated Transportation Information System, which enables accurate system monitoring and effective control/operations.

5 - Augmenting Text Mining to Numerical Analysis to Improve Lift

Anurag Agarwal, Professor, University of South Florida, Information Systems and Decision Sciences, College of Business, Sarasota, FL, 34243, United States, agarwala@usf.edu

We show how lift and classification accuracy can be improved by augmenting numerical data analysis with text mining, if text data is available in addition to numeric data for a classification problem.

Non-convex and Convex Optimization

Sponsored: Optimization, Global Optimization

Sponsored Session

Chair: Daniel Bienstock, Columbia University, New York, NY, 10027, United States, dano@columbia.edu

1 - On the Construction of Converging Hierarchies for Polynomial Optimization Based on Certificates of Global Positivity

Amir Ali Ahmadi, Princeton University, Dept. of Operations Research&Financial Eng., Sherrerd Hall (Room 329), Charlton Street, Princeton, NJ, 08544, United States, a_a_a@princeton.edu, Georgina Hall

In recent years, techniques based on convex optimization that produce converging hierarchies of lower bounds for polynomial optimization problems (POPs) have gained much popularity. At their heart, these hierarchies rely crucially on Positivstellensatze from the late 20th century (e.g., due to Putinar and Schmudgen) that certify positivity of a polynomial on an arbitrary basic semialgebraic set. In this paper, we show that such hierarchies could in fact be designed from much more limited Positivstellensatze dating back to the early 20th century that only certify positivity of a polynomial globally.

2 - Rank-one Generated Spectral Cones Defined by Homogeneous Linear Matrix Inequalities

Charles J. Argue, Carnegie Mellon University, Pittsburgh, PA, 15213, United States, cjargue@gmail.com, Fatma Kilinc-Karzan

A cone K which is a subset of positive semidefinite cone, is called rank-one generated (ROG) if all of its all of its extreme rays are rank one matrices. Semidefinite relaxations of non-convex quadratic optimization problems are exact for every linear objective function if and only if they lead to conic programs over ROG cones. We study the necessary and sufficient conditions under which the intersection of the positive semidefinite cone with two homogeneous linear matrix inequalities is an ROG cone. Our results also yield a method for giving efficient certificates for whether such a cone is ROG or not.

3 - Volume Computation for Sparse Boolean Quadric Relaxations

Jon Lee, University of Michigan, 1205 Beal Avenue, Ann Arbor, MI, 48109-2117, United States, jonxlee@umich.edu, Daphne Skipper

Motivated by understanding the quality of tractable convex relaxations of intractable polytopes, Ko et al. gave a closed-form expression for the volume of a standard relaxation Q(G) of the BQP P(G) of the complete graph. We extend to structured sparse graphs, giving: (i) an efficient algorithm for calculating vol(Q) when G has bounded tree width, (ii) closed-form expressions (and asymptotic behaviors) for vol(Q) for all stars, paths, and cycles, and (iii) a closed-form expression for vol(P) for all cycles. We show that when G is a cycle, the light Q is a very close model for the heavy P.

4 - Computational Experiments and Methodology for QCQPs

Daniel Bienstock, Columbia University, Dept of IEOR, 342 Mudd, New York, NY, 10027, United States, dano@columbia.edu

We describe current computational work using linear relaxations and binary approximations to continuous variables in the context of polynomial optimization problems.

Sponsored Session

Chair: Colin P Gillen, University of Pittsburgh, 1025 Benedum Hall, Pittsburgh, PA, 15261, United States, cpg12@pitt.edu

1 - An Efficient Algorithm of Constructing Highly Fault Tolerantvirtual Backbone to Reduce the Transmission Cost with Damage Loss Uncertainty in Wireless Network

Mengnan Chen, University of Central Florida, 12800 Pegasus Drive, P.O. Box 162993, Orlando, FL, 32816-2993, United States, cmn891127@knights.ucf.edu

We study the problem of constructing virtual backbones in wireless network to reduce the transmission cost and maintain the network when the backbone nodes are damaged, called the virtual backbones for cost reduction and network maintenance (VBRM) problem. The backbone node is the foundation of this routing scheme. This is two level problem modeled by the stochastic programming. Our model can find the optimal solution between guaranteed rates of data delivery within different situation.We also consider to improve energy-efficient of data communications by reducing the transmission cost.

2 - Exact Algorithms for the Minimum Cost Vertex Blocker Clique Problem

Farzaneh Nasirian, University of Massachusetts Boston, 100 William T. Morrissey Blvd, Boston, MA, 02125, United States, Farzaneh.Nasirian001@umb.edu, Foad Mahdavi Pajouh, Josephine Namayanja

This talk addresses the minimum cost vertex blocker clique problem which is to find a minimum cost subset of vertices whose removal bounds the maximum weight of a clique in a network. We propose a new characterization of the set of feasible solutions that results in new linear 0-1 programming formulations solved by lazy-fashioned branch-and-cut algorithms. We also develop the first combinatorial branch-and-bound algorithm for this problem. The computational performance of these exact algorithms is studied on a test-bed of randomly-generated and real-life instances.

3 - Maximum Induced Path in a Graph

Dmytro Matsypura, The University of Sydney, Sydney, 2006, Australia, dmytro.matsypura@sydney.edu.au, Alexander Veremyev, Oleg A.Prokopyev, Eduardo Pasiliao

We consider the problem of finding the maximum induced path in a graph. We develop three conceptually different MIP formulations and study their properties. We develop a number of valid inequalities and various enhancements to the proposed MIPs. We also propose exact iterative algorithms to solve the problems. Finally, we conduct an extensive computational study to evaluate the performance of the proposed algorithms and to reveal the properties of the proposed formulations.

4 - Robust Node Hardening Against Influence Propagation

Colin P. Gillen, University of Pittsburgh, 405 Franklin Avenue, #1, Pittsburgh, PA, 15221, United States, cpg12@pitt.edu

We consider a variation of the classical Linear Threshold model in which the node thresholds are known, but the arc weights (influence) is uncertain. The decision maker wishes to harden a set of nodes, within a limited budget, in order to minimize the spread of influence given a set of seed nodes. NP-hardness of the problem is proved, some polyhedral results are discussed, and solution approaches are presented. Some computational results demonstrating the effectiveness of our algorithms and their enhancements are shown.

Blockchain for Supply Chain and Logistics

Invited: Operations Research and the Future of Computing

Invited Session

Chair: Robin Lougee, IBM Research, Yorktown Heights, NY, 10598, United States, rlougee@us.ibm.com

Co-Chair: Chandra Narayanaswami, IBM Research, NY, United States, chandras@us.ibm.com

1 - The Systemic Adoption of Blockchain with in the Aviation Ecosystem

Robert J. Rencher, The Boeing Company, Seattle, WA, 98008, United States, robert.j.rencher@boeing.com

This presentation is intended to provide to the participants a background on aviation industry supply chain as it exists today, challenges it is facing - in speed, trust, repetitive work, complexity, provenance, disputes, etc. We will discuss the following: 1) Why Blockchain is of interest to the aviation industry. 2) A primer on the state of managing information in the aviation ecosystem. 3) Challenges for Blockchain adoption by the aviation industry and 4) Value propositions blockchain brings to the aviation industry.

2 - Blockchain Technology for Ocean Container Shipping

Jeffrey L. Howard, INTTRA, Parsippany, NJ, 07504, United States, jeff.howard@inttra.com

Jeff Howard, SVP and Chief Product Officer of ocean shipping e-commerce leader INTTRA, will discuss his observations of the use and potential benefits of Blockchain technologies in the ocean shipping industry and logistics. Howard will also share his observations of challenges facing the ocean container shipping industry including complex, multi-party transactions, the need for digitization, issues with trust across transactions and parties, transaction velocity and workflow, as well as the desire to balance transaction confidentiality and security with increased visibility to required workflow milestones.

3 - Introduction to Blockchain Technology and Supply Chain Use Cases

Chandra Narayanaswami, Principal Research Staff Member, IBM.Research, 1101 Kitchawan Road, Yorktown Heights, NY, 10598, United States, chandras@us.ibm.com

A Permissioned Blockchain provides an immutable, shared ledger that is kept consistent using distributed and resilient consensus protocols, along with inherent provisions for data separation, privacy and security among the participants. Executable smart contracts orchestrate automation and efficiency. Additional analytics offer insights on aspects such as compliance and quality.

Together it provides what is needed for an efficient next generation supply chain, with provable provenance, for ordering, tracking, and maintaining assets and services need to operate in distributed cross-organizational settings where partial lack of trust among organization is common.

Computational Methods in Healthcare

Sponsored: Computing

Sponsored Session

Chair: Amin Khademi, Clemson University, Central, SC, 29630, United States, khademi@clemson.edu

1 - Infectious Disease Modeling in a Meta-Population

Ceyda Yaba, Clemson University, 833 Old Greenville Highway, Apt 614, Clemson, SC, 29630, United States, cyaba@g.clemson.edu, Burak Eksioglu, Amin Khademi

We studied an infectious disease without cure in a meta-population over a geographical region that is divided into subpopulations. Each individual is either susceptible or infected; and the rate of infection is independent for every subpopulation. We model this scenario as a Markov Decision Process, where the actions are defined as the number of people to quarantine in every subpopulation under a capacity constraint for the entire population. We solve this model by Approximate Dynamic Programming approach in which a column generation algorithm is used. The results from the column generation are then compared to a simulation model to offer bounds for the value functions of the Markov Decision Process.

2 - Mitigating Ambiguity in Markov Decision Processes using Multiple Models of Parameters

Lauren N.Steimle, University of Michigan, 3261 Bolgos Circle, Ann Arbor, MI, 48105, United States, steimle@umich.edu, David L. Kaufman, Brian T. Denton

Markov decision processes (MDPs) are a powerful tool for optimizing sequential decision-making under uncertainty. However, the usefulness the resulting policy is often at the mercy of the data used to parameterize the MDP. Often times, the transition probabilities must be estimated from external sources, and it can be unclear which source is most appropriate to use. In this talk, we describe a new method for mitigating the effects of parameter ambiguity by allowing for multiple models of the MDP parameters. We discuss properties of optimal policies, the complexity, and solution methods. We highlight the merits of this approach using a case study in the context of cardiovascular disease management.

3 - Establishing an Optimal IRT Threshold for Cystic Fibrosis

S. Saloumeh Sadeghzadeh, PhD Candidate, Virginia Tech, 428 Harding Ave, Blacksburg, VA, 24060, United States, saloumeh@vt.edu, Ebru Korular Bish, Douglas R. Bish

Cystic Fibrosis (CF) is one of the most prevalent genetic diseases in the United States. Newborn screening for CF allows for early diagnosis, and can substantially improve outcomes. Most first-tier screening for CF in the United States is performed via the IRT test, which measures the level of a CF-related biomarker. However, newborn testing practices for CF that involve the IRT test vary significantly among the states. We determine optimal testing schemes for newborn CF screening. Our case study demonstrates the value of the proposed testing schemes in newborn screening.

4 - Optimal Set of Interventions for Childhood Obesity: Benefit and Cost

Parisa Zahiri, M.Sc., Tehran Azad University, Tehran, Iran, Islamic Republic of, zahiriparisa86@gmail.com

Childhood obesity is a public health crisis in many other countries. The cause of childhood obesity is complex, involving biological, behavioral, psychosocial, demographic, economic, community, and environmental factors. The goal of this project is to create a model to estimate the effect of each intervention on childhood obesity over time considering a broad range of risk factors widely accepted in the literature and adherence. The most cost-effective set of interventions is then investigated.

Co-Chair: Mario Eduardo Villanueva, PhD, Texas A&M University, College Station, TX, United States, me.villanueva@tamu.edu

1 - Global Optimization based on Edge-Concave Underestimators

M.M. Faruque Hasan, PhD, Texas A&M.University, College Station, TX, United States, hasan@tamu.edu

A new relaxation technique is developed for the deterministic global optimization of twice-differentiable continuous problems. Instead of using a convex underestimator, the relaxation is based on an underestimator which is edge-concave. The underestimator is constructed by subtracting a positive quadratic expression. We use the linear facets of the vertex polyhedral convex envelope of the edge-concave underestimator to obtain a linear programming (LP)-based relaxation of general nonconvex functions. The method will be presented with theoretical results and will be compared with convexification/ underestimation techniques such as BB and its variants through test examples.

2 - Global Optimization of Differential Games

Mario Eduardo Villanueva, Texas A&M.University, Research Parkway, College Station, TX, 77845, United States, me.villanueva@tamu.edu, Xuhui Feng, Boris Houska

This talk presents novel strategies of formulating 2-stage dynamic games in the form of a generalized optimal control problem (OCP) for systems with two control inputs. The first control input is chosen by Player 1. Player 2 plays after Player 1 by choosing the second control input. Both players have to satisfy state- and control constraints or loose the game. In addition, one of the players tries to minimize an objective that is maximized by the other player. First, we discuss differences and similarities to standard robust OCPs. Then, we outline numerical strategies for analyzing and solving dynamic games by using algorithms from the field of set-valued propagation and dynamic global optimization.

3 - Linear Convex Underestimators for Dynamic Systems
Kamil Khan, PhD, McMaster University, Hamilton, ON, Canada, kamilkhan@mcmaster.ca

A new efficient adjoint-based method is presented for computing useful affine underestimators for solutions of parametric ordinary differential equations, to provide bounds to methods for deterministic dynamic global optimization. This method harnesses several recent advances, including a general framework for convex relaxation generation by Tsoukalas and Mitsos, an instance of this framework that yields continuously differentiable relaxations, and a technique by Scott and Barton for describing convex relaxations for ODE systems as solutions of hybrid discrete/continuous systems.

1 - Learning Combinatorial Structures
Swati Gupta, Massachusetts Institute of Technology, Cambridge, MA, 02139, United States, swatig@mit.edu, Michel X. Goemans, Patrick Jaillet

We study the minimization of separable strictly convex functions over polyhedra. This problem is motivated by online convex optimization methods whose bottleneck relies on the minimization of a (often) separable, convex metric, known as the Bregman divergence. We provide a conceptually simple algorithm, Inc-Fix, in the case of submodular base polyhedra. For cardinality-based submodular polytopes, we show that Inc-Fix can be speeded up to be the state-of-the-art method for minimizing uniform divergences. We show that the running time of Inc-Fix is independent of the convexity parameters of the objective function.

2 - Posterior Sampling for Reinforcement Learning: Worst-case Regret Bounds
Randy Jia, PhD Candidate, Columbia University, New York, NY, United States, rqj2000@columbia.edu, Shipra Agrawal

We present a posterior sampling aka Thompson sampling based algorithm for the reinforcement learning problem. Our main result is a \tilde{O}(D\sqrt{SAT}) bound on the worst-case (minimax) regret of our approach when the underlying unknown Markov Decision Process (MDP) is communicating with a finite diameter D, finite number of states S and actions A. Here, regret compares the total reward achieved by the reinforcement learning algorithm to the total expected reward of an optimal infinite-horizon undiscounted average reward policy, over a finite time horizon T.

3 - Dynamic Data-driven Estimation of Non-parametric Choice Models
Nam Ho-Nguyen, Carnegie Mellon University, 5000 Forbes Avenue, Pittsburgh, PA, 15213, United States, hnh@andrew.cmu.edu, Fatma Kilinc-Karzan

We study non-parametric models for consumer choice behaviour. These models were introduced to alleviate unreasonable assumptions and issues of suboptimal model fit/selection present in traditional parametric approaches. We present a simple convex optimization-based framework to efficiently learn a non-parametric choice model from data. Our method enjoys provable convergence guarantees and extends naturally to the dynamic observation model. Each iteration of our method, as well as existing approaches from the literature, requires solving a combinatorial subproblem. We examine this in detail and identify conditions under which it can be efficiently solved.

3 - Dynamic Stochastic Approximation for Multistage Stochastic Optimization
Zhiqiang Zhou, Georgia Institute of Technology, Atlanta, GA, Contact: zzhoubrian@gatech.edu, Guanghui Lan

This paper considers optimizing a multi-stage programing problem with stochastic conic constraints in every stage. We first present a new algorithm, namely Dynamic stochastic approximation (DSA), to handle this optimization problem. We show this algorithm can achieve an optimal rate O(1/\epsilon^4) of convergence in terms of number of random samples when applied to a 3-stage stochastic optimization problem under the assumption that objective function is general convex, and we also show this rate can be improved to O(1/\epsilon^2) when the objective function is strongly convex. Moreover, we present a variant of DSA when applied to an extended multi-stage programming problem..

Constantine Caramanis, University of Texas, Mail Code C0806, Austin, TX, 78712-0240, United States, constantine@utexas.edu

Abstract not available.

2 - Computational Sensitivity Analysis for High-Dimensional Linear Programs
Stewart Curry, Georgia Tech, scurry9@gatech.edu

Sensitivity analysis is an integral part of decision-making using optimization modeling. Such analysis is particularly important in situations where the input parameters are uncertain. Global sensitivity analysis estimates the variance of the optimal objective value attributable to each input parameter. However, it relies on solving a given optimization problem for randomly generated data points, and methods for doing so efficiently are not studied. In this talk, we will discuss recent efforts to make global sensitivity analysis more computationally efficient and, in doing so, provide insights into the geometry of parametric linear programs.

3 - Communication-Efficient Decentralized Stochastic Optimization
Soomin Lee, Georgia Tech, 144 Ponce de Leon Avenue NE, Apt 1608, Atlanta, GA, 30308, United States, soomin.lee@isye.gatech.edu, Guanghui Lan, Yi Zhou

Optimization problems arising in decentralized multi-agent systems have gained significant attention combined with privacy preservation and distributed data mining/processing issues. The distributed nature of the problems is inherent due to partial knowledge of the problem data, which necessitates costly communications among neighboring agents. In this talk, we present a new class of decentralized first-order methods for nonsmooth and stochastic optimization problems which can significantly reduce the number of inter-node communications and efficiently solve subproblems through linearizations of their local objective functions.

Data-driven Distributed Optimization and Learning for Modern Power Systems

Sponsored: Energy, Natural Res & the Environment Electricity

Sponsored Session

Chair: Andy Sun, Georgia Institute of Technology, Atlanta, GA, 30312, United States, andy.sun@isye.gatech.edu

1 - Deep Learning in Power Markets
Joel Macaluso, Texas A&M University, jmacaluso@tamu.edu

In this work, we are interested in exploring deep learning techniques and their application to power markets. Power markets are known for extreme price volatilityand sensitivity to random variables such as weather. Electricity dispatch requires planning ahead while taking into account reliability concerns. In this work we apply deep learning to the task.

2 - A Multi-sensor Feedback Estimator for Forecasting Variability in Local Area Photo-voltaic Power Generation
Jeff Manning, University of Texas at Austin, Austin, TX, United States, jeff.manning@rastrac.com

We propose and investigate the tractability of prediction of surface-driven convective cumulus clouds in a local area by use of a feedback estimator. The estimator senses the spatio-temporal cloud shadow field and uses a Navier-Stokes fluid solution to estimate the surface heating field and ultimately the evolution of the future cloud field which results therefrom. Such clouds have lifetimes ranging from five to thirty minutes, so a predictor must account for cloud evolution in addition to mere horizontal advection. The design is challenged by loss of information due to convective turbulence in the ABL, so we investigate conditions under which the problem may or may not be practically solvable.

3 - Optimal Price Threshold Control for Battery Operation with Aging Phenomenon

Yuhai Hu, Lehigh University, 200 West Packer Avenue, Bethlehem, PA, 18015, United States, yuh212@lehigh.edu, Boris Defourny

This talk is concerned with grid-level battery storage operations, taking battery aging into consideration. Battery operations under price uncertainty are modeled as a Markov Decision Process with expected cumulated discounted rewards. An algorithm that takes advantage of the problem structure and works directly on the continuous state space is developed to maximize the objective over the life of the battery. Computational results are presented to compare the proposed approach to a standard dynamic programming method, and to evaluate the impact of refinements in the battery model. Error bounds for the proposed algorithm are established to demonstrate its accuracy.

4 - Load Scheduling for Residential Demand Response on Smart Grids

Luce Brotcorne, INRIA, Lille, 59000, France, luce.brotcorne@inria.fr, Miguel Anjos, Martine Labbé, Maria Restrepo

We present a mixed integer linear program for a load scheduling problem in the context of residential demand response. The model schedules the operation time and power consumption level of each load and controls the use of energy storage devices to minimize the total energy cost and manage peak in power consumptions. Numerical results show that electricity cost savings and reductions in power peak consumptions can be achieved by shifting demands and using efficiently the battery.

Data Envelopment Analysis

Contributed Session

Chair: Erhan Berk, National Defence University, Hava Harp Okulu Komutanligi Yesilyurt, Istsnbul, 34149, Turkey, eberk@hho.edu.tr

1 - University Selection for Masters Degree with Data Envelopment Analysis and Analytical Hierarchy Process

Xiaojun (Gene) Shan, University of Houston-Clear Lake, Houston, TX, United States, shan@uhcl.edu, Mukesh Dachapally

Efficiency of 20 similar U.S. universities were evaluated using data envelopment analysis (DEA) and analytical hierarchy process (AHP). The inputs for DEA are tuition fees, Student to faculty ratio and number of research-only faculty while the outputs are graduation rate, freshman retention rate and number of publications. Then, AHP was applied to identify the best university for master's degree. 64 participants participated in a survey to identify criteria. The five criteria are tuition fee, University global ranking, weather, scholarship and Career opportunities. This study found Binghamton University as the most efficient university.

2 - A Research on Energy Efficiency under Dual Mechanisms of Inter-provincial Trade and R&D Investment in China

Rui Wang, Tongji University, Shanghai, China, 2822930768@qq.com, Dajian Zhu

Market segmentation is the backward areas' trade protection behavior of not participating in cooperation and work division in order to obtain technical progress in high technology industry, but it causes the efficiency loss of resources allocation. Based on the panel data of Chinese 30 provinces from 2003 and 2014, this paper uses the SFA model contracted with joint estimation of technical inefficiency and influencing factors to investigate the influence of Chinese provincial trade and its work with different levels of R&D activities on energy efficiency, we find that these R&D activities play heterogeneous roles in different forms of inter-provincial trade's improvement of energy efficiency.

3 - A Predictive Model for Estimating the Generation of Solar PVS and Wind Turbines with Various Predictors within the United States

Narjes Nouri, PhD Student, University of Wisconsin-Milwaukee, Milwaukee, WI, 53211, United States, nourin@uwm.edu, Mohammad Hasan Balali

Development in PV panels and wind turbines technologies and growing number of operable solar and wind farms made these two renewable sources best potentials for traditional sources in the last decades.There are various types of parameters which affect the installed capacity of these sources. There are many articles which studied the impact of environmental parameters such as wind speed and air temperature on the renewable energy generation. On the other hand, there are social parameters which have indirect effects that might not be as evident as environmental parameters. In this study, a regression model has been presented between renewable energy generation and some selected social parameters.

4 - A Two Stage Data Envelopment Analysis Model for the Efficiency Assessments of 39 State's Wind Power in the United States

Umit Saglam, Assistant Professor, East Tennessee State University, Department of Management and Marketing, P.O. Box 70625, Johnson City, TN, 37614, United States, saglam@etsu.edu

Wind power is the second largest renewable energy source to generate electricity in the United States. Therefore, in this study, a two-stage Data Envelopment Analysis (DEA) is developed to quantitatively evaluate the relative efficiencies of the 39 state's wind power performances for the electricity generation. Both input- and output-oriented CCR and BCC models are applied to pre-determined four input and six output variables. The sensitivity analysis is conducted to test the robustness of the DEA models. Tobit regression models are conducted by using the DEA results for the second stage analysis. The DEA results indicate that more than half of the states operate wind power efficiently.

5 - Using Data Envelopment Analysis Approach to Analyze the Impacts of Technical Efficiency in Turkey

Erhan Berk, National Defence University, Hava Harp Okulu Komutanligi Yesilyurt, Istanbul, 34149, Turkey, eberk@hho.edu.tr

This study aimed to measure the technical efficiency of healthcare centers in Turkey by size and to identify the possible factors affecting their technical inefficiency. In the first stage, an input oriented data envelopment analysis was adopted to compute the technical efficiency scores for three types of healthcare centers by two DEA models. In the second stage, in order to classify the healthcare centers for which the assessment values equal to 1, the super efficiency model was used for further sorting to determine the factors that affect technical inefficiency of the healthcare centers. The study revealed that the average technical efficiency score of healthcare centers was 64%.

Stability-constrained Optimal Operation of Electric Power Systems

Sponsored: Energy, Natural Res & the Environment Electricity

Sponsored Session

Chair: Andy Sun, Georgia Institute of Technology, Atlanta, GA, 30312, United States, andy.sun@isye.gatech.edu

1 - Design, Stability and Control of Ad-hoc Microgrids

Konstantin Turitsyn, Massachusetts Institute of Technology, Cambridge, MA, United States, turitsyn@mit.edu, Kathleen Cavanagh, Petr Vorobev

Low voltage microgrids is a promising technology for bringing power to about 1 billion of people living in non-electrified regions. Modern planning and operation practices cannot be easily downscaled to these microgrids. This talk will introduce a concept of ad hoc microgrid that remain stable for arbitrary interconnection topologies. After discussing the main destabilization mechanisms related to large gain droops, constant power loads and inductive delays in lines, we will develop a systematic theory for derivation of design constraints that guarantee stability for arbitrary topologies. The nature of worst case scenarios and conservativeness of the constraints will be discussed in the end.

2 - A New Voltage Stability-constrained Optimal Power Flow Model: Sufficient Condition, SOCP Representation, and Relaxation

Bai Cui, Georgia Tech, Atlanta, GA, United States, bcui7@gatech.edu

Simple characterization of the solvability of power flow equations is of great importance in the monitoring, control, and protection of power systems. In this presentation, we introduce a sufficient condition for power flow Jacobian nonsingularity. We show that this condition is second-order conic representable when load powers are fixed. Through the incorporation of the condition, we propose a voltage stability-constrained optimal power flow formulation as a second-order cone program. An approximate model is introduced to improve the scalability of the formulation to larger systems. Extensive computation results on standard instances confirm the effectiveness of the formulation.

3 - Necessary and Sufficient Conditions for Voltage Stability in Homogeneous Balanced Radial Networks

Enrique Mallada, Johns Hopkins University, Baltimore, MD, United States, Mallada@jhu.edu, Krishnamurthy Dvijotham, John Simpson-Porco

Voltage stability is a critical constraint for the safe operation of power systems. However, enforcing voltage stability in power flow optimization problems is quite challenging due to the implicit nature of the stability constraint. We derive necessary and sufficient conditions on the power injections for the existence of a voltage stable power flow solution in radial distribution networks with homogeneous lines. We further show that the solution satisfies several desirable properties (unique high-voltage solution and voltage-regularity). We use this formulation to show that robust ACOPF in power distribution networks can be solved exactly via a convex relaxation under natural assumptions.

Chair: Kai Pan, University of Florida, Gainesville, FL, 32611, United States, kpan@ufl.edu

1 - Design and Dispatch Optimization of a Solid-oxide Fuel Cell Assembly for Unconventional Oil and Gas Production

Alexandra M. Newman, Colorado School of Mines, 1500 Illinois St, Golden, CO, 80401, United States, anewman@mines.edu, Gladys Anyenya, Neal Sullivan, Robert Braun

We present a multi-objective design and dispatch optimization model of a solid-oxide fuel cell (SOFC) assembly for unconventional oil and gas production. Heat produced by SOFCs during electricity generation is used to pyrolyze kerogen into a mixture of oil, hydrocarbon gas and carbon-rich shale coke. The Geothermic Fuel Cell (GFC) system costs, heating and electrical efficiencies are optimized, subject to geology heating demands, auxiliary component electric power demands and the GFC system performance characteristics. The resulting optimal cost of oil and gas produced using the GFC technology is about $39/bbl which is comparable to that from other unconventional oil extraction techniques.

2 - The Community Microgrid Distribution System of the Future

Lei Wu, Clarkson University, 8 Clarkson Avenue, P.O. Box 5720, Potsdam, NY, 13676, United States, lwu@clarkson.edu

Community microgrids (CMG) connect critical loads and distributed energy resources of multiple owners for providing reliable and resilient electricity services through distribution lines owned by a local power utility company. Thus, different from current single-owner microgrids, CMGs present significant new design goals, operating constraints, and business models. This presentation discusses key characteristics, identifies operation challenges, and proposes potential solution methodologies for the operation and control of the future CMGs. A practical community resilience microgrid that is underway for serving Potsdam, NY will also be discussed.

3 - Pricing Electricity Considering Non-convexity and Uncertainty in the Day-ahead Pool Market

Jianhui Wang, Southern Methodist University, Dallas, TX, United States, jianhui@smu.edu

Jianhui Wang, Argonne National Laboratory, Argonne, IL, United States, jianhui@smu.edu

A new market clearing mechanism for the day-ahead market is proposed in this paper, which considers both the non-convexity caused by the unit commitment decisions, and the uncertainty of real-time operation. By applying this method, sufficient flexibility can be reserved through proper commitment decisions. Meanwhile, every dispatched unit is guaranteed for adequate revenue to recover costs without additional side payments. A primal-dual approach associated with specific revenue adequacy rules is applied to formulate the problem.

4 - Optimization of Food and Biofuel Production with Economic and Environmental Impacts

Halil Cobuloglu, Senior Analytics Fellow, McKinsey & Company, 404 wyman st Suite 300, Boston, MA, 02451, United States, halil.cobuloglu@gmail.com, Esra Buyuktahtakin

Biofuel production from food crops leads to debates about the security of the food supply while biofuels offer positive environmental impacts. To solve this trade-off, we propose a multi-objective mixed-integer optimization model to investigate the economic and environmental impacts of biofuel and food production using switchgrass and corn. This model provides optimal decisions regarding land allocations to food and energy crops, seeding time, harvesting time and amount, and budget allocations to farm operations. Finally, we present a two-stage MIP model that maximizes the economic and environmental benefits of food and biofuel production.

Approximate Dynamic Programming for Stochastic Optimization

Sponsored: Optimization, Optimization Under Uncertainty

Sponsored Session

Chair: Selvaprabu Nadarajah, College of Business, University of Illinois at Chicago, College of Business, University of Illinois at Chi, Chicago, IL, 60607, United States, selvan@uic.edu

1 - Dynamic Matching of Workers to Jobs with Learning Curves

Daniel Adelman, University of Chicago, Booth School of Business, 5807 South Woodlawn Avenue, Chicago, IL, 60637, United States, dan.adelman@chicagobooth.edu, Adam J. Mersereau

We consider the dynamic assignment of multiple workers to multiple classes of jobs. Workers are heterogeneous and become more effective at a job class with experience, and therefore the scheduler faces a tradeoff between matching workers with familiar jobs to minimize short-term cost versus matching workers with unfamiliar jobs to build expertise. A deterministic version of the problem has distinct structure that we leverage to derive price-directed approximations to stochastic versions featuring randomly arriving workers and jobs.

2 - Learning Symmetries for Faster Reinforcement Learning

Theja Tulabandhula, UIC, Chicago, IL, 60607, United States, tt@theja.org, Anuj Mahajan

We explore methods to exploit symmetries for achieving sample efficiency in reinforcement learning. This problem is motivated by recent advances in the use of deep networks for complex tasks that end up requiring large amounts of training data. We propose a method for detecting symmetries using reward trails observed during episodic experiences and provide a framework for incorporating these discovered symmetries in functional approximation based architectures. Finally we show that the use of potential based reward shaping is especially effective for our symmetry exploitation mechanism. Experiments show that our methods improve performance significantly when symmetry is exploited.

3 - Approximations to Stochastic Dynamic Programs via Information Relaxation Duality

David Brown, Duke University, Fuqua School of Business, 100 Fuqua Drive, Durham, NC, 27708, United States, dbbrown@duke.edu, Santiago Balseiro

A common technique in the analysis of stochastic systems is the use of "hindsight bounds," in which decisions are made after all uncertainties are revealed. In some applications, however, hindsight bounds may lead to very weak performance guarantees. We show how to obtain stronger guarantees by incorporating penalties that punish the use of additional information, and demonstrate the technique on several applications, including stochastic knapsack problems.

4 - Revisiting Approximate Linear Programming using Root Finding and First Order Methods

Selvaprabu Nadarajah, College of Business, University of Illinois at Chicago, 601 South Morgan Street,, U. H.2406, Chicago, IL, 60607, United States, selvan@uic.edu, Qihang Lin, Negar Soheili Azad

Approximate linear programs (ALPs) are well-known models for approximating high dimensional Markov decision processes (MDPs). Solving ALPs exactly remains challenging, for instance, in applications where (i) the MDP includes nonlinear reward and transition dynamics and/or (ii) rich basis functions are required to obtain a good VFA. We address this tension between ALP theory and solvability by proposing a novel ALP reformulation and solution approach that combines root finding and first order methods. We present convergence guarantees for our approach and test it on inventory control and energy storage applications.

Chair: Grani Adiwena Hanasusanto, The University of Texas at Austin, ETC 5.120, Austin, TX, 78712, United States, grani.hanasusanto@utexas.edu

1 - "Dice"-sion Making under Uncertainty: When can a Random Decision Reduce Risk?

Erick Delage, HEC Montreal, 3000 Ch de la Cote-Sainte-Catherine, Montreal, QC, H3T.2A7, Canada, erick.delage@hec.ca, Daniel Kuhn, Wolfram Wieseman

Consider an Ellsberg experiment in which one can win by calling the color (red or blue) of the ball that will be drawn from an urn in which the balls are of unknown proportions. It is well known (yet rarely advertised) that selecting the color based on a fair sided coin completely eradicates the ambiguity about the odds of winning. In this talk, we explore what are conditions under which a decision maker that employs a risk measure should have his action depend on the outcome of an independent random device. Surprisingly, we show that for any ambiguity averse risk measure there always exists a decision problem in which a randomized decision strictly dominates all deterministic decisions.

2 - Value of Randomization in Distributionally Robust Facility Location Problems

Ahmed Saif, University of Waterloo, 1095 Whetherfield St., Unit 39, London, ON, N6H0B6, Canada, ansaif1976@yahoo.com, Delage Erick

We study two classical facility location problems with distributional ambiguity and provide data-driven tractable reformulations that use a finite number of sample points: An UFLP with a Wasserstein-metric-based ambiguity set and a nonlinear location-inventory problem with a moment-based ambiguity set. We also study the potential benefit of randomization in MIP problems, prove that for a minimax problem, the solution of the corresponding maximin problem provides an upper bound on the value of randomization and identify the conditions under which this bound is tight. Finally, we devise and implement an efficient column-generation algorithm for facility location problems with randomization.

3 - Robust Optimization under Endogenous Uncertainty

Nikolaos Lappas, Carnegie Mellon University, 5000 Forbes Avenue, Pittsburgh, PA, 15213, United States, nlappas@andrew.cmu.edu, Anirudh Subramanyam, Chrysanthos E. Gounaris

When applying Robust Optimization (RO) in settings that feature uncertainty of endogenous nature, one needs to capture functional changes in parameter correlations induced by the decision-maker's policies as well as eradicate conservatism e ects from parameters that become irrelevant in view of the optimal decisions. To that end, we introduce generic decision-dependent polyhedral uncertainty sets, and we derive the corresponding RO counterpart models as well as discuss a number of relevant algorithmic considerations. We demonstrate the versatility of our proposed sets via a number of case studies stemming from a wide range of applications.

4 - Robust Quadratically Constrained Quadratic Programming

Can Gokalp, University of Texas, Austin, TX, United States, cangokalp@utexas.edu, Grani Adiwena Hanasusanto

We study robust convex QCQPs where the uncertain problem parameters can contain both continuous and integer components. Under the natural boundedness assumption on the uncertainty set, we show that the generic problems are amenable to exact copositive programming reformulations. The emerging convex optimization problems are NP-hard but admit a conservative SDP approximation that can be solved efficiently. We prove that this approximation is stronger than the state-of-the-art approximate S-lemma scheme and demonstrate its effectiveness on a wide spectrum of computational experiments.

Statistics- and Information-based Approaches to Stochastic Optimization

Sponsored: Optimization, Optimization Under Uncertainty

Sponsored Session

Chair: Saumya Sinha, University of Washington, University of Washington, Seattle, WA, 98105, United States, saumya@uw.edu

1 - A Bayesian Risk Approach to Data-Driven Stochastic Optimization

Di Wu, Georgia Institute of Technology, 1995 Defoor Ave NW, Apt C, Atlanta, GA, 30318, United States, woody10074026@gmail.com, Enlu Zhou, Helin Zhu

A large class of stochastic programs involve optimizing an expectation taken with respect to some underlying distribution that is unknown in practice. When data is available, a popular way to deal with such uncertainty is via distributionally robust optimization, which usually aims to hedge against the worst case over an ambiguity set. To explore the middle ground between completely ignoring the distributional uncertainty and optimizing over the worst case, we propose a Bayesian risk approach for parametric underlying distributions, which is to optimize a risk measure taken with respect to the posterior distribution of the unknown distribution parameter.

2 - Monte Carlo Tree Search with Sampled Information Relaxation Dual Bounds

Daniel Jiang, University of Pittsburgh, 1002 Benedum Hall, 3700 O'Hara Street, Pittsburgh, PA, 15261, United States, drjiang@pitt.edu, Lina Al-Kanj, Warren B.Powell

MCTS is a well-known strategy for solving sequential decision problems, particularly in the area of game-play AI. We propose a new technique called Primal-Dual MCTS that utilizes sampled information relaxation (Brown et. al., 2010) bounds on potential actions in order to make tree expansion decisions. The approach shows promise when used to optimize the behavior of a driver navigating a graph while operating on a ride-sharing platform.

3 - Robust Countable-state Markov Decision Processes

Saumya Sinha, University of Washington, 5204 15th Avenue NE, Apt 101, Seattle, WA, 98105, United States, saumya@uw.edu, Archis Ghate

Robust optimization is a technique used to account for parameter uncertainty in stochastic optimization and has been applied extensively to the study of Markov decision processes (MDPs). For the countable-state case, however, the existing theoretical and algorithmic results are limited. In this talk, we will discuss theory as well as convergent solution-methods for countable-state robust MDPs.

4 - Probably Approximately Correct (PAC) Selection in Simulation/Best-Arm Problems

David J.Eckman, Cornell University, 118 Compton Rd, Ithaca, NY, 14850, United States, dje88@cornell.edu, Shane Henderson

For the problem of selecting the best from a set of simulated alternatives, the multi-armed bandit and simulation communities concentrate on two contrasting fixed-confidence guarantees. Best-arm identification procedures often guarantee selecting a near-optimal arm, i.e., probably approximately correct (PAC) selection, while ranking-and-selection procedures commonly guarantee the probability of correct selection (PCS) under the indifference-zone formulation. We discuss why PAC selection guarantees are superior and present conditions under which procedures with PCS guarantees under the indifference-zone formulation simultaneously deliver PAC selection guarantees.

Sports Scheduling Meets Business Analytics

Plenary

Invited Session

1 - Sports Scheduling Meets Business Analytics

Mike Trick, Carnegie Mellon University in Qatar

Over the last 20 years, the ability of operations research techniques to create practical sports schedules has increased tremendously. Some of this increased ability is due to faster computers and better underlying optimization software. Increased understanding of the unique aspects of sports scheduling optimization has also played a role. This is allowing the integration of predictive and prescriptive analytics resulting in schedules that are not just playable but are also profitable.

Sunday, 4:30 - 6:00PM

Developments in Utility Theory

Sponsored: Decision Analysis

Sponsored Session

Chair: Ying He, University of Southern Denmark, Odense, M, 5230, Denmark, yinghe@sam.sdu.dk

1 - Multiattribute Utility with Bounded Tradeoffs

Ilia Tsetlin, INSEAD, 1 Ayer Rajah Avenue, Singapore, 138676, Singapore, ilia.tsetlin@insead.edu, Alfred Müller, Marco Scarsini, Robert L. Winkler

Suppose that, in a multiattribute setting, more of an attribute is preferred to less and states that some of the tradeoffs are bounded - e.g., both high sales and high profit are good, and one is willing to trade a particular number of units of sales for one unit of profit. We establish the form of a multiattribute utility function satisfying pre-specified bounds on the tradeoffs. Then we relate the tradeoff bounds to other preference conditions, such as the one-switch property, preferences for combining good with bad and stochastic dominance. One relevant context is the one of time preferences, where "more is better and "earlier is better" and there is also some bound on period-to-period discount rate.

2 - Foundations of Discounted Satiation
Manel Baucells, PhD, Darden School of Business, University of Virginia, 100 Darden Blvd, Charlottesville, VA, United States, BaucellsM@darden.virginia.edu

We provide axiomatic foundations for a representation of preferences that relaxes the time separability axiom of discounted utility. Our goal is to account for diminishing marginal utility in a dynamic setting where recent past consumption decreases the marginal utility of current consumption. We clarify the relationships between satiation, durability and time-separable preference, and offer an analytical characterization of the optimal consumption profile that maximizes satiation preferences.

3 - Range Dependent Utility for Risk and Time
Manuel Baucells, Darden School of Business, University of Virginian, Charlottesville, VA, United States, BaucellsM@darden.virginia.edu

We propose Frame Dependent Utility, a behavioral model to evaluate risky prospects, possibly with temporal delay. Frame dependent utility is able to explain the most robust anomalies (four-fold pattern, common ratio and common consequence, hyperbolic discounting, and the magnitude effect), as well as the preference reversal phenomenon which has eluded many descriptive theories of decision making. The model is simpler to use than cumulative prospect theory because it does not require sorting outcomes from highest to lowest.

4 - Revisiting Ellsberg and Machina's Paradoxes: A Two-Stage Evaluation Model under Ambiguity
Ying He, University of Southern Denmark, Campusvej 55, Odense, M, 5230, Denmark, yinghe@sam.sdu.dk

We revisit the Ellsberg paradox by showing that the preferences satisfy the independence axiom. Such an observation motivates us to develop a two-stage evaluation model under ambiguity. Events in state space are classified into ambiguous and risky events. We define a special type of risky event as hedge. In our model, a conditional subjective expected utility (SEU) on each hedge is nested into an SEU to represent preferences over acts. We show that our two-stage model can not only accommodate preferences in different Ellsberg's paradoxes but also the preferences in paradoxes in Machina (2009) and Machina (2014) that challenge the validity of many existing models for decision making under ambiguity.

Data-Driven Bayesian Modeling

Sponsored: Decision Analysis

Sponsored Session

Chair: Debarun Bhattacharjya, IBM, T J Watson Research, Yorktown Heights, NY, 12, United States, debarun@us.ibm.com

Co-Chair: Hiba Baroud, Vanderbilt University, Nashville, TN, 37240, United States, hiba.baroud@vanderbilt.edu

1 - Design Optimization for Resilience for Risk-averse Firms
Ramin Giahi, Iowa State University, Ames, IA, United States, rgiahi@iastate.edu, Cameron MacKenzie

Engineered systems can face various adverse conditions during their lifetime. Designers should try to design systems that are resilient to these conditions. This research quantifies the resilience of an engineered system under time-dependent adverse conditions by simulating the degradation and recovery of the system's components. The firm incorporates the future conditions under which the system operates into a risk-averse utility function or via a value-at-risk measure. Since the optimization model requires a complex simulation to evaluate the objective function, we use Bayesian Optimization, in conjunction with the ranking and selection method, to optimize the design of the system.

2 - Bayesian Decision-making of Smart Systems under Uncertainty
Saideep Nannapaneni, Vanderbilt University, Nashville, TN, United States, saideep.nannapaneni@vanderbilt.edu, Abhishek Dubey, Sankaran Mahadevan

This talk discusses a model-based framework for the quantification of multiple uncertainty sources affecting the performance of a smart system. With strong feedback coupling between the subsystems of a smart system (plant, cyber, actuation, sensors), the uncertainty in the system output amplifies over time. The coupling occurs at two levels: (1) coupling between individual subsystems, and (2) coupling between computational nodes. The coupled smart system is decoupled and considered as a feed-forward system over time and modeled using a two-level Dynamic Bayesian Network; one at each level of coupling. The proposed methodology is demonstrated for the design of a smart infrastructure system.

3 - Hierarchical Bayesian Modeling of Infrastructure Network Recovery
Mackenzie G. Whitman, Graduate Research Assistant, Vanderbilt University, Nashville, TN, 37203, United States, mackenzie.g.whitman@vanderbilt.edu, Hiba Baroud

Risk managers are interested in measuring and improving the ability of critical infrastructure systems to withstand and recover from disruptions which constitutes to the system's resilience. This work utilizes hierarchical Bayesian methods to assess the recovery rate of network components using multiple data sources to estimate recovery parameters, offering probabilistic instead of deterministic outcomes to better account for uncertainty. We apply this method to three interdependent infrastructure systems that represent the water, electric, and gas distribution networks for Shelby County, Tennessee.

4 - Event Sequence Models for Scenario Recommendations
Debarun Bhattacharjya, IBM.TJ.Watson Research Center, 501 East 78th Street, Apt. 2A, New York, NY, 10075, United States, debarunb@us.ibm.com, Nicholas Mattei

Predicting the future is a ubiquitous human endeavor, practiced from antiquity to modern professions including business, finance and intelligence analysis. Our intent is to build systems that can support long-term predictions using knowledge generalized from the past and learned from a variety of sources including historical event datasets. In this talk, I will present some ongoing work on models for predicting future event sequences. The emphasis will primarily be on probabilistic models for prediction, but I will also discuss other approaches such as prediction by analogy.

Metabolic Networks and Modern Research Problems in Operations Research

Invited: Tutorial

Invited Session

Chair: Jiming Peng, University of Houston, Houston, TX, 77204, United States, jopeng@Central.uh.edu

Chair: Rajan Batta, University at Buffalo (SUNY), 410 Bell Hall, Buffalo, NY, 14260, United States, batta@buffalo.edu

1 - Metabolic Networks and Modern Research Problems in Operations Research
J. Paul Brooks, Virginia Commonwealth University, Dept of Stat. Science and OR, P.O. Box 843083, Richmond, VA, 23284, United States, jpbrooks@vcu.edu, Allen Holder

Biochemical reactions that sustain life are modeled as a system of differential equations, forming a metabolic network. These nonlinear systems curtail into linear, algebraic systems under asymptotic assumptions, which thus define the feasible flux states of a cell in equilibrium. An optimization problem is then imposed to further identify metabolic conditions in an optimal growth situation. The result is a linear programming (LP) technique called Flux Balance Analysis (FBA), and the primary goal of this tutorial is to illustrate several modern research questions about FBA that are compliant with operations research. We pose several open avenues for research that touch LP, mixed-integer programming (MIP), nonlinear programming, combinatorial optimization, optimization under uncertainty, and robust optimization.

Stochastic Dynamics on Networks and Graphs

Sponsored: Applied Probability

Sponsored Session

Chair: Kavita Ramanan, Brown University, Providence, RI, 02912, United States, kavita_ramanan@brown.edu

1 - High Frequency Trading and Limit Order Book Dynamics: from Point Processes to Stochastic Pdes
Rama Cont, Imperial College London, London, SW7 2AZ, United Kingdom, Rama.Cont@imperial.ac.uk

The advent of high frequency electronic trading has lead to a heterogeneous market landscape where algorithms at different trading frequencies interact through the limit order book, whose evolution summarizes the dynamics of supply, demand and price. We show that the dynamics of the limit order book may be described by a stochastic partial differential equation (SPDE), obtained as scaling limit of a queueing model with high and low frequency traders. The dynamics of bid/ask prices is endogenous and derived from the dynamics of order flow. We exhibit an analytically tractable class of solution and show that they reproduce empirical features of limit order book profiles and price dynamics.

2 - Weakly Interacting Particle Systems on Inhomogeneous Random Graphs
Ruoyu Wu, Brown University, 182 George Street, Providence, RI, 02912, United States, ruoyu_wu@brown.edu, Shankar Bhamidi, Amarjit Budhiraja

We consider weakly interacting diffusions on time varying random graphs. The system consists of a large number of nodes in which the state of each node is governed by a diffusion process that is influenced by the neighboring nodes. The collection of neighbors of a given node changes dynamically over time and is determined through a time evolving inhomogeneous random graph process. A law of large numbers and a propagation of chaos result is established for a multi-type population setting, in which the edge probability is allowed to decay to 0 as the size of the system grows. A central limit theorem is established for the single-type population case under stronger conditions on the edge probability function.

3 - Ranking on Inhomogeneous Directed Random Graphs
Mariana Olvera-Cravioto, Visiting Associate Professor, University of California, Berkeley, 4125 Etcheverry Hall, Berkeley, CA, 94720, United States, molvera@berkeley.edu

We present results for a broad family of inhomogeneous directed random graphs which includes as special cases directed versions of the Erdos-Renyi, Chung-Lu, and Norros-Reittu models, among others. We discuss how they can be used to model scale-free directed complex networks, e.g., the web graph, Twitter, ResearchGate, and establish their basic connectivity structure. We then show how recent results for Google's PageRank algorithm extend to this new family of random graphs, and how this provides a more natural way to model the relationship between highly ranked nodes and their attributes. We also discuss new insights on the influence of in-degree/out-degree correlations on ranking results.

4 - Metastability of Queuing Networks with Mobile Servers
Francois Baccelli, University of Texas, Austin, TX, United States, Baccelli@math,utexas.edu

We study symmetric queuing networks with moving servers and FIFO service discipline. The mean-field limit dynamics demonstrates unexpected behavior which we attribute to the meta-stability phenomenon. Large enough finite symmetric networks on regular graphs are proved to be transient for arbitrarily small inflow rates. However, the limiting non-linear Markov process possesses at least two stationary solutions. The proof of transience is based on martingale techniques.

Emerging Topics in Pricing and Revenue Management

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Pnina Feldman, University of California-Berkeley, Berkeley, CA, 94720, United States, feldman@haas.berkeley.edu

1 - Social Learning and the Design of New Experience Goods
Ella Segev, Ben-Gurion University of the Negev, Beer Sheva, 84105, Israel, ellasgv@bgu.ac.il, Pnina Feldman

Consumers often consult the reviews of their peers before deciding whether to purchase a new experience good; however, their initial quality expectations are typically set by the product's observable attributes. In this talk we discuss the implications of social learning for a monopolist firm's choice of product design.

2 - Loyalty Program Liabilities and Point Values
Nikolaos Trichakis, MIT, 100 Main Street, E62-576, Cambridge, MA, 02143, United States, ntrichakis@mit.edu, So Yeon Chun, Dan Andrei Iancu

A loyalty program (LP) introduces a new currency, the points, through which customers transact with a firm. Such points constitute a promise for future service, and therefore count as liabilities on the firm's balance sheet. Since the value of points is controlled by the firm, this introduces subtle channels through which decisions affect profitability. We study the problem of setting the monetary value of loyalty points in view of these liabilities. We show that the value of points can be thought of as inventory, and optimal policies set this value, and the associated liability, to reach "base-stock" targets.

3 - Dynamic Pricing under Debt: Spiraling Distortions and Efficiency Losses
Dan Andrei Iancu, Stanford University, 655 Knight Way, Stanford, CA, 94107, United States, daniancu@stanford.edu, Omar Besbes, Nikolaos Trichakis

Firms often finance their inventories through debt. The pricing of products is consequently driven by both inventory and debt servicing considerations. We show that limited liability under debt induces sellers to charge higher prices and to discount products at a lower pace. We find that these distortions result in revenue losses that compound over time, leading to some form of performance spiral down. We quantify the extent to which these inefficiencies can be mitigated by practical debt contract terms that emerge as natural remedies from our analysis, and find debt amortization or financial covenants to be the most effective, followed by debt relief and early repayment options.

4 - The Revenue Impact of Dynamic Pricing Policies on Major League Baseball Ticket Sales
Joseph Xu, Carnegie Mellon University, Pittsburgh, PA, United States, jiaqixu@andrew.cmu.edu, Peter Fadet, Senthil Veeraraghavan

We study the implementation of multiproduct dynamic pricing by a Major League Baseball franchise for single game tickets. We develop a customer choice model to help design dynamic pricing policies for the franchise. Our model encompasses relevant aspects of customer demand generation process, including ticket quantity and seat section choice. Furthermore, our demand model incorporates external factors that drive the overall sport ticket price sensitivity such as the home team's on-field performance, as well as the correlation between customers' arrival timing and product choice. Our counterfactual results show potential revenue improvement of up to 17.2% through dynamic pricing.

Aligning Operational and Marketing/Financial Incentives

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Panos Kouvelis, Washington University in St. Louis, Saint Louis, MO, 63130-4899, United States, kouvelis@wustl.edu

Co-Chair: Duo Shi, Olin Business School, Washington University-St Louis, Olin Business School, St. Louis, MO, 63130, United States, dshi@wustl.edu

1 - Co-opetition in Service Clusters with Waiting-area Entertainment
Tinglong Dai, Johns Hopkins University, 100 International Dr, Baltimore, MD, 21202, United States, dai@jhu.edu, Gongtao Lucy Chen, Srinagesh Gavirneni, Xuchuan Yuan

Unoccupied waiting feels longer than it actually is. Service providers operationalize this psychological principle by offering entertainment options in waiting areas. In a service cluster with a shared waiting space, firms have an opportunity to cooperate in the investment for providing entertainment options. In this paper, we model co-opetition in a service cluster with shared entertainment options for waiting customers. We show that as much as co-opetition facilitates resource sharing in a service cluster, it also heightens price competition. Furthermore, as the intensity of price competition increases, service providers may opt to charge higher service fees.

2 - Who Compensates the Sales Agent?
Duo Shi, Olin Business School, Washington University-St Louis, K.H.401, Olin Business School, 1 Brookings Drive, St. Louis, MO, 63130, United States, dshi@wustl.edu, Panos Kouvelis

We analytically study a value chain consisting of three segments: a manufacturer, a retailer, and a sales agent. Five distinct value-chain structures are considered: an integrated value chain, an integrated distribution channel (the manufacturer and the retailer) compensating the sales agent, non-integrated channels with the manufacturer compensating the sales agent, with the retailer compensating the sales agent, and with joint compensation. We compare the strategic implications across all these value-chain structures.

3 - The Effects of International Tax Policy on Firms Production Outsourcing Strategies
Yixuan Liu, The University of Texas at Austin, yixuan.liu@utexas.edu, Guoming Lai, Wenqiang Xiao

We study the effects of international tax policy on firms' production outsourcing strategies. We find that the U.S. tax deferral system may result in subtle changes of a firm's strategy with international tax disparity. Our analysis shows that besides the general concern of income shifting, tax considerations can further lead to operational distortions. We then discuss the implications of a frequently raised tax reform proposal that suggests prohibiting tax deferral but lowering the home country tax rate. We find that there can exist a win-win tax rate region from a specific firm's and the stakeholders' perspectives.

Emerging Topics in Responsible Operations

Sponsored: Manufacturing & Service Oper Mgmt, Sustainable Operations

Sponsored Session

Chair: Jayashankar M. Swaminathan, University of North Carolina, University of North Carolina, Chapel Hill, NC, 27599-3490, United States, msj@unc.edu

1 - Improving Supplier Compliance through Joint and Shared Audits with Collective Penalty

Prashant Chintapalli, University of California, Los Angeles, Anderson School of Management, 11000 Weyburn Drive, Apt# 419, Los Angeles, CA, 90024, United States, prashant.chintapalli.1@anderson.ucla.edu, Felipe Caro, Kumar Rajaram, Chris Tang

When suppliers fail to comply with safety regulations, buyers improve supplier compliance by auditing and imposing penalties. We analyze three audit mechanisms namely, independent, joint, and shared mechanisms. While in independent audit the buyers audit the supplier individually, in joint audit they audit jointly and share the audit cost. In shared audit they audit individually but share the information. We compare the three mechanisms in terms of audit levels, compliance levels, and the profits of the buyers, the supplier and the supply chain. We identify the cases when joint audit can improve supply chain profit so that both the buyers and the supplier can benefit from joint audits.

2 - Cover-up of Safety Hazards in Product Recalls

Woonam Hwang, HEC Paris, Jouy-en-Josas, 78350, France, hwang@hec.fr, Soo-Haeng Cho, Victor DeMiguel

Product safety regulators often have to rely on manufacturers' voluntary disclosure of information when investigating product defects. However, manufacturers may not always truthfully report all safety hazard information. In this paper, we investigate how regulators can induce manufacturers to truthfully report any safety issues in a timely manner. Specifically, we examine the different regulatory policies employed in the automotive industry in the U.S. and the U.K., and compare their effects in inducing truthful reports from manufactures and the resulting social welfare.

3 - Optimal Seeding Policy under Rainfall Uncertainty

Ying Zhang, University of North Carolina, Chapel Hill, NC, 27599, United States, ying_zhang@kenan-flagler.unc.edu, Jayashankar M. Swaminathan

In this paper, we develop a model to determine the optimal seeding policy under rainfall uncertainty using a finite-horizon stochastic dynamic program. In our model, a farmer needs to decide the amount of seeds to plant in each period given the soil moisture. We show that the optimal planting policy is a time dependent threshold-type policy. Utilizing field weather data from Southern Africa, we investigate the impact of climate conditions on the relative yield advantage of the optimal planting schedule over commonly used heuristics in practice. For a real size planting problem, our computational study demonstrates significant relative yield advantage of the optimal planting schedule.

4 - Sustainable Sourcing Practices: Global Coverage, Characteristics and Drivers

Joann De Zegher, jfdezegher@stanford.edu, Tannis Thorlakson, Eric Lambin

Companies use a variety of Sustainable Sourcing Practices (SSPs) to address social and environmental challenges in their supply chains. Our current understanding of such SSPs is largely based on theoretical models, literature reviews and case studies. We use a random sample of 450 public companies to study the range of SSPs that companies pursue, addressing the following questions. What SSPs do companies adopt? How many tiers in the supply chain do SSPs cover and to what extent are these SSPs audited? What factors explain the type of SSP a company adopts and are these factors in line with theoretical predictions? This research helps direct the research agenda in sustainable supply chain management.

Advances in Healthcare Logistics

Sponsored: Health Applications

Sponsored Session

Chair: Eva Lee, Georgia Tech, Atlanta, GA, 30332-0205, United States, evakylee@isye.gatech.edu

1 - Medical Imaging Log Files: Big Data Analysis & Findings

Larissa P.G. Petroianu, University of Washington, 3801 Brooklyn Avenue NE, Stevens Court - K302, Seattle, WA, 98105, United States, lpetroia@uw.edu, Rebecca J.Mieloszyk, Christina Mastrangelo

MRIs are important for the detection and monitoring of specific conditions; however, the exam is expensive. Wasted scanner time caused by poor scheduling, failed/low value sequences, or idleness is to be avoided. This Philips Healthcare project analyzes data from scanner logs containing over 230,000 observations. We use machine learning to work with big data and focus on reducing "wasted" time to ascertain the root causes of unintended utilization patterns. Prior work utilized human observation which is subject to error, while this work develops analyses based on machine information. We will discuss the challenges of working with log files, present results and discuss the impact of these findings.

2 - Inventory Management and Scheduling for Blood Products: An Effect of Transfer among Regional Block Blood Centers

Mari Ito, Tokyo University of Science, 2641 Yamazaki, Noda-shi, Chiba, 278-8510, Japan, mariito@rs.tus.ac.jp, Ryuta Takashima, Kazuhiro Kobayashi

We investigate a management for regional block blood centers, which are established by Japanese Red Cross, by means of an inventory control and scheduling model for blood products. We propose a mathematical programming model which minimizes the number of discarded blood products and maintains a minimum blood supply. This model determines the number of blood products transferred from one regional block blood center to another one at one day and collected in one regional block blood center at one day. We show an effect of regional block blood centers on the number of collected, transferred and discarded blood products.

3 - Vaccine Prioritization for Optimal Population Health Protection

Eva Lee, Georgia Tech, Industrial & Systems Engineering, Ctr for Operations Research in Medicine, Atlanta, GA, 30332-0205, United States, evakylee@isye.gatech.edu, Yifan Liu

This study is joint with CDC. When the vaccine supply is limited during infectious disease outbreaks, prioritized vaccination is broadly considered as an effective strategy. In this study, we present a general-purpose framework to model the effect of mass vaccination during pandemics. This model integrates compartmental model for disease propagation and stochastic queueing for vaccination operations. Results for a smallpox outbreak will be discussed.

Emergency Services Analytics

Sponsored: Health Applications

Sponsored Session

Chair: David L Kaufman, University of Michigan - Dearborn, Dearborn, MI, 48126, United States, davidlk@umich.edu

1 - Emergency Department Capacity Planning in Presence of Competition

Elham Torabi, Assistant Professor, James Madison University, 421 Bluestone Dr., MSC 0202, Harrisonburg, VA, 22807, United States, torabiex@jmu.edu, Baback Vaziri

Emergency departments (EDs) use historical patient arrival data to forecast future demand. The foretasted demand is then used for capacity planning purposes. However, this task becomes challenging if there is new competition in the region. We analyze the case of two EDs over a five-year period - one is a new ED entering the market and the other is an established ED facing new competition. We derive useful operational and managerial insights for EDs trying to cope with challenges in capacity planning in presence of competition.

2 - ED Physician Staffing via a Multiclass Multistage Network: Opening the Blackbox

Caglar Caglayan, Georgia Institute of Technology, 765 Ferst Drive , Room 321 ISyE Main Building, Atlanta, GA, 30332, United States, ccaglayan6@gatech.edu, Yunan Liu, Mustafa Y. Sir, Turgay Ayer, David Nestler, Kalyan Pasupathy

We propose an "intuitive", "realistic" and "tractable" emergency department (ED) staffing model. More specifically, we analyze a multi-class multi-stage (MCMS) queuing network with time-varying arrivals where the objective is to determine the optimal number of ED physicians, stabilizing tail probability of delay for each patient class and treatment stage. We apply our proposed method to real data from Mayo Clinic for numerical analysis and test its performance by a realistic simulation model under different routing rules. We further analyze the staffing of "efficiency-driven queue without abandonments" since this structure represents most of the queue stations appearing in the MCMS network.

3 - Improving Patient Transport Services through Crew Flexibility

Craig Froehle, University of Cincinnati, 2925 Campus Green Drive, Cincinnati, OH, 45221-0130, United States, craig.froehle@uc.edu, David James Rea, Elizabeth Powell

Patient transport services, where stable patients are moved between facilities using a variety of crew and vehicle types, are a largely unexplored part of healthcare operations. We build a discrete-event simulation model based on a dataset of ~30,000 patient transports to identify preferential policies regarding crew flexibility and vehicle location. In addition to system-level operational performance, a financial analysis also permits assessment of the policies' overall cost-effectiveness.

4 - Introducing Swing Shifts to Dynamically Respond to Emergency Department Workload Uncertainty

David L.Kaufman, University of Michigan - Dearborn, 19000 Hubbard Drive, Fairlane Center South, Dearborn, MI, 48126, United States, davidlk@umich.edu, Kalyan Pasupathy, Daniel Cabrera, Mustafa Y. Sir

A fundamental problem of emergency care is matching resources to uncertain patient demands. Staffing allocation decisions require good matching with workloads but also consider the needs of emergency providers at very high risk of burnout. Mayo Clinic Emergency Department recently introduced a "swing shift," which allows physicians to leave early depending on a workload threshold. While popular, swing shifts introduce several challenges: How to design a threshold mechanism? What is the optimal length of the furlough? When should these shifts start and what is their impact? We introduce an effective and tractable data-driven optimization model for a complex stochastic problem.

Modeling and Optimization for Cancer Screening and Treatment

Sponsored: Health Applications

Sponsored Session

Chair: Jennifer Mason Lobo, University of Virginia, Charlottesville, VA, 22902, United States, jem4yb@virginia.edu

1 - A Dynamic Model for Understanding Long-term Trends in Prostate Cancer Screening

Ozge Karanfil, Harvard T.H. Chan School of Public Health, 651 Huntington Avenue, FXB Building, 643E, Boston, MA, 02115, United States, karanfil@hsph.harvard.edu, Hazhir Rahmandad, Jack Homer, John D. Sterman

Whereas guidelines for routine screening should be based on medical evidence, evidence often has relatively little impact on practice, which has led to ongoing controversy and conflict over guidelines. There are significant variations in clinical practice, including evidence of both over and underscreening. To explain the patterns of overscreening, fluctuations, and low adherence to guidelines, we develop an explicit broad boundary feedback theory tested in a formal model. The model presents an extended case study specific to PSA screening, including realistic presentations for test specifics, natural progression of the disease, and respective changes in population size and composition.

2 - Personalized Modeling for Assessing HPV Vaccination Strategies for Females

Shengfan Zhang, University of Arkansas, 4207 Bell Engineering Center, Department of Industrial Engineering, Fayetteville, AR, 72701, United States, shengfan@uark.edu, Fan Wang

Human papillomavirus (HPV) is the most common sexually transmitted infection in the United States. Currently, catch-up vaccines are recommended for males and females through age 21 and age 26, respectively, if they did not get vaccinated previously. In this research, we hypothesize that the cut off age of catch-up vaccine should be determined based on every single woman's risk characteristics, rather than a one-size-fit-all age 26. We develop a discrete-event simulation model, incorporating patient-specific HPV risk estimation, to evaluate multiple clinical consequences after a woman get vaccinated based on a number of personal attributes.

3 - A Cost-effectiveness Analysis of Adjuvant Paclitaxel and Trastuzumab Regimen in Early Node-negative, Her2-positive Breast Cancer

Ali Hijjar, University of Wisconsin-Madison, 1513 University Avenue, 3233 Mechanical Engineering Building, Madison, WI, 53706, United States, hjaar@wisc.edu, Mehmet Ergun, Murtuza Rampurwala, Oguzhan Alagoz

Patients with early node-negative, HER2-positive breast cancer do not receive standard treatment since most were excluded from adjuvant trastuzumab trials. In this study, we investigated the cost-effectiveness of a novel one-year adjuvant paclitaxel and trastuzumab therapy that shows a decrease in the relapse rate and toxicity adverse events using a Markov model. We performed sensitivity and probabilistic analyses to evaluate the impact of uncertainty on model results.

4 - Optimal Liver Cancer Surveillance in Hepatitis C-infected Population

Qiushi Chen, Massachusetts General Hospital, 101 Merrimac St., 10th FL, Apt D3, Boston, MA, 02114, United States, qchen@mgh-ita.org, Turgay Ayer, Jagpreet Chhatwal

Liver cancer incidence rates have increased sharply in the United States. Although surveillance for liver cancer has shown survival benefit, the optimal surveillance policy remains unknown. To identify the most cost-effective surveillance policy, we develop a mixed-integer programming-based framework which allows to formulate practical policy structures. Our numerical results find that (1) the optimal surveillance interval should depend on patient's stage of hepatitis C and age, and (2) expanding surveillance to earlier stage of hepatitis C improves the cost-effectiveness of HCC surveillance.

Stochastic Models in Health Systems Engineering

Sponsored: Health Applications

Sponsored Session

Chair: Anil Aswani, UC Berkeley, San Francisco, CA, 94103, United States, aaswani@berkeley.edu

Co-Chair: Philip Kaminsky, University of California-Berkeley, Berkeley, CA, 94720-1777, United States, kaminsky@berkeley.edu

1 - Data-driven Appointment Scheduling

Tugce Gurek, University of California, Berkeley, 6141 Etcheverry Hall, Berkeley, CA, 94720, United States, tugce.gurek@berkeley.edu, Philip Kaminsky

We focus on appointment scheduling of stochastic tasks on a highly utilized server where the task processing durations are challenging to estimate. Appointment scheduling involves both sequencing tasks, and setting estimated start times of those tasks. Tasks types are known prior to the appointment date, but task duration data is initially limited so duration estimates are continuously updated. Our goal is to develop a data-driven approach to sequencing and scheduling these tasks that also integrates expert knowledge into the scheduling decision.

2 - Improving Predictions of Pediatric Surgical Durations with Supervised Learning

Zhengyuan Zhou, 160 Comstock Circle - Unit 106002, Stanford, CA, 94305, United States, zyzhou@stanford.edu

We consider a model of multi-agent online learning under imperfect information, where the reward structures are given by a general continuous game. After introducing a general equilibrium stability notion, called variational stability, we examine the well-known online mirror descent learning algorithm and show that the iterates converge to variationally stable Nash equilibria under a variety of imperfect feedback. We then present two applications: non-convex stochastic optimization and power management in random wireless networks. We conclude with a discussion on further extensions.

3 - Data-driven Incentive Design in the Medicare Shared Savings Program

Auyon Siddiq, 1749 Oxford St, Unit 22, Unit 22, Berkeley, CA, 94709, United States, auyon@berkeley.edu, Anil Aswani, Zuo-Jun Max Shen

The Medicare Shared Savings Program (MSSP) was created to control escalating Medicare spending by incentivizing providers to deliver healthcare more efficiently. We formulate the MSSP as a principal-agent model and propose a new type of contract that includes a performance-based subsidy for the provider's investment. We show that the proposed contract dominates the existing MSSP contract by producing a strictly higher expected payoff for both Medicare and the provider. We then present a maximum likelihood approach for estimating the parameters of the principal-agent model as well as the potential increase in savings under the proposed contract.

4 - Mixed-Integer Linear Programming Applications in Public Policy
Matt Olfat, PhD Student, UC Berkeley IEOR, Berkeley, CA, 94702, United States, molfat@berkeley.edu

We present two applications of integer programming in policy. The first showcases the power of integer programming in capturing the nuances of individual behavior, allowing policymakers more accurate insights in the potential responses of constituent populations to their policies. In the second, we target fairness constraints in classification algorithms. In particular, we seek to handle FTC regulations on equitable lending. We propose a new discrete SVM framework to maintain this additional restriction. Further, we provide a duality argument to ensure that non-predictability is maintained at any level of thresholding.

Frontiers in Supply Chain Management

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Sang Kim, Yale University, 165 Whitney Ave, New Haven, CT, 06520, United States, sang.kim@yale.edu

1 - Supply Chain Design for Substitutable Digital and Physical Information Goods
Zhenhuan Lei, PhD Student, Duke University, 100 Fuqua Drive, Mailbox #300, Durham, NC, 27708, United States, zhenhuan.lei@duke.edu, Robert Swinney

We consider a firm selling two partially substitutable goods, one digital and one physical, e.g., a downloadable and DVD version of the same movie. The physical good is characterized by non-zero marginal production cost, positive production leadtime, and, potentially, a mismatch between supply and demand. The digital good is characterized by zero marginal cost and no inventory constraints. We consider how market and product characteristics drive the firm to price each product, determine inventory, choose a selling strategy involving one or both goods, and design its supply chain.

2 - Grocery Access and Food Waste
Elena Belavina, University of Chicago Booth School of Business, 5807 S.Woodlawn Ave, Chicago, IL, 60637, United States, elena.belavina@chicagobooth.edu

This paper studies how access to grocery stores influences food waste. Our investigation reveals that store density in most American cities is well-below optimal level, and modest increases in store density substantially reduce waste; e.g. in Chicago, just 3-4 more stores (per 10 sq-km) can lead to a 6-9% waste reduction, and a 1-4% decrease in grocery expenses. These results arise from the principal role of consumer waste, suggesting that activists and policy makers' focus on retail waste may be misguided. Store operators, urban planners and decision makers should aim to increase store densities to make grocery shopping more affordable and sustainable.

3 - Social Learning and the Design of New Experience Goods
Yiangos Papanastasiou, University of California, Berkeley, Berkeley, CA, United States, yiangos@berkeley.edu, Pnina Feldman, Ella Segev

This work focuses on the implications of social learning from product reviews for a monopolist firm's choice of product design. Our main finding is that, in the presence of social learning, the firm's design choice results in a product whose expected quality is lower either in the absolute sense, or relative to the product's price.

4 - Competing to Discover Compliance Violations: Self-inspections and Enforcement Policies
Sang-Hyun Kim, Yale University, 165 Whitney Ave, PO Box 208200, New Haven, CT, 06520, United States, sang.kim@yale.edu, Saed Alizamir

In this study we consider dynamic interactions between a regulator and a firm who perform competitive inspections of a production facility that undergoes random compliance violations. Upon detecting noncompliance, the regulator orders the firm to restore compliance via either temporary fix or permanent fix. On the other hand, if the firm detects noncompliance, he restores compliance privately via temporary fix, preempting the regulator's detection. The incentive conflict that arises from these interactions gives rise to equilibrium outcomes that shed light on strengths and weaknesses of different enforcement policies that the regulator can employ.

5 - Analysis of Critical Success Factors for Sustainable Supply Chain Management in the Indian Steel Sector: An Application of Structural Equation Modelling
Kunal Gaurav, Indian Institute of Technology Kharagpur, Kharagpur, India, kg.kunalgaurav@gmail.com, Rudra P. Pradhan

Organizational sustainability performance is highly dependent on organization's culture and work practices including sustainable supply chain management. External pressures influence organizational practices and this also reflects on the sustainability performance indicators. This study presents an analysis of their inter-relationships in the context of Indian steel sector. The twenty one measures representing dimensions of external pressure, organizational internal practices and sustainability performance were developed based on literature survey and inputs from industry experts. A conceptual model has been proposed which has been empirically tested by survey data collected from 145 industry practitioners through online and offline survey. Using structural equation modelling technique, the study establishes that organizational practices positively impact the sustainability performance in the context of Indian steel sector.

Responsible Research in Business and Management

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Serguei Netessine, University of Pennsylvania, Wharton School, Philadelphia, PA, 138676, United States, netessin@wharton.upenn.edu

Co-Chair: Christopher S. Tang, University of California-Los Angeles, Los Angeles, CA, 90095-1481, United States, chris.tang@anderson.ucla.edu

1 - Socially and Environmentally Responsible Value Chain Innovations: New Operations Management Research Opportunities
Christopher S.Tang, University of California-Los Angeles, UCLA Anderson School of Management, Operations and Technology Management, Los Angeles, CA, 90095-1481, United States, chris.tang@anderson.ucla.edu

I will discuss opportunities in Responsible Research that emerge from the subject of socially and environmentally responsible value chains. I will talk about topics that are likely to become important going forward.

2 - Responsible Research in Business and Management
Serguei Netessine, University of Pennsylvanuia, Philadelphia, PA, United States, netessin@wharton.upenn.edu

I will report on the new initiative led by 24 faculties across disciplines on Responsible Research in Business and Management (RRBM), which culminated in a white paper "A Vision of Responsible Research in Business and Management: Striving for credible and useful knowledge".

3 - What do we Mean by Responsible Research in Operations Management?
Luk Van Wassenhove, INSEAD, Fontainebleau, France, luk.van-wassenhove@insead.edu

Operations management is a problem-driven applied discipline rooted in the realities of business. Within that context, Responsible can mean many things. First, who decides and are all stakeholders taken into account? Second, what about being Responsible for the correctness of our recommendations? Third, should we strongly involve decision makers in problem description, and validating results? Very few studies support their findings with high-quality empirical evidence. Fourth, Responsible could mean we should study large societal problems to justify the cost of our research to society. I propose a few thoughts from my personal experience.

Economics of Queueing Systems: Learning, Pricing, Priorities, and Reneging

Sponsored: Manufacturing & Service Oper Mgmt, Service Operations

Sponsored Session

Chair: Philipp Afeche, University of Toronto, Toronto, ON, M5S 3E6, Canada, afeche@rotman.utoronto.ca

Co-Chair: Shiliang Cui, Georgetown University, McDonough School of Business, Washington, DC, 20057, United States, shiliang.cui@gmail.com

1 - Learning and Earning for Congestion-prone Service Systems
N. Bora Keskin, Duke University, Fuqua School of Business, 100 Fuqua Drive, Durham, NC, 27708-0120, United States, bora.keskin@duke.edu, Philipp Afeche

Consider a firm selling a service in a congestion-prone system to price- and delay-sensitive customers. The firm faces Bayesian uncertainty about the consumer demand for its service and can dynamically make noisy observations on the demand. We characterize the structure and performance of the myopic Bayesian policy and well-performing variants.

2 - Coverage, Coarseness and Classification: Determinants of Social Efficiency in Priority Queues
Martin Lariviere, Northwestern University, 2001 Sheridan Road, Evanston, IL, 60208, United States, m-lariviere@kellogg.northwestern.edu, Itai Gurvich, Can Ozkan

In a service system with a continuum of customers, a decision maker must determine how much of the market to cover, how coarse a priority scheme to offer, and how to classify admitted customers to priority levels. We show that differences between revenue maximization and social optimality are largely questions of classification.

3 - Invite Your Friend and You'll Move Up in Line
Luyi Yang, Johns Hopkins University, Baltimore, MD, United States, luyi.yang@jhu.edu, Laurens G.Debo

The referral priority program, an emerging business practice adopted by a growing number of technology companies that manage a waitlist of customers, enables existing customers on the waitlist to gain priority access if they successfully refer new customers to the waitlist. We study the effectiveness of such a scheme as a marketing tool for customer acquisition and an operational approach for waitlist management.

4 - In-Queue Observation and Abandonment
Shiliang Cui, Georgetown University, Washington, DC, 20057, United States, Shiliang.Cui@georgetown.edu, Senthil Veeraraghavan, Jinting Wang, Yu Zhang, Yu Zhang

Waiting in a line for service is not pleasant. Reneging happens when the initial estimated delay was tolerable so a customer joined the queue upon arrival. However, after spending some time waiting, the customer realizes that the actual service speed is slower than what he anticipated and the revised prediction of waiting time has exceeded his tolerance threshold. We investigate in this paper whether and when a revenue-maximizing server is in its best interest to reveal service speed information to customers upfront in the presence of such reneging behavior.

1 - Pricing and Optimization in Shared Vehicle Systems: An Approximation Framework
Daniel Freund, Cornell University, Ithaca, NY, 14850, United States, df365@cornell.edu, Siddhartha Banerjee, Thodoris Lykouris

Optimizing shared vehicle systems is more challenging compared to traditional resource allocation due to complex network externalities. In particular, pricing/rebalancing in any location affects future supply throughout the system within short timescales. Such externalities are captured by steady-state Markovian models. However, using such models to design control policies is computationally difficult since the resulting optimization problems are high-dimensional and non-convex. To this end, we develop a general approximation framework that provides the first efficient algorithms with rigorous approximation guarantees for a wide range of objective functions and controls.

2 - Pooling Queues with Discretionary Service Capacity
Hummy Song, The Wharton School, University of Pennsylvania, 560 Jon M. Huntsman Hall, 3730 Walnut Street, Philadelphia, PA, 19104, United States, hummy@wharton.upenn.edu, Mor Armony, Guillaume Roels

Contrary to traditional queuing theory, recent case studies in health care and call centers indicate that pooling queues may not necessarily result in less expected work-in-process. We develop a game-theoretic model that proposes that this may arise when servers have some discretion over their choice of service capacity and are work averse, i.e., bear a cost associated with either their expected workload or their degree of busyness. Our work suggests that system designers may need to consider the servers' type and extent of work aversion as well as their degree of capacity choice discretion before pooling their workload.

3 - Matching while Learning
Ramesh Johari, Stanford University, Huang Engineering Center Rm 311, 475 Via Ortega, Stanford, CA, 94305-4121, United States, ramesh.johari@stanford.edu

We consider the problem faced by a service platform that needs to match supply with demand, but also to learn attributes of new arrivals in order to match them better in the future. We introduce a benchmark model with heterogeneous workers and jobs that arrive over time. Job types are known to the platform, but worker types are unknown and must be learned by observing match outcomes. Workers depart after performing a certain number of jobs. The payoff from a match depends on the pair of types and the goal is to maximize the steady-state rate of accumulation of payoff. Our main contribution is a complete characterization of the structure of the optimal policy in the limit that each worker performs many jobs.

4 - Pricing and Matching with Forward Looking Buyers and Sellers
Yiwei Chen, Singapore University of Technology and Design, Singapore, Singapore, yiwei_chen@sutd.edu.sg, Ming Hu

We study a dynamic market for a single product or service in which buyers with heterogeneous private valuations and sellers with heterogeneous private supply costs dynamically arrive. A single market-making intermediary decides dynamically on the ask and bid price that will be posted to buyers and sellers, respectively, and on the matching decisions after buyers and sellers agree to buy and sell. Buyers and sellers can wait strategically for better prices after they arrive. We use the mechanism design methodology to analyze the problem. We propose a simple matching and pricing policy that is asymptotically optimal. Under this policy, buyer and sellers behave myopically.

Health Care, Therapy and Treatment

Contributed Session

Chair: Ning Liu, Pennsylvania State University, University Park, PA, United States, nul147@psu.edu

1 - Barriers to use Clinic Decision Support and Computerized Provider Entry Among Physician Practices
Yunfeng Shi, Assistant Professor, The Pennsylvania State University, 504E Ford Building, University Park, PA, 16802, United States, yus16@psu.edu

In this study, using a unique dataset from Minnesota, we longitudinally analyzed the major challenges faced by physician practices in adopting and using two main HIT functionalities - Clinical Decision Support (CDS) and Computerized Provider Order Entry (CPOE). We found that although the adoption rate increased between 2014 and 2016, the proportion of physician practices facing challenges in using these two functionalities also increased. We identified several major challenges reported in the data, and examined the physician practice characteristics associated with these challenges.

2 - Predicting Hospital Participation in Accountable Care Organizations
Onyi Nwafor, University of Houston, 5710 Ballina Canyon Ln, Houston, TX, 77041, United States, onyid.nwafor@gmail.com, Norm Johnson

Hospitals are increasingly joining Accountable Care Organizations (ACOs). Evidence suggests that this trend is primarily due to the financial rewards ACOs offer these hospitals when they are able to save costs without diminishing quality of care. Though such rewards may explain why hospitals join ACOs, the profile of hospitals that join tend to differ. Not knowing what this profile is for members and non-members of ACO implies that the net value of participation in ACOs is not clear. To address this problem, we conduct a study that uses a data-driven technique and a large data set to uncover the profile of these two groups. Our analysis reveals a new standard for entities seeking to join ACOs.

3 - Mining and Interpreting Patient Satisfaction Survey Data
Ning Liu, Pennsylvania State University, University Park, PA, United States, nul147@psu.edu, Soundar Kumara

Patient satisfaction is one of the most important metrics for measuring the quality of health care services. This research aims to focus on identify the key drivers of patient satisfaction and improving the quality of care from the patients' perspective. In this paper, we establish a framework to evaluate the patterns of patients' care experience by learning and interpreting the self-reporting survey data. We develop methods based on regularized locally weighted regression to individually explain model result so as to discover the reasons behind patients' experiences and overall satisfaction. We focus on the negative patient experience to find the drivers of quality healthcare.

Advances in Healthcare Policy

Sponsored: Manufacturing & Service Oper Mgmt, Healthcare Operations

Sponsored Session

Chair: Soroush Saghafian, Harvard Univeristy, Cambridge, MA, 02138, United States, soroush_saghafian@hks.harvard.edu

1 - Analyzing Approaches to the Backlog of Untested Sexual Assault Kits in the U.S.
Lawrence M.Wein, Stanford University, Graduate School of Business, 655 Knight Way, Stanford, CA, 94305-5015, United States, lwein@stanford.edu, Can Wang

Motivated by the debate over how to deal with the huge backlog of untested sexual assault kits in the U.S., we use data from Detroit to build and analyze a mathematical model that predicts the number of hits (i.e., DNA matches to the database) as a function of both the proportion of the backlog that is tested and whether the victim-offender relationship is used to prioritize which kits are tested. Our analysis suggests that the entire backlog should be tested.

2 - Redesigning Primary Care Delivery: Customized Office Revisit Intervals and E-visits
Hessam Bavafa, Wisconsin School of Business, 4284C Grainger Hall, 975 University Avenue, Madison, WI, 53706, United States, hbavafa@bus.wisc.edu, Sergei Savin, Christian Terwiesch

The demand for physician services in primary care is shaped by the number of patients associated with each physician and the frequency of scheduled office visits. While a physician can typically set the size of her patient panel without regard for individual patient preferences, office revisit intervals are determined jointly by the physician and her patients. We analyze these decisions by modeling patient demand for office visits as a function of office revisit intervals.

3 - Impact of the United States Health Care Delivery System Reform on Care Patterns: Evidence from Cancer Care
Lina Song, Harvard University, 11 Peabody Terrace, #509, Cambridge, MA, 02138, United States, dahye.lina.song@gmail.com, Soroush Saghafian

The recent U.S. health care delivery reform could alter the care patterns by changing the provider-side resources. We take advantage of the exogenous changes in area-level provider structures such as hospital closures or horizontal mergers to gain insights into how provider-side resource variables (e.g., patient-provider distance, provider density, and hospital capacity) affect care patterns. We draw evidence from cancer diagnosis and treatment delay times, and use Medicare data to examine multiple types of cancer patients. We find that the shift of patients from low- to high-volume hospitals does not affect the patient-provider distance and reduces the diagnostic and treatment delays.

4 - Hospital-patient Alignment in Healthcare Systems
Soroush Saghafian, Harvard Univeristy, Kennedy School of Government, 79 John F. Kennedy Street, Cambridge, MA, 02138, United States, soroush_saghafian@hks.harvard.edu, Wallace J.Hopp

Choice of hospital is a key determinant of healthcare quality. But lack of transparent information and other factors introduce distortion into the alignment between patient choices and hospital capabilities. We study ways that patients, payers, and hospitals can improve patient outcomes by achieving better alignment.

Game Theory in Supply Chains

Sponsored: Manufacturing & Service Oper Mgmt, Supply Chain

Sponsored Session

Chair: Tinglong Dai, Johns Hopkins University, Baltimore, MD, 21202, United States, dai@jhu.edu

1 - Omni-channel Retailing with Consistent Products and Pricing
Xiaomeng Guo, Assistant Professor, Hong Kong Polytechnic University, Kowloon, Hong Kong, xiaomeng.guo@polyu.edu.hk, Panos Kouvelis, Danko Turcic

This paper develops a game-theoretical model to compare the traditional multi-channel strategy and omni-channel strategy in a supply chain setting. We examine whether and when implementing omni-channel strategy by offering consistent products and prices across multiple channels can benefit firms.

2 - Signaling Supplier Risk through Buy-back Contract
Shouqiang Wang, The University of Texas at Dallas, Naveen Jindal School of Management, 800 W. Campbell Rd, Richardson, TX, 75080, United States, Shouqiang.Wang@utdallas.edu, Haresh B.Gurnani, Upender Subramanian

Buyback Contracts are a widely used contractual arrangement in supply chains across a variety of industries. However, legal disputes involving alleged breach of contracts caused by the suppliers' failure to honor the return clauses abound. Can the buyback contract terms carry information about such supplier's risk? How does it differ from the situation where the supplier tries to signal its demand information.

3 - Efficient Dynamic Auction Mechanisms for Resource Allocation with Information Asymmetry
Yimin Yu, City University of Hong Kong, Department of Management Sciences, 83 Tat Chee Ave., Kowloon, Hong Kong, yiminyu@cityu.edu.hk

We study the impact of multilateral information asymmetry on the efficiency of markets when there is insufficient capacity for a resource. We consider a "distribution system", in which one upstream principal allocates a resource across multiple downstream agents. Based on the market mechanism, we propose a new dynamic auction mechanism under the multilateral information asymmetry. Surprisingly, our dynamic auction mechanism is a first best iterated dominant-strategy incentive compatible mechanism given that every party is aware of insufficient capacity. Moreover, our dynamic auction mechanism is practical as it is simple and privacy preserving.

4 - Crowdfunding in Green Energy Investment
Ying Xu, Singapore University of Technology and Design, 8 Somapah Road, Engineering System & Design, Singapore, 487372, Singapore, xu_ying@sutd.edu.sg, Ronghuo Zheng, Katia P. Sycara

This paper studies a new green energy investment model —- green crowdfunding, in which a green energy project is financed by many small individual investors. In this paper, we develop a sequential game model to study the factors that can affect the total green energy investment volume in such green crowdfunding. Surprisingly, we find that the total volume might decrease as crowdfunders are more aware of the environmental benefit of green energy investment, especially when the installation cost of green energy project is low. Moreover, the impact of the crowdfunders' awareness is affected by the business structure of crowdfunding.

Chair: Daniel Taylor, The Ohio State University, Fisher College of Business, Columbus, OH, United States, taylor.465@osu.edu

1 - Order Policy of Short Life-cycle Products Based on Dynamic Demand Forecasting
Xianhao Xu, Huazhong University of Science & Technology, 1037 Luoyu Road, Wuchang, Wuhan, 430074, China, xxhao@hust.edu.cn

Based on the characteristics of short life-cycle products, a twice procurement strategy model of short life cycle products based on the dynamic demand forecast is discussed. The results show that the procurement strategy of short life-cycle products based on dynamic demand forecasting in line with the real business has a better performance than the procurement strategy based on static demand forecasting.

2 - Value of IoT in Spare Parts Logistics Networks
Erhan Kutanoglu, University of Texas-Austin, OR/IE Graduate Program, Dept. of Mechanical Engineering, Austin, TX, 78712, United States, erhank@mail.utexas.edu, Ilyas Iyoob, Krishna T.Rekapalli

We introduce a framework to evaluate the impact of continuous data feed on the maintenance condition of in-use equipment shared via the Internet of Things technology on a multi-echelon spare parts logistics network. We develop a simulation model and conduct extensive experiments to study the system-wide effects of different factors like shipment times, inspection intervals, replacement policies, etc. The simulation results help us analyze different policies as wells as the impact of IoT on several measures such as cost, inventory levels, and system efficiency under different settings. We introduce a metric that reflects the cost to benefit ratio for IoT investment.

3 - Collaborative Robots for Material Handling in Dynamic Environments
Henry I. Ibekwe, GreenBerry Logistics, 10777 Westheimer, Suite 1100, Houston, TX, 77042, United States, hibekwe@startmail.com

Modern state-of-the-art material handling systems are highly dynamic and complex requiring sophisticated automated facilities, advanced inventory management systems, and material moving equipment. There is constantly a need to optimize the process to reduce cost and increase output. This has led to interest in the application of adaptive, learning collaborative robots to perform repetitive and mundane tasks in contrast to the traditional fixed robot manipulator systems. We explore various models of collaborative robots that perform tasks alongside human personnel as a means to improve the operational efficiency and reduce the complexity of material handling in diverse environments.

4 - Channel Competition for Inventory with in an Omnichannel Ship-from-store Network: Examining Channel Sales Cannibalization
Daniel Taylor, PhD Candidate, The Ohio State University, Fisher College of Business, Columbus, OH, 43210, United States, taylor.465@osu.edu, Keely Croxton, A. Michael Knemeyer

Implementing buy-online-ship-from-store (BOSS) tends to increase online sales. Without inventory adjustment, the policy can also result in a decline of in-store sales. Shifting inventory from an online distribution center to store-based fulfillment centers tends to increase in-store sales at those centers, but may place some online sales in jeopardy. This paper uses simulation and stochastic optimization to demonstrate these phenomena and to illustrate the effect of some BOSS inventory policies on channel service levels.

Optimal Control of Stochastic Systems

Sponsored: Applied Probability

Sponsored Session

Chair: Mark S Squillante, IBM Thomas J. Watson Research Center, Yorktown Heights, NY, 10598, United States, mss@us.ibm.com

1 - Electrical Vehicle Charging: A Queueing Approach
Bert Zwart, Buddy Boldenlaan 44, Eindhoven, 5629RD, Netherlands, Bert.Zwart@cwi.nl

We propose and analyse stochastic systems that model the performance of large-scale electrical vehicle charging systems.

2 - Revenue Management for Finite-buffered Tandem Queues
Tonghoon Suk, IBM.Thomas J. Watson Research Center, 1101 Kitchawan Road, Yorktown Heights, NY, 10598, United States, tonghoon.suk@gmail.com, Xinchang Wang

We study pricing policies for a tandem queueing system finite buffers. The problem is formulated as an infinite-horizon Markov decision process model maximizing the long-run average revenue. We propose a simple static policy and show that the policy is asymptotically optimal over all possible policies as the buffer size before the first station becomes sufficiently large. A variety of numerical studies are offered to test the performance of the simple static policy, and quite interestingly, we learn from the numerical results that the revenue obtained under the simple policy is quite close to the maximum obtainable revenue even for moderate-sized buffer for the first station.

3 - On the Optimality of Reflection Control, with Production-Inventory Applications
Hengqing Ye, Assistant Professor, Hong Kong Polytechnic University, Kowloon, Hong Kong, lgtyehq@polyu.edu.hk, Jiankui Yang, David Yao

We study the control of a Brownian motion (BM) with a negative drift, so as to minimize a long-run average cost objective. We show the optimality of a class of reflection controls that prevent the BM from dropping below some negative level r, by cancelling out from time to time part of the negative drift; and this optimality is established for any holding cost function h(x) that is increasing in |x|. Furthermore, we show the optimal reflection level can be derived as the fixed point that equates the long-run average cost to the holding cost. We also show the asymptotic optimality of this reflection control when it is applied to production-inventory systems driven by discrete counting processes.

4 - On the Control of Density-dependent Stochastic Population Processes with Time-varying Behavior
Mark S. Squillante, IBM.Thomas J. Watson Research Center, Thomas J. Watson Research Center, 1101 Kitchawan Road, Yorktown Heights, NY, 10598, United States, mss@us.ibm.com, Yingdong Lu, Chai W. Wu

We study a class of density-dependent stochastic population processes in which the rates that impact the density-dependent population structures and behaviors are time varying. Under a mean-field scaling, we extend classical results to show that such density-dependent stochastic population processes converge to a corresponding dynamical system and that the optimal control of such density-dependent stochastic population processes converges to the optimal control of the limiting dynamical system. We further investigate local (micro) and global (macro) behaviors within these processes and extend our results to support nearly completely decomposable stochastic process structures.

Stochastic OR Methods in Machine Learning

Sponsored: Applied Probability

Sponsored Session

Chair: Jose Blanchet, Columbia University, New York, NY, 10027, United States, jose.blanchet@gmail.com

1 - Unbiased Monte Carlo Computations for Optimization and its Applications
Yanan Pei, Columbia University, 506 W. 122nd St Apt 22, New York, NY, 10027, United States, yp2342@columbia.edu, Jose Blanchet, Peter W. Glynn

We present general principles for the design and analysis of unbiased Monte Carlo estimators for optimal solutions of general stochastic optimization. Our estimators possess finite work-normalized variance under mild regularity conditions, such as uniqueness of optimizer and Lipschitz continuity of objective functions. With such unbiased estimators, it is convenient to implement estimations in parallel computations in practice. We apply our estimators to various settings of interest, such as regularized logistic regression and LASSO. Numerical experiments are also given to illustrate our result on real industry data.

2 - Robust Wasserstein Profile Inference: A Novel Approach Towards Choosing Regularization Parameters in Machine Learning
Karthyek Murthy, Columbia University, New York, NY, United States, karthyek@gmail.com, Jose Blanchet, Yang Kang

The objective of this talk is to introduce a novel, distributionally robust optimization based inference procedure called Robust Wasserstein Profile Inference (RWPI). The proposed procedure exploits connections between Empirical Likelihood, Distributionally Robust Optimization (DRO) and the theory of Optimal Transport. A key element of RWPI is the so-called Robust Wasserstein Profile function, a suitably scaled version of which, as we shall see, allows us to optimally choose tuning parameters for popular machine learning estimators such as generalized Lasso, regularized logistic regression, etc., without having to use the brute-force tuning approach of cross-validation.

3 - Doubly Robust Data-driven Distributionally Robust Optimization
Fei He, Columbia University, IEOR.Department, Mudd 345, New York, NY, 10027, United States, fh2293@columbia.edu

We formulate a double robust framework for optimal transport based distributionally robust optimization (DRO), and explore its applications in statistical learning. We apply robust optimization (RO) method to metric learning to learn a robust data-driven cost function and apply the cost function into DRO formulation, where we call it double robust DRO. DRO deals with finite sample uncertainty in model fitting; while RO metric learning takes care of the noisy estimation in constraints set. The double robust DRO provides a robust data-driven regularization for model fitting. Numerical experiments on real data sets shows that our method is superior comparing to its single robust counterpart.

4 - Data Driven Optimal Transport Cost Selection for Distributionally Robust Optimization
Fan Zhang, Stanford University, Stanford, CA, United States, fzh@stanford.edu, Jose Blanchet, Yang Kang, Karthyek Murthy

Recently, Blanchet, Kang and Murthy (2016) have shown that many machine learning algorithms, such as generalized Lasso, Support Vector Machines, and regularized logistic regressions, among many others, can be exactly represented as distributionally robust optimization (DRO) problems. The distributional uncertainty is defined as a neighborhood centered at the empirical distribution. We propose a methodology which learns such neighborhood in a natural data-driven way, thereby improving both theoretically and empirically (as we demonstrate) upon the classical algorithms.

Operations Issues in Agriculture

Sponsored: Manufacturing & Service Oper Mgmt, iFORM

Sponsored Session

Chair: Onur Boyabatli, Singapore Management University, Singapore, 178899, Singapore, oboyabatli@smu.edu.sg

1 - Reining in Onion Prices by Introducing a Vertically Differentiated Substitute: Models, Analysis, and Insights

Omkar Palsule-Desai, Indian Institute of Management Indore, Indore, India, omkardpd@iima.ac.in, Muge Yayla Kullu, Srinagesh Gavirneni

We examine the pricing ordeal in India's onion markets caused by the fresh produce traders. As a remedy, policy makers have been proposing to establish processed produce competition in the market by either cooperatives or private firms. We formulate and analyze this situation in a mathematical model that captures (i) competition between non-profit and for-profit organizations, (ii) consumers' valuation discount for the processed produce, and (iii) perishability of the fresh produce. We identify and discuss the conditions under which (i) it is optimal to introduce the processed produce; and (ii) the processed onion should be managed by cooperatives instead of private firms.

2 - Pricing of Wine Futures and Recently Bottled Wines under Weather Uncertainty

Burak Kazaz, Syracuse University, Whitman School of Management, 721 University Avenue, Syracuse, NY, 13244, vUnited States, bkazaz@syr.edu, M.Hakan Hekimoglu

Using a comprehensive set of data gathered from Liv-ex and the world's largest wine distributor, this study examines the pricing of wine futures (i.e., wine sold in advance before it is bottled) and recently bottled wines. Our study helps wine distributors build a more sophisticated understanding of how young wine prices evolve based on various weather and market indicators.

3 - Understanding Farmers Crop Allocation Decisions and the Role of Intermediaries

Sripad K. Devalkar, Indian School of Business, Ac3 L1 Room 3114, Hyderabad, 500032, India, sripad_devalkar@isb.edu, Sridhar Seshadri, Bharat Ramaswami

Exclusive cultivation of high yield varieties of rice and wheat crops has led to depletion of groundwater tables and soil fertility in many states of India. In this research, we identify major factors including access to labour, markets, and information that affect the farmers' decisions not to diversify to alternate crops that are beneficial to the farmer and the environment. We consider the role of supply chain intermediaries in enabling farmers to diversify and test the model using data on farmers' crop allocation decisions in the state of Punjab.

4 - Optimal Supply Planning for Commercial Seeds

Utku Serhatli, INSEAD, Constance de le Boulevard, Fontainebleau, 77590, France, utku.serhatli@insead.edu, Andre Du Pin Calmon, Enver Yucesan

We analyze the optimal production and inventory assortment decisions of a seed manufacturer. We first derive the structure of the optimal decisions for the general case and characterize solutions for the single-period case. Second, we demonstrate the impact of operational flexibility: Salvaging opportunity motivates higher production through the mitigation of yield risk and postponement strategy impacts the optimal production quantity via overage cost reduction and demand pooling effects. Third, our numerical results show that while the salvaging strategy provides protection against yield uncertainty, the postponement strategy is an effective defense against demand uncertainty.

Design Choices in Innovation Management

Sponsored: Technology, Innovation Management & Entrepreneurship

Sponsored Session

Chair: Pascale Crama, Singapore Management University, Singapore, 178899, Singapore, pcrama@smu.edu.sg

1 - Delegated Testing of Design Alternatives

Jochen Schlapp, University of Mannheim, Wilhelm-Leuschner-Str. 241, Griesheim, 64347, Germany, jschlapp@bwl.uni-mannheim.de

The testing of different design alternatives is a vital element of any R&D process. Yet, in reality, the benefits of testing are not easy to harvest because these activities are usually delegated to experts who may pursue their own agenda. We examine how to optimally incentivize these experts and how to design the testing process.

2 - The Valuator's Curse is Entrepreneur's Boon: Decision Analysis of Post-launch Surprise

Onesun Steve Yoo, University College London, School of Management, Gower Street, London, WC1E 6BT, United Kingdom, onesun.yoo@ucl.ac.uk, Kevin F.McCardle

Evidence from IPOs show that entrepreneurial ventures tend to be initially over-valued. A common explanation is irrationality, e.g. overconfidence. We provide a rational explanation which we term the valuator's curse. It is similar in nature to the winner's curse in auctions and the optimizer's curse in decision analysis, but the source is neither from the competitive nor optimization effects. The effect is generated in the evaluation itself, even though the inputs to the evaluation are unbiased. We formalize it in a Bayesian setting, and suggest several approaches to mitigate the effect.

3 - Effect of Flexibility on Consumption of Services

Sreekumar R. Bhaskaran, Southern Methodist University, Cox School of Business, P.O. Box 750333, Dallas, TX, 75275, United States, sbhaskar@mail.cox.smu.edu, Rajiv Mukherjee, Sanjiv Erat

In this paper, we experimentally investigate how flexibility in consumption interacts with the actual usage of a service by consumers. Subsequently, we study a firm's pricing and capacity planning decision under the presence of these effects. The results have interesting implications in industries where managing congestion is an important consideration.

4 - Sourcing Innovative Goods: System or Component

Zhi Chen, INSEAD, 1 Ayer Rajah Avenue, Singapore, Singapore, zhi.chen@insead.edu, Jurgen Mihm, Jochen Schlapp

Many purchasing projects involve buying complex systems, which require the suppliers to perform some custom product or technology development regardless of whether they win the project or not. Viewing such a procurement setting through the lense of contest, we study under which circumstances a buying firm should source an integrated system or individual components.

Data-driven Decision Making in Healthcare

Invited: InvitedHealthcare Systems and Informatics

Invited Session

Chair: Taewoo Lee, University of Houston, Houston, TX, 77204-4008, United States, tlee20@central.uh.edu

1 - Patient Specific Radiotherapy Treatment Policy: A Data-driven POMPD Framework

Nasrin Nouri, University of Houston, Houston, TX, United States, nnouri2@uh.edu, Gino Lim

In radiotherapy treatment planning the goal is to deliver the prescribed dose to the tumor structure while sparing organs at risk and normal tissues. Currently an equal dose is delivered in all treatment sessions, however tumor biological response to radiation is not constant during the whole treatment horizon. Depending on tumor density and shape, the growth rate of tumor cells and their sensitivity to radiation will change. Therefore, a dynamic customized treatment plan is required for each patient and each tumor site. In this study, we develop an indefinite horizon, constrained POMDP framework to provide optimal treatment policy where the state of tumor before each treatment session is uncertain.

2 - Personalizing Health Treatments using Bayesian Inverse Optimization

Anil Aswani, UC Berkeley, 8 10th St, Apt 1704, San Francisco, CA, 94103, United States, aaswani@berkeley.edu, Philip Kaminsky, Yonatan Mintz, Elena Flowers, Yoshimi Fukuoka

Treatments for managing chronic disease are sensitive to patient adherence, as well as to the treatment efficacy on each patient. Better quantification of such parameters can improve the efficiency of health care delivery (by more accurate allocation of costly treatment resources) and improve health outcomes (by prompting earlier escalation of care when needed). This talk describes a Bayesian approach to inverse optimization that can quantify such parameters. We provide mathematical programming formulations for and theoretical results about our approach, and conclude with simulations that show the effectiveness of our approach in personalizing a weight loss and physical activity treatment.

3 - Solution Methods for Generalized Inverse Optimization

Rafid Mahmood, University of Toronto, 3831 Janice Drive, Mississauga, ON, L5M.7Y6, Canada, rafid.mahmood@mail.utoronto.ca, Timothy Chan, Taewoo Lee, Daria Terekhov

Practitioners of inverse optimization often create specialized methods to solve a specific problem. A previous work introduced a generalized inverse optimization (GIO) formulation for linear programs, that could easily specialize to the different custom methods. In this work, we extend the previous formulation to the case of multiple observed decisions. Although the prior work introduced solution methods for the classically non-convex problem, we extend these results to show how the problem and it's specializations can be solved efficiently in nearly all scenarios. Finally, we provide a set of guiding rules for practitioners in implementing inverse problems.

4 - Data-driven Objective Selection in Multi-objective Optimization

Temitayo Ajayi, Rice University, Houston, TX, United States, temitayo.ajayi@rice.edu, Taewoo Lee, Andrew J.Schaefer

A challenge in radiation therapy treatment planning is selecting which clinical objectives to use in the optimization. We propose the inverse optimization method with a cardinality constraint to infer the most important objectives from historical treatment plans. We use a greedy algorithm to select objectives and provide theory, a generalization of a result by Nemhauser (1978), to support our results. We compare the proposed method to the cardinality-constrained inverse problem, and show that our method efficiently finds a small number of objectives that generates clinical quality treatment plans.

Revenue Management with Intertemporal Consumer Behavior

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Ilan Lobel, New York University, New York, NY, 10012, United States, ilobel@stern.nyu.edu

1 - Dynamic Pricing Model for a Subscription Contract Offered to Strategic Customers with Fixed Term Lengths in a Growing Market

Roozbeh Yousefi, Queen's University, 310 Bath Rd., Unit 1112, Kingston, ON, K7M9H1, Canada, r.yousefi@queensu.ca, Jue Wang, Yuri Levin, Mikhail Nediak

Subscriptions are agreements between a company which commits to deliver a service or provide access to a service and its customers. We present a continuous time dynamic pricing model for a monopolist offering a fixed term subscription contract without per-use charges and limit of access, to strategic customers whose utility is affected by the number of subscribers. We formulate the monopolist's problem in terms of optimal control, derive its optimality conditions, and study the structure of the stationary optimal solution. We demonstrate the optimal pricing results in numerical experiments.

2 - Joint Pricing and Inventory Management with Strategic Customers

Yiwei Chen, Singapore University of Technology and Design, Singapore, Singapore, Yiwei_chen@sutd.edu.sg, Cong Shi

We study a joint pricing and inventory management problem with strategic customers. Demand is allowed to be backlogged. The seller incurs fixed ordering cost and inventory holding cost. Our model allows customers to be heterogeneous in arriving times and valuations. We use mechanism design approach to characterize the seller's optimal pricing and inventory policy and customer equilibrium behaviors.

3 - Intertemporal Price Discrimination with Time-varying Valuations

Victor Araman, American University of Beirut, Beirut, Lebanon, va03@aub.edu.lb

Customers approach the firm and can either purchase the product on arrival, or remain in the system for a period of time. During this time, each customer's valuation changes following a discrete and homogenous Markov chain. We show that, in this context, cyclic strategies are optimal, or nearly optimal. When the pace of pricing is constrained we characterize the cycle length and obtain an efficient algorithm that yields the optimal solutions. We cast part of our results in a general framework of optimizing the long-run average revenues for a class of payoffs that we call weakly coupled.

4 - Dynamic Pricing with Heterogeneous Patience Levels

Ilan Lobel, New York University, 44 West 4th St, Kmc 8-71, New York, NY, 10012, United States, ilobel@stern.nyu.edu

We consider the problem of dynamic pricing in the presence of patient consumers. We call a consumer patient if she is willing to wait a certain number of periods for a lower price and will purchase as soon as the price is equal to or below her valuation. We allow for arbitrary joint distributions of patience levels and valuations. We propose an efficient algorithm for finding optimal pricing policies. The dynamic program requires a larger state space than its counterpart for a strategic consumers model. We find numerically that optimal policies can take the form of incomplete cyclic policies, combining features of both nested sales policies and decreasing cyclic policies.

Pricing and Revenue Management in Retail Operations

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Mehmet Sekip Altug, maltug@gwu.edu

1 - Curing the Addiction to Growth

Marshall L. Fisher, University of Pennsylvania, Wharton School Oper & Info Mgmt. Dept, Jon M. Huntsman Hall, Room 542, Philadelphia, PA, 19104, United States, fisher@wharton.upenn.edu, Vishal Gaur, Herbert Kleinberger

Successful retailers grow quickly in their early years simply by opening new stores, but what happens when growth inevitably slows? To answer this question, we examined the financials of 37 publically traded retailers continuously active during 1993-2014 whose average top line growth slowed from 14.1% initially to 4.6% in the last 5 years. Despite slower top line growth, 17 of these retailers outperformed the S&P during 2011-15 by following a strategy of curtailing new store opening and instead increasing sales in their existing stores through a variety of initiatives.

2 - Assortment Planning with N-pack Purchasing Customers

Ying Cao, University of Texas at Dallas, 19251 Preston Rd, Apt 1324, Dallas, TX, 75252, United States, Ying.Cao@utdallas.edu, Dorothee Honhon

For many product categories, customers often buy multiple differentiated products on a given store visit for staggered consumption until the next store visit. Such customers are referred to as n-pack purchasing customers in Fox et al (2016). We consider a retailer who makes product assortment decisions in a given product category facing n-pack purchasing customers. We study the structural properties of the optimal assortment under three different customer choice rules. And we explore how the retailer's assortment decision and total profits are impacted when the retailer ignores the "choice premium" which captures the utility that consumers derive from variety in their shopping basket.

3 - Trusting the Computer: Adherence to the Recommendations of a Pricing Decision Support System

Anna Saez de Tejada Cuenca, UCLA Anderson School of Management, Los Angeles, CA, United States, anna.sdtc.1@anderson.ucla.edu, Felipe Caro

We analyze empirically the drivers of adherence to the prices recommended by a decision support system during the sales season of a fast fashion retailer. We study the effect on two interventions (nudges) aimed to encourage adherence to the DSS's recommendations on the overall season adherence, as well as the effect of inventory levels and impatience on the evolution of adherence over each sales season.

4 - Optimal Dynamic Allocation of Sales and Rental Inventory at a Retailer

Mehmet Sekip Altug, George Washington University, 2201 G. Street NW, Funger 415, Washington, DC, 20052, United States, maltug@gwu.edu, Oben Ceryan

We consider a retailer that simultaneously sells and rents its product over a given horizon. In every period, the retailer faces uncertain demand that splits between renters and buyers based on their utility. We characterize the optimal dynamic rental allocation policy and study its properties. We propose various implementable heuristics. We then extend our results to the duopoly case and characterize the equilibrium. We derive the conditions that lead to "pure sales", "pure rental" or "mixed" strategy equilibrium and discuss their implications.

Innovative Topics in Revenue Management

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: So Yeon Chun, McDonough School of Business, Georgetown Universit, Wyashington, DC, 20057, United States, sc1286@georgetown.edu

1 - Advance Selling to Strategic Consumers: the Advance Selling Target and the Preorder Contingent Production Strategy

Mingcheng Wei, University at Buffalo, 326C Jacobs Management Center, Buffalo, NY, 14260, United States, mcwei@buffalo.edu, Fuqiang Zhang

Motivated by emerging industry practices, this paper studies the effectiveness of a new advance selling strategy in counteracting strategic consumer behavior: the preorder contingent production (PCQ) strategy, where the seller's production decision is contingent on preorder quantities. We find that compared to the traditional advance selling strategy, the PCQ strategy is effective in mitigating strategic waiting behavior and thus can significantly improve the seller's profit performance.

2 - Selective Selling in Social Networks

Ruslan Momot, INSEAD, Boulevard de Constance, Fontainebleau, 77305, France, ruslan.momot@insead.edu, Elena Belavina, Karan Girotra, Karan Girotra

We consider the use and value of social network information in selectively selling goods and services whose value derives from exclusive ownership among network connections. Our model accommodates customers who are heterogeneous in their number of friends (degree) and proclivity for social comparisons (conspicuity). We show how the firm with information on either (or both) of these traits can use it to increase profits making a product selectively available to the firm's best targets - high-conspicuity customers within intermediate-degree segments. We find that information about degree is more valuable than information about conspicuity and that the two are substitutes.

3 - The Effects of Menu Costs on Supply Chain Efficiency: Evidence from Adoption of the Electronic Shelf Label Technology

Ioannis (Yannis) Stamatopoulos, University of Texas at Austin, McCombs School of Business, 2110 Speedway, B6000 Austin, TX 7870, Office 6484, Austin, TX, United States, yannis.stamos@mccombs.utexas.edu, Antonio Moreno-Garcia, Achal Bassamboo

We use the differential timing of adoption of electronic shelf labels (ESLs) in stores of a major international grocery retailer in the UK to identify the effects of reducing physical menu costs on supply chain efficiency. ESLs effectively eliminate the physical costs associated with price adjustment (e.g., costs of printing and distributing price tags). We find that the elimination of physical menu costs benefits all supply chain stakeholders.

4 - Loyalty Program Design and Consumer Decisions to Redeem Points or Spending Money

So Yeon Chun, McDonough School of Business, Georgetown University, 37th & O.Streets, Hariri Building, office #542, Washington, DC, 20057, United States, sc1286@georgetown.edu, Rebecca Hamilton

In many loyalty programs, customers earn points for their purchases, which they can later exchange for additional products and services. In a sense, points function as a currency that consumers can spend on products instead of spending money. However, we uncover systematic differences in the way consumers spend loyalty points compared with money. To highlight different mechanisms by which loyalty program design characteristics may influence redemption, we first propose a model of the consumer's choice to redeem points or use money for a specific purchase, and then we conduct a series of studies to investigate the impact of these characteristics on consumers' choices.

Outsourcing Innovation and Product Development

Invited: New Product Development

Invited Session

Chair: Ersin Korpeoglu, University College London, London, N17 9GL, United Kingdom, e.korpeoglu@ucl.ac.uk

Co-Chair: C Gizem Korpeoglu, University College London, London, WC1E 6BT, United Kingdom, c.korpeoglu@ucl.ac.uk

1 - Technology Choice in Dynamic Competition

Feng Tian, University of Michigan, 1760 Broadway St, Apt 303, Ann Arbor, MI, 48105, United States, ftor@umich.edu, Izak Duenyas, Mohamed Mostagir

Two firms innovate over time and the firm that produces the better innovation by the end of the horizon wins. Firms have access to different technologies and have to decide which technology to use in each time period given the past choices and outcomes. Technologies are heterogeneous along several dimensions: they may have different variances, costs, and ability to learn from previous attempts. We characterize the equilibria of this dynamic competition and compare their welfare properties as a function of the different parameters of the problem.

2 - The Role of Feedback in Dynamic Crowdsourcing Contests: A Structural Empirical Analysis

Zhaohui Jiang, PhD Student, University of Michigan, Ann Arbor, MI, 48109, United States, jiangzh@umich.edu, Yan Huang, Damian Beil

This paper examines the impact of performance feedback on the outcome of crowdsourcing contests. We develop a dynamic structural model to capture the economic processes that drive contest participants' behavior, and estimate the model using a data set collected from a major online crowdsourcing platform. The model captures key features of the crowdsourcing context, including a large participant pool, entries by new participants throughout the contest, and exploitation and exploration behaviors by contest incumbents. Using counterfactual simulations, we show that providing feedback throughout the contest may not be optimal; the late feedback policy leads to a better overall contest outcome.

3 - Optimal Stochastic Feedback in Asymmetric Dynamic Contests

Jurgen Mihm, Insead, Boulevard De Constrance, Boulevard de Constance, 77305, France, jurgen.mihm@insead.edu, Jochen Schlapp

A contest is an incentive mechanism in which a number of contestants compete against each other at their own expense of effort to provide the best performance and to win a limited number of prizes. Feedback can be a mechanism for contest holders to increase the effort levels of the contestants and hence contest outcomes. In this talk, we characterize a contest holder's optimal choice of (stochastic) public feedback for asymmetric dynamic contests.

4 - Contest Among Contest Organizers

C. Gizem Korpeoglu, University College London, Gower Street, London, WC1E 6BT, United Kingdom, c.korpeoglu@ucl.ac.uk, Ersin Korpeoglu, Isa Hafalir

We study multiple contests where contest organizers elicit solutions to innovation-related problems from a set of agents. Each agent may participate in multiple contests and exert effort to improve her solution, but the quality of her solution also depends on an output uncertainty. We show, somewhat surprisingly, that organizers benefit from agents' participation in multiple contests when agents' output uncertainty is sufficiently large. We then show that the organizer profit is unimodal in the number of contests, and more interestingly, the optimal number of contests increases with agents' output uncertainty. This finding may explain why many organizations run multiple contests in practice.

DEA Applications

Invited: Data Envelopment Analysis

Invited Session

Chair: Kankana Mukherjee, Babson College, Wellesley, MA, 02481, United States, kmukherjee@babson.edu

1 - Efficiency and Productivity Dynamics of Indian Bank Branches
Kankana Mukherjee, Babson College, Babson Park, MA, United States, kmukherjee@babson.edu, Subhash C.Ray, Abhiman Das

This paper examines the trajectory of efficiency and productivity dynamics of a network of branches of a large Indian bank during the post Great Recession period. We use Data Envelopment Analysis to study branch level data for the years 2009-10 through 2016-17. By isolating the contributions of technical change, efficiency change, and scale change to overall productivity change of each branch, we are able to identify the sources of superior versus inferior branch level performance, which helps to provide guidelines for improving the performance of the bank at the institutional level.

2 - Environmental Productivity Growth in Consumer Durables
Xun Zhou, Doctoral Candidate, Aalto University School of Business, Runeberginkatu 22-24, Helsinki, 00100, Finland, xun.zhou@aalto.fi

Only one previous study considers environmental performance of consumer durables. This is somewhat surprising because during their use phase consumer durables are actually production units that consume energy to provide services for consumers and thus contributors to pollutions. This study aims to develop an index of environmental productivity change specific to consumer durables. We first specify how to model the production activity during the use of consumer durables. Then we present an overview of conventional measurements of environmental productivity and describe how they can be applied in this study. Finally we use a Finnish dataset to illustrate interpretations of the proposed index.

3 - Building Models for Efficiency and Effectiveness in the Financial Industry
Abbas Attarwala, University of Waterloo, 200 University Avenue West, Waterloo, ON, N2L.3G1, Canada, abbas.attarwala@gmail.com, Stanko Dimitrov

We review recent work on evaluating models of efficiency and effectiveness for the financial industry. Using the reviewed evaluation procedure and publicly available data we computationally efficiently and systematically search the space of efficiency and effectiveness data envelopment analysis models to present models of efficiency and effectiveness valid for multiple datasets. We conclude with some key managerial takeaways from our findings.

Ideas And Discussing Relating to the Future of Social Media Analytics Research

Invited: Social Media Analytics

Invited Session

Chair: Christopher M Smith, Air Force Institute of Technology, Air Force Institute of Technology, Xenia, OH, 45385, United States, cms3am@virginia.edu

1 - Ideas and Discussion Relating to the Future of Social Media Analytics Research
Chris Smith, Air Force Institute of Technology, 2950 Hobson Way, 2950 Hobson Way, Wright-Patterson AFB, OH, 45433, United States, cms3am@virginia.edu

A brief general overview of our cluster is provided. Trends in the literature are reviewed as well as in topics within past INFORMS clusters. A set of discussion topics are proposed for all the participants and, ideally, for the audience.

2 - Review of Decision Problems in Social Media Analytics
Theodore T. Allen, Ohio State University, Columbus, OH, 43210-1271, United States, allen.515@osu.edu

This presentation focuses on reviewing recent decision problems explored in social media analytics. An example is so-called "Timely Decision Analysis" enabled by social media analytics. Yet, many other examples ranging from financial investments to optimal target identification

3 - Role Identification and Modeling of Online Health Communities"
Jiaqi Zhou, C ity University of Hong Kong, 12-200 Lau Ming Wai, Hong Kong, jiaqi.zhou@my.cityu.edu.hk, Qingpeng Zhang, Mingyang Li

Online health communities present a platform for users to exchange information and get social support from other users, particularly those suffering from similar diseases. In this study, we focus on the impact of OHCs on people with depression. We combined text mining, social network analysis, and econometric analysis and characterized their roles with topological measures. Finally, we discovered the changing patterns of users' roles dynamically and found that patients' emotion could be significantly enhanced by responses of other OHC users."

4 - Review of Business Strategy Problems in Social Media Analytics
Michel Ballings, University of Tennessee, University of Tennessee, Knoxville, TN, 37996, United States, michel.ballings@utk.edu

A review of business strategy research is given with an emphasis on building networks and their roles in marketing and sales.

Combinatorial Mechanisms

Invited: Auctions

Invited Session

Chair: Benjamin Lubin, Boston University, Boston, MA, 02215, United States, blubin@bu.edu

1 - Probably Approximately Efficient Combinatorial Auctions via Machine Learning
Benjamin Lubin, Boston University, School of Management, 595 Commonwealth Avenue, Boston, MA, 02215, United States, blubin@bu.edu, Gianluca Brero, Sven Seuken

A well-known problem in combinatorial auctions is the exponential growth of the value space in goods, burdening both bidders and the auctioneer. We introduce a new design paradigm for CAs based on machine learning. Bidders report bids to a proxy agent via a small number of value queries. The proxy then uses an ML algorithm to generalize from those bids to the whole value space, and the efficient allocation is computed over these generalizations. We introduce the concept of probably approximate efficiency (PAE) to measure the efficiency of the new ML-based auctions, and formally show how the generelizability of an ML algorithm relates to the efficiency loss incurred by the corresponding ML-based auction.

2 - Efficient Dynamic Auctions for Private Valuations
Oleg V. Baranov, University of Colorado-Boulder, 256 UCB, Boulder, CO, 80309, United States, oleg.baranov@colorado.edu

The literature on dynamic implementation of the VCG mechanism routinely uses price-demand queries for preference elicitation. As a result, all known dynamic auction procedures that implement the Vickrey outcome for the general private valuation domain are impractical. The paper makes two contributions. First, we show that the general problem of designing a dynamic VCG mechanism is reduced to a problem of specifying an appropriate elicitation process that satisfies certain properties. Second, we characterize an ascending auction that implements the Vickrey outcome for general private valuation domain while using a single linear and anonymous price trajectory for preference elicitation.

3 - Competitive Equilibrium Pricing in Auctions and Exchanges
Robert Day, University of Connecticut, 2100 Hillside Road U-1041, Storrs, CT, 06269-1041, United States, Bob.Day@business.uconn.edu

Cutting plane methods allow us to generate competitive equilibrium prices for an arbitrary combinatorial auction. We explore the computational aspects of these methods and their extension to the arbitrary case of combinatorial exchanges.

Healthcare Informatics

Sponsored: Artificial Intelligence

Sponsored Session

Chair: Haijing Hao, University of Massachusetts-Boston, 12 Inman Street Apt 31, Cambridge, MA, 02139, United States, haohaijing@gmail.com

1 - Social Media and Health Insurance Choice in China

Haijing Hao, University of Massachusetts-Boston, 12 Inman Street Apt 31, Cambridge, MA, 02139, United States, haohaijing@gmail.com, Yunfeng Shi, Anqichen Shi

China has been undertaking health insurance reforms in the past couple of decades, transforming from narrow coverage of government paid insurance to limited government staff to wider population from all walks of people. Chinese people have more and flexible choices of health insurance. This study examines the daily social media usage and health insurance choices in China based on a national survey study.

2 - Dynamics and Misinformation in Health Social Networks

Wencui Han, University of Illinois at Urbana Champaign, 1206 S. Sixth Street, 350 Wohlers Hall, Champaign, IL, 61820, United States, wenhan@illinois.edu

Health social networks provide patients opportunities to connect with each other. However, misinformation on these platforms poses threats to patient safety. This paper uses physician-evaluated posts collected from a popular health social network site to explore factors can be used to predict and monitor misinformation. We focus on the impacts of two main concepts that embedded in the dynamics of the interaction on social networks: similarity between responder and question poster, and dynamic clique variables.

3 - Digital Divide in Online Health Community

Haijing Hao, University of Massachusetts-Boston, 12 Inman Street Apt 31, Cambridge, MA, 02139, United States, haohaijing@gmail.com

The present study intends to explore what factors may have an impact on online health utilization in China by examining various economic-related variables. We use Tableau mapping features to illustrate the geographical visualization and also run quantitative fixed effect regression models. Our preliminary results show that percentage population that can access the Internet of a province in China has a statistical significant impact on the online health utilization of that province.

4 - Efficiently Identifying Trends in Healthcare using Text Mining, and Topic Detection and Tracking

Yu-Hung Chiang, National Cheng Kung University, Tainan City, Taiwan, momois87@hotmail.com

Most published healthcare research literature is recorded online databases such as PubMed. As the number of online articles increases rapidly, it becomes challenging for researchers to accurately and efficiently identify current research trends in specific topics of healthcare. In this study, we construct a trend analysis method to obtain research topics from PubMed. Using text mining methods and topic Detection and Tracking (TDT), we aim to improve the efficiency in identifying and tracking topics from large databases.

Social Media Use and New Product Development Performance

Invited: Social Media Analytics

Invited Session

Chair: Debasish N Mallick, University of St. Thomas, Minneapolis, MN, 55403, United States, dnmallick@stthomas.edu

Chair: Julie Zhang, University of Massachusetts Lowell, Lowell, MA, 01854, United States, juheng_zhang@uml.edu

1 - Social Media Use & New Product Development Performance

Debasish N. Mallick, University of St. Thomas, Opus College of Business, 1000 La Salle Avenue # TM.H.443, Minneapolis, MN, 55403, United States, dnmallick@stthomas.edu

Use of social media is becoming increasingly popular in NPD. Yet, the performance impact of social media use in NPD remains inconclusive. Using a cross industry survey of new product development projects, we explore the factors affecting the relationship between social media use and NPD performance

2 - Using Microblogging to Predict IPO Success

Dirk Van den Poel, Professor of Data Analytics/Big Data, Ghent University, Faculty of Economics and Business Administration, Tweekerkenstraat 2, Gent, B.9000, Belgium, Dirk.VandenPoel@UGent.be, Michel Ballings

This research investigates the influence of microblogging - in particular Twitter social media messages - on Initial Public Offering (IPO) success. We analyze the (potential) impact of the number of tweets and their sentiment on (1) the difference between the IPO price and the closing price of the stock at the day of becoming public, and (2) the difference between the closing price on the first day of trading and the closing price after three months of trading.

George B. Dantzig Dissertation

Invited: The George B. Dantzig Dissertation Prize

Invited Session

Chair: Wedad Elmaghraby, University of Maryland, R H Smith, College Park, MD, 2, United States, welmaghr@rhsmith.umd.edu

1 - Robust Optimization for Renewable Energy Integration in Power System Operations

Álvaro Lorca, Pontificia Universidad Católica de Chile, Departamento de Ingeniería Eléctrica, Av Vicuna Mackenna 4860, Santiago, 7820436, Chile, alvarolorca@uc.cl

Motivated by the increasing adoption of variable renewable energy sources such as wind and solar power, this talk will present robust optimization models and algorithms that determine innovative methods to operate modern power systems. In particular, we will present a multistage adaptive robust optimization model for the unit commitment problem, i.e. for the problem of scheduling power generation over one whole day, including on/off and dispatch decisions. The most innovative aspect of this model is that the causality of the dispatch process is respected, that is, dispatch decisions at any given time can only depend on the revealed uncertainty up to that time. We will also discuss solution methods based on cutting planes, the concept of dynamic uncertainty sets to account for spatial and temporal correlations in renewable power uncertainty, and the potential impact in the electric power industry.

2 - Deep Exploration via Randomized Value Functions

Ian Osband, Stanford University, Stanford, CA, United States, ian.osband@gmail.com

In this dissertation we present an alternative approach to deep exploration through the use of randomized value functions. Our work is inspired by the Thompson sampling heuristic for multi-armed bandits which suggests, at a high level, to "randomly select a policy according to the probability that it is optimal". We provide insight into why this algorithm can be simultaneously more statistically efficient and more computationally efficient than existing approaches. We leverage these insights to establish several state of the art theoretical results and performance guarantees. Importantly, and unlike previous approaches to deep exploration, this approach also scales gracefully to complex domains with generalization. We complement our analysis with extensive empirical experiments; these include several didactic examples as well as a recommendation system, Tetris, and Atari 2600 games.

3 - Robust Solutions for Geographic Resource Allocation Problems

Mehdi Behroozi, Northeastern University, Allston, MA, 02134, United States, m.behroozi@neu.edu

The concept of geography is a fundamental one in many domains such as transportation, facility location, logistics, surveillance, reconnaissance, and territory division, among many others. This dissertation is devoted to the study of geographic resource allocation (GRA) problems. In such a problem, our goal is to minimize or maximize an objective function that is defined over a geographic region. The distinguishing attribute of such problems is that spatial properties such as distance, shape, perimeter, area, connectedness, fatness, or convexity will appear in these problems either in the objective function or as a constraint. This dissertation considers these problems under uncertainty and aims to achieve some sort of robustness against that uncertainty. In order to take advantage of the above spatial properties and geometric principles to overcome the drawbacks of current approaches to solving such problems, we adopt an interdisciplinary approach that combines concepts, theories, and methods from computational geometry, geometric probability theory, calculus of variations, infinite-dimensional optimization, and topology. We first show the inability of the existing operations research tools to obtain reasonable solutions for some special but common and practical cases, like clustered data, and then we show that our approach makes these problems easy to solve. The results of this research have been used by Oracle Labs in a routing package for their forthcoming spatial database products and by a major mapping company in a worldwide LIDAR surveying project to scan neighborhoods and collect street level data in five continents

4 - Real-Time Optimization of Personalized Assortments
Negin Golrezaei, University of Southern California, 812 S.Marengo Avenue, Unit 6, Pasadena, CA, 91106, United States, golrezae@usc.edu

Motivated by the availability of real-time data on customer characteristics, we consider the problem of personalizing the assortment of products for each arriving customer. Using actual sales data from an online retailer, we demonstrate that personalization based on each customer's location can lead to over 10% improvements in revenue compared to a policy that treats all customers the same. We propose a family of index-based policies that effectively coordinate the real-time assortment decisions with the backend supply chain constraints. We allow the demand process to be arbitrary and prove that our algorithms achieve an optimal competitive ratio. In addition, we show that our algorithms perform even better if the demand is known to be stationary. Our approach is also flexible and can be combined with existing methods in the literature, resulting in a hybrid algorithm that brings out the advantages of other methods while maintaining the worst-case performance guarantees.

5 - Velocity-based Storage and Stowage Decisions in a Semi-automated Fulfillment System
Rong Yuan, Massachusetts Institute of Technology, 2014, 235 Albany St., Cambridge, MA, 02139, United States, rongyuan@mit.edu

Our research focuses on a new semi-automated operating architecture of an order fulfillment system where the inventory is stored on mobile pods, moved by robotic drives, and picked manually by stationary operators. Our work is one of the first research efforts to optimize the design and operational processes of a real world large-scale semi-automated storage system. We proposed novel and effective operational policies for the storage (where to return a pod upon the completion of a pick or stow operation) and stowage (in which zone and on which pod to store the receiving inventory) decisions. We further use simulations to verify our findings with real world data provided by our industrial partner.

Drone Delivery Systems - IV

Invited: InvitedDrone Delivery Systems (tentative title)

Invited Session

Chair: Andrea Arias, Texas Tech University, andrea.arias@ttu.edu

1 - A Dynamic Programming Approach for the Traveling Salesman Problem with Drone
Niels Agatz, Rotterdam School of Management, Erasmus University, Burg. Oudlaan 50, Rotterdam, Netherlands, nagatz@rsm.nl, Paul Bouman, Marie Schmidt

A promising new operating model is the use of a delivery truck that collaborates with a drone to make deliveries. This model gives rise to a new planning problem that we call the Traveling Salesman Problem with Drone (TSP-D). In this contribution, we propose an exact solution approach based on dynamic programming and present experimental results of different dynamic programming based heuristics.

2 - Optimal Path Construction and Routing of Drones for Inspecting Disaster-affected Regions
Sudipta Chowdhury, Mississippi State University, 260 McCain Engineering Building, ISE Department, Starkville, MS, 39762, United States, sc2603@msstate.edu, Sandip Kumar, Mohammad Marufuzzaman, Linkan Bian

Aerial drones are one of the most promising and powerful new technologies to improve disaster response and relief operations. This study introduces a heterogeneous fleet routing problem for drones, by considering multiple charging stations and respecting operational requirements. First, paths are constructed for the drones by obeying the restrictions set by the Federal Aviation Agency (FAA), technological, geographical, and environmental factors into account. We then propose a hybrid metaheuristic to solve the heterogeneous fleet routing problem. A case study, using three disaster-prone coastal counties in Mississippi, is developed to visualize and validate the algorithmic results.

3 - GPU Enhanced Shortest Path Finding for an Unmanned Aerial Vehicle
Roksana Hossain, University of Calgary, Calgary, AB, Canada, rhossain@ucalgary.ca, Sebastian Magierowski, Geoffery G. Messier

Situated robots like unmanned aerial vehicles (UAVs) need to decide the sequence of multiple destinations. The traveling salesman problem (TSP) is used for identifying an efficient sequence of goals. For real-time mission-critical operations, such decisions need to be made quickly with sufficient accuracy. In this report, to enhance the computational execution rate without incurring excessive system cost, a graphics processing unit (GPU) is used. A genetic algorithm and clustering algorithms is used to solve the TSP in an aerial network delivery context. The implemented GPU code works 4.8 times faster than serially implemented code and the algorithm can solve large problems with 4000 waypoints.

4 - Decomposition Heuristics for the Last-mile Delivery Problem
Andrea Arias, Pontificia Universidad Catolica de Valparaiso, Valparaiso, Chile, Andrea.arias@ttu.edu
Andrea Arias, Texas Tech University, Lubbock, TX, United States, Andrea.arias@ttu.edu, Ricardo Gatica, Jimena Pascual, Timothy I. Matis

We consider an extension of the Vehicle Routing Problem in which a single Unmanned Aerial Vehicle (UAV) is used to support a delivery truck in the last-mile delivery process. In this problem, the objective is to determine a coordinated tour for both the truck and the UAV, such that all the packages are delivered at a minimum cost. It is assumed that once the UAV is launched from the truck to deliver a package, the truck continues visiting other clients and meets the UAV in a later position of the tour. We propose alternative decomposition-based heuristics for the problem and show results on preliminary computational tests.

Studies and Scheduling

Sponsored: Military Applications

Sponsored Session

Chair: Andrew Oscar Hall, United States Military Academy, 86 B Patridge Pl, West Point, NY, 10996, United States, andrew.hall@usma.edu

1 - Nato Systems Analysis Studies Panel
Richard F. Deckro, Professor of Operations Research, Air Force Institute of Technology, Afit/ENS; Bldg 641, 2950 Hobson Way, Wright Patterson AFB, OH, 45433-7765, United States, richard.deckro@afit.edu, Timothy Povich

The NATO Science and Technology Organization's System Analysis and Studies (SAS) Panel fosters co-operative research, exchange of information, and the advancement of science and technology among the NATO Nations in the field of operations for defense and security. This presentation provides an overview of the SAS Panel's mission, goals and operations. Selected examples of previous studies will be provided.

2 - Kalman Filtering for Artillery Fire Shift
Michael Bendersky, Holon Institute of Technology, 52 Golomb St Holon, Holon, 58102, Israel, michael.bendersky@gmail.com, Israel David

Firing Shift or transfer of Fire is the shifting of artillery fire from one target to another with the application of corrections determined from the adjustment on the first target to the initial firing data for the second. In introducing a linear model for artillery fire accuracies - the parameters of which are easily obtainable from extant Firing Tables - we propose a new algorithm for making the shift, based on a static Extended Kalman Filter. It assumes concurrent fire adjustments on multiple auxiliary targets. Numerical examples are included, which attest to the potential of the approach.

3 - A New Optimization Approach for Unmanned Aerial Vehicle Assignment and Scheduling

Haitao Li, University of Missouri-St Louis, College of Business Administration, 229 Express Script Hall, St Louis, MO, 63121-4400, United States, lihait@umsl.edu

Managing unmanned aerial vehicles (UAVs) operations to accomplish military missions is often a formidable task, as it requires both assignment and scheduling decisions to be made simultaneously to optimize performance metrics, while satisfying various technical requirements. We develop a new modeling framework based on assignment-type resource-constrained project scheduling (RCPSP), and devise a decomposition algorithm to obtain optimal or near-optimal solutions for large-scale instances in reasonable computational time. A real world use case is presented to demonstrate the effectiveness and efficiency of our solutions.

Supply Chain Management

Contributed Session

Chair: Zahra Azadi, Clemson University, 110 Heritage Riverwood Drive, Apt M, Central, SC, 29630, United States, zazadi@clemson.edu

1 - Value of RFID in a Non-profit Supply Chain Subjected to Inventory Inaccuracy

Arun Kumar Biswal, Research Scholar, IIT Kharagpur, ISE Department, IIT Kharagpur, West Medinipur, Kharagpur, 721302, India, akb@iem.iitkgp.ernet.in, Arun Kumar Biswal, Mamata Jenamani, Sri Krishna Kumar

This research investigates the impact of RFID in a Non-profit supply chain to study the effect of shrinkage,misplacement and shrinkage recovery rate on overall costs.We model the situation as a Newsvendor problem to minimize the total expected cost and compare two scenarios with and without RFID. We incorporate deprivation cost in the model to account for the human suffering due to delay in delivery of critical items.We apply the model to Indian Public Distribution System and the results show that ,incentive to deploy RFID depends on the severity of error, the shrinkage recovery rate and the deprivation cost.

2 - Simulation and Optimization for Reevaluating Order Fulfillment Decisions in an Online Retail Environment"

Matthew Petering, University of Wisconsin-Milwaukee, Industrial and Manufacturing Engineering Dept, Ems E367, Milwaukee, WI, 53201, United States, mattpete@uwm.edu, Amir Kalantari

We devise a discrete event simulation (DES) and optimization framework to compare options for assigning the orders placed with an online retailer to the retailer's fulfillment centers. We show that large online retailers can meaningfully reduce total shipping costs by intelligently reevaluating their order fulfillment plans. Importantly, the optimization routines in our framework are fully embedded within a DES model so that both the decisions made, and the computation time used, by the optimization routines affect the future evolution of the DES model from time 0 to time infinity.

3 - Stochastic Optimization Models for Vaccine Supply Chain Network Design

Zahra Azadi, clemson university, 110 Heritage Riverwood Drive, Apt M, Central, SC, 29630, United States, zazadi@clemson.edu, Sandra D.Eksioglu

The main objective of this research is to increase vaccine coverage in low-middle income countries by improving the performance of the corresponding supply chain. We develop a stochastic optimization model which identifies optimal supply chain designs and management strategies. The model considers the limited shelf life of vaccines, variation in manufacturing lead time, facility and transportation costs, as well as variations in patient arrivals at health clinics. The proposed model is an extension of the supply chain network design model. We use a two-stage stochastic Benders decomposition algorithm within a rolling horizon framework to solve the problem.

Chair: Chiehyeon Lim, UC Merced; POSTECH, 790-784, Engineering Building #4-316, San 31, Hyoja-Dong Nam-Gu, Gyungbuk, Na, Korea, Republic of, chlim@unist.ac.kr

1 - Physical Internet Inspired Network Design for Daily Cyclic Routes

Zhengyang Hu, Research Assistant, Iowa State University, 3014 Black Engineering, Ames, IA, 50014, United States, zhengya@iastate.edu, Guiping Hu

Conventional dispatching logistics network requires a single trucker picks up at source and delivers to sink. Relay networks have been proposed for improving trucker life as well as solving other drawbacks of conventional networks like high deadhead cost. More recently, Physical Internet has renewed interest by introducing different modeling strategy. In this paper a two-stage mixed integer programming model is proposed for hub and routing design. The model determines the locations and capacities of hubs to meet uncertain demand. The model minimizes overall cost including fixed cost, deadhead cost, transportation cost. A real case study based on the highway grid for Western United State is considered to demonstrate operational practice of the model.

2 - Mechanisms of Smart Service Systems

Chiehyeon Lim, Assistant Professor, UNIST.(Ulsan National Institute of Science and Technology), Ulsan, Korea, Republic of, chlim@unist.ac.kr, Paul Maglio

Smart service systems are everywhere - in homes and in transportation, energy, and healthcare sectors. In this talk, we discuss mechanisms of smart service systems based on text mining of the broad literature of smart service systems and R&D projects concerning the design of smart transportation, health, energy, and home systems. A model based on such empirical studies is proposed for smart service system design.

3 - Shop Floor Lot-sizing and Scheduling under Uncertain Demand and Workforce Efficiency

Yihua Li, Iowa State University, 3014 Black Engineering, Ames, IA, 50014, United States, yihuali@iastate.edu, Guiping Hu

A two-stage stochastic programming model is proposed to solve the shop floor lot-sizing and scheduling problem under two sources of uncertainties - products demand from the market, and workforce effectiveness caused by different operational issues (e.g. proficiency of workers, parts availability). The model aims to determine optimal lot sizes and the sequence of lots that minimize total system costs over the production planning horizon, including setup, inventory and fixed costs. A case study is preformed to a supply chain producing brake equipment in the automotive industry.

Best IBM Service Science Student Paper Award Competition IV

Sponsored: Service Science

Sponsored Session

Chair: Robin Qiu, Pennsylvania State University, Malvern, PA, 19355, United States, robinqiu@psu.edu

1 - Strategically Giving Service: the Effect of Real-Time Information on Service Efficiency

Nil Karacaoglu, Northwestern University, 531 Grove Street, Evanston, IL, 60201, United States, n-karacaoglu@kellogg.northwestern.edu, Antonio Moreno, Can Ozkan

Real-time information in on-demand services provides agents with access to an unprecedented amount of information about their competitors. We study the impact of the increased availability of real-time information on the behavior of strategic agents and the implications of this phenomenon for service efficiency using data from an e-hailing taxi platform in South America. We find that agents scatter when they receive real-time information indicating the entry of new competitors into the area. The response is heterogeneous. Agents with a high scattering propensity achieve higher utilization. We investigate the consequences of this behavior for the efficiency of service systems.

2 - Dynamic Availability and Pricing of Upgrades

Xiao Zhang, The University of Texas at Dallas, 800 West Campbell Rd, Richardson, TX, 75080, United States, xiao.zhang@utdallas.edu, Metin Çakanyıldırım, Özalp Özer

Upgrading, a travel industry practice to mitigate supply-demand mismatches, is often implemented either at the booking time or at the check-in time. We consider dynamically-offered upgrades between the booking and the check-in times by a firm that sells two types of products (premium and regular). The firm decides on the number of regular product purchasers to receive an upgrade notification that includes a link to an upgrade website. A regular product purchaser may accept or reject the upgrade after clicking the link and observing an upgrade fee dynamically determined by the firm. The optimal number of notifications and the optimal upgrade fee are monotone with respect to the leftover capacities.

3 - Selling Off-Grid Light to Liquidity Constrained Consumers
Bhavani Shanker Uppari, INSEAD, 1 Ayer Rajah Avenue, Singapore, 138676, Singapore, BhavaniShanker.Uppari@insead.edu, Ioana Popescu, Serguei Netessine

A large proportion of the world's population has no access to electricity and so relies on noxious kerosene for their lighting needs. As an alternative, there are business models relying on rechargeable light bulbs that are sold at a subsidized price (which renders them affordable) and require regular micropayments for recharges (which eases liquidity constraints). These bulbs provide a cheaper and healthier light source than kerosene, yet their adoption is lower than expected and some consumers continue to use kerosene. This paper explores the potential drivers of such preferences and proposes strategies to alter them.

Bilevel Optimization and Applications

Sponsored: Multiple Criteria Decision Making

Sponsored Session

Chair: Kalyanmoy Deb, Michigan State University, East Lansing, MI, 48824, United States, kdeb@egr.msu.edu

1 - Comparison of Multiobjective Optimization Approaches for Spatially Targeting Agri-environmental Policy
Bradley Barnhart, United States EPA, 200 SW. 35th Street, Corvallis, OR, 97333, United States, bradleybarnhart@gmail.com, Gerald Whittaker, Moriah Bostian, Zhichao Wu, Ankur Sinha, Kalyanmoy Deb

Spatially targeting agri-environmental policy has been widely studied and requires optimization of multiple objectives from multiple stakeholders, including policy makers and policy followers. This study tests the Platypus package in Python for multiobjective optimization and compares the results of multiple algorithms available within the framework (e.g., NSGAII, NSGAIII, MOEA/D) for spatially targeting a fertilizer tax that aims to reduce nonpoint source pollution and increase water quality throughout a heterogeneous, mixed-use watershed. The resulting policy trade-offs are compared to the DEAP package in Python and the MATLAB implementation of BLEAQ.

2 - Optimal Management of Naturally Regenerating Uneven-aged Forests
Pekka Malo, Aalto University School of Business, Runeberginkatu 22-24, Helsinki, 00100, Finland, pekka.malo@aalto.fi, Ankur Sinha, Janne Rämö, Olli Tahvonen, Markku Kallio

A shift from even-aged forest management to uneven-aged management practices leads to a problem rather different from the existing straightforward practice that follows a rotation cycle of artificial re-generation, thinning of inferior trees and a clearcut. A lack of realistic models and methods suggesting how to manage uneven-aged stands in a way that is economically viable and ecologically sustainable creates difficulties in adopting this new management practice. To tackle this problem, we propose an algorithm that is able to handle a realistic uneven-aged stand management model that is otherwise computationally tedious and intractable.

3 - Hub Interdiction and Protection Problem: Models and Solution Approaches
Ankur Sinha, PhD, IIM Ahmedabad, India, IIM Ahmedabad, India, Ahmedabad, India, asinha@iimahd.ernet.in

Many of the important sectors in the economy such as transportation, communication and energy deploy a hub-and-spoke network. Hub-and-spoke networks are attractive because of its cost advantages, but is also prone to severe network disruption in the event of one or more hubs failing. We present different formulations and solution methods for the hub interdiction and protection problem. We model the interdiction problem as a bilevel mixed integer linear program and then utilize the problem properties to reduce the number of optimization levels to one. We also study the three level protection problem, where we utilize the ideas developed for interediction to solve the trilevel optimization task.

1 - Optimal Pipeline Maintenance Policy with Sipmath in Native Excel
Brian H.Putt, Self Employed, 4372 Nagle Way, Fremont, CA, 94536, United States, brianputt@theputts.com, Sam L.Savage

The US has thousands of miles of pipelines that have been in the ground for many years. Pipeline failures near residential and commercial locations are costly and deserve a higher maintenance priority because of their potential cost. But the maintenance budget is constrained and we want to stay within the budget. Which pipes should we replace based on Likelihood of Failure (LoF), uncertain Cost of Failure (CoF) and uncertain cost to maintain? In the San Francisco Bay Area we also have the potential for earthquakes. Maintenance of the pipelines reduces the LoF when an earthquake occurs. We will show how all these uncertainties are modeled using SIPmath and Excel, and then optimized using Excel's Solver.

2 - Selecting a Technology Application in Upstream using Sipmath
Ahren Lacy, Chevron, 1400 Smith St, 38188, Houston, TX, 77002, United States, ahrenlacy@gmail.com

Selecting technologies for selecting in upstream projects involves assessing, quantifying, and evaluating uncertainties in cashflows. The author will present an example of using SIPmath to quickly incorporate uncertainty into common cashflow worksheets.

Behavioral Considerations in Pricing and Revenue Management Models

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Javad Nasiry, Hong Kong University of Science and Technology-HKUST, Lee Shau Kee Business Building, Room 4079, Hong Kong, nasiry@ust.hk

Co-Chair: Ningyuan Chen, HKUST, Hong Kong, nychen@ust.hk

1 - Information Provision and Revenue Management in the Presence of Consumer Search Costs
Zizhuo Wang, University of Minnesota, 1009 5th Street SE, Minneapolis, MN, 55414, United States, zwang@umn.edu, Yan Liu, William L.Cooper

Should a seller make product information readily accessible, so that customers do not have to incur substantive cost to learn about those products? We consider a stylized model with two products to answer this question. We find that if product uncertainties are small but highly correlated, then withholding both products' information is best for the seller. If the uncertainties are small in both magnitude and correlation, then providing one product's information but not the other is the best. If the uncertainties are large in both magnitude and correlation, then providing both products' information is the best. Also, when correlation is low, withholding both products' information cannot be optimal.

2 - Consumer Choice Models with Reference Prices
Ruxian Wang, The Johns Hopkins Carey Business School, 100 International Dr, Baltimore, MD, 21202, United States, ruxian.wang@jhu.edu

We incorporate reference price into consumer choice models and investigate the problems on revenue management and pricing.

3 - Are Markets with Loss-averse Consumers More Sensitive to Losses?
Zhenyu Hu, National University of Singapore, 15 Kent Ridge Drive, Mochtar Riady Building, BIZ1 8-69, Singapore, 119245, Singapore, bizhuz@nus.edu.sg, Javad Nasiry

Behavioral pricing and revenue management aims to incorporate realistic consumer behavior into firms' pricing and inventory models. The key input to these models is market demand, which is often assumed to inherit the characteristics of consumer behavior—as when, for example, one assumes that a market consisting of loss-averse consumers is more responsive to losses than to gains. The empirical evidences on loss-sensitive demand, however, are frustratingly mixed. We offer one explanation on why gain-sensitive demand and loss-averse consumers can coexist by accounting for the heterogeneity in consumer valuation and examine its implication on firm's optimal pricing policies.

4 - Loss Aversion and Uniform Pricing: Are they Related?
Ningyuan Chen, Hong Kong University of Science and Technology, Clear Water Bay, Kowloon, Hong Kong, nychen@ust.hk, Javad Nasiry

We study the optimality of price markdowns when consumers are loss averse. We show that even if the overall demand function is more sensitive to losses than to gains, the firm may find it optimal to offer periodic discounts to maximize its profits.

Health Care, Modeling and Optimization

Contributed Session

Chair: Liqun Lu, University of Illinois at Urbana-Champaign, Urbana, IL, United States, liqunlu2@illinois.edu

1 - Evidence Based Optimal Control Method with Heuristic in Clinical Treatment
Kaiming Bi, PhD Student, Kansas State University, 2061 Rathbone Hall, 1701 D.Platt St., Manhattan, KS, 66502, United States, bikaiming@ksu.edu, John C.Wu, Yuyang Chen

In real disease clinic dynamic system, both the system or measurment errors are inevitable, thus it is necessary to consider it into treatment strategy. This research addresses a general problem with considering uncertain errors in disease system, since the traditional control methods frequently is not able to provide precise control strategies for disease treatments or medigation when uncertain errors are involved. A new Evidence Based Optimal Control approach is presented combining both traditional optimal control and machine learning methods. Four machine learning algorithms were tested and the most suitable approach were then combined with the traditional optimal control.

2 - Improving Out-of-hospital Response Time with a Dynamic Ambulance Relocation Model: the Case of Emergency Medical Services in Antofagasta, Chile
Hernan Caceres, Assistant Professor, Universidad Catolica del Norte, Avenida Angamos 0610, Antofagasta, 1270709, Chile, hcaceres@ucn.cl, Carlos Olivos, Rajan Batta, Qing He

In this research, we focus on the problem of locating ambulances to improve out-of-hospital response time, and thus, survival rates. The emergency medical service in Antofagasta keeps its ambulances at their bases, and the effectiveness of their location has not been assessed. We developed a dynamic relocation model that considers stochastic demand dependent on the time of day, the day of the week, traffic and emergency type. Mathematical formulations for this problem are developed and analyzed. Results from a case study along with algorithmic computational results will be presented.

3 - Nonlinear Optimization for Nonparametric Image Segmentation
Maduka R. Balasooriya, Southern Illinois University-Edwardsville, Box 1653, Edwardsville, IL, 62026, United States, mbalaso@siue.edu, Sinan Onal, Xin W. Chen

Precise object boundary detection for automatic image segmentation is critical for image analysis. However, such detection traditionally uses model and model-free based approaches requiring selection of optimal parameters. Identifying optimal parameter values requires time-consuming multiple runs and provides results that vary by user expertise. We are proposing a nonparametric model, in which the problem is formulated as a nonlinear program and solved using brute force search technique. The proposed model can be applied to any image datasets without using any preprocessing steps.

4 - Epidemic Control with Targeted Screening Policy
Liqun Lu, University of Illinois at Urbana-Champaign, 205 N.Mathews Ave., Urbana, IL, 61801, United States, liqunlu2@illinois.edu, Yanfeng Ouyang

Contagious diseases always pose threats to human society, and high social connectivity in the modern era further exacerbates epidemic propagation. This study establishes a modelling framework to describe epidemic dynamics in a multi-group social network, and then proposes and optimizes a control strategy to mitigate disease propagation via targeted screening. The effectiveness of such a control policy is demonstrated with numerical examples.

Additive Manufacturing I

Invited: Advanced Manufacturing

Invited Session

Chair: Qiang Huang, University of Southern California, Los Angeles, CA, 90089, United States, qiang.huang@usc.edu

1 - Predictive Model Building Across Different Process Conditions and Shapes in 3D Printing
Arman Sabbaghi, Assistant Professor, Purdue University, 150 N. University Street, West Lafayette, IN, 47907, United States, sabbaghi@purdue.edu, Qiang Huang

Predictive deformation models constitute an important component in quality control for 3D printing. However, model building is made difficult by the wide variety of process conditions and shapes. A methodology that can make full use of data on different shapes and conditions is necessary. We develop a new Bayesian procedure based on effect equivalence and modular deformation features that incorporates all data for the systematic construction of deformation models. Our method is applied to model the multiple deformation profiles in cylinders with different cavities. Ultimately, our Bayesian approach unifies quality control in 3D printing across different process conditions and shapes.

2 - A Convolution Formulation to Learn Complex Inter-layer Bonding Effects in Additive Manufacturing
Qiang Huang, University of Southern California, Dept of Industrial & Systemes Engineering, 3715 Mcclintock Avenue, Ger 240, Los Angeles, CA, 90089, United States, qiang.huang@usc.edu, Yuan Jin, Zhengyu Zhang

In the lay-to-layer Additive manufacturing (AM) processes, there is insufficient understanding of interactions among layers and its effect on geometry deformation. This study establishes a convolution formation to analyze the interlayer interactions through learning from experimental data.

3 - Quality Monitoring and Control in Additive Manufacturing for Metal Products
Bianca Maria Colosimo, Professor, Politecnico di Milano, Milano, Italy, biancamaria.colosimo@polimi.it

This contribution describes quality issues in metal additive manufacturing. Possible strategies for in-situ monitoring and process control are presented.

Financial Incentives and Health System Performance

Sponsored: Public Sector OR

Sponsored Session

Chair: Dimitrios Andritsos, Paris, France, andritsos@hec.fr

1 - Incentive Programs for Reducing Readmissions when Patient Care is Co-produced
Dimitrios Andritsos, HEC Paris, Departement MOSI, 1 Rue De La Liberation, Jouy-en-Josas, 78351, France, andritsos@hec.fr, Christopher S. Tang

To compare the effectiveness of three different hospital reimbursement schemes (i.e., Fee-for-Service, Pay-for-Performance and Bundled Payment) in reducing readmissions, we develop a "health co-production" model in which the patient's readmission is "jointly controlled" by the efforts exerted by both the hospital and the patient.

2 - Something from Nothing: Financial, Operational, and Social Benefits of Need-based Free Healthcare
Vikrant Vaze, Dartmouth College, 14 Engineering Drive, Murdough Center, Hanover, NH, 03755, United States, vikrant.s.vaze@dartmouth.edu, Srinagesh Gavirneni, Omkar D. Palsule-Desai, Sobhan Asian

Need-based free healthcare is an emerging business model that is delivering greater social benefits concurrently with higher financial gains due to its underlying innovative operational, marketing, and philanthropic features. Using Aravind Eye Hospital in India as the setting, we evaluate the role of operational learning, spill-over effects of marketing, and customer segmentation in enabling the success of this philosophy that is increasingly attractive in communities with rampant inequality commonly found in developing countries.

3 - The Business of Healthcare: Physician Integration in Bundled Payments

Turgay Ayer, Georgia Institute of Technology, School of Industrial and Systems Engineering, Groseclose 417, Atlanta, GA, 30332, United States, ayer@isye.gatech.edu, Jan Vlachy, Mehmet U.S. Ayvaci, Srinivasan Raghunathan

Under the prevailing fee-for-service payments, incentives of hospitals and physicians are misaligned, leading to large inefficiencies. Bundled payments unify payments to the hospital and physicians and are expected to encourage care coordination and reduce costs. However, as hospitals differ in their relationships with physicians in influencing care level of physician integration, it remains unclear what spectrum of physician integration will facilitate bundling. We study (1) the impact of the level of integration between the hospital and physicians in the uptake of bundled payments, (2) the consequences of bundling with respect to overall care quality and costs/savings.

4 - Hospital Quality, Medical Charge Variation, and Operational Performance: Implications for Bundled Payment Reform Models

Seokjun Youn, Texas A&M.University, 320 Wehner Building, 4217 Texas A&M.University, College Station, TX, 77840-4217, United States, syoun@mays.tamu.edu, Gregory R. Heim, Subodha Kumar, Chelliah Sriskandarajah

The premise of a bundled payment is to aggregate a number of care delivery services around an episode of care, and to set a priori reimbursement irrespective of actual cost. As such, the bundled payment aims to concomitantly "decrease variability," resulting in reduced and predictable costs. However, a fundamental question, whether the lower variability in practice can leads to better operational performances, is unexplored. We tackle this issue preceded by measuring practice variation based on fee-for-service medical charges of inpatients in NY and FL. We provide implications for designing incentives of bundled payment programs.

Pro Bono Analytics

Sponsored: Public Sector OR

Sponsored Session

1 - Pro Bono Analytics Panel Session

David T. Hunt, Oliver Wyman, One University Square, Suite 100, Princeton, NJ, 08540, United States, david.hunt@oliverwyman.com

Pro Bono Analytics (PBA) is an INFORMS program to match analytics professionals who are willing to volunteer their skills with nonprofit organizations that would benefit from analytical techniques. This panel session will begin with a brief description of some actual PBA projects, and will then focus on a discussion by volunteers and nonprofit representatives about the experiences and challenges of introducing analytics solutions into nonprofit organizations. The discussion will include defining the project outcome, overcoming data problems, and implementing the project results.

2 - Panelist

Vineet Madasseri Payyappalli, University at Buffalo, 38 Embassy Square Apt 7, Tonawanda, NY, 14150, United States, vineet.mp86@gmail.com

JFIG Paper Competition I

Sponsored: Junior Faculty JFIG

Sponsored Session

Chair: Jose Luis Walteros, University at Buffalo, SUNY, 413 Bell Hall, Buffalo, NY, 14260, United States, josewalt@buffalo.edu

1 - JFIG Paper Competition I

Jose Luis Walteros, University at Buffalo, SUNY, 413 Bell Hall, Bu, NY, 14260, United States, josewalt@buffalo.edu

The 2017 JFIG paper competition features paper submissions from a diverse array of talented junior faculty members. The prize committee evaluated submissions based on the importance of the topic, appropriateness of the approach, and significance of the contribution. After careful review, the prize committee selected a group of finalists to present their research in one of the two JFIG sessions. For information on the finalists and their papers, please refer to the online program.

2 - Optimal Signaling Mechanisms in Unobservable Queues

David Lingenbrink, Cornell University, Ithaca, NY, United States, d.lingenbrink@gmail.com, Krishnamurthy Iyer

We consider the problem of optimal information sharing in the context of a service system. In particular, we consider an unobservable single server queue offering service at a fixed price to a Poisson arrival of delay-sensitive customers. The service provider can observe the queue, and may share information about the state of the queue with each arriving customer. The customers are Bayesian and strategic, and incorporate any information provided by the service provider into their beliefs about the queue size before deciding whether to join the queue or leave without obtaining service. We pose the following question: which signaling mechanism should the service provider adopt to maximize her revenue? We establish that, in general, the optimal signaling mechanism requires the service provider to strategically conceal information from the customers to incentivize them to join. In particular, we show that a signaling mechanism with two signals and a threshold structure is optimal. Furthermore, for the case of linear waiting costs, we obtain analytical expressions for the thresholds of the optimal signaling mechanism. Finally, we prove that the optimal signaling mechanism under the optimal fixed price can achieve the revenue of the optimal state-dependent pricing mechanism. This suggests that in settings where state-dependent pricing is not feasible, the service provider can effectively use optimal signaling to achieve the optimal revenue. Our work contributes to the literature on Bayesian persuasion in dynamic settings, and provides many interesting directions for extensions.

3 - Optimization of Tree Ensembles

Velibor Misic, UCLA Anderson School of Management, 110 Westwood Plaza, Suite B406, Los Angeles, CA, 90095, United States, velibor.v.misic@gmail.com

Tree ensemble models such as random forests and boosted trees are among the most widely used and practically successful predictive models in applied machine learning and business analytics. Although such models have been used to make predictions based on exogenous, uncontrollable independent variables, they are increasingly being used to make predictions where the independent variables are controllable and are also decision variables. In this paper, we study the problem of tree ensemble optimiza- tion: given a tree ensemble that predicts some dependent variable using controllable independent variables, how should we set these variables so as to maximize the pre- dicted value? We formulate the problem as a mixed-integer optimization problem. We theoretically examine the strength of our formulation and exploit the structure of the problem to develop two large-scale solution methods, one based on Benders decom- position and one based on iteratively generating tree split constraints. We test our methodology on a real data set in the domain of drug design, where we show that our methodology can efficiently solve large-scale instances to near or full optimality and outperforms solutions obtained by heuristic approaches. Moreover, specific to the drug design context, our approach can be used to efficiently identify candidate compounds that optimally trade-off predicted performance and novelty with respect to existing, known compounds.

Project Management 2

Invited: Project Management and Scheduling

Invited Session

Chair: Vera Tilson, University of Rochester, Rochester, NY, 14627, United States, Vera.Tilson@simon.rochester.edu

1 - Project Scheduling under the Threat of Disruption

Joseph Szmerekovsky, North Dakota State University, NDSU. Dept 2420, P.O. Box 6050, Fargo, ND, 58108-6050, United States, Joseph.Szmerekovsky@ndsu.edu, Prahalad Venkateshan, Peter D. Simonson

The problem of scheduling a project under the threat of disruption is studied. Objectives include expected net present value, maximum possible loss at a give time, and minimum possible loss at a given time. Mathematical programming formulations and complexity results are presented. Railcar and roadrunner strategies are investigated.

2 - Markovian Pert Networks: New CTMC and Benchmark Results

Stefan Creemers, IESEG School of Management, Rue de la digue 3, Lille, 59000, France, sc@cromso.com

Stefan Creemers, KU. Leuven, Leuven, Belgium, sc@cromso.com

Markovian PERT networks were first studied by Kulkarni and Adlakha (1986), who use a CTMC to determine the exact distribution of the completion time of a project where activities have exponentially-distributed durations. All existing work on Markovian PERT networks adopts the CTMC of Kulkarni and Adlakha (1986). We define a new CTMC that drastically reduces memory requirements. Our CTMC can be used to develop scheduling procedures for a wide variety of problems. We outperform the current state-of-the-art in optimal project scheduling procedures, and are able to solve instances of the PSPLIB J90 and J120 data sets.

3 - A Mixed-integer Linear Programming Formulation of the RCPSP Based on Explicit Assignment and Sequencing Decisions

Norbert Trautmann, University of Bern, FM Quantitative Methoden, Bern, 3012, Switzerland, norbert.trautmann@pqm.unibe.ch, Tom Rihm

The resource-constrained project-scheduling problem RCPSP consists in determining start times for a set of precedence-interrelated activities that require time and scarce resources during execution such that the project makespan is minimized. We present a novel MIP formulation of the RCPSP which is based on explicit assignment and sequencing decisions. The computational results indicate that the novel formulation outperforms two state-of-the-art models known from the literature in particular when the resource capacities are very scarce.

Sponsored Session

Chair: Yingda Lu, Rensselaer Polytechnic Institute, Rensselaer Polytechnic Institute, Troy, NY, 12180, United States, luy6@rpi.edu

1 - Informative or Emotional? Examining the Spillover Effect of Online Video Ads

Liang Zhao, Rensselaer Polytechnic Institute, Troy, NY, United States, zhaol11@rpi.edu, Yingda Lu, Chaoqun Deng

In this study we examine the mechanism of spillover among online ads in the context of Youtube.com. We use the Super Bowl videos on YouTube in 2016 and investigate the role of informative and emotional elements in these ads in spillover process. We propose that there are short term as well as long term spillover among online video clips, and informative and emotional elements have different impact on these two types of spillover mechanism. Implications for researchers and managers will be discussed.

2 - Gender Differences in Equity Crowdfunding

Mingfeng Lin, University of Arizona, 1130 E. Helen St, Tucson, AZ, 85721, United States, mingfeng@eller.arizona.edu

This paper studies gender biases and differences in the context of online equity crowdfunding, using proprietary data from a leading platform.

3 - Innovation, Innovation Spillover and Economic Growth: Evidence from China

Bob Liao, Peking University, Beijing, China, bobliaobo@gmail.com, Fei Ren

This paper specifically investigates the innovation spillover phenomenon, which refers to the inter-regional mutual influence through innovation investment. Based on conventional spatial econometric model, our research verifies the existence of innovation spillover effect in the context of China's institution. Further, we extend the classical Cobb-Douglas productivity function and figure out the economic consequence from innovation spillover. As suggested by our empirical result, we can firmly conclude that a region's innovation investment can stimulate others' innovation input but innovation spillover plays a significant negative role in the economic growth.

Behavioral Aspects of Managing Innovation

Sponsored: Behavioral Operations Management

Sponsored Session

Chair: Stephen Leider, University of Michigan, Ann Arbor, MI, 48109, United States, leider@umich.edu

Co-Chair: Evgeny Kagan, Ann Arbor, MI, 48103, United States, ekagan@umich.edu

1 - Designing Incentives in Startup Teams: Form and Timing of Equity Contract

Evgeny Kagan, University of Michigan, 701 Tappan Ave, Ross School of Business, Office R5425, Ann Arbor, MI, 48103, United States, ekagan@umich.edu, Stephen Leider, William S.Lovejoy

The conventional logic in the entrepreneurial press is that equal division of startup equity encourages free riding among the founders. Our experimental results confirm the link between equal splits and depressed effort, but suggest a different causal sequence relative to the conventional wisdom. Rather than the contract form being the primitive and the behavior the derived consequence, our results suggest the reverse. The differences in contract performance are driven primarily by the sorting of high contributors into non-equal contracts and of low contributors into equal contracts. However, delaying the contracting mitigates these sorting effects reducing the effort gap between contracts.

2 - Institutional Designand the Creative Process: An Experimental Study

Vish Krishnan, University of California-San Diego, Rady School of Management MC0553, Otterson Hall, La Jolla, CA, 92093-0553, United States, krishnan@alum.mit.edu, Lakshminarayana Nittala, Sanjiv Erat

The process of Innovation often takes the form of problem solving and requires creative insights for achieving success. In an experimental setting we use tasks that are representative of such problems and study the role of institutional design on the creative output and the underlying search process.

3 - Leaps in Innovation

Joel Wooten, University of South Carolina, 1014 Greene St., Columbia, SC, 29208, United States, joel.wooten@moore.sc.edu

Search over a landscape of possibilities is central to innovation contest solution generation. Using 25,898 distinct attempts at innovation for a set of Kaggle contests, we look at how agents respond to both incremental and discontinuous progress.

4 - Motivating Innovation: the Effect of Loss Aversion on the Willingness to Persist

Yaroslav Rosokha, Purdue University, 403 W. State Street, Room 410, West Lafayette, IN, 47907, United States, yaroslav.rosokha@gmail.com, Kenneth Younge

We investigate the willingness of individuals to persist at exploration in the face of failure. Prior research suggests that a "tolerance for failure" may motivate individuals to select more exploratory courses of action. Little is known, however, about how individuals persist at exploration when confronted by prolonged periods of negative feedback. To examine this question, we design a two-dimensional maze game to capture the essential trade-offs between exploration and exploitation, develop predictions for the game using computational models of reinforcement learning, and run a series of randomized experiments with human subjects in the game.

Sustainable Travel Incentives

Sponsored: TSL, Urban Transportation

Sponsored Session

Chair: Bilge Atasoy, MIT, MIT, Cambridge, MA, 02139, United States, batasoy@mit.edu

1 - Reward Allocation for Maximizing Energy Saving in a Transportation System

Adewale Oduwole, University of Massachussets, Amherst, MA, 01002, United States, aoduwole@umass.edu, Song Gao, Hyoshin Park, Moshe Ben-Akiava

We study the optimal reward allocation problem to maximize energy saving in a transportation system. In the first version, no personalized menu optimization is considered. In the second version, a bi-level optimization problem is formulated where the high level optimization aims at maximizing system-wide energy saving, while a low-level consumer surplus maximization problem is solved for each user. Numerical tests are carried out study the effects of an array of system parameters, e.g., token budget and menu length, on the solutions. An array of parameterized token allocation strategies are proposed, and their performances against the optimal solution are investigated.

2 - Developing a Multi-scale and Multi-modal Agent-based Modeling Framework for Assessing Network-wide Energy/Fuel Consumption Impacts of Travel Incentive Strategies

Hesham Rakha, Professor of Civil and Environmental Engineering, Virginia Polytechnic Institute and State University, Blacksburg, VA, 24061, United States, hrakha@vt.edu

This presentation will describe the various building blocks of the PARC and VTTI's proposed modeling tool, that include: (a) traveler behavior modeling; (b) modeling of train dynamics; (c) agent-based modeling of driver and vehicle longitudinal and lateral movement; (d) modeling of multi-modal energy/fuel consumption (light duty gasoline vehicles, electric vehicles, plugin hybrid electric vehicles, trucks, Compressed Natural Gas (CNG) buses, and electric trains); (e) integration of microscopic and mesoscopic traffic modeling into a fully-integrated multi-scale multi-modal agent-based modeler.

3 - The COPTER System: An Overview and Preliminary Testing in the Greater LA Area

Matthew Klenk, PARC, 3333 Coyote Hill Rd, Palo Alto, CA, 94304, United States, Matthew.Klenk@parc.com

COPTER identifies the energy-efficient routes most likely to be adopted by a traveler. The COPTER project brings together expertise in behavioral modeling and analytics algorithms to understand travel needs of users, their constraints, and how likely they are to respond to suggested travel options. In this talk, we describe our approach, the key design decisions of the system, and our interactions with the city of Los Angeles and commercial entities around fielding the technology.

4 - Personalized Menu Optimization for an Incentivized Smart Mobility Solution

Bilge Atasoy, MIT, 77 Massachusetts Avenue, MIT.1-180, Cambridge, MA, 02139, United States, batasoy@mit.edu, Xiang Song, Mazen Danaf, Moshe Ben-Akiva

We present a personalized menu optimization model for an app-based travel incentive system, Tripod. For each traveler arriving to the system, a customized set of options are presented based on the preferences of the traveler in real-time. The preferences are updated as the traveler performs new trips through an MCMC procedure. Therefore, the personalized menu is based on the most up to date behavioral update. Incentives are allocated based on the guidance from a system optimization model that minimizes network wide energy consumption. Different formulations are evaluated under different scenarios in order to show the added value of personalized nature of the model and the updated preferences.

5 - incenTrip: A Real-Time Personalized Information and Incentivization Tool as a Smart-Mobility Solution

Chenfeng Xiong, University of Maryland-College Park, 149 Westway, Apartment 201, Greenbelt, MD, 20770, United States, cxiong@umd.edu, Lei Zhang

Different types of incentives in the transportation systems have recently drawn increasing attention to form smart-mobility solutions. Instead of using presumed and fixed amount of incentives, we develop an integrated, personalized and real-time traveler information and incentive technology, incenTrip, to incentivize more energy efficient travel, such as eco-driving, flex-time departures, and ride-sharing. Available in Android and iOS systems, incenTrip smartphone app provides precise and predictive traffic information, coupled with personalized and pro-social incentives, to help its users make smarter travel decisions. Driven by a computationally efficient agent-based modeling system modeling, incenTrip technology simulates the entire transportation systems in real-time and employs artificial-intelligence algorithms to predict the traffic evolution. This online modeling leverages real-time transportation big-data streams supplied by one of the biggest transportation data warehouses in the U.S., the Regional Integrated Transportation Information System (RITIS), hosted at the University of Maryland. Then a control optimization system is developed based on behavior research, travel intent prediction, and incentive optimization, in order to provide optimized incentives and route/departure time guidance.

Digital Markets and Platforms

Sponsored: Information Systems

Sponsored Session

Chair: Yan Huang, University of Michigan, yphuang@umich.edu

1 - Data-driven Promotion Planning for Mobile Applications

Manqi Li, University of Michigan, 710 Tappan Avenue, Ann Arbor, MI, 48105, United States, manqili@umich.edu, Yan Huang, Amitabh Sinha

The mobile app market is one of the fastest growing markets. In this work, we propose a two-step analytical approach to optimize the price promotion strategy for mobile apps. In the first step, we empirically estimate the immediate and long-term effects of price promotions on app download volume. The estimation results reveal two interesting characteristics: (1) promotion effect; and (2)visibility effect. Based on the estimated download function, we then formulate a longest-path problem to solve for optimal policy. The resulting optimal promotion strategy makes the best use of visibility effect and significantly increases developers' long-term revenue compared with their current practice.

2 - Linking Clicks to Bricks: Estimating Causal Effects of Email Ads on Offline Sales

Mi Zhou, Carnegie Mellon University, 4800 Forbes Ave, Pittsburgh, PA, 15213, United States, mzhou1@andrew.cmu.edu, Vibhanshu Abhishek, Ritwik Sinha, Nikos Vlassis

Online advertising market is soaring and has attracted the attention of many researchers. However, research in this area has almost entirely focused on consumers' online behaviors and has not incorporated their decision-making in the offline setting, which may lead to incomplete understanding of online advertising effectiveness in today's multi-channel world. In this paper, we use a Big Data which links consumers' online behaviors to their purchase records offline, and find that email ads have non-linear positive effects on offline sales. Further, we use a supervised Machine Learning method to estimate heterogeneous effects of email ads in different subpopulations partitioned by causal trees.

3 - The Centre Cannot Hold: Fragmentation in Multisided Markets

Abhishek Roy, University of Texas-Austin, 2110 Speedway Stop B6500, Austin, TX, 78712-1277, United States, abhishek.roy@utexas.edu, Edward G. Anderson, Geoffrey Parker

Existing literature on multi-sided markets, or platforms, examine the effect of opening up the platform to third-party developers on the platform sponsor. However, in some cases, opening up of certain aspects of a platform results in a fragmented platform that causes negative externalities on other third-party developers or sellers. We develop a model to analyze the effect of such fragmentation in the context of mobile operating systems, where the device side of the ecosystem is opened up, on the application developers, and in turn, on the platform itself.

4 - Ad-Blockers, Advertisers & Internet - Economic Implications of Ad Blocking

Abhishek Ray, Purdue University, 401S, Grant Street, West Lafayette, IN, 47907, United States, ray52@purdue.edu, Hossein Ghasemkhani, Karthik Kannan

The rise of ad-blockers as two-sided platforms has prompted discussions on whether ad-blockers are good for the online ecosystem. Considering the structure of interactions among the end-users, ad-blockers charge advertisers membership fees for certifying quality of their ads (whitelisting) and letting them through, but are free for the users. Our main research question is to study this mechanism and investigate whether it is optimal. Using a game-theoretic model using which we provide answers to questions such as which side (user or advertiser) should be charged by the ad-blocker, the impact of optimal price structure on end-user participation and overall implications for ad quality online.

Recent Innovations in Last-Mile Urban Deliveries

Sponsored: TSL, Urban Transportation

Sponsored Session

Chair: Bo Zou, University of Illinois, Chicago, IL, 60607, United States, bzou@uic.edu

1 - Designing Mechanisms for Efficient Crowdsourced Urban Parcel Delivery

Bo Zou, University of Illinois at Chicago, 2073 Engineering Research Facility, 842 W. Taylor Street, Chicago, IL, 60607, United States, bzou@uic.edu, Nabin Kafle

This paper presents a mechanism design based approach to crowdshipping. A Delivery Service Provider solicits private information from individuals such as willingness-to-ship and available time window, based on which to assign shipments with minimum total shipping cost. The mechanisms recognize that individuals can misreport private information to gain self-interest, and devise joint shipment assignment-payment schemes to incentivize truthful participation of individuals. Both static and dynamic cases are investigated. Numerical results with a case study of the near north side of Chicago demonstrate the cost advantage of the mechanisms over the state-of-the-practice crowdshipping.

2 - Crowdshipping Consolidation in Urban Logistics

Jane Lin, University of Illinois-Chicago, 842 W. Taylor Street (M/C 246), Chicago, IL, 60607, United States, janelin@uic.edu, Sudheer Ballare

Crowdshipping involves making use of everyday individuals with spare time and capacity to fulfill the variable delivery demand generated by e-commerce. This study performs preliminary investigation of an existing crowdsourcing delivery company with respect to the operational factors such as package size, delivery distance, demand frequency and distribution, the user characteristics including customer and driver profiles, and the pricing model. We further investigate the opportunities of consolidating crowdshipping tasks to further reduce cost and environmental impact. The findings will shed light on the market demand trending and growth opportunities in crowdsourcing deliveries.

3 - Reliability and the Edge of Vulnerability in Crowdsourced Shipping

Alireza Ermagun, Post-doc, Northwestern University, 2145 Sheridan Rd, Evanston, IL, United States, Alireza.ermagun@northwestern.edu, Amanda Stathopoulos

This study introduces reliability indices to measure the vulnerability of crowd-shipping as an innovative urban delivery system. This is a critical matter in the start-up phase of crowd-shipping services, as failing in providing a reliable system discourages registered customers and dissuades other potential customers to use the service. The results are informative to understand the caveats of the system in detail and to implement effective policies to augment the reliability where it is needed and leverage the resources across the system.

4 - Multi-channel Network Planning

Vincent Karels, Eindhoven University of Technology, Eindhoven, Netherlands, V.C.G.Karels@tue.nl

Investigations are made on whether different channels (e-tail, detail and retail) can be better integrated in planning, scheduling and execution. Resources can be effectively shared over and within the three channels. A framework facilitating this integration, with an emphasis on routing, is introduced. This framework is subsequently applied on test- and real-life instances. From these instances it can be shown that integration leads to large benefits.

5 - Bidding, Accepting, and Delivering: On Performance Assessment of Crowd-shipping

Alireza Ermagun, Northwestern University, Evanston, IL, United States, alireza.ermagun@northwestern.edu, Amanda Stathopoulas

This study assesses the performance of crowd-shipping as an innovative urban delivery system. We develop a set of hazard-based duration models to explore socioeconomic, built-environment, and intra-system characteristics that describe the bidding, accepting, and delivering status of packages as a function of time. The results from a real crowdshipping market operating over two years are informative to design policies and incentives relating to prediction, pricing, or promotion for delivery performance, and thereby to improve the efficiency and acceptability of crowd-shipping systems.

Emerging Data Sources and Travel Demand Modeling II

Invited: TSL, Intelligent Transportation Systems (ITS)

Invited Session

Chair: Ali Arian, University of Arizona, 415 N Park Avenue, Tucson, AZ, 85719, United States, arian@email.arizona.edu

1 - Real Time Transportation Mode Detection with Wearable Devices and Neural Networks

Young-Ji Byon, Associate Professor, Khalifa University of Science Technology, 216F Al Saada St and Muroor Rd, P.O. Box 127788, Abu Dhabi, 127788, United Arab Emirates, youngji.byon@kustar.ac.ae, Chung-Suk Cho, Jun Su Ha, Heungjo An, Taeyeon Kim

For traffic monitoring purposes, Departments of Transportation collects data from various dedicated sensors and probe vehicles throughout the road networks. If the modes of transportation the users of smartphones are in can be determined, DOTs can collect mode-specific data from the users as if they are probes themselves. In general, a smartphone is embedded with an accelerometer and a GPS sensor. Emerging wearable devices can provide multiple streams of acceleration values that can enhance mode-detection performances. It is found that having access to acceleration values of multiple parts of the body of a traveler helps identifying the modes

2 - Community Detection with Similar and Dissimilar Travel Activity Patterns

Ali Arian, University of Arizona, 415 N. Park Avenue, Tucson, AZ, 85719, United States, arian@email.arizona.edu, Alireza Ermagun, Yi-Chang Chiu

This research introduces a model to detect communities benefiting from the similarities and dissimilarities in the activity patterns of individuals based on an activity-network. We test a set of community detection methods trip information of 438 individuals using an incentive-based mobility app, Metropia, over 300 days in Tucson, Arizona. The model is validated in predicting the carpooling behavior of users.

3 - Travel Behavior Classification with Social Networkand Deep Learning

Yu Cui, University at Buffalo, 204c Ketter Hall, 429-7333, SUNY Buffalo, NY, 14228, United States, ycui4@buffalo.edu, Qing He, Alireza Khani, Qian Wang

We build a social network for all travelers and employ community detection algorithm to cluster travelers based on the identified similarities of travel patterns. We further create an image of activity map from each traveler's activity matrix. Finally, a deep learning approach with convolutional neural network is employed to classify travelers into corresponding groups according to their activity maps.

4 - Passenger Behavior Analysis in Beijing Metro Network using AFC Data and Agent-based Simulation

Alireza Khani, University of Minnesota, Minneapolis, MN, United States, na, Kai Lu, Baoming Han

AFC data in Beijing metro system has both entry and exit time and location stamps for each passenger. This study based on Beijing AFC data, calibrates the parameters for trip chaining model with the statistical and cluster methods and finds out the passenger trip chain pattern in Beijing network.

1 - Optimization of a Supply Chain for the Production of Biofuel from Corn Stover

Hernan Chavez, University of Texas at San Antoni, San Antonio, TX, United States, chavezpaurhc@ornl.gov, Krystel Castillo-Villar, Erin Webb

Second generation biomass exhibits more variability on its physical properties than first generation. Hence, the quality of feedstock does not always meet the specifications demanded by the conversion processes. This research aims to quantify the cost of imperfect feedstock quality in a biomass-to-biorefinery supply chain (SC) and to develop a model that supports the tactical decisions related to the design and execution of operations that have relevant effects on the physical properties of the biomass. The proposed simulation-based optimization model is based on an extension from the Integrated Biomass Supply and Logistics (IBSAL) simulation model. We present a case study in Ontario, Canada.

2 - Discrete Rate Simulation of Combine Harvester Operations

David Krahl, Kromite LLC, 243 N.Union Street, Lambertville, NJ, 08530, United States, dkrahl@kromite.com

A combine harvester is a moving factory. As the combine moves through a field harvesting grain, one or more external carts transfer the grain from the harvester's internal buffer storage to a roadside semi-trailer. An ExtendSim model will be presented that uses discrete-rate simulation for the process of harvesting grain, filling the combine's internal storage, and transferring the storage to the carts, and discrete-event simulation to represent the availability of carts. The goal of the model is to balance the desired operation of the combine with the number of carts.

3 - Smart Farming: Howthe Internet-of-Things will Spark a Data Revolution in Agriculture

Jay Ham, Colorado State University, Ft. Collins, CO, United States, jay.ham@colostate.edu

The Internet of Things (IoT) is rapidly migrating onto the farm and food supply chain. New sensor technology coupled with improved connectivity in rural areas (LoRa, cellular gateways) will stream farm data to the cloud at unprecedented rates. This presentation will highlight Ag-IoT projects at Colorado State University and show how innovations in data science are needed to fully profit from the coming revolution in Ag technology.

Sponsored Session

Chair: Chaithanya Bandi, Northwestern University, 2001 Sheridan Rd, 566, Evanston, IL, 60208, United States, c-bandi@kellogg.northwestern.edu

1 - Machine Learning Based Robust Optimization Models for Limit Order Books to Predict Price Movements

Chaithanya Bandi, Northwestern University, 2001 Sheridan Rd, 566, Evanston, IL, 60208, United States, c-bandi@kellogg.northwestern.edu

This paper develops a machine learning based robust optimization model to estimate structure of limit order books. The new architecture yields a low-dimensional model of price movements deep into the limit order book, allowing more effective use of information from deep in the limit order book (i.e., many levels beyond the best bid and best ask). Due to its more effective use of information deep in the limit order book, the spatial neural network especially outperforms the standard neural network in the tail of the distribution, which is important for risk management applications.Our data-driven approach offers new benefits for practical applications.

2 - Machine Learning and Portfolio Optimization

Gah-Yi Ban, London Business School, Regent's Park, London, NW1 4SA, United Kingdom, gban@london.edu, Noureddine El Karoui, Andrew Lim

We adapt two machine learning methods, regularization and cross-validation, for portfolio optimization. We introduce performance-based regularization (PBR), where the idea is to constrain the sample variances of the estimated portfolio risk and return, which steers the solution toward one associated with less estimation error in the performance. We show that the PBR models can be cast as robust optimization problems with novel uncertainty sets and establish asymptotic optimality of PBR solutions. We find PBR dominates all other benchmarks for two out of three Fama-French data sets where parameters are calibrated using a new, performance-based k-fold cross-validation algorithm.

3 - Interpreting Neural Networks

Enguerrand Horel, Stanford University, Stanford, CA, United States, ehorel@stanford.edu, Kay Giesecke

Although neural networks can provide highly accurate predictions, they are often considered as opaque "black boxes". The difficulty of interpreting their predictions often prevents their use in financial practice, where regulators and auditors often insist on model explainability. In this project, we formulate the objectives of interpretability and define it for neural networks. We then consider the interplay between network architecture, identifiability, and interpretability. Considering neural networks as nonparametric models, we show how to use nonparametric variable significance tests to assess the importance of covariates. Tests using mortgage data illustrate our results.

Non-standard Applications of Location Methods

Sponsored: Location Analysis

Sponsored Session

Chair: Dmitry Krass, University of Toronto, University of Toronto, Toronto, ON, M5S 3E6, Canada, krass@rotman.utoronto.ca

1 - Online Grocery Retail and its Environmental Impact

Ekaterina Astashkina, INSEAD, Boulevard de Constance, Fontainebleau, 77305, France, ekaterina.astashkina@insead.edu, Elena Belavina, Simone Marinesi

We build a stylized model for traditional and online grocery retail chains to understand the drivers of the consumer and retailer carbon footprint, including emissions that come from food waste and transportation. In our model, consumers make endogenous choices between different channels and the associated food-buying policies, while retailers optimally manage their inventory replenishment. We find that, in most cases, the availability of an online retailer reduces the emissions associated with the grocery sector in a city. We also consider the effectiveness of alternate policy instruments including sales and carbon taxes, and identify actions that improve the behavior of the worst offenders.

2 - Competitive Store Location Models Considering Comparison-shopping

Vladimir Marianov, Professor, Pontificia Universidad Catolica de Chile, Department of Electrical Engineering, Vicuna Mackenna 4860, Santiago, 782-0436, Chile, marianov@ing.puc.cl, H.A. Eiselt, Armin Lüer-Villagra

Consumers' behavior strongly influences the location patterns of retail stores. In competitive settings, firms locate their stores to take advantage of this behavior to maximize their market share. A common behavior is comparison-shopping, by which consumers visit more than one store selling products that are mutual substitutes, before making their purchase decision. We include comparison-shopping into competitive facility location models, and compare the obtained results with those of current models.

3 - Optimal Scheduling of Bridge Maintenance using Geometric Brownian Motion Process

Tsuyoshi Nobata, Tokyo University of Tokyo, Ce-408, 4-6-1, Komaba, Tokyo, Japan, t-nobata@iis.u-tokyo.ac.jp, Yudai Honma

It is well known that there are many studies using Markov chain model in considering uncertainty in bridge asset management. However, there are only a few studies that consider the degradation process of bridges as a continuous model. In addition, considering the scheduling on multiple bridges is very important. In this paper, we propose a degradation model using the geometric Brownian motion and formulate a scheduling strategy for inspection and repair of multiple bridges.

4 - Understanding the Impact of Complexity on Facility Location
Mozart Batista de Castro Menezes, Kedge Business School - Bordeaux, Office: 1449, Talence, 33405, France, mozart.menezes@me.com, Diego Ruiz-Hernandez

Facility location problems are well known problems in the combinatorial optimization field of study, where the objective is to minimize the cost incurred to serve customer from a set of facilities. Our study brings to the field of facility location the concept of operations complexity, opening up a new research line within the field. When defining facility location one should aim not only to reduce operational costs but also to keep complexity in what we call complexity comfort range in which tactical and operational decisions are at their bests. The preliminary (empirical) results suggest that ignoring complexity matters may hurt that same bottom line that the locational problem is trying to improve.

Enhanced Estimation and Sampling in Multi-model Setting

Sponsored: Simulation

Sponsored Session

Chair: Giulia Pedrielli, Arizona State University, Tempe, AZ, 85281, United States, giulia.pedrielli.85@gmail.com

1 - Stratification in Debiased Multi-level Monte Carlo
Zeyu Zheng, Stanford University, CA, United States, zyzheng@stanford.edu, Peter W. Glynn

It has long been known, when dealing with a finite partition, that stratification can yield significant variance reductions. To apply this idea to debiased multi-level Monte Carlo (MLMC), we extend the framework to infinitely many strata. While new mathematical issues arise in the infinitely stratified setting, we are still able to develop a central limit theorem in this context that permits the construction of asymptotically valid confidence intervals. Furthermore, we suggest and theoretically justify sequential stopping procedures for such estimators that allow for easy recursive updating. This work is joint with Peter Glynn.

2 - Efficient Simulation Sampling Allocation using Multi-fidelity Models
Yijie Peng, George Mason University, VA, United States, pengy10@fudan.edu.cn, Jie Xu, Loo Hay Lee, Jian-Qiang Hu, Chun-Hung Chen

We present a new framework that integrates information from multi-fidelity models to increase computational efficiency for selecting the best high-fidelity systems. A Gaussian mixture model is proposed to capture important information contained in low-fidelity models that might not accurately approximate the performance of the high-fidelity simulation model. Posterior information obtained by Gaussian mixture model-based clustering analysis incorporates both cluster-wise information and idiosyncratic information for each design. A new budget allocation method is proposed to efficiently allocate high-fidelity simulation replications, utilizing posterior information.

3 - Parallel Simulation for Transportation Networks
Feliza Vazquez-Abad, CUNY, New York, NY, United States, felisav@hunter.cuny.edu

For simulation of a large public transportation network, we propose an accelerated method using nearly decomposable Markov Chains. This allows parallelization of the simulation, thus achieving great improvement in efficiency. The Kemeny constant is a measure of the strength of links for the stationary Markov chain. Its derivative an be used to assess the sensitivity of individual transitions (in the stationary operation). Using this information, we can decompose a Markov chain into smaller classes approximating the stationary regime. Each class is assigned a processor for simulation, but statistical corrections have to added in order for the parallel simulation to provide good estimates.

Location Analysis

Sponsored: Transportation Science & Logistics

Sponsored Session

Chair: Noor Alam, Northeastern University, md.alam@northeastern.edu

1 - Modeling Interdependent Transportation and Power Systems under Dynamic Supercharging Demand of Electric Vehicles
Liqun Lu, University of Illinois at Urbana-Champaign, 205 N.Mathews Ave., Urbana, IL, 61801, United States, liqunlu2@illinois.edu, Yanfeng Ouyang

With an increasing number of electric vehicles (EVs) and supercharging stations, the daily power load profile is experiencing a noticeable reshape caused by travel demand in the transportation network. This study proposes a modeling framework to find a market equilibrium between EV users and power generators under dynamic travel demand. It is shown that traffic flow on transportation network and electricity loads/generations in power grids have mutual impacts via EV users' routing decisions.

2 - An Algorithms to Measure Distance Between Irregular Regions
Ruilin Ouyang, Northeastern University, Boston, MA, United States, ouyang.ru@husky.neu.edu, Dinghao Ma, md.noor.e.alam

This talk will present an algorithm to measure distance between two irregular shapes regions used for location analysis.

3 - Datacenter Location Allocation Models
MD Noor. E. Alam, Northeastern University, 334 Snell Engineering Center, 360 Huntington Avenue, Boston, MA, MA 02115, United States, md.alam@neu.edu, Tasnim Ibn Faiz

A Datacenter facilitates high volume online transactions. Its location, capacity and configuration decisions are driven by customer demand volume, latency and uptime requirements respectively. An MILP model is presented that provides optimal decisions for meeting customer demand with required service levels. A second MILP model is presented to meet replication demand associated with each customer. A two-stage decision algorithm is proposed for making global optimal decisions by solving two models sequentially. Numerical results show that the models are scalable and the algorithm is efficient.

Joint Session MIF/HAS: Decision Making in Healthcare

Sponsored: Minority Issues

Sponsored Session

Chair: Shannon Harris, The Ohio State University, Columbus, OH, 43212-3085, United States, harris.2572@osu.edu

1 - Emergency Department Capacity Planning and Scheduling Decisions within a Large Multi-facility Network

Krista Foster, University of Pittsburgh, 1622 Beechwood Boulevard, Apt 1, Pittsburgh, PA, 15217, United States, kmf88@pitt.edu, Jennifer S.Shang

The growing trend of emergency department (ED) consolidation in the US has intensified the complexity of managing emergency physicians. Large-scale physician groups are simultaneously challenged with capacity planning and scheduling decisions across many facilities. We propose a model to optimally staff facilities throughout the network with emergency physicians and advanced practice providers.

2 - The Benefit of Waiting: A Bayesian MDP to Evaluate Mode of Delivery

Karen T. Hicklin, University of North Carolina at Chapel Hill, 308 Bynum Hall, Chapel Hill, NC, 27599, United States, khicklin@email.unc.edu, Julie Simmons Ivy

Optimal mode of delivery decisions lead to better short- and long-term health outcomes for mothers and children. When a woman enters labor, she will either have vaginal or cesarean delivery. However, at the onset of labor, the delivery outcome is unknown. Patients who have slow or stalled labor progression are considered failure-to-progress thus leading to the need for a C-section. In this model formulation, we combine Bayesian updating into a Markov decision process to determine under what circumstances it is appropriate to gather more information before making a decision regarding mode of delivery as a function of cervical dilation progression and patient type (i.e., failure-to-progress or not).

3 - Standardized Patient Mentoring Program for Kidney Transplant Patients

Yeojun Chun, The Ohio State University, 4438 Mobile Dr #306, Columbus, OH, 43220, United States, chun.159@osu.edu

Approximately 1 in 3 post-transplant kidney recipients are readmitted to the hospital within 30 days of initial discharge. Patient anxiety and lack of adherence to post-transplant discharge instructions contribute to readmission rates. To minimize patient anxiety and occurrence of preventable readmissions, a standardized patient mentoring program was designed and tested in a randomized controlled experiment. Standardization focused on the interactions specific to post-transplant adherence to the medical regimen. Preliminary analysis of the first two months of data will be shared.

City Logistics Advances

Sponsored: TSL, Freight Transportation & Logistics

Sponsored Session

Chair: Tom Van Woensel, Eindhoven University of Technology, Eindhoven University of Technology, Mb Eindhoven, NL5600, Netherlands, t.v.woensel@tue.nl

1 - Coordinated Delivery to Nanostores in Traditional Retail Channel

Ruidian Song, Tsinghua University, Tsinghua University, Beijing, China, srd13@mails.tsinghua.edu.cn, Lei Zhao, Tom Van Woensel, Jan C.Fransoo

Tens of thousands of traditional mom-and-pop grocery stores (nanostores) aggregately remain a major retail channel in megacities in emerging economies. However, these independently operated stores also create a large amount of high frequency, small size, and uncoordinated replenishment orders. We model, study, and compare various coordination strategies to delivery to these stores and study the impact of delivery coordination.

2 - The Pickup and Delivery Problem with Transfers

Lucas Petrus Veelenturf, Eindhoven University of Technology, School of Industial Engineering (PAV.F.12), P.O. Box 513, Eindhoven, 5600 MB, Netherlands, l.p.veelenturf@tue.nl, Afonso Henrique Sampaio Oliveira, Martin W. P.Savelsbergh, Tom Van Woensel

In this research we include transfer opportunities in the pickup and delivery problem with time windows to construct more cost-effective and robust transportation plans. Transfer points are locations in the network where requests can be transferred between vehicles and temporarily stored. Hence, more than one vehicle can be used to serve a request, e.g., a request may be picked up at its origin by one vehicle, then dropped off at a transfer point where another vehicle (with other characteristics) will pick it up and drop it off at its destination. The introduction of transfer opportunities allows serving more requests with a given set of vehicles and/or serving a given set of requests with fewer vehicles.

3 - Business-to-consumer E-commerce: Home Delivery in Megacities

Martin W. P.Savelsbergh, Georgia Institute of Technology, School of Industrial and Systems Engineering, Atlanta, GA, 30332-0205, United States, martin.savelsbergh@isye.gatech.edu, Lei Zhao, Yixiao Huang

We study the design and deployment of two-echelon logistics systems for home delivery in megacities. We show that by restricting the set of potential routes deployed in one or both of the echelons, it is possible to significantly reduce the complexity of the delivery operations without sacrificing performance.

4 - An Exact Solution Approach for the Multi-commodity Two-echelon Vehicle Routing Problem with Time Windows

Tom Van Woensel, Eindhoven University of Technology, Industrial Engineering, Den Dolech 2, Pav F08, Mb Eindhoven, NL5600, Netherlands, t.v.woensel@tue.nl

The two-echelon vehicle routing problem (2E-VRP) is a two-echelon distribution system where goods are transferred to customers by using intermediate facilities (called satellites). We take non-substitutable demands into account by introducing commodities: a commodity consists of the destination customer, origin depot, a specific volume, and a time window which the delivery should take place within. The described problem is referred as the multi-commodity two-echelon vehicle routing problem with time windows (MC-2E-VRPTW). Numerical results are presented.

Energy and Climate 4

Invited: Energy and Climate

Invited Session

Chair: Peter Larsen, Lawrence Berkeley National Laboratory, PHLarsen@lbl.gov

1 - Sequencing Distributed and Central Power Supply in Systems with Low Electricity Access and Low Reliability: An Application of the GAP Model

Juan Pablo Carvallo, University of California-Berkeley, CA, United States, jpcarvallo@lbl.gov, Daniel Kammen, Duncan Callaway

Over 1.1 billion people do not have access to electricity, 600 million in Africa alone. We develop a novel and spatially explicit approach to jointly assess the sequencing and pacing of centralized, distributed, and off-grid electrification strategies. We develop and employ the linear program and network optimizer Grid Access and Planning (GAP) model. Contrary to existing results, we find that optimal electrification strategies involve co-existence of grid and off-grid technologies. We assess the impact of several variables in defining the strategy and suggest policy frameworks for their implementation.

2 - Impact of High Variable Renewable Energy Penetrations on Demand and Supply Side Decisions

Andrew Mills, Lawrence Berkeley National Laboratory, CA, United States, admills@lbl.gov

Many long-lasting decisions for supply- and demand side electricity infrastructure and programs are made based on historical observations or assuming a business-as-usual (BAU) future. As the share of variable renewable energy (VRE) increases, however, fundamental characteristics of the power system will change. Decisions related to the supply of or demand for electricity made based on an assumed BAU future may not achieve their intended objective in a high VRE future. We highlight how the potential shift to high VRE futures can impact wholesale prices in ways that should be considered in decisions related to long-lasting supply- and demand-side electricity infrastructure and programs.

3 - Scenarios with and with out Overshoot for End of Century Climate Goals

Felipe A. Feijoo, Pacific Northwest National Laboratory, 5825 University Research Court, Suite 3500, College Park, MD, 20740, United States, felipe.feijoo@pnnl.gov

Over 3000 scenarios for global temperature over the 21st century were generated by a single integrated assessment model (GCAM) to explore pathways that either do not exceed a global average temperature target or reach that target in 2100. All scenarios reached above 1.8 C in 2050. Temperature pathways from present to 2045 were found to be less sensitive to climate policy assumptions (carbon price in GCAM) than uncertainty in Earth system modeling. Following 2045 pathway diverge to reach in 2100 from just 0.75 C to 3.5 C (reference case) in 2100 (1.5 to 3.5 C when CCS is excluded).

4 - Quantifying the Contribution of Water and Environmental Management to the Economies of Developing Countries

Brent Boehlert, Industrial Economics, Inc., Cambridge, MA, United States, bboehlert@indecon.com

Brent Boehlert, Massachusetts Institute of Technology, Cambridge, MA, United States, bboehlert@indecon.com, Kenneth M. Strzepek, Kenneth M. Strzepek, James Thurlow

Most developing countries face increasing challenges to management of water and environmental resources. To ensure these resources are sustainably managed, it is important to clearly articulate their contribution to economic growth and development. We present a modeling framework that evaluates the macroeconomic implications of investments in water and environmental resources through a series of impact channels that link biophysical model outputs to an economy-wide model. For illustration, we focus on the case of the Ugandan economy, and find that enhanced investment in management of these resources can increase per capita GDP by 9% in 2040.

Joint session DM/QSR: Process Monitoring for Diverse Types of Data

Sponsored: Data Mining

Sponsored Session

Chair: Youngseon Jeong, China, youngseonjeong@gmail.com

Co-Chair: Behnam Tavakkol, Rutgers University, 5200 BPO Way, Piscataway, NJ, 08854, United States, btavakkol66@gmail.com

1 - Detection Method of Abnormal Condition in Fabrication Process using Wafer Gradient Vector Based on Semiconductor EDS Chip Data

Dongkyu Jeon, Samsung Electronics, 1, Samsungjeonja-ro, Hwaseong-si, 18448, Korea, Republic of, jdkclub85@gmail.com, BokYoung Kang, ByongHun Cho, Jung-Chan Ahn, ChiYong An, Kil Soo Kim, Seung Hoon Tong

In general, abnormal condition detection in a Fabrication process uses wafer-level representative statistics summarizing EDS (Electrical Die Sorting) data that exist in each semiconductor chip unit. However, this conventional method has a limitation in that the numerical discrimination power of the wafer defects in a specific area decreases in the statistical summarization process. In this research, we propose a methodology to detect abnormal condition in fabrication process through Density based Clustering Algorithm using Wafer Gradient Vector based on EDS chip data. In addition, we verified the proposed algorithm through real-life cases.

2 - Online Bayesian Learning Process Monitoring and Control

Sangahn Kim, Rutgers University, 1050 George St. Apt. 6B, New Brunswick, NJ, 08901, United States, sk1389@scarletmail.rutgers.edu, Myong Kee Jeong, Elsayed Elsayed

Conventional statistical process control and monitoring methodologies in Phase II commonly assume that the parameters obtained in Phase I are fixed over time and sufficient to test whether the process is normal or out of control. However, as new observations become available in Phase II, they are incorporated in monitoring as prior knowledge through a Bayesian framework and the parameters obtained in Phase I are continuously updated. In this presentation, we introduce a new process control scheme in which we update the prior distribution at every sampling point. A Bayesian hierarchical model enables us to apply the proposed method in monitoring of high-dimensional processes with sparse mean shifts.

3 - Clustering Validity Indices for Uncertain Data Objects

Behnam Tavakkol, Rutgers University, 5200 BPO.Way, Piscataway, NJ, 08854, United States, btavakkol66@gmail.com, Myong Kee Jeong, Susan L.Albin

In cluster analysis, clustering validity indices are the main tools of evaluating the quality of the formed clusters. In this study, we develop a few clustering validity indices for a type of data objects known as uncertain data. Uncertain data objects can be considered as probability density functions or samples of observations. To our best knowledge, in the existing literature, there is not any clustering validity index for uncertain data.

4 - A Low-Rank Multivariate General Linear Model for Multi-Subject fMRI Data and a Non-Convex Optimization Algorithm for Brain Response Comparison

Minh Pham, University of Virginia, 1555 Montessori Terrace, Charlottesville, VA, 22911, United States, mtp9b@eservices.virginia.edu, Tingting Zhang

The focus of this talk is on identifying brain regions with different responses using stimulus-evoked functional magnetic resonance imaging (fMRI) data. To jointly model many brain voxels' responses to designed stimuli, we present a new low-rank multivariate general linear model for stimulus-evoked fMRI data. We show that the proposed method can outperform several existing voxel-wise methods by achieving both high sensitivity and specificity. We apply the proposed method to the fMRI data and identify anterior dACC to have different responses to a designed threat and control stimuli.

5 - Group Classification Methods for SAR Imagery Data

Mariya Naumova, Rutgers University, 640 Bartholomes Road, Piscataway, NJ, 08854, United States, mnaumova@rci.rutgers.edu

Given a finite number of learning samples from several populations (groups) and a collection of samples from the union of these populations, we classify the entire collection (not a single sample) to one of the groups. Such problems often arise in medical, chemical, biological and technical diagnostics, classification of signals, etc. We consider different parametric statistical methods of solving the problem and make comparison of their quality based on numerical results. We give an illustrative example with SAR imagery data to demonstrate the effectiveness of the classification methods.

Data Mining in Churn Decision Analytics

Sponsored: Data Mining

Sponsored Session

Chair: Roy Jafari Marandi, Mississippi State University, rj746@msstate.edu

1 - A New Algorithm for Segmented Modeling: An Application in Customer Churn Prediction

Arno De Caigny, IÉSEG School of Management, France, a.de-caigny@ieseg.fr, Kristof Coussement, Koen W. De Bock

Heterogeneity between customers poses a challenge for churn prediction models. Therefore a new algorithm, the logit leaf model, has been developed to better classify data that is characterized by heterogeneous groups. Logit leaf modeling consists of two stages: a segmentation phase and a prediction phase. In the first stage customer segments are identified using decision rules while in the second stage a model is created for every leaf of this tree. This approach is benchmarked against ensembles, statistical approaches and decision trees with regards to the predictive performance and comprehensibility.

2 - Churn Prediction in Telecommunication: Sampling, Feature Selection and Ensemble Methods

Adnan Idris, The University of Poonch, Rawalakot, District Poonch, Pakistan, adnanidris@upr.edu.pk

Efficient churn prediction is helpful for Telecommunication industry to retain customers. Development of any efficient churn prediction system depends upon the appropriate selection of sampling, feature selection and classification methods due to enormous nature of telecom datasets. In this bid, various feature selection, sampling and classification methods have been explored to efficiently tackle this challenging research problem. Minimum Redundancy and Maximum Relevancy based feature extraction, PSO based intelligent undersampling along with tree based ensembles ,Genetic Programming(GP) and AdaBoosting based ensemble methods attain improved prediction performance.

3 - Profit Driven Comparison of Social Network Analytics Methods for Predicting Customer Churn in TELCO

María Óskarsdóttir, KU. Leuven, Naamsestraat 69, Leuven, Belgium, maria.oskarsdottir@kuleuven.be

Social network analysis is being used in telco to build profit driven applications for predicting customer churn. In this benchmarking study, a unique number of call-detail record data sets from across the world is used to statistically evaluate the effect of relational classifiers and collective inference methods on the predictive power of relational learners. In addition, using the Expected Maximum Profit measure, we evaluate the performance of various models where relational learners are combined with traditional methods of predicting customer churn in order to find the optimal model.

4 - Customer Decision Making Dynamics in a Multichannel Context

Wenyu Jiao, ESSEC Business School, Cergy, France, wenyu.jiao@essec.edu, Nicolas Glady

This paper aims at understanding the purchase channel dynamic on the customer-firm relationship and the Customer Lifetime Value(CLV). To this purpose, we address two important research questions in a multichannel context: (i) how does the customers' channel usage history dynamically impact the components of the CLV, and (ii) are the multichannel customers who start from offline channels and those who start from online channels equally valuable? We propose a hidden Markov model to understand the customer-firm relationship dynamic in a multichannel setting and to estimate the CLV. Our dynamic model is necessary in order to account for the evolution of customer behavior across different states.

5 - Optimum Churn Decision Making by Cost-sensitive SOED ANN in Telecommunication Industry

Roy Jafari Marandi, Mississippi State University, 260 McCain Engineering Buildin, Mississippi, Mississippi State, MS, 39762, United States, rj746@msstate.edu, Brian K. Smi

Churn prediction can only be as good as the hidden pattern in the dataset used for prediction. Attempting to captures the individuality of each customer before arriving at a prediction decision can bring about another dimension in the improvement of churn prediction decisions. The existing data analysis techniques only extract different patterns existing in datasets and apply them to all of the rows of the data in the same manner. In reality, every row is very different and have a different level of importance when it comes to making a final decision. This presentation will introduce Cost-Sensitive SOED Artificial Neural Network which has assuaged these shortcomings.

Facility Layout

Sponsored: TSL, Facility Logistics

Sponsored Session

Chair: Sadan Kulturel-Konak, Penn State Berks, Reading, PA, 19610, United States, sadan@psu.edu

1 - Are Curved Racks Better than Straight Racks for Retail Layouts?

Pratik J. Parikh, Wright State University, 3640 Colonel Glenn Highway, 207 Russ Engineering Center, Dayton, OH, 45435-0001, United States, pratik.parikh@wright.edu, Bradley R. Guthrie

Because retail shopper's will only purchase products on a shopping trip that they see, designing retail layouts with product visibility as a key priority has been widely discussed in literature. To this extent, we have developed analytical and computational models for the dynamic interaction between a shopper's field of view and a layout of racks in 3D. We focus on two design variables: (i) rack orientation and (ii) rack curvature. Based on an experimental study with varying values of shopper head rotation, rack height, and traffic patterns, we find that curved racks can offer an improvement in exposure over traditional straight racks.

2 - Placement of M Finite-size Rectangular Facilities in an Existing Layout: Lower Bounds and Dominance Results

Rakesh Nagi, University of Illinois at Urbana-Champaign, Department of Industrial & Enterprise Systems, 117 Transportation Building, MC-238, Urbana, IL, 61801, United States, nagi@illinois.edu, Aishwarya Anandan, Ketan Date

We study the problem of optimally placing M new finite size rectangular facilities (NFs) in a layout with N existing rectangular facilities (EFs). Interactions are present between different pairs of EFs and NFs, serviced through the Input/output points located on the facility boundary. We present a dominance procedure utilizing different lower bounding techniques, which is shown to outperform the explicit enumeration procedure.

3 - Dynamic Facility Layout with Input / Output Points

Sadan Kulturel-Konak, Penn State Berks, Tulpehocken Road, P.O. Box 7009, Reading, PA, 19610, United States, sadan@psu.edu

When the locations of the departments in a facility have to be decided where there are multiple planning periods and the interdepartmental material flows change over the planning periods, the problem in concern is called the Dynamic Facility Layout Problem (DFLP). The main challenge in the DFLP is that there are two conflicting objectives of the problem: minimizing the material handling cost and the rearrangement cost. The proposed approach, a new matheuristic, considers determining relative department locations, their dimensions, as well as input/output (I/O) points concurrently for the first time in the literature.

4 - Optimal Unit Load Warehouse Designs by using Visibility Graph

Sabahattin Gokhan Ozden, Pennsylvania State University, Jenkintown, PA, 19046, United States, sgo7@psu.edu, Alice E. Smith, Kevin R. Gue

We introduce the visibility graph as a new way of estimating the length of a route traveled by order pickers in a warehouse. Following aisle centers leads to longer travel distances when an order picker picks items within picking aisles which have angles other than 90 degrees between cross aisles. We present optimal/near-optimal designs by solving single and double cross aisle designs. We compare them with the optimal designs by using aisle centers as the length of a route estimation method (i.e. Chevron and Leaf layouts).

1 - A Flexible Method for Building Degradation Index from Multivariate Degradation Signals
Yili Hong, Virginia Tech, 213 Hutcheson Hall, Department of Statistics, Blacksburg, VA, 24061, United States, yilihong@vt.edu, Zhongnan Jin, Zhiyang Zhang, Xinwei Deng, Ran Jin, Sam Davanloo Tajbakhsh

Most of the existing research on degradation modeling assumes that the degradation index is provided. Modern sensor technology allows one to collect multi-channel sensor data that are related to the underlying degradation process, which may not be sufficiently represented by any single channel. Thus, constructing a degradation index is a fundamental step in degradation modeling. In this paper, we develop a general approach for degradation index building based on an additive-nonlinear model with variable selection. The approach is more flexible than a linear combination of sensor signals, and it can automatically select the most informative variables to be used in the degradation index.

2 - A Predictive Analytic Methodology via Modeling High-dimensional Signals with Missing Observations
Xiaolei Fang, Georgia Institute of Technology, 1546 Woodlake Dr NE, Apt F, Atlanta, GA, 30329, United States, xfang33@gatech.edu, Kamran Paynabar, Nagi Gebraeel

Many complex engineering systems operate in harsh environments that often have a significant impact on the quality of the raw sensor data due to errors in data acquisition, communication, read/write operations, etc. Consequently, the resulting degradation signals often contain significant levels of missing and corrupt observations. In this talk, we present a scalable prognostic methodology capable of modeling poor quality (ultra)high-dimensional degradation signals to predict residual lifetime. Numeric studies are used to evaluate the performance of the proposed model.

3 - Detecting and Locating Pipe Burst with Spatial and Temporal Analysis
Yifei Yuan, University of Arizona, Tucson, AZ, United States, yifeiyuan@email.arizona.edu, Jian Liu, Kevin Lansey

A pipe burst is a major water distribution system failure and will result in lower water pressures at customer taps. A large number of meters are usually installed in the pipe systems to continuously monitor the water pressure, from spatially distributed locations. The data collected from these meters forms a spatial and temporal information stream. In this research, a spatio-temporal data analysis method is proposed to effectively and efficiently detect and locate the pipe burst. A simulation based case study was conducted to validate the method.

4 - Neighborhood Vector Autoregressive Model for High-dimensional Time Series
Shyam Ranganathan, Department of Statistics, Virginia Tech, Blacksburg, VA, United States, shyam81@vt.edu, Xinwei Deng

Vector autoregression (VAR) models are popular for studying multiple dependent timeseries, with broad applications in analyzing sensor data, imaging data, and network data. One key challenge for VAR models in high dimensions is on how to insightfully explore the inherent dependency in the data to enable meaningful interpretation, and accurate prediction. To tackle this challenge, we present a neighborhood VAR model to explore meaningful sparse structures induced by underlying interactions among multiple time series, thus achieving accurate prediction with low computational cost. Numerical examples are shown to evaluate the performance of the proposed method.

Big Data

Contributed Session

Chair: Iman Vasheghani Farahani, North Carolina State University, Raleigh, NC, United States, ivasheg@ncsu.edu

1 - Application of a Novel Nonlinear Support Vector Machine Based Feature Selection Algorithm for Fault Detection & Diagnosis
Melis Onel, Texas A&M.Energy Institute, College Station, TX, United States, melis@tamu.edu, Chris A.Kieslich, Yannis A. Guzman, Christodoulos A. Floudas, Efstratios N. Pistikopoulos

We present a new data-driven framework for fault detection and diagnosis, a critical task in industry processes to attain a safe operability and minimize loss of productivity and profit. Central to the framework are novel theoretical and algorithmic developments in nonlinear support vector machine (SVM)-based feature selection which encapsulates highly nonlinear relationships between features, thus improving fault detection model accuracy and guiding fault diagnosis. We present results of a recent extensive benchmark dataset consisting 90,400 batches with numerous and diverse fault types.

2 - Energy Optimization in Water and Wastewater Cycle
Ali Reza Asadi, PhD Candidate, Wayne State University, 4815 Fourth Street, Room 2033, Detroit, MI, 48201, United States, ali.asadi@wayne.edu

Implementation of big data techniques in the water/wastewater treatment cycle provide grounds for minimization of overall energy consumption as well as improvements in food and water safety. This methodology allows consideration of new threats such as water reservoir pollution, microorganisms and antibiotics resistance in to the optimization model.

3 - Estimating an Inverse Mean Subspace
Jiaying Weng, Graduate Student, University of Kentucky, 300 Alumni Drive, Apt 179, Lexington, KY, 40503, United States, jiaying.weng@uky.edu, Yin Xiangrong

We develop a new sufficient dimension reduction method called Fourier transformation inverse regression to capture the directions in the central subspace. Under linearity condition, the space spanned by Fourier transformation inverse regression would be in the central subspace. By forming a kernel matrix using Fourier transformation, we construct asymptotic dimensional test via weighted chi-squared distribution. Our new method performs better than existing methods in the simulation study and real data analysis. In addition, we further develop our new method for variable selection and for large p and small n problems.

4 - An Investigation into Online Video Sharing as a Source of Consumer Safety Hazard Reports
Leila Nasri, Virginia Tech, Blacksburg, VA, United States, leilan@vt.edu, Alan S. Abrahams, Johnathon P. Ehsani

This study focuses on online video-based product reviews as possible sources to detect safety hazard issues. Reviewing over 15,000 possible product reviews from YouTube, we show that the set of smoke words are a more accurate predictor of safety hazards in video-based product reviews than sentiment words.

5 - Time Series Classification using Normalized Subsequences
Iman Vasheghani Farahani, North Carolina State University, 400 Daniels Hall, Raleigh, NC, 27695-7906, United States, ivasheg@ncsu.edu
Iman Vasheghani Farahani, SAS.Institute Inc, 100 SAS.Campus Dr, Cary, NC, 27513, United States, ivasheg@ncsu.edu, Alex Chien, Russell Edward King

In time series classification problems, finding normalized subsequences, whose distances from a time series indicates its label, requires a prior information on the length of the subsequence and a similarity measure between series. This may require a costly search be performed on the entire dataset. To address this problem, we examine the efficiency of data transformation using symbolic aggregate approximation. This transformation keeps the local structure of a time series, that enables us to find similar subsequences repeated in samples time series. We use decision trees classifiers and information gain as the criterion to grow the tree.

Journal of Global Optimization: INFORMS Issue

Sponsored: Optimization, Global Optimization

Sponsored Session

Chair: Sergiy Butenko, Texas A&M University, College Station, TX, 77843-3131, United States, butenko@tamu.edu

1 - Parallel Distributed Block Coordinate Descent Methods Based on Pairwise Comparison Oracle
Kota Matsui, Nagoya University, Nagoya, Japan, matsui.k@med.nagoya-u.ac.jp, Wataru Kumagai, Takafumi Kanamori

We present a block coordinate descent method to solve unconstrained optimization problems. Our algorithm uses only pairwise comparison of function values, which tells only the order of function values over two points. In our algorithm,a Newton-type search direction is estimated and then a numerical solution is updated along the direction. The computation in the direction estimate can be easily parallelized, and thus, the algorithm works efficiently. Also, we theoretically derive an upper bound of the convergence rate for our algorithm and show that it achieves the optimal query complexity for specific cases. In numerical experiments, we show that our method outperforms some existing methods.

2 - Geodesic and Contour Optimization using Conformal Mapping
Ricky Fok, York University, Toronto, ON, Canada, ricky.fok3@gmail.com, Aijun An, Xiaogang Wang

We devise the shadow casting scheme, in which global basins of attraction are mapped to a much larger space and recovered by a reverse mapping. Under certain criteria, the enlarged space can be as larger the search space. We also introduce a novel trajectory method that couples to the shadow casting scheme. Local search methods such as Newton-Ralphson are employed to find the global optimum. Experimental results indicate that our proposed method can outperform recent derivative-free DIRECT variants in number of function/gradient evaluations on functions with many optima or when the global optimum is very close to a local one.

3 - Igreen: Green Scheduling for Peak Demand Minimization
Shaojie Tang, TX, United States, Shaojie.Tang@utdallas.edu, Jing Yuan, Zhao Zhang, Ding-zhu Du

Home owners are typically charged differently when they consume power at different periods within a day. Specifically, they are charged more during peak periods. Thus, in this paper, we explore how scheduling algorithms can be designed to minimize the peak energy consumption of a group of homes served by the same substation. We study both offline and online models.

4 - Solving Linear Optimization Over Arithmetic Constraint Formula
Li Chen, Institute of Software, Chinese Academy of Sciences, Beijing, China, chenli@nfs.iscas.ac.cn, Yongji Wang

Since Balas extended linear programming problem to disjunctive programming (DP) problem, researchers explored this optimization under various scenarios such as generalized disjunctive programming (GDP) and optimization modulo theories (OMT). In this paper, we convert linear DP/GDP model and linear-arithmetic OMT problem into an equivalent form referred to as linear optimization over arithmetic constraint formula (LOACF). A branch-and-bound based algorithm named RS-LPT for LOACF is proposed. We evaluate RS-LPT against two DP/GDP methods, three OMT solvers, and disjunctive transformation based method on different benchmarks. Our results favor RS-LPT especially for large scale cases.

5 - Incorporation of Delivery Times in Stereotactic Radiosurgery Treatment Optimization
Dionne Aleman, University of Toronto, 5 King's College Road, Toronto, ON, M5S.3G8, Canada, aleman@mie.utoronto.ca, Hamid R.Ghaffari, David A.Jaffray, Mark Ruschin

Although mathematical optimization can greatly improve the quality of treatment plans in radiation therapy, one complication is the clinically unrealistic nature of optimized treatments. The difficulty arises from long treatment times and machine limitations that govern the minimum amount of radiation delivery time, which requires binary variables. We examine these issues within the penalty-based sector duration optimization (SDO) model for Elekta's Leksell Gamma Knife Perfexion and the combined SDO and isocentre location model to reduce beam-on time and to ensure machine limitations are met.

Network Flow Problems in Applications

Sponsored: Optimization, Network Optimization

Sponsored Session

Chair: Alexander Nikolaev, University at Buffalo, Buffalo, NY, 14260-2050, United States, anikolae@buffalo.edu

1 - Monotonicity and Conformality in Multicommodity Network-flow Problems
Frieda Granot, Sauder School of Business, Vancouver, BC, Canada, frieda.granot@sauder.ubc.ca

We present a monotonicity theory for the important class of minimum convex-cost parametric multicommodity network-flow problems defined over general graphs. The results determine when it is possible to predict, without numerical computations, the direction of change of optimal multicommodity flows resulting from changes in arc-commodity parameters. In particular, we provide necessary and sufficient conditions that for every cost function satisfying a submodularity-convexity-compactness hypothesis there exists an optimal multicommodity flow for which the flow of a commodity in a given arc a is nondecreasing (resp., nonincreasing) in the parameter of a distinct commodity in arc b.

2 - A Mesoscopic Model to Evaluate the Evacuation Dynamics in a University Campus
Jorge Huertas, Universidad de los Andes, Calle 115 No 55 C.- 54, Bogota, 11111, Colombia, ja.huertas1845@uniandes.edu.co, Jony A. Zambrrano, Andres Medaglia

In this work we integrate a macroscopic and a microscopic model to evaluate the evacuation dynamics in a university campus. The macroscopic approach is a network optimization model that determines the optimal evacuation paths. The microscopic model is a discrete event simulation that models the congestion on the paths determined by the first model. We propose an iterative process in which the output of one model is the input of the other one, achieving a convergence on the evacuation time. The result is a mesoscopic model that considers bottlenecks, direction of flows, speed fluctuations, and congestion during an evacuation. Finally, we compare our results with real evacuation exercises in the campus.

3 - Reach Maximization for Direct Incentive-Driven Pro-Environmental Social Programs
Alexander Nikolaev, University at Buffalo, 409 Bell Hall, Buffalo, NY, 14260-2050, United States, anikolae@buffalo.edu, Jose Walteros

While exploiting the power of network-based social influence for the societal benefit is a breakthrough in itself, further research is required to boost the impact of such programs with direct incentives. We present investigations into the design and planning of randomized incentive programs — social lotteries — that inform consumers of their peers behaving pro-environmentally while being rewarded for doing so. We conduct calculated maximization of the "reach" of such a program or policy, exploiting column generation in mixed-integer programming.

Emerging Computational Optimization Techniques

Sponsored: Computing

Sponsored Session

Chair: Chris Lourenco, Texas A&M University, clouren@tamu.edu

1 - Roundoff-Error-Free Framework for the Exact Solutions of Sparse Linear Systems

Christopher J.Lourenco, Texas A&M.University, Dept. of Industrial and Systems Engineering, 3131 Tamu, College Station, TX, 77843, United States, clouren@tamu.edu, Adolfo Raphael Escobedo, Erick Moreno-Centeno, Timothy A.Davis

LU factorizations are the key tool used to solve the sparse systems of linear equations that arise in many classes of mathematical programs. In many documented cases however, roundoff errors accrued during the implementation of these factorizations can cause solvers to output infeasible or suboptimal solutions, especially for numerically unstable instances. To address this, we developed an exact left-looking LU framework to solve sparse linear systems in which all operations are performed entirely in integer arithmetic. Also presented are computational results, which show that the novel left-looking LU framework significantly outperforms modern state-of-the art sparse exact solvers.

2 - Optimization for L1-norm Error Fitting via Data Aggregation

Young Woong Park, Iowa State University, Ames, IA, United States, ywpark@iastate.edu

We propose a data aggregation-based algorithm with monotonic convergence to a global optimum for a generalized version of the L1-norm error fitting model. The proposed algorithm can solve multi-dimensional fitting problems with arbitrary constraints on the fitting coefficients. Any model following the form can be solved optimally using the proposed algorithm. The generalized problem includes popular models such as regression, principal component analysis, and the orthogonal Procrustes problem. The results of the computational experiment show that the proposed algorithms are faster than the state-of-the-art benchmarks for the problems and data sets studied.

3 - Mining High-Quality Solutions to Learn Effective and Interpretable Heuristics

Michele Samorani, Santa Clara University, 500, El Camino Real, Santa Clara, CA, 95053, United States, msamorani@scu.edu, Manuel Laguna

We propose a method to automatically design effective and interpretable heuristic algorithms. Our method employs data mining to analyze the optimal solutions of a training set of problem instances. Then, it finds an interpretable rule that can be applied at each step of a constructive algorithm to tackle new instances. We test our method on a variety of binary optimization problems, such as the knapsack and the max-cut problems.

4 - Improved Basic Procedure for Chubanovs Algorithm

Carlos Deck, University of California-Berkeley, 2100 Channing Way, Apartment 316, Berkeley, CA, 94704, United States, cgdeck@berkeley.edu

This work improves Chubanov's projection algorithm for the linear feasibility problem of finding a non-negative vector in Ker(A). This is done by working in the original space of the x-variables instead of solving the alternative system. By changing the solution space, we can focus on solutions within the unit simplex instead of the unit hypercube, which strengthen the cuts provided by Chubanov and Roos. We show how to perform the rescaling in this setting, given that the feasible region is no longer homogeneous. Our computational experiments show a significant improvement compared to Chubanov and Roos' variants of this algorithm in practice.

1 - Proximal-proximal-gradient Method

Ernest Kang Ryu, UCLA, 10910 Wellworth Ave., Apt. 310, Los Angeles, CA, 90024, United States, ernestryu87@gmail.com

We present the proximal-proximal-gradient method (PPG), a novel optimization method that is simple to implement and simple to parallelize. PPG is applicable to minimization problems written as a sum of many differentiable and possibly non-differentiable convex functions. We furthermore present a related variation, which we call stochastic PPG (S-PPG). S-PPG can be interpreted as a generalization of Finito and MISO. We present many applications that can benefit from PPG and S-PPG and prove convergence for both methods. A key strength of S-PPG is its ability to directly handle a large sum of non-smooth non-separable functions with a constant stepsize independent of the number of functions.

2 - When Cyclic Coordinate Descent Outperforms Randomized Coordinate Descent

Nuri Denizcan Vanli, Graduate Student, Massachusetts Institute of Technology, Cambridge, MA, 02141, United States, denizcan@mit.edu, Mert Gurbuzbalaban, Asuman Ozdaglar

Coordinate Descent (CD) method is a classical optimization algorithm that has seen a revival of interest. The state-of-the-art convergence rate estimates suggest randomized coordinate descent (RCD) performs better than cyclic coordinate descent (CCD), although numerical experiments do not provide clear justification for this comparison. We provide problem classes for which CCD is faster than RCD in terms of asymptotic worst-case convergence. We present lower and upper bounds on the amount of improvement on the rate of CCD relative to RCD. We also provide a characterization of the best deterministic order in terms of the combinatorial properties of the Hessian matrix of the objective function.

3 - Multi-agent Constrained Optimization of a Strongly Convex Function over Time-varying Directed Networks

Erfan Yazdandoost Hamedani, Pennsylvania State University, 310 Leonard Building, Pennsylvania State University, University Park, PA, 16802, United States, evy5047@psu.edu, Necdet Serhat Aybat

We consider cooperative multi-agent consensus optimization problems over time-varying directed communication networks. The objective is to minimize the sum of agent-specific composite convex functions subject to agent-specific conic constraint sets. Assuming the sum function is strongly convex, we propose a distributed primal-dual algorithm, DPDA-TV. While each agent's function can still be merely convex, we provide O(1/k^2) convergence rates for suboptimality, infeasibility and consensus violation of the ergodic iterate sequence in the iteration number k where the k-th iteration of DPDA-TV requires O(log(k)) local communication rounds with the neighboring nodes.

4 - Zeroth Order Nonconvex Multi Agent Optimization

Davood Hajinezhad, Iowa State University, 62 B.Schilletter village, Ames, IA, 50010, United States, dhaji@iastate.edu, Mingyi Hong, Alfredo A.Garcia

We consider distributed optimization problems over a multi-agent network, where each agent can only partially evaluate the objective function, and it is allowed to exchange messages with its immediate neighbours. Differently from all existing works, our focus is given to optimizing a class of difficult non-convex problems, and under the challenging setting where each agent can only access the zeroth-order information of its local functions. For different types of network topologies, we develop a number of efficient distributed algorithms and rigorously analyze their convergence and rate of convergence.

Co-Chair: John W Chinneck, Carleton University, Systems and Computer Engineering, 1125 Colonel By Drive, Ottawa, ON, K1S 5B6, Canada, chinneck@sce.carleton.ca

1 - Fast Approximate Solution of Very Large Linear Programs

John W. Chinneck, Carleton University, Systems and Computer Engineering, 1125 Colonel By Drive, Ottawa, ON, K1S.5B6, Canada, chinneck@sce.carleton.ca

It can be useful to find an approximate solution quickly for huge linear programs, e.g. for screening options or providing an advanced start for an accurate solver. I present a method that optimizes a combined objective function that has a quadratic penalty term for constraint violations, a movement direction based on simultaneous projection and a quadratic approximation to the combined objective function. Initial points are scattered over a gradually shrinking box surrounding the current best solution. Empirical results show that the method often provides good approximate solutions in seconds for models which require hours of computation for an accurate solution via commercial LP solvers.

2 - High Performance Computing with GAMS

Frederik Fiand, GAMS.Software GmbH, Augustinusstr. 11b, Frechen-Koenigsdorf, Germany, ffiand@gams.com, Michael Bussieck

BEAM-ME is a project addressing the need for new and improved solution approaches for energy system models of vast size. The focus is on large-scale LPs having a block structure that is not well exploited by state-of-the-art LP solvers. Without considering this structure the models quickly become intractable. We develop new solution algorithms that exploit the block structure and utilize HPC environments. We discuss extensions to GAMS that allow annotations specifying block structure, as well as other challenges overcome to produce some initial results.

3 - Geometric Visualization of Linear Programming Algorithms

Robert J.Vanderbei, Princeton University, Operations Research & Financial Engineering, 209 Sherrerd Hall, Princeton, NJ, 08544, United States, rvdb@princeton.edu

Algorithms for linear programming can be described both algebraically and geometrically. While the geometrical view is highly compelling, it is hard to grasp in dimensions higher than three. In this talk, I will provide a geometric perspective to some optimization algorithms as they apply to problems that have thousands of variables but the stem from a physical problem in two or three dimensional space. Viewing the progression of these algorithms in this highly comprehensible low dimensional space provides some interesting insights into the nature of the various algorithms.

Analytic Hierachy Process

Contributed Session

Chair: Xiaojun (Gene) Shan, UHCL, Houston, TX, United States, shan@uhcl.edu

1 - Sustainable Public Administration

Yuji Sato, Professor, Chukyo University, 101 Yagotohonmach, Showa, Nagoya, Aichi, 466-8666, Japan, ysatoh@1988.jukuin.keio.ac.jp

This paper considers sustainable public administration. Based on the property of public services and the characteristic of public sector quantified by the AHP, the best matching between public services and their responsible organization will be considered, in which properties of each public service and characteristics of alternative sectors is quantified. The results imply the scheme of sustainable public administration.

2 - Comparing Traditional, Online and Hybrid MBA with Analytic Hierarchy Process

Xiaojun (Gene) Shan, University of Houston Clear Lake, Houston, TX, United States, shan@uhcl.edu, Saranya Sarika

This paper compares the different modes of instruction in the MBA class (traditional, online, and hybrid) with analytic hierarchy process. The important criteria for the comparison were identified based on literature review and then a survey was conducted to derive sub criteria considering the previous research as well as the students' opinions. The survey data was analyzed and was applied to the criteria and sub criteria. The best mode of MBA instruction was determined to be traditional teaching. This supports that though technology has developed beyond imagination, classroom teaching is still the best medium for a student to understand, participate and learn from the MBA class.

3 - Selection of Solid Waste Management Program for the University of Houston - Clear Lake using Analytic Hierarchy Process

Xiaojun (Gene) Shan, University of Houston Clear Lake, Houston, TX, United States, shan@uhcl.edu, Krishna Deep Kambhampati

As a university grows, there is an increase in waste generated on campus. If the waste is not properly disposed of, it could lead to health hazards for both humans and other lives and disrupt the ecosystem of the campus. Therefore, it is important for educational institutions to implement a Solid Waste Management (SWM) program. This paper studies the different kinds of SWM programs that are currently in use. The objective of this paper is to identify the best SWM practice suitable for the University of Houston Clear Lake (UHCL). To evaluate the different SWM practices, the Analytic Hierarchy Process (AHP) is used. The results show that waste reduction is the most appropriate SWM program for UHCL.

4 - Courier Delivery Services Company Selection using Analytical Hierarchy Process and Data Envelopment Analysis

Xiaojun (Gene) Shan, University of Houston Clear Lake, Houston, TX, 77058, United States, shan@uhcl.edu, Sindhuja Yerroju

Business owners face the challenge of choosing the best third-party logistics provider among many alternatives. This problem could be formulated as a multi-criteria decision making problem. In this study, we apply analytical hierarchy process (AHP) to select the best provider in terms of the types of services provided, the number of depots, and delivery mode. The results from the analytical hierarchy process are evaluated against the results of data envelopment analysis (DEA). In DEA, the various Decision Making Units (DMU's) are evaluated considering number of depots, number of employees and amount of equipment as inputs and revenue as an output.

5 - Using Analytical Hierarchy Process (AHP) to Select the Best Thermo Scientific Co2 Incubator

Xiaojun (Gene) Shan, UHCL, houston, TX, United States, shan@uhcl.edu, Juilee Shukla

Incubators are used in the tissue culturing laboratories to maintain a stable environment for the growth of cells, cultures and antibodies. Since incubators involve significant investment, it is important to select the best incubator for the purpose. The purpose of this study is to find the best incubator among the four Thermo Scientific CO2 Incubators, using Analytical Hierarchy Process (AHP) with five criteria. Each Incubator has its own range of precision to control the temperature suitable for tissue cell growth, humidity to maintain a stable environment, CO2 range to avoid the desiccation of the cells and the number of shelves, which signifies the storage volume available inside the incubator.

5:15 - 6:00 Lumina Decision Systems

Invited: Vendor Tutorial

Invited Session

1 - Why Go "Beyond the Spreadsheet" with Analytica 5.0?

Max Henrion, Lumina Decision Systems, Inc, Los Gatos, CA, United States, henrion@lumina.com

Practitioners of analytics and OR increasingly recognize spreadsheets as an obstacle to clear and scalable modeling. They are moving to visual modeling tools like Analytica using influence diagrams to structure models at the same level that you conceptualize them. You identify key decisions, uncertainties, objectives, and constraints. You define relationships between these objects, which may be multidimensional rather than at the level of cells. Analytica models are typically 10 to 100 times simpler than equivalent spreadsheets, and correspondingly faster to build, understand and audit. This tutorial is a rare chance to see Max Henrion, the originator of Analytica, using influence diagrams to structure a problem. He will demonstrate agile development, using Intelligent Arrays to scale models and integrate Monte Carlo simulation and optimization. Max will also show what's new in release 5.0 of Analytica, including an updated interface, parallel processing, and web deployment on the Analytica Cloud Player.

Multi-Item and Multi-Location Revenue Management Models II

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Candace Arai Yano, University of California-Berkeley, IEOR Department, 4141 Etcheverry Hall, Berkeley, CA, 94720-1777, United States, yano@ieor.berkeley.edu

1 - Managing Revenue via Inventory Allocation for a Multi-location Retailer with Planned Price Promotions

Kevin Li, University of California—Berkeley, Berkeley, CA, 94720, United States, kbl4ew@berkeley.edu, Candace Arai Yano

We address a retailer's choice of the initial order quantity from a distant supplier and the policy for allocating inventory to stores over a multi-period horizon for a short lifecycle product when there are planned price promotions. We characterize the optimal inventory allocation policy given a fixed initial order quantity and stochastic multiplicative demand and present a near-optimal heuristic policy. We then investigate the optimal initial order quantity. We also present examples that provide insights into how promotional patterns affect optimal inventory allocations.

2 - Optimal Pricing under Diffusion-choice Models

Hongmin Li, Arizona State University, WP.Carey School of Business, Dept of Supply Chain Management, Tempe, AZ, 85287, United States, hongmin.li@asu.edu

We develop a solution approach to the centralized pricing problem of a firm managing multiple substitutable products. Demands of these products undergo a diffusion process and customers choose among the products, with the choice probability of each product given by the logit model. We examine the firm's optimal pricing problem when product demand can be described by such "diffusion-choice" models. In particular, we focus on two models with proven merits, proposed by Jun and Park (1999) and Weerahandi and Dalal (1992) respectively. We establish the uniqueness of the optimal solution, propose an efficient solution approach, in addition to characterizing the optimal prices and their time trend.

3 - Car Rental Network Revenue Management

Zhan Pang, City University of Hong Kong, Hong Kong, zhan.pang@cityu.edu.hk, Dong Li

We consider a general car rental network of multiple stations. Customers can book round trips or one-way rentals from any station to another station for a time periods within a finite time window. The operator makes shuttling and booking limit decisions jointly to maximize its total discounted profit over an infinite horizon. We formulate this problem as a stochastic dynamic program and develop two approximate dynamic programming heuristics. We conduct a numerical study and apply our approach in case study using a sample of real world data to explore some practical insights.

Chance-Constrained Optimization and Applications

Sponsored: Optimization, Optimization Under Uncertainty

Sponsored Session

Chair: Ruiwei Jiang, University of Michigan, University of Michigan, Ann Arbor, MI, 48109, United States, ruiwei@umich.edu

1 - An Algorithm for Binary Chance Constrained Problems using Infeasible Irreducible Systems

Bernardo Kulnig Pagnoncelli, Universidad Adolfo Ibáñez, Diagonal Las Torres 2540, Santiago, Chile, Gianpiero Canessa, Lewis Ntaimo

We propose an algorithm based on Infeasible Irreducible Systems (IIS) to solve general binary chance-constrained problems. By leveraging on the problem structure we are able to generate good quality upper bounds to the optimal value early in the algorithm, and the discrete domain is used to guide us efficiently in the search of solutions. We test our methodology on instances of a vaccine problem, and in versions of the probabilistic set covering problem. In most cases the number of nodes visited by the algorithm is drastically reduced when compared to commercial solvers.

2 - Distributional Robust Chance-constrained Optimal Power Flow with Wasserstein Ambiguity Set

Yuanyuan Guo, University of Michigan, 1205 Beal Avenue, Ann Arbor, MI, 48109, United States, yuanyg@umich.edu, Ruiwei Jiang

The uncertain renewable energy creates new challenges for the power system operators to ensure network constraints. The chance-constrained program is a convenient method to ensure the constraints are satisfied with a high probability. However, it is hard to accurately estimate the joint distribution of all the random variables. We study a distributionally robust chance-constrained optimal power flow model with the Wasserstein ambiguity set, which can provide powerful out-of-sample performance guarantee. The model can be reformulated as a linear or a second-order cone programming depending on the choice of the Wasserstein metric. Our approach is compared with two benchmark approaches.

3 - An Adaptive Model with Joint Chance Constraints for a Hybrid Wind-Conventional Generator System

Bismark Singh, University of Texas at Austin, 2501 Lake Austin Blvd, Apt F203, Austin, TX, 78703, United States, bismark.singh@utexas.edu, David Morton, Surya Santoso

We analyze scheduling a hybrid wind-conventional generator system to make it dispatchable. Our models ensure that with high probability we satisfy the day-ahead power promised, using combined output of the conventional and wind generators. We consider two scenarios—whether the conventional generator must commit to its schedule prior to observing the wind or has flexibility to adapt in real-time to these realizations. The adaptive model is a two-stage stochastic integer program with joint chance constraints. We develop an iterative regularization scheme in which we solve a sequence of sample average approximations under a growing sample size to dramatically reduce computational effort.

4 - Ambiguous Chance-constrained Bin Packing under Mean-covariance Information

Ruiwei Jiang, University of Michigan, 1205 Beal Ave., Ann Arbor, MI, 48109, United States, ruiwei@umich.edu, Yiling Zhang, Siqian Shen

We study chance-constrained bin packing with random item weights and assume that only the mean and covariance matrix of the uncertainty is available. Using two types of ambiguity sets, we equivalently reformulate this model as 0-1 second-order cone (SOC) programs. We further exploit the submodularity of the 0-1 SOC constraints under special and general covariance matrices, and utilize the submodularity to derive extended polymatroid inequalities to strengthen the 0-1 SOC formulations. We demonstrate the computational efficacy of our approaches on various test instances.

Online Algorithms and Applications

Sponsored: Optimization, Optimization Under Uncertainty

Sponsored Session

Chair: Shashank Goyal, University of Minnesota, Minneapolis, MN, 55414, United States, goyal030@umn.edu

1 - Time-indexed Relaxations for the Online Bipartite Matching Problem

Alfredo Torrico, Georgia Institute of Technology, 201 16th Street NW, Apartment 1, Atlanta, GA, 30363, United States, atorrico3@gatech.edu, Alejandro Toriello

We study an i.i.d. model of the classical online bipartite matching problem, in which one side of the bipartition is fixed and known in advance, while vertices from the other side appear sequentially as i.i.d. realizations of a uniform distribution. Each one of these arrivals must be matched or discarded. We study several relaxations in a time-indexed space. We derive valid inequalities for the polyhedron of achievable matching probabilities, and discuss when they are facet-defining. In contrast to previous works, we show that our inequalities either theoretically dominate the constraints presented before, or provide empirically superior bounds.

2 - Online Covering with Norm Objectives and Applications

Xiangkun Shen, University of Michigan, Ann Arbor, MI, 48109, United States, xkshen@umich.edu, Viswanath Nagarajan

We consider fractional online covering problems with lq-norm objectives. The covering constraints arrive online over time. We provide an online log-competitive algorithm. This is based on the online primal-dual framework where we use the dual program. Our result expands the class of convex objectives that admit good online algorithms: prior results required a monotonicity condition on the objective which is not satisfied here. This result is nearly tight even for the linear special case. As direct applications, we obtain (i) improved online algorithms for non-uniform buy-at-bulk network design and (ii) the first online algorithm for throughput maximization under lq-norm edge capacities.

3 - Online Algorithms for Rental Requests

Shashank Goyal, University of Minnesota, 1071 17th Ave SE, Minneapolis, MN, 55414, United States, goyal030@umn.edu, Diwakar Gupta

Web platforms such as Airbnb and Craigslist provide individuals the ability to post availability of a resource they own and rent it to different customers for short periods of time. A customer can place a request with the owner, indicating the desired rental start time and duration. The owner must then decide whether to accept or decline the request. A key trade-off that the owner confronts is the reward he earns from the current request and the potential loss of reward from a higher-value future requests that may clash with the current one. We propose online algorithms for the problem that have provable worst-case performance and also present bounds on the best performance that any algorithm can achieve.

4 - Online Optimization of Google Ad-click Auctions

Donghun Lee, Princeton University, 9 Lawrence Drive, Apt 202, Princeton, NJ, 08540, United States, donghunl@princeton.edu, Warren B. Powell

We present online optimization framework to maximize the return of advertisement campaign through repeated real-time bidding auctions under budget constraints.

The framework learns the properties of the auction environment online, and makes on-the-fly optimization with optimal learning algorithms.

We test the performance of the framework by testing on real-time bidding auction simulator based on Google Adwords platform history of placing hotel advertisements on the web.

Chair: Jim R Luedtke, University of Wisconsin-Madison, Madison, WI, 53706, United States, jim.luedtke@wisc.edu

1 - Dual Decision Rules for Stochastic Integer Programming

Jim R.Luedtke, University of Wisconsin-Madison, 3236 Mechanical Engineering, 1513 University Ave, Madison, WI, 53706, United States, jim.luedtke@wisc.edu, Merve Bodur

We consider decision rules for multi-stage stochastic integer programming problems. We investigate techniques for using these decision rules to obtain bounds on the optimal solution, and compare the strength of the relaxation from different techniques. Numerical results will be presented.

2 - Stochastic Dual Dynamic Integer Programming

Shabbir Ahmed, Georgia Institute of Technology, 765 Ferst Drive, Atlanta, GA, 30332, United States, sahmed@isye.gatech.edu

We extend the Stochastic Dual Dynamic Programming (SDDP) algorithm to solve multistage stochastic integer programs with binary state variables. Various case studies in energy systems is discussed.

3 - Two-stage Stochastic MIPS with Structured Non-linear Programs

Yingqiu Zhang, Graduate Student, Virginia Tech., Blacksburg, VA, 24060, United States, yqzhang7@vt.edu, Manish Bansal

We present our recent developments for solving two stage stochastic mixed integer programs with structured mixed integer non-linear programs in the second stage. We utilize globally valid parametric cuts within Benders' decomposition to tighten the second stage programs, and provide results of our computational experiments.

Strategic Decisions

Sponsored: Decision Analysis

Sponsored Session

Chair: Dharma Kwon, University of Illinois at U-C, University of Illinois at U-C, Champaign, IL, 61820, United States, dhkwon@illinois.edu

Co-Chair: Youngsoo Kim, University of Illinois at Urbana-Champaign, Champaign, IL, 61820, United States, ykim180@illinois.edu

1 - It is Time to Get Some Rest

Manel Baucells, University of Virginia, Darden School of Business, 100 Darden Boulevard, Charlottesville, VA, 22903, United States, mbaucells@gmail.com, Lin Zhao

We introduce the fatigue disutility model in continuous-time. It captures in a precise way the notion that fatigue accumulates with effort, decays with rest, and increases marginal instant disutility. While prescriptive, the model rationalizes several behavioral anomalies. Under very general conditions the most efficient temporal profile of effort exhibits a high-low-high pattern. We examine the optimal management of fatigue and productivity under various scenarios. We bring the model to the data and provide a calibration that predicts well the speed profiles observed in swimming competitions.

2 - Product Management and Innovation in a Supply Chain

Junghee Lee, University of California, San Diego, 9500 Gilman Drive, #0553, La Jolla, CA, 92093-0553, United States, junghee.lee@rady.ucsd.edu, Hyoduk Shin, Vish Krishnan, Oleksiy Viktorovych Mnyshenko

How can we achieve broader market coverage for innovative products, i.e., inclusive innovation? Grounded in industrial practice, we show that deliberately choosing the contract leader and the investor in a multi-tiered supply chain can have a significant impact on market coverage. We discuss leadership handovers along the product life cycle.

3 - Audit and Remediation Strategies in the Presence of Evasion Capabilities

Shouqiang Wang, The University of Texas at Dallas, Naveen Jindal School of Management, 800 W. Campbell Rd, Richardson, TX, 75080, United States, Shouqiang.Wang@utdallas.edu, Francis E. De Vericourt, Peng Sun

Companies often have means and incentive to conceal a negative issue, which, if not addressed promptly, is likely to result in detrimental consequences. Such evasive actions render audits no longer effective in revealing such an issue. We Examine how to uncover and remedy it in the presence of evasive actions.

4 - Strategic Investment in Shared Suppliers with Quality Deterioration

Youngsoo Kim, University of Illinois at U-C, 1206 South Sixth Street, 350 Wohlers Hall, Champaign, IL, 61820, United States, ykim180@illinois.edu, Dharma Kwon, Anupam Agrawal

Motivated by manufacturers' quality investment in shared suppliers, we study an investment game with spillover and uncertainty. Each manufacturer repeatedly decides either to invest in the declining quality of the supplier or to wait for the other to do so. We find that a unique mixed strategy equilibrium exists if and only if asymmetry in investment costs is not too large. Moreover, a mixed strategy equilibrium disappears if investment opportunities are not repeated. We then consider Nash bargaining as a resolution for the potential inefficiency from a mixed strategy equilibrium. Using the field-collected data, we demonstrate the efficacy of bargaining to avoid a mixed strategy equilibrium.

Military Decision Analysis

Sponsored: Decision Analysis

Sponsored Session

Chair: Greg Parnell, University of Arkansas, gparnell@uark.edu

1 - Lessons Learned from Adaptive Red Team System Assessments

Simon Goerger, PhD, ERDC, CEERD-IE, 3909 Halls Ferry Road, Vicksburg, MS, 39180-6199, United States, Simon.R.Goerger@usace.army.mil, Niki C.Goerger, Michael Rainey, Randy K.Buchanan, John R.Burt

The Adaptive Red Team draws from a portfolio of methods to identify potential vulnerabilities in emerging technologies designed for Soldier use in contested environments, with interoperability challenges, adaptability needs, and training constraints. This presentation describes novel data collection and assessment system developed to support live experiment data collection. It shows the connection to resilient system designs by identifying hidden vulnerabilities introduced by the physical environment, congestion and frequency overload, and electronic warfare and computer network attacks.

2 - Considering System Resilience as Active and Passive Response Strategies to Perturbations Over Time

Randy K. Buchanan, ERDC-Vicksburg, MS, 3909 Halls Ferry Road, Vicksburg, MS, 39180, United States, randy.k.buchanan@erdc.dren.mil, Adam M. Ross, Christina Rinaudo

Despite no widely-accepted definition of resilience, the need for developing systems that can deal with the potential impact of uncertainties (i.e. perturbations) is a real one. In this research, we propose a practical approach toward framing, eliciting, and guiding analysis of tradeoffs for implementing aspects of resilience in military systems. The approach involves partitioning resilience into four related components: 1) assessing response coverage of perturbations, 2) assessing active strategies (e.g. flexibility), 3) assessing passive strategies (e.g. versatility), and 4) assessing timescale of responses.

3 - Using Process Improvement Techniques to Develop an Innovation Pipeline Procedure

Niki Goerger, Business Development Director, U.S. Army Engineer Research and Development Center, 3909 Halls Ferry Road, Vicksburg, MS, Postal code39180-619, United States, Maria.N.Goerger@usace.army.mil, Christina Rinaudo, Simon Goerger

An enterprise innovation pipeline process can provide an organized and structured methodology to ensure that new ideas are continuously generated, evaluated, and matured. Process improvement techniques were used to develop and refine a baseline innovation pipeline process. This presentation explores process improvement methods and techniques used to develop an enterprise innovation pipeline process at the Engineer Research and Development Center.

4 - Quantifying Resilience for Engineered Systems

Gregory S. Parnell, University of Arkansas, 4207 Bell Engineering Center, Fayetteville, AR, 72701, United States, gparnell@uark.edu

A resilient engineered system is able to successfully complete its planned mission(s) in the face of environmental and adversarial threats, and has capabilities allowing it to flexibly adapt to future missions with evolving threats. We use this definition to propose four methods to assess resilience for military systems: updated mission chain calculations for each performance measure; a Value-Focused Thinking Model with mission and platform resilience measures; a multiple objective value model with mission resilience value measures; and two separate value models: one including mission reliance and one for platform resilience.

Introduction to Disaggregate Demand Models

Invited: Tutorial

Invited Session

Chair: Jiming Peng, University of Houston, Houston, TX, 77204, United States, jopeng@Central.uh.edu

Co-Chair: Rajan Batta, University at Buffalo (SUNY), 410 Bell Hall, Buffalo, NY, 14260, United States, batta@buffalo.edu

1 - Introduction to Disaggregate Demand Models

Michel Bierlaire, EPFL, Lausanne, Switzerland, michel.bierlaire@epfl.ch, Virginie Lurkin

Demand information is an input for a great deal of operations research models. Assumed as given in many problem instances addressed in the literature, demand data are difficult to generate. In this tutorial, we provide an introduction to disaggregate demand models that are designed to capture in detail the underlying behavioral mechanisms at the foundation of the demand.

Cloud Computing and Data Centers in Applied Probability II

Sponsored: Applied Probability

Sponsored Session

Chair: Siva Theja Maguluri, IBM, Sleepy Hollow, NY, 10591, United States, siva.theja@gmail.com

1 - Dynamic Resource Provisioning in Data Centers via Robust Queueing Theory

Chaithanya Bandi, Northwestern University, 2001 Sheridan Road, Suite 566, Evanston, IL, 60208, United States, c-bandi@kellogg.northwestern.edu, Vineet Goyal, Omar El Housni

We consider the problem of dynamic resource provisioning and use tools from robust queueing theory and multi-stage optimization to present tractable solutions.

2 - Efficient Redundancy in Cloud Systems

Gauri Joshi, Carnegie Mellon University, Pittsburgh, PA, United States, gaurij@andrew.cmu.edu

The throughput (rate of task completion) of a multi-server system is typically the sum of the service rates of individual servers. Recent works show that task replication can boost the throughput, in particular if the service time distribution has high variability. This paper seeks to find the fundamental limit of the throughput boost achieved by task replication, which is an open problem. The optimal replication policy can be found using a Markov Decision Process framework, which is hard to solve in general. We obtain a converse bound on the service capacity, and propose a close-to-optimal replication policy based on it.

3 - Bounds on Coflow Scheduling in Datacenter Networks

Javad Ghaderi, Columbia University, jghaderi@ee.columbia.edu

In many data-parallel computing frameworks, intermediate parallel data is often produced which needs to be transferred among servers in the datacenter network. Coflow is a networking abstraction to capture such communication patterns. We consider the problem of efficiently scheduling coflows with release dates in a shared datacenter network so as to minimize the total weighted completion time of coflows. We present a deterministic algorithm with approximation ratio of 5, which improves the prior best known ratio of 12. For the special case when all coflows are released at time zero, we obtain a deterministic algorithm with approximation ratio of 4 which improves the prior best known ratio of 8.

4 - Joint Congestion Control and Scheduling for Optimal Delay in Stochastic Processing Networks

Qiaomin Xie, Massachusetts Institute of Technology, 32-D771B, 32 Vassar Street, Cambridge, MA, 02139, United States, qxie@mit.edu, Devavrat Shah

We consider the problem of designing and analyzing joint congestion control and scheduling mechanisms for large-scale stochastic systems, exemplified by datacenter networks, the Internet and wireless networks. We propose a scheme that guarantees a per-flow end-to-end delay bound of O(# of hops). Designing such a scheme involves two subproblems: rate control and packet scheduling. We design a flow-level rate control policy by using an insensitive rate allocation policy in so-called bandwidth-sharing networks. A packet-level scheduling scheme is obtained by adapting the Last-In-First-Out Preemptive-Resume policy.

Sponsored Session

Chair: Gustavo Jose Vulcano, Universidad Torcuato di Tella, Universidad Torcuato di Tella, Buenos Aires, na, Argentina, gvulcano@utdt.edu

1 - Demand Modeling in the Presence of Unobserved Lost Sales

Pavithra Harsha, IBM.Research, 1101 Kitchawan Rd, Room 34-225, Yorktown Heights, NY, 10598, United States, pharsha@us.ibm.com, Shivaram Subramanian

We present an integrated optimization approach to parameter estimation for discrete choice demand models where data for one or more choice alternatives are censored. We employ a mixed-integer program to jointly determine the prediction parameters associated with the customer arrival rate and their

substitutive choices. This approach enables us to recover proven, near global optimal parameter values with respect to the chosen loss-minimization objective function. We test the method on simulated and real data, and present results for a variety of single- and multi-item demand prediction scenarios, and for learning the unobserved market shares of competitors.

2 - Demand Estimation under the Multinomial Logit Model from Sales Transaction Data

Tarek Abdallah, New York University, Stern School of Business, New York, NY, United States, tabdalla@stern.nyu.edu, Gustavo Jose Vulcano

We study a multinomial logit (MNL) model of demand when customers arrive over time in accordance to a non-homogeneous Poisson process. The model is suitable for retail settings where only sales and product availability data are recorded, not all products are displayed in all periods, and the seller has information about her own aggregate market share. We characterize conditions under which the model is identifiable and the maximum likelihood estimates are consistent. We propose a Minorization-Maximization (MM) algorithm that is guaranteed to converge to the global optimal solution when the model is identifiable.

3 - Salesforce Incentives for Managing Product Returns

Rashmi Sharma, Pennsylvania State University, University Park, PA, United States, rashmi.sharma@psu.edu, Aydin Alptekinoglu

We study a setting where product sales and returns are effort-dependent and the selling activity is conducted by a salesforce. We investigate the effect of salesforce behavior on net sales and compare different incentive schemes to identify optimal incentive strategies.

4 - An Expectation-maximization Algorithm to Estimate the Parameters of the Markov Chain Choice Model

A. Serdar Simsek, University of Texas-Dallas, Naveen Jindal School of Management, 800 W. Campbell Road, Richardson, TX, 75080, United States, serdar.simsek@utdallas.edu, Huseyin Topaloglu

We develop an expectation-maximization algorithm to estimate the parameters of the Markov chain choice model (MCCM). We prove theoretical convergence guarantees and our computational experiments show that the MCCM, coupled with our expectation-maximization algorithm, can yield better predictions of customer choice behavior when compared with other commonly used alternatives.

Chair: Andrew M. Davis, Cornell University, Ithaca, NY, 14853, United States, adavis@cornell.edu

1 - Heterogeneity of Reference Effects in the Competitive Newsvendor Problem

Anton Ovchinnikov, Queen's School of Business, 143 Union Street, Kingston, ON, K7L.3N6, Canada, ao37@queensu.ca, Sam Kirshner

This paper examines two recently-proposed reference effect formulations for the newsvendor problem and extends them to a competitive setting. The analysis of the resultant game shows that the heterogeneity of newsvendors' reference effects can explain multiple regularities observed in recent experimental studies of newsvendor competition. Specifically, the observations that a behavioral newsvendor may effectively ignore the orders of the competitor, receive a significantly smaller profit, and over-order when there is no expected demand overow can all be attributed to the heterogeneous reference effects in our model's equilibrium.

2 - Omnichannel Service Operations with Online and Offline Self-order Technologies

Fei Gao, Indiana University, Bloomington, IN, United States, fg1@iu.edu, Xuanming Su

Many restaurants have recently implemented self-order technologies across both online and offline channels. We study the impact of both online and offline self-order technologies on consumer demand, employment levels, and restaurant profits.

3 - Predicting Order Variability in Inventory Decisions: A Model of Forecast Anchoring

Dayoung Kim, Cornell University, 201D Sage Hall, Ithaca, NY, 14853, United States, kdy928@gmail.com, Andrew M. Davis, Li Chen

We develop a forecast anchoring model that explains and predicts order variability behavior in a multi-period newsvendor problem. Our model assumes that people anchor on random point forecast and insufficiently adjust toward the profit-maximizing quantity. We apply GMM to fit our model across different experimental data sets, and further conduct our own experiment for a robustness check. Our results show that the order variability at the individual level and the variability at the aggregate level is caused by different sources of behavior. By providing better predictions, our model can help firms better anticipate the order variability from the downstream buyers.

4 - How Bounded Rationality Generates Bias in Demand Forecasting and Product Choice

Jordan Tong, University of Wisconsin-Madison, Madison, WI, United States, jordan.tong@wisc.edu, Daniel Feiler

Humans are boundedly rational and make random error. Can initial random error, even if it is unbiased, generate future systematic decision bias? We uncover and model an important operations context for which the answer is yes: when managers both choose which product to sell and make a forecast for their chosen product, random error (and failure to account for it statistically) causes them to systematically forecast too high. Two experiments, one with managers in a single-period setting and the other with students in a periodic review setting, test the behavioral model's predictions - illustrating how and why human random error causes bias and illuminating mitigation techniques.

Chair: Asligul Serasu Duran, Kellogg School of Management, Kellogg School of Management, Chicago, IL, 60657, United States, a-duran@kellogg.northwestern.edu

1 - An Analysis of Demand Response Programs in the Wholesale Electricity Market

Asligul Serasu Duran, Kellogg School of Management, 825 W. Cornelia Avenue, Apt GDN, Chicago, IL, 60657, United States, a-duran@kellogg.northwestern.edu, Baris Ata, Ozge Islegen

This project explores the impact of the participation and compensation of demand response (DR) providers in the wholesale electricity market on the electricity supply, electricity prices, generators and DR providers' profits, and consumer welfare. Specifically, we model a supply function equilibrium for generators and DR providers where DR resources offer "negawatts" in the wholesale market. Then, we analyze the change in the electricity supply, and in the welfare of the market participants due to the varying compensation rates of DR providers. We show that generators' profits decrease, and consumers' energy bills may increase with the entry of DR providers to the wholesale electricity market.

2 - Government Financing for Clean Technology Development

Seung Hwan Jung, Washington University in St. Louis, 1552 E. Swan Cir., Brentwood, MO, 63144, United States, seunghwan.jung@wustl.edu, Lingxiu Dong

We study government financing for a firm's clean technology development under a financial constraint. The main interest of this paper is to investigate the impact of government financing on environment and the firm's bankruptcy risk when market uncertainty exists. Our analysis shows that government financing improves environment, compared to bank financing. Surprisingly, the government financing, however, exposes the firm to higher bankruptcy risk. However, our analysis further shows that the government financing benefits both the firm and consumers. Hence, our results also shed light on the benefit of the government financing.

3 - Mind the Gap: Coordinating Energy Efficiency and Demand Response

Eric Webb, PhD Student, Indiana University, 2915 W. Winterberry Ct., Bloomington, IN, 47404, United States, eric.michael.webb@gmail.com, Owen Wu, Kyle D.Cattani

Traditionally, energy demand-side management programs are each designed in isolation. Breaking with this tradition, we examine the interactions between long-term energy efficiency upgrades and daily demand response participation at an industrial firm. Upon re-examining the long-studied energy efficiency gap, we find that the gap is typically smaller when demand response is considered. Policies aiming to close or reduce the energy efficiency gap, such as investment subsidies and carbon taxes, may fail to achieve their desired outcomes when firms participate in demand response.

4 - Supply Function Equilibria in Electricity Markets under Uncertainty

Chaithanya Bandi, Northwestern University, 2001 Sheridan Rd, 566, Evanston, IL, 60208, United States, c-bandi@kellogg.northwestern.edu, Ermin Wei, Yuanzhang Xiao

We study a two-stage electricity market with renewables. Each energy producer in the market has a portfolio of both renewable and conventional energy generators. In the real-time market, each producer tries to fulfill its DA committed energy with (zero-cost) renewables. We study the robust supply function equilibrium (SFE) where each producer has incomplete information about the other producers' marginal costs and the distribution of renewable energy, and performs worst-case optimization. We fully characterize the unique robust SFE, and study the impact of the feed-in tariff on the equilibrium outcome.

Analytics & Optimization in Chronic Disease Screening and Management

Sponsored: Health Applications

Sponsored Session

Chair: Turgay Ayer, Georgia Institute of Technology, Atlanta, GA, 30332, United States, ayer@isye.gatech.edu

Co-Chair: Caglar Caglayan, Georgia Institute of Technology, 765 Ferst Drive, Atlanta, GA, 30332, United States, ccaglayan6@gatech.edu

1 - Analytics for Personalized Healthcare using Mobile Devices

Anil Aswani, UC Berkeley, 8 10th St, Apt 1704, San Francisco, CA, 94103, United States, aaswani@berkeley.edu, Elena Flowers, Yoshimi Fukuoka, Ken Goldberg, William Haskell, Philip Kaminsky, Yonatan Mintz, Eric Vittinghoff, Mo Zhou

Mobile technologies hold much promise for management of chronic diseases. However, algorithm design requires careful consideration of the data-transmission and computational capabilities of mobile technologies. This talk describes the development of a personalized physical activity intervention. First, we describe the results of a clustering analysis of objectively measured physical activity patterns in women. Insights from this analysis are used in development of a ROGUE bandit algorithm for the design of personalized physical activity interventions. A key innovation of our ROGUE bandit model is the ability to capture habituation that occurs with repeated exposure to a single treatment.

2 - A Comparative Analysis of Data Mining Approaches to Characterize Colorectal Cancer Screening Behavior Trajectories

Maria Esther Mayorga, North Carolina State University, 400 Daniels Hall, Dept. of Industrial & Systems Engineering, Raleigh, NC, 27695, United States, memayorg@ncsu.edu, Rachel M. Townsley

Patient behavior patterns can heavily impact outcomes and policy efficacy in the context of cancer screening, but are difficult to replicate in health policy simulation models. Using censored claims data we investigate the validity of common screening behavior assumptions and their impact on relevant individual health outcomes in the context of colorectal cancer (CRC). We compare data driven strategies for modeling trajectories of screening behavior over time.

3 - Assessing Multi-Modality Screening Policies for Women at High Risk of Breast Cancer

Caglar Caglayan, Georgia Institute of Technology, 765 Ferst Drive, Atlanta, GA, 30332, United States, ccaglayan6@gatech.edu, Turgay Ayer, Donatus U. Ekwueme

Women with breast density, family history of breast or ovarian cancer, or BRCA1 and BRCA2-mutation-carriers are at higher risk of breast cancer. For such women, non-mammographic modalities such as ultrasound or MRI, adjunct to or instead of mammogram, can overcome the limitations of mammogram and hence, be beneficial. Currently there is no consensus on the optimal use of these modalities in high-risk women. We study multi-modality breast cancer screening problem for the high-risk population and identify practical and cost-effective optimal screening policies. Our results show that screening with ultrasound is cost-effective and optimal over a wide range of budget levels in young high-risk women

4 - Identifying Factors that Influence Outcome for Prostate Cancer Patients

Eva Lee, Professor and Director, Georgia Tech, Ctr for Operations Research in Medicine, Atlanta, GA, 30332-0205, United States, eva.lee@gatech.edu

This work is joint with Kaiser Permanente. We analyze 10 years of prostate cancer patients to investigate factors that influence the outcome. Unsupervised learning will be performed to uncover outcome patterns and to subgroup patients according to their outcome and health similarities. Machine learning is then performed to identify factors that are critical for achieving treatment outcome. Modeling and computational challenges will be discussed.

Health Data Analytics for Policy Making

Sponsored: Health Applications

Sponsored Session

Chair: Ilbin Lee, PhD, Georgia Tech, 755 Ferst Drive, Atlanta, GA, 30332, United States, ilee79@gatech.edu

1 - Quantifying the Cost of Pediatric Depression in the Medicaid Population

Erin Garcia, Auburn University, Auburn, AL, United States, eg3gatech@gmail.com

Co-morbid depression often results in increased health care costs and worse outcomes in studies focused on particular conditions and groups of people. To determine the long term cost of pediatric depression in the Medicaid population, we identify the population of children with and without depression from the CMS data files. Each child with depression is matched to a child without depression based on a set of socioeconomic and health factors so that we can treat the data as paired samples. Healthcare utilization and cost data for each child in the final sample are computed from the CMS data, and pairwise analysis is conducted to identify differences between the populations with and without depression.

2 - Spatial Access to Psychotherapy Services for Publicly-insured Children

Pravara M.Harati, Georgia Tech, Atlanta, GA, United States, pharati3@gatech.edu

Access to specialty care is typically worse for publicly-insured children than for privately-insured. We estimate local level spatial access, including provider congestion and average travel distance, to child psychotherapy services by first using CMS Medicaid claims data to obtain the locations and annual capacities of mental health professionals who have provided psychotherapy to publicly-insured children. We then estimate the local level prevalence of mental health conditions using a simulation model based on demographic data. Finally we match the demand to supply in an optimization model to obtain the access measures, from which we can identify geographic areas needing improvement.

3 - Using Infusion Pump Data Analytics to Study Medication Safety Issues

Kang-Yu Hsu, Purdue University, Gerald D. and Edna E. Mann Hall, 203 S Martin Jischke Drive, Lafayette, IN, 47907, United States, hsu66@purdue.edu, Poching DeLaurentis, Yuehwern Yih, Yuval Bitan, Dan Degnan

An infusion pump is a medical device used to intravenously deliver fluids into a patient's body in controlled amounts and rates. These infusion pumps have safety features incorporated in a software program known as Dose Error Reduce Systems (DERS) that uses customized Drug Limit Library (DLL). DLLs in infusion pumps may not be updated efficiently. The inconsistency between DLL in pumps and the most current DLL may put patient safety at risk such as dosage/rate miscalculation, false alerts and missed alerts. In this study, we quantify the impact of adopting out-of-date DLL through investigating infusion logs, and examine infusions which potentially jeopardized patient safety with outdated DLL usage.

4 - The Longitudinal Trajectories of Medication Adherence for Patients with Chronic Conditions

Shan Xie, Purdue University, 315 N. Grant Street, W. Lafayette, IN, 47907, United States, xie34@purdue.edu, Alan Zillich, Yuehwern Yih

Poor adherence to medication has been associated with increased healthcare costs and adverse health outcomes, thus improving medication adherence is important to realize the full benefit of medication therapies. The current claims-based quality reporting measures only provide an aggregate number to estimate patients' adherence level over a long-term period, which are easy to implement but lack the ability to distinguish between different adherence patterns. Therefore, we used group based trajectory models to stratify patients into groups with distinct longitudinal adherence trajectories. We hope to provide useful insight to help design targeted and tailored interventions.

Modeling for Complex Conditions

Sponsored: Health Applications

Sponsored Session

Chair: Julie Simmons Ivy, North Carolina State University, Raleigh, NC, 27695-7906, United States, jsivy@ncsu.edu

1 - Modeling Complex Trajectories in Patients with Sepsis

Nisha Nataraj, North Carolina State University, 111 Talisman Way, Apt 220, Raleigh, NC, 27615-4958, United States, nnatara@ncsu.edu, Julie Simmons Ivy, Muge Capan, James R. Wilson, Jeanne Marie Huddleston, Ryan Arnold

Sepsis, infection plus systemic manifestations of infection, is the leading cause of in-hospital mortality. The lack of a gold-standard diagnostic test makes sepsis difficult to diagnose and necessitates timely intervention. The trajectory of sepsis is difficult to clearly define and recent definition changes have complicated matters further. This research uses inpatient electronic health record data over multiple visits from a large hospital system to study the implications of different definitions and guidelines on the diagnosis and treatment of septic patients with comorbidity via a simulation-based framework.

2 - Decision Modeling in Sepsis Patients

Shadi Hassani Goodarzi, North Carolina State University, Raleigh, NC, United States, shassan3@ncsu.edu

Sepsis is a complication caused by body's overwhelming response to an infection. It can lead to organ failure and death. According to NIH, more than one million Americans are diagnosed with sepsis each year, about 28% to 50% of which result in mortality. Due to the fast progression of sepsis, a timely apt intervention is critical before sepsis causes organ failure which can result in long-term complications and increased chance of death. We used EHR to develop a Markov decision process to optimize intervention timing minimizing the chance of organ failure and death caused by sepsis.

3 - Sepsis and Organ Failures: A Single Center Study of Prevalence and Mortality

Muge Capan, Christiana Care Health System, Wilmington, DE, 19801-3082, United States, mcapan@ncsu.edu, Stephen Hoover, Julie Simmons Ivy, Jeanne Marie Huddleston, Ryan Arnold

Increasing incidence and mortality rate mark sepsis, a life-threatening organ dysfunction caused by response to infection as a significant healthcare burden. Considering the uncertainties in sepsis diagnosis and treatment, inpatients with a presumed infection may exhibit various trajectories of sepsis-induced episodes. Utilizing electronic health records allows identifying factors associated with organ dysfunction associated with sepsis episodes. We present a systematic approach to identify the impact of organ dysfunction on mortality based on clinical physiology in sepsis populations by investigating all-cause inpatient mortality among nested subgroups (N=210,289 visits).

Stochastic Modeling in Healthcare

Sponsored: Health Applications

Sponsored Session

Chair: Murat Kurt, Merck & Co., Inc., 351 N. Sumneytown Pike., North Wales, PA, 19454, United States, murat.kurt@merck.com

Co-Chair: Iakovos Toumazis, Stanford University, Stanford, CA, United States, iakovos.toumazis@stanford.edu

1 - Optimal Static Risk-based Group Testing

Hrayer Y. Aprahamian, Virginia Tech, 1145 Perry Street, Blacksburg, VA, 24060, United States, ahrayer@vt.edu, Ebru Korular Bish, Douglas R. Bish

Group testing, where multiple subjects are tested simultaneously with a single test, is an essential tool for classifying a large number of subjects for a binary characteristic. An important decision is the testing design, i.e., group sizes needed to test a set of subjects, each with a given risk profile. The testing design is a tactical decision, and has to be made under uncertainty on both the number of subjects to be tested and their risk profile. We model this problem as a two-stage stochastic programming problem and characterize key structural properties of optimal testing designs. Our case study establishes the effectiveness of optimal risk-based testing within a public health framework.

2 - Impact of False Positives on the Cost-effectiveness of Lung Cancer Screening

Iakovos Toumazis, Stanford University, Stanford, CA, United States, iakovos.toumazis@stanford.edu, Emily Tsai, Ayca Erdogan, Summer Han, Ann Leung, Sylvia Plevritis

We assess the benefits and costs of various screening strategies for lung cancer (LC) using a data driven microsimulation model. We simulate individuals' LC progression in the presence and absence of screening strategies, which vary in terms of starting and stopping age, screening frequency, and smoking exposure. We identify the efficiency frontier and show that the cost-effectiveness of LC screening is significantly affected by the management of false-positive results. We examine the effect of the number of subsequent exams and disutility associated with false-positives and conduct univariate sensitivity analyses to test the robustness of our findings to changes in key input model parameters.

3 - Determining Effective and Practical Colonoscopy Screening and Surveillance Policies

Gizem Nemutlu, PhD Candidate, University of Waterloo, Faculty of Engineering University of Waterloo Carl A. Pollock Hall 4323 200 University Avenue West, Waterloo, ON, N2L.3G1, Canada, gsnemutlu@uwaterloo.ca, Fatih Safa Erenay, Oguzhan Alagoz

Efficient colonoscopy screening and surveillance policies are desired to cost-effectively reduce colorectal cancer incidence and mortality. We developed a partially observable Markov decision process model to dynamically schedule colonoscopy operations based on accumulated risk of having advanced lesions and other risk-factors. However, clinicians may find such optimal policies too complex to adopt. Using a stochastic model, we derive simple yet effective dynamic colonoscopy screening policies which perform closely to the optimal policies and are easy-to-implement in clinical practice.

4 - Dynamic Classification Approach for Classifying Patient in Chronic Disease: with Application to Glaucoma

Esmaeil Keyvanshokooh, University of Michigan, Ann Arbor, MI, United States, keyvan@umich.edu, Mark P.Van Oyen, Joshua Stein, Mariel Lavieri

We design a dynamic classification method for patient types in Glaucoma. Our first goal is to effectively identify which patient is "fast" versus "slow" progressor meaning that he/she is experiencing relatively rapid or slow Glaucoma progression. To this aim, we combine machine learning methodologies with Kalman filter method to dynamically classify patients into different categories. Our second purpose is to accurately predict/estimate the quantities of the state variables for future testing periods of each patient.

Interface of Operations, Finance, and Risk Management

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Jiri Chod, Boston College, Chestnut Hill, MA, 02467, United States, chodj@bc.edu

1 - A Signaling Theory of In-Kind Finance

Jiri Chod, Boston College, 140 Commonwealth Avenue, Fulton Hall, Chestnut Hill, MA, 02467, United States, chodj@bc.edu, Nikolaos Trichakis, Gerry Tsoukalas

We argue that by borrowing in kind (e.g., through trade credit) rather than in cash (e.g., through bank credit), firms may be able to convey private information about their fundamental value to creditors more efficiently. This is because borrowing illiquid, and potentially perishable, goods, constitutes a more credible commitment, and hence a stronger signal of a firm's quality. Our theory rationalizes preference for supplier financing under information asymmetry, and, unlike existing explanations, it does so without ascribing any prior informational advantage to the supplier and without relying on buyer opportunism/moral hazard.

2 - Cancelability in Trade Credit Insurance

S. Alex Yang, London Business School, Regent's Park, London, NW1 4SA, United Kingdom, sayang@london.edu, Nitin Bakshi, Christopher J.Chen

Trade credit insurance (TCI) is a risk management tool commonly used by suppliers to guarantee against payment default by buyers. Unlike insurance policies in other sectors, TCI policies often allow the insurer to cancel this "guarantee" during the insured period. In this paper, we offer an economic rationale of this phenomenon. We also explain the shortcoming of this type of contract, and thus shedding light on the recent emergence of non-cancelable contract.

3 - Optimal Timing of Inventory Decisions with Price Uncertainty
Nikolay Osadchiy, Emory University, 1300 Clifton Rd Ne, Atlanta, GA, 30322, United States, nikolay.osadchiy@emory.edu, Vishal Gaur, Sridhar Seshadri, Marti Subrahmanyam

We study the problem of optimal inventory order timing when the selling price and demand are random and their forecasts improve with time. We derive the structure of the ordering policy and study the value of order timing flexibility.

4 - Inventory Operations under the Shadow of Company Stock Price
Qi Wu, Case Western Reserve University, Cleveland, OH, United States, qxw132@case.edu, Guoming Lai

Inventory management is one central problem of operations. The classical inventory theories typically focus on the operational tradeoffs to optimize the inventory decisions. In practice, however, many firms are public that often have short-term interests in their market value. Our analysis reveals that public firms may install more inventory in equilibrium to influence their earnings. We discuss the determinants of such an effect as well as the empirical evidence.

1 - Vicarious Goal Pursuit Outweighs Herding in Crowdfunding: Evidence from Kickstarter.com
Dennis Zhang, Washington University in St. Louis, 8342 Delcrest Drive, Apt 328, University City, MO, 63124, United States, denniszhang@wustl.edu, Hengchen Dai

We examine backers' contribution patterns using a novel dataset on 26,516 projects at 10-minute resolution from Kickstarter - the largest crowdfunding website where creators only receive capital committed by backers and deliver rewards if they reach a specific funding goal.

2 - Online Product Support Forums: Customers as Partners in the Service Delivery
Konstantinos Stouras, Post-doctoral Research Fellow, The Darden School, University of Virginia, 100 Darden Boulevard, Charlottesville, VA, 22903, United States, kostas@virginia.edu

Firms increasingly provide service to their customers via an online product support forum in which service delivery is partially delegated to an active community of firm customers (community users). Our results establish that it may be to the best interest of the firm to strategically reduce its service rate to boost a faster response rate from the community of users.

3 - The Impact of Fintech on Consumer Consumption: Evidence from Credit Card Data
Yuqian Xu, University of Illinois at Urbana-Champaign, Champaign, IL, United States, lillian.xyq@gmail.com, Anindya Ghose, Binqing Xiao

The recent development of FinTech has expanded the traditional banking channels. In this paper, we use a detailed consumer credit card transaction data set which contains both transactions made through traditional banking channels as well as transactions through FinTech (Alipay) Channels. We analyze the impact of the introduction of FinTech Channels on consumer consumption behaviors.

4 - Strategic Provision of Inventory Information under Competition
Katherine Ashley, Montclair State University, 36 Valley Rd Apt 215, Montclair, NJ, 07042, United States, ashleyk@montclair.edu

Firms in many industries provide customers with real-time inventory availability information, which is typically unverifiable by consumers. We use a game-theoretic model to characterize the information provision strategies that emerge in equilibrium when two firms compete and both customers and firms act strategically in sending and interpreting messages.

Economics of Service Operations

Sponsored: Manufacturing & Service Oper Mgmt, Service Operations

Sponsored Session

Chair: Guillaume Roels, UCLA, Los Angeles, CA, 90095, United States, groels@anderson.ucla.edu

1 - Payment Models to Coordinate Healthcare Providers with Limited Accountability
Sampath Rajagopalan, University of Southern California, Marshall School of Business, 3670 Trousdale Pky Bridge Hall 400D, Los Angeles, CA, 90089, United States, raj@marshall.usc.edu, Chunyang Tong

This work studies a referral based healthcare system in which general practitioners refer patients to specialist, whose capacity is limited. Moreover, it may not be possible to hold the specialist fully accountable for patient outcomes. We evaluate the effectiveness of different payment systems, including bundled and unbundled payments, in coordinating the decisions of the general practitioner and specialist by a single payer which impact referrals, specialist workload and care quality. We show how limited accountability of specialists for service outcomes interacts with payment systems to distort referral and specialist decisions and impact various quality and cost metrics.

2 - Peer-to-peer Trading of Usage Allowances
Behrooz Pourghannad, University of Minnesota, Minneapolis, MN, United States, behrooz@umn.edu, Saif Benjaafar, Jian-Ya Ding

A growing number of businesses are being built around a model that provides customers access to a product or a service up to a specified amount or allowance. Examples include cloud-based data storage, mobile phone service plans, and fractional ownership of vacation homes, jets, and boats. We study the impact of allowing customers to trade among themselves unused portions of their allowances and examine conditions under which this is beneficial to both the firms and consumers.

3 - Designing New Services: How Much Should Customers Co-create?
Stylianos Kavadias, University of Cambridge, Judge Business School, Trumpington Street, Cambrige, CB2 1AG, United Kingdom, s.kavadias@jbs.cam.ac.uk, Ioannis Bellos

Service blueprints vary significantly across industries and they range all the way from minimal service provider involvement (self-service systems) to heavy engagement between the provider and the customer. How should service providers consider the "right" blueprint for the customer types they aim to attract? This presentation adopts a widely used structure in designing services (customer journeys) to identify how the structural features of the possible service touchpoints, as well as the capabilities of the service providers and the customers, shape different eventual service blueprints.

4 - Optimal Practice Processes for Performance
Guillaume Roels, UCLA, 110 Westwood Plaza, Gold Hall Suite B511, Los Angeles, CA, 90095, United States, groels@anderson.ucla.edu

We consider a practice process with a defined objective, such as arises in learning processes (e.g., studying for an exam) or training processes (e.g., training for a marathon). We introduce an analytical model that captures nonlinear returns of effort on performance, fatigue and strength accumulation, and reference effects and we characterize the optimal practice process that maximizes performance. We find that the optimal process can be N-shaped or alternate sessions of high intensity with sessions with low intensity. We validate our model with running data.

Resource Allocation and Matching

Sponsored: Manufacturing & Service Oper Mgmt, Service Operations

Sponsored Session

Chair: Weihua Zhang, University of British Columbia, Vancouver, BC, V6T 2G9, Canada, icystrawberry@hotmail.com

Co-Chair: Yichuan Ding, University of British Columbia, Vancouver, BC, V6T 1Z2, Canada, daniel.ding@sauder.ubc.ca

1 - Advance Service Reservations with Heterogeneous Customers

Xinshang Wang, Columbia University, New York, NY, United States, xw2230@columbia.edu, Clifford Stein, Van-Anh Truong

We study a model of resource allocation in which a finite number of resources must be assigned in an online manner to a heterogeneous stream of customers. The customers arrive randomly over time according to known stochastic processes. Each customer requires a specific amount of capacity for each of the resources. The system must find a feasible assignment of each customer to a resource or must reject the customer. The aim is to maximize the total expected capacity utilization of all the resources. We present online algorithms with bounded competitive ratios. Our algorithms perform extremely well compared to common heuristics as demonstrated on a real data set from a large hospital system in New York City.

2 - Ohm's Law Approximation for FCFS Stochastic Matching

Edward H.Kaplan, Beach Professor of Operations Research, Yale University, Evans Hall, 165 Whitney Avenue, New Haven, CT, 06511, United States, edward.kaplan@yale.edu, Mohammad Fazel-Zarandi

The FCFS stochastic matching model developed from queueing problems addressed by Kaplan (1984) for public housing assignments. The goal of this model is to determine the matching rates between eligible customer and server types. This model was solved in a beautiful paper by Adan and Weiss (2012), but the resulting equation for the matching rates is quite complicated, involving the sum of terms over all permutations of the server types. Here we develop approximations for the matching rates based on Ohm's Law. As our approximations only require the solution of a system of linear equations along with the identification of a small number of terms, they provide a tractable alternative to the exact solution.

3 - A Novel KPD Mechanism to Increase Transplants when Some Candidates have Multiple Willing Donors

Tuomas W. Sandholm, Carnegie Mellon University, Gates Center for Computer Science, Pittsburgh, PA, 15213, United States, sandholm@cs.cmu.edu, Gabriele Farina, John Dickerson, Ruthanne Leishman, Darren Stewart, Richard Formica, Carrie Thiessen, Sanjay Kulkarni

Most current kidney exchanges allow candidates to list multiple willing donors, but only one will donate if the candidate is matched. There are cases where multiple donors would be willing to donate if that resulted in their intended candidate being transplanted. We conducted a dynamic simulation (using real UNOS kidney exchange data) to study the effects of having two donors donate in such cases. The new approach yielded more than a 10% gain in the number of priority-weighted transplants. This also means shorter wait times. Future research includes simulating other variants, studying the candidates' and donors' incentives, and considering the ethics.

4 - A Centralized Allocation Mechanism for Public Housing

Weihua Zhang, University of British Columbia, Mailbox 66 0, 6335 Thunderbird Crescent, Vancouver, BC, V6T.2G9, Canada, weihua.zhang@sauder.ubc.ca, Yichuan Ding, Daniel Granot, Mahesh Nagarajan

In 2014, US programs of federal rental assistance helped nearly five million families. We model the affordable housing allocation problem as a centralized decision problem. The HA strives to accommodate move-in requests as well as requests of transfer between housing types. We assume that households list the housing types that they would accept without specifying their complete preference order. We further assume that the housing units of each type are homogeneous. For minimizing vacancy rate and maximizing portability (the responsiveness of the HA to households' accommodation requests), we formulate the problems as network flow problems and characterize the optimal solutions.

Chair: Haoqiang Jiang, Florida International University, 800 SW 104th Ct A-105, Miami, FL, 33174, United States, jhq820422@hotmail.com

1 - The Effect of Failure on Individual Performance Over Time

Emmanouil Avgerinos, Assistant Professor, IE Business School, c/ María de Molina, 13, CIF.- G81711459, Madrid, 28006, Spain, emmanouil.avgerinos@ie.edu, Bilal Gokpinar

Learning from past failures constitutes a key factor in modern organizations. While the phenomenon has been widely studied, the effect of failure over time has received little attention. More importantly, little is known about what management should do right after a failure is experienced by its employees in terms of team and task allocation. Using a unique dataset of 4,306 cardiac surgery operations from the cardiac unit of a private hospital in Europe we investigate the effect of failure over time and propose new ways for managers to help their employees recover from their recent failures.

2 - A Bayesian Approach for Estimating Out-of-network Referral Patterns in Accountable Care Organizations

Iulian Ilies, Northeastern University, 360 Huntington Avenue, 1200 - 177, Boston, MA, 02115, United States, i.ilies@neu.edu, Parth R. Vadera, James C. Benneyan

Outside utilization (patients receiving care from out-of-network providers) considerably limits the ability of accountable care organizations to coordinate care, ensure quality standards are followed, and reduce costs. We developed a Bayesian method for inference of referral links between care providers from historical insurance claims records, and evaluated this approach on synthetic data generated from provider networks of different sizes and topologies. Our approach was able to reconstruct the network structure with high accuracy, thereby providing an avenue to adjust referral patterns and reduce outside utilization.

3 - Implication of Codified Knowledge Sharing on Operational Failures

Bilal Gokpinar, UCL, Management Science/Innovation, Gower Street, London, WC1E 6BT, United Kingdom, b.gokpinar@ucl.ac.uk, Mecit Can Emre Simsekler

Focusing on codified knowledge sharing among healthcare personnel in the form of written guidance documents, we examined the role of codified knowledge on operational failures in healthcare. We used a unique dataset from hospitals in England and employed text-mining techniques to investigate the impact of documents on operational failures.

4 - Development and Evaluation of Context-based Work Planning Policies for Inpatient Care

Lucy Aragon, Student, Wichita State University, 1845 Fairmount Street, Wichita, KS, 67260, United States, lgaragon@shockers.wichita.edu, Lucy Aragon, Student, Pontificia Unviersidad Catolica del Peru, Lima, Peru, lgaragon@shockers.wichita.edu, Laila Cure

The short-term inpatient care work planning problem consists of assigning tasks to hourly rounds. Due to the fast pace of healthcare systems and the cognitive limitations of humans, work planning strategies are often static and may be inadequate on particular workdays. This research studies work planning policies that can be applied by healthcare workers using limited computational resources. The problem was formulated as a variation of the 0-1 generalized assignment problem with nonlinear capacity constraints. Current, optimal, and practical work planning strategies were evaluated in terms of quality and added workload to the provider.

5 - Integrated Forecasting Simulation Approach for Call Center Workforce Management

Mohammadsadegh Mikaeili, Binghamton University, 1815 Kater Street, Philadelphia, PA, 19146, United States, mmikaei1@binghamton.edu

Call center operations management has been a challenging task due to rising cost of operations. Major source of loss in the call center expenses is associated with poor staffing, such as over-staffing or under-staffing. The call center staffing is challenging because of a random and stochastic behavior of the demand, that is, the inbound call volume. This research aims to create a practical, robust, and flexible decision making framework for more efficient and effective planning of the staffing and scheduling in contact centers. This framework is based on demand forecasting and a simulation model of the call center operations combined with the forecasting data.

6 - Multi-objective Workload Balancing for Subjective Tasks
Haoqiang Jiang, PhD Candidate, Florida International University, 11200 S.W. 8th Street, Miami, FL, 33193, United States, hjian006@fiu.edu, Debra VanderMeer

Resource-task assignment is a critical problem in operations management. Many studies focus on workload balance across available working units using quantitative measures. However, familiarity with a work case can help individual to perform better in subjective tasks, which rely on personal judgement for unique task instances. We propose work assignment methods for subjective workloads that aim to simultaneously satisfy quantitative workload balance goals and maximize benefits of case familiarity. We study our methods in a simulated healthcare setting focused on nurse-patient assignment.

Empirical Healthcare and Service Operations

Sponsored: Manufacturing & Service Oper Mgmt, Healthcare Operations

Sponsored Session

Chair: Diwas S KC, Emory University, Atlanta, GA, 30322, United States, diwas.kc@emory.edu

1 - Task Scheduling under Worker Discretion
Maria Ibanez, Harvard Business School, Boston, MA, United States, mibanez@hbs.edu, Michael Toffel

Scheduling research investigates the optimal allocation of scarce resources (e.g., a worker) to tasks' completion over time, typically overlooking the role of worker discretion. In practice, workers are often involved in these processes, influencing and being affected by job schedules. We examine how scheduling choices impact operational performance empirically using data from the field.

2 - The Impact of Buffer Location on Patient Satisfaction
Dawson Kaaua, Wharton, 3730 Walnut Street, Suite 500, Philadelphia, PA, 19104, United States, kaaua@wharton.upenn.edu, Christian Terwiesch

Service operations research has typically focused on a customer's wait time without taking into account the fact that customers often wait in multiple locations before completing a service of interest. We examine how the location of waits can impact patient satisfaction in an ambulatory perioperative setting at a hospital. Specifically, we find that patients prefer to wait in the reception area versus the pre-operative area. Given this finding, we suggest that a CONWIP (pull) system could serve as a solution to managing the flow of patients. Finally, we uncover that the hospital is not using a pull system and could thus benefit from implementing one.

3 - Measuring Primary Care Performance using ED-Level Data
Sandra Suelz, Erasmus University Rotterdam, Rotterdam, 50931, Netherlands, sulz@bmg.eur.nl, Nicos Savva

Measuring access and clinical quality of GP care is difficult either due to data unavailability, low frequency of data collection, or inconsistent data collection across GPs. ED-level data, however, exists and is comparable across hospitals. We use UK-based data to analyze whether ED-level data can be used to assess GP performance thereby distinguishing between accessibility for acute conditions and management of long-term care conditions.

4 - Predicting Custom Product Returns
Hailong Cui, University of Southern California, Marshall School of Business, Data Sciences and Operations, Los Angeles, CA, 90089-0809, United States, Hailong.Cui.2019@marshall.usc.edu, Sampath Rajagopalan, Amy R.Ward

Product returns are a major issue for many firms and especially for those making custom goods. We develop a model for predicting returns at a leading manufacturer of custom car accessories. The model takes into account product, retailer and production process characteristics. Several model specifications are explored and tested, including high dimension models. We identify the model specifications that do very well in out-of-sample prediction. Our analysis is useful to the firm in operational planning as well as in investigating products, retailers and other characteristics that tend to have high returns and return rates.

Interface of Finance Risk and Operations Management

Sponsored: Manufacturing & Service Oper Mgmt, Supply Chain

Sponsored Session

Chair: William Schmidt, Cornell University, Ithaca, NY, 14850, United States, wschmidt@cornell.edu

1 - Mitigating Disruption Risks in Delivery Supply Chains to Serve Contracted Customers
Mert Hakan Hekimoglu, Rensselaer Polytechnic Institute, 110 8th Street, Pittsburgh Building, Troy, NY, 12180, United States, hekimm@rpi.edu, John H.Park, Burak Kazaz

Motivated by an implementation in a Fortune 150 company, we examine the role of risk aversion on capacity decisions in a delivery supply chain in the presence of supply disruptions. The delivery supply chain involves fulfillment centers that are responsible for delivering orders within the next day. The proactive capacity decisions are coupled with reactive contingency routing decisions to mitigate the effects of disruptions.

2 - Suppliers as Liquidity Insurers
Panos Markou, Cambridge Judge Business School, Cambridge, United Kingdom, p.markou@jbs.cam.ac.uk, Daniel S. Corsten, Reint Gropp

We examine how financial constraints in portfolios of suppliers affect customer cash holdings. Using a data set of private and public firms and their suppliers, we show that customers rely on unconstrained suppliers to provide them with backup liquidity and stockpile around 10% less cash than customers with constrained suppliers. We further show that customers with unconstrained suppliers simultaneously receive more trade credit; that the reduction in cash holdings is greater for firms with stronger ties to their unconstrained suppliers; and that customers reduce cash holdings following a significant relaxation in their suppliers' financial constraints through an IPO.

3 - Inaccurate Durations and Supply Chain Disruptions
William Schmidt, Cornell University, 314 Sage Hall, Ithaca, NY, 14850, United States, wschmidt@cornell.edu, Mili Mehrotra

We quantify the performance impact of inaccurate disruption duration estimates using the supply chain data from a multinational division of a Fortune 100 manufacturing firm. We find that inaccurate information on the duration of a disruption can significantly increase the cost of the disruption. In many of those cases we find that a disruption will only be materially costly to the firm if the disruption duration is misestimated. These costs are (1) incremental to the cost of a disruption whose duration is accurately estimated, (2) are incurred regardless of whether the disruption duration is initially over-estimated or under-estimated, and (3) can be large even for small estimation errors.

4 - Worker Poaching in a Supply Chain: Enemy from with in?
Evan Barlow, Weber State University, Goddard School of Business & Economics, 1337 Edvalson St, Ogden, UT, 84408, United States, evanbarlow@weber.edu, Gad Allon, Achal Bassamboo

Poaching workers has become a universal practice. We explore worker poaching between firms linked in a supply chain. We show that the classical intuition from labor economics is insufficient in explaining poaching between supply chain partners. We also show how and under what conditions worker poaching can actually improve supply chain performance. Finally, we show how the equilibrium identity of the supply chain bottleneck depends on the interaction between hiring, poaching, and productivity.

Inventory Management

Contributed Session

Chair: Stef Lemmens, KU Leuven, Naamsestraat 69 Box 3555, VAT BE 0419.052.173, Leuven, 3000, Belgium, stef.lemmens@kuleuven.be

1 - Joint Replenishment Problem with Batch Ordering

Ana Muriel, University of Massachusetts Amherst, Dept of Mechanical & Industrial Eng, 160 Governors Drive, Amherst, MA, 01003, United States, muriel@ecs.umass.edu, Michael Prokle

Motivated by industrial partners who are exploring the benefit of coordinating the ordering and shipping of a variety of parts sold in boxes of a given size, we study the JRP with batch ordering. Given a constant reorder interval, we determine the length of a regeneration period and derive a closed-form expression for the average inventory. We find the optimal constant reorder interval and show the savings relative to an uncoordinated strategy and the joint EOQ policy. The optimal ordering policy under constant demand, however, requires a non-constant reorder interval. We propose a MIP to determine the optimal policy and explore the relative quality of constant reorder interval policies.

2 - The Impact of Political Preference on Inventory Decisions

Yi Tan, University of Kansas, 1654 Naismith Drive, Lawrence, KS, 66045, United States, vieiraty0113@gmail.com, Yaoyi Xi

We conduct an empirical investigation of whether and how CEO political ideology affects firm inventory strategies. Using a panel that contains quarterly data from 1991 to 2016 for 2,745 unique U.S. firms covered by Compustat, we find that firms tend to hold more inventories when the Party their CEOs prefer holds the Presidency. We perform further analyses on firm financial performance to investigate the underlying mechanisms for this finding.

3 - Global Dual Sourcing and Order Smoothing

Stephen M.Disney, Professor of Operations Management, Cardiff Business School, Aberconway Building, Colum Drive, Cardiff, CF10 3EU, United Kingdom, disneysm@cardiff.ac.uk, Robert Boute, Jan A.Van Mieghem

Companies often experience non-stationary demand as products evolve over their life cycle. We investigate a tractable family of single and dual sourcing policies tailored to such demand environment. We adopt a conventional discrete time inventory model with a linear control rule that smooths orders and allows an exact analytical analysis of an easy to implement dual sourcing policy.

4 - Not Centralizing your Inventory? It may be Fine

Bo Li, Assistant Professor, Ningbo Supply Chain Innovation Institute China, Ningbo, China, libo@alum.mit.edu, Antonio Arreola-Risa, Mark L. Spearman

Centralizing inventory, especially safety stocks, is often a proposed solution to cut inventory. In this talk, we consider a two-tier production-inventory system and illustrate how the benefit of centralizing inventory can be negligible under certain situations.

5 - Performance Measurement of a Rotavirus Vaccine Supply Chain by Integrating Production Capacity into the Guaranteed Service Approach

Stef Lemmens, KU. Leuven, Naamsestraat 69 Box 3555, VAT.BE 0419.052.173, Leuven, 3000, Belgium, stef.lemmens@kuleuven.be, Nico Vandaele, Catherine Jenny Decouttere, Mauro Bernuzzi, Amir Reichman

Previous research has integrated multi-echelon inventory management into the design of a responsive supply chain by the use of the guaranteed service approach. We model the production capacity with a queuing network to handle the variability of the batch production processes as well as the demand variability. The focal point is the tail of the lead time distribution which has an impact on the supply chain safety stock. We apply our model to the rotavirus vaccine supply chain. The impact of modelling capacity on lead times and thus safety stocks and working capital is significant.

1 - Microfoundations of Multifactor Model for Trading Volume in Speculative Market

Seungki Min, PhD Candidate, Columbia University, 1 16th St Broadway, New York, NY, 10027, United States, smin20@gsb.columbia.edu

The joint distribution of trading volume across multiple securities, as a stochastic model of liquidity, needs to be considered in the execution of portfolio transactions. We propose a microstructural model that explains trading volume with the investors' activity responding to sequential information arrival. Only with idiosyncratic investors, our model restores 'Market Microstructure Invariance' hypothesis of Kyle and Obizhaeva (2016). With factor portfolio investors, it suggests a factor structure in trading volume which we observe empirically for U.S. equities. We also observe the increase in factor investment during the recent years that implies the growth of passive investing.

2 - A Separation Principle for Dynamic Portfolio Optimization

Ciamac Cyrus Moallemi, Columbia University, Columbia Business School, 3022 Broadway Uris 416, New York, NY, 10027, United States, ciamac@gsb.columbia.edu, Benjamin Van Roy

We consider multi-period portfolio optimization problems in the presence of predictablereturns. In our setting, we establish that that the term structure of future conditional meanreturns is a sufficient statistic for optimal decision making. This provides a separationprinciple that partitions optimal trading into two natural steps: (1) forecast the term structureof future expected returns; (2) compute the optimal trading decision by solving a single-period,deterministic Markowitz-style mean-variance optimization problem, but with an endogenouslydetermined effective time horizon.

3 - Robust Wasserstein Profile Inference in Distributionally Robust Mean-variance Model

Lin Chen, Columbia University, New York, NY, 10025, United States, lc3110@columbia.edu, Jose Blanchet, Xunyu Zhou

This project is concerned with a distributionally robust mean-variance model. By solving its dual problem, we can get a data driven model with penalty on norm of portfolio. We use RWPI method to choose the regularization parameter without the use of cross validation and then design an algorithm to solve the optimization problem. Numerically experiments are given to compare the performance of portfolio obtained by traditional Markovitz model and RWPI method.

Stochastics and Behavioral Operations

Sponsored: Applied Probability

Sponsored Session

Chair: Yash Kanoria, Columbia Business School, New York, NY, 10027, United States, ykanoria@gmail.com

1 - Traffic Scheduling:Large Population Optimality

Harsha Honnappa, Purdue University, 315 N. Grant Street, West Lafayette, IN, 47906, United States, honnappa@gmail.com

We solve the problem of scheduling appointments for a finite customer population to a service facility with customer no-shows to minimize customer waiting time and server overtime costs. We study the problem in fluid and diffusion frameworks. We find that it is optimal to schedule traffic so that the system is in critical load. That is, heavy-traffic is obtained as a result of optimization rather than as an assumption. Our proposed schedules are proved to be asymptotically optimal for a finite horizon in the fluid scaling and for large and finite horizon in the diffusion scaling. We also provide some initial results on solving the finite horizon problem.

2 - Strategic Open Routing in Service Networks
Andrew E. Frazelle, Duke University-Fuqua School of Business, 2616 Erwin Rd, #1302, Durham, NC, 27705, United States, andrew.frazelle@duke.edu, Alessandro Arlotto, Yehua Wei

We study the behavior of strategic customers in an open-routing service network with multiple stations. When a customer enters the network, she is free to choose the sequence of stations that she visits, with the objective of minimizing her expected total system time. We propose a two-station game with all customers present at the start of service and deterministic service times, and we find that strategic customers "herd," i.e., in equilibrium all customers choose the same route. We find that the herding behavior is also prevalent in many other congested open-routing service networks, including those with arrivals over time, those with stochastic service times, and those with more than two stations.

3 - Dynamic Decision Making under Customer Abandonment Risk
Jiaqi Lu, Columbia Business School, c/o Clara Magram, 30 22 Broadway, New York, NY, 10027, United States, jlu20@gsb.columbia.edu, Yash Kanoria, Ilan Lobel

We consider a firm repeatedly interacting with a customer. At any time, the firm has to choose between a risky and a safe mode of service. The customer has a propensity to leave if her "happiness", an average of recent rewards, is low. The hazard rate is a step function that drops to zero at what we call "happiness threshold". We study how the firm can maximize (discounted) rewards over the customer lifetime by optimally trading off between myopic rewards and the risk of customer abandonment in future. The optimal policy uses the service mode with higher average reward rate everywhere *except*, being risk-averse just above the threshold and risk-seeking just below the threshold.

4 - Choice Paralysis on Operational Decision Making
Rene A. Caldentey, The University of Chicago, Booth School of Business, 5807 S.Woodlawn Ave, Chicago, IL, 60637, United States, rene.caldentey@chicagobooth.edu

We empirically investigate the notion of Choice paralysis (i.e., too many options can paralyze a consumer and make them more prone to not purchasing) and study its implications on assortment and inventory decisions. We propose a modification to the nested logs model to incorporate the choice paralysis effect.

Sponsored Session

Chair: Selvaprabu Nadarajah, University of Illinois at Chicago, College of Business, Chicago, IL, 60607, United States, selvan@uic.edu

Co-Chair: Nicola Secomandi, Carnegie Mellon University, Pittsburgh, PA, 15213, United States, ns7@andrew.cmu.edu

1 - Networked Resources and Market Interactions
John R. Birge, University of Chicago, Booth School of Business, 5807 South Woodlawn Avenue, Chicago, IL, 60637, United States, John.Birge@ChicagoBooth.edu

Networked resources, such as electricity, gas, and data, often involve multiple markets that apply to flows (input and output) and to capacity. Large producers or consumers can often exercise market power that is reduced in the presence of financial traders. Interactions across markets, however, can subvert the goals of financial trader participation and allow for market manipulation. This talk will discuss the design of markets to avoid such situations.

2 - A Spectrum of Optimal Policies for Risk-averse Electric Vehicle Charging
Daniel Jiang, University of Pittsburgh, 1002 Benedum Hall, 3700 O'Hara Street, Pittsburgh, PA, 15261, United States, drjiang@pitt.edu, Warren B.Powell

We consider the sequential decision problem faced by the manager of an electric vehicle (EV) charging station who faces stochastic spot prices and present new methodology that generates an approximate "spectrum" of risk-averse policies under dynamic risk measures. We investigate the connection to the more traditional risk vs. reward framework.

3 - Managing Aluminium Smelter Robustness
Stein-Erik Fleten, Norwegian University of Science & Technology, Dept of Ind Econ & Tech Mgmt, Trondheim, Norway, stein-erik.fleten@iot.ntnu.no, Alessio Trivella, Selvaprabu Nadarajah, Denis Mazieres, David Pisinger

Commodity and energy production assets face shutdown risk due to fluctuations in input/output prices and exchange rates. We formulate a new shutdown-specific risk-averse model able to handle the risk of shutdown by operational hedging. An approximate dynamic programming method, the regress-later variant of Least-squares Monte Carlo, is extended to compute risk-averse operating policies. We tested the new model on a real application related to an aluminium smelter with mothballing and shutdown flexibility. Our results show that the new shutdown risk-averse policy outperforms CVaR-based policies, providing more efficient trade-offs between asset value and shutdown probability.

4 - Optimal Custom Hedge of Quantity Risk
Andrea Roncoroni, ESSEC Business School, Cergy-Pontoise, France, roncoroni@gmail.com

Commodity-linked positions often exhibit a combined exposure to both market prices and nontradable terms (e.g., harvest, volume, load). We provide a general theory of customized contract design aimed at optimally hedging the corresponding joint risk. Tailored hedges are derivatives written on the underlying tradable and any quoted variable exhibiting statistical dependence on the quantity term. Given agent's beliefs, mean-variance preferences, and a copula-based setting, we derive analytical solution sought among two-asset contingent claims and numerical solutions for portfolios of one-asset customized hedges. Closed-form solution are computed under separable copula densities.

Emerging Issues in Innovation Management

Sponsored: Technology, Innovation Management & Entrepreneurship

Sponsored Session

Chair: Bilal Gokpinar, b.gokpinar@ucl.ac.uk

1 - Shifts in the Counts of Employees and Locations: Impact on Startup Survival
Berke Emre Guzelsu, Boston University, 595 Commonwealth Avenue, Boston, MA, 02215, United States, bguzelsu@bu.edu, Nitin Joglekar, Moren Levesque

Fifty percent of business startups survive after five years, while about one third survive after ten years. To improve their survival odds, startups must pay attention to changes in their workforce size and in the number of locations in which they operate during their initial unsettled years. We use annual panel data and hazard rate models to analyze the impact of these operational factors on startup survival rates.

2 - Search and Sequential Innovation in Mobile App Development
Nilam Kaushik, B-116, Tufnell House, London, N70EG, United Kingdom, uceikau@ucl.ac.uk

The process of search, identification, and acquisition of new knowledge is essential for the success of new products. We explore how firms search for ideas in sequential product development through the highly competitive and dynamic setting of mobile application development. Using novel text-mining techniques, we derive measures of similarity between a focal app's update and updates made by competitor apps and study performance implications thereof. We also explore the performance implications of the dissimilarity of an app's update with respect to its past updates.

3 - The Impact of Asymmetric Information in Procurement Auctions
Joel Wooten, University of South Carolina, 1014 Greene St., Columbia, SC, 29208, United States, joel.wooten@moore.sc.edu

Web-based technologies have enabled new possibilities in procurement auctions. We investigate asymmetric information conditions and the behavior of participants with respect to these in an experiment around bids for construction projects.

4 - Dual Innovation, Innovation Abandonment and Innovation Performance
Sriram Narayanan, Michigan State University, 632 Bogue Street, Room N357 North Business College Complex, East Lansing, MI, 48824, United States, narayanan@broad.msu.edu, Adrian S.Choo, Ravi Srinivasan, Soumodip Sarkar

In this study, we focus on investigating the impact of firms thta undertake dual innovations (both products and services) and innovation abandonment on innovation performance. We perform a large sample investigation to examine this problem using a unique set of archival data with 11,558 manufacturing and service firms located in 11 countries in Europe. We find that dual innovation positively influences a firm's innovation performance. Innovation performance are measured by sales turnovers and product introductions that are new to the market and new to the firm.

Supply Chain Finance

Sponsored: Manufacturing & Service Oper Mgmt, iFORM

Sponsored Session

Chair: Lingxiu Dong, Washington University, Saint Louis, MO, 63130-4899, United States, dong@wustl.edu

1 - Supplier Diversification under Buyer Risk

Gerry Tsoukalas, Wharton School of Business, 3730 Walnut Street, 567 Jon M. Huntsman Hall, Philadelphia, PA, 19104, United States, gtsouk@wharton.upenn.edu, Jiri Chod, Nikolaos Trichakis

Arguably the most common explanation of supplier diversification is hedging against supplier risks. We provide an alternative explanation based on buyer risks: In the presence of information asymmetry regarding buyer creditworthiness, buyers may take costly action to signal their quality to suppliers. We find that while signaling is effective at overcoming initial information asymmetry, under single sourcing, it leaves the supplier with an information monopoly that leads to hold-up in future periods. In this context, we show that ex ante supply base diversification can be effective at alleviating ex post informational holdup, but also comes at the expense of higher upfront costs.

2 - A Supply Chain Theory of Factoring and Reverse Factoring

Fasheng Xu, Washington University in St. Louis, Saint Louis, MO, 63130, United States, fasheng.xu@wustl.edu, Panos Kouvelis, Wenhui Zhao

To free up supplier's liquidity inhibited by retailer's payment deferral, factoring contracts are often used as post-shipment financing schemes. We find that in a pull system the benefits of recourse factoring are limited, but non-recourse factoring achieves surprisingly better performance by eliminating market frictions and reducing the cash-to-cash cycle. Further, we show how the retailer can help shoulder the supplier's financial burden through reverse factoring contracts with payment guarantee. We find it's not always optimal to extend payment term and the optimally designed reverse factoring contract can coordinate the decentralized supply chain with arbitrary profit allocation.

3 - Financing SME Sellers via E-commerce Platform

Lingxiu Dong, Washington University, Campus Box 1156, One Brookings Drive, Saint Louis, MO, 63130-4899, United States, dong@wustl.edu, Long Ren, Dennis Zhang

Small-business sellers selling products via e-retailing platforms often face capital constraints that limit their ability to build inventory and expand product offerings. E-commerce platform steps up with new financing scheme to help these sellers to grow. We consider sellers' financing issue with e-commerce platform intervention, in both monopoly and competition scenarios. We show that although in the monopoly setting both the seller and the platform benefit from the platform's loan, in the competition setting the platform's loan may intensify the seller competition. We suggest alternative loan offerings to dampen the competition.

Topics in Revenue Management

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Dragos Florin Ciocan, INSEAD, INSEAD, Fontainebleau, France, florin.ciocan@insead.edu

1 - Near-optimality of Myopic Markdowns in the Presence of Strategic Consumers

Anton Ovchinnikov, Stephen J.R. Smith School of Business, Queen's University, anton.ovchinnikov@insead.edu, Dragos Florin Ciocan

Much of the research on dynamic pricing with strategic consumers assumes that all consumers are strategic. The empirical data, and the experimental results, however, show that a non-insignificant proportion of consumers behave myopically. Our paper demonstrates that in such situations pricing as if all consumers are myopic often leads to higher revenues than pricing as if all consumers are strategic.

2 - Operational Challenges for Decentralized Manufacturing

Andre Du Pin Calmon, INSEAD, Boulevard de Constance, Fontainebleau, 77300, France, andre.calmon@insead.edu, Victor Araman, Anton Ovchinnikov

Motivated by a social enterprise in Kenya that manufactures fashion accessories using a distributed network of artisans, we analyze the operational challenges of managing a decentralized "virtual" factory. The artisans have limited budgets, capabilities, and varying production quality, while the company faces uncertain demand. We investigate various operational issues that emerge in this unique business model.

3 - Non Stationary Online Macthing

Victor Araman, American University in Beirut, Lebanon, va03@aub.edu.lb, Dragos Florin Ciocan

We consider a number of nodes and an input traffic. Each arrival needs to be matched with one node out of a subset that is selected following a nonstationary distribution. We suggest a simple online allocation policy that performs extremely well.

4 - Optimal Pricing and Introduction Timing of New Virtual Machines

Spyros Zoumpoulis, INSEAD, 15 Rue Daubenton, Paris, 75005, France, spyros.zoumpoulis@insead.edu, Ian Kash, Peter Key

We characterize the optimal pricing and timing of introductions of new virtual machines for a cloud service provider in the face of customers who are averse to upgrading to improved offerings. We show that a simple policy of periodic introductions and Myerson pricing is near optimal in many situations.

Pricing for Logistics and Distribution

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Sila Cetinkaya, sila@lyle.smu.edu

1 - Can Dynamic Pricing Reduce What Consumers Pay?

Naveed Chehrazi, McCombs School of Business, 2110 Speedway, Stop B6000, Austin, TX, 78712, United States, naveed.chehrazi@mccombs.utexas.edu, Yannis Stamatopoulos, Achal Bassamboo

We illustrate that when pricing decisions are made in conjunction with other operational decisions, dynamic pricing can result in increased system efficiencies, which can pass-through to consumers. To demonstrate this point, we equip the traditional economic order quantity (EOQ) setting with a rich demand model and compare social outcomes under two alternatives, dynamic and static pricing. We show that dynamic pricing Pareto-dominates static pricing: it generates higher profit and sales rate for the retailer, while it reduces the average price paid per unit sold for consumers.

2 - Delivery Pricing Strategies for Competing Retailers

Chinmoy Mohapatra, University of Texas at Austin, Austin, TX, United States, smilingchin@gmail.com, Anant Balakrishnan, Shankar Sundaresan

We study competition between two retailers who can offer consumers different delivery pricing choices: a pay-for-delivery option and/or a subscription option with limited free deliveries. Using a novel utility-based framework with heterogeneous consumers, we demonstrate that the firms can avoid aggressive price competition by offering complementary delivery pricing options in a Stackelberg equilibrium. We characterize the equilibrium delivery pricing policies for both retailers and develop interesting insights.

3 - Smart Logistics in E-commerce - Pricing in Last Mile Delivery

Lan Lu, HKUST, Dept. of IELM, Clear Water Bay, Hong Kong, Hong Kong, 00000, Hong Kong, na, Chung-Yee Lee, Chung Piaw Teo

We consider a delivery service pricing problem in the view of an e-commerce platform which coordinates the deliveries of many logistics companies. The objective is determining a parcel delivery price to each area to balance the worst-case profits of the couriers. We use the method of optimal transport to model the distributional uncertainty in delivery locations, and propose a cutting plane approach to solve for the optimal set of prices.

4 - A Mathematical Model for Short Term Liquefied Natural Gas (LNG) Delivery

Fatih Mutlu, Qatar University, Doha, Qatar, fatihmutlu@qu.edu.qa

LNG suppliers prepare approximate annual plans for the delivery of LNG contracts. During the implementation stage, short-term portions of these plans should be adjusted so as to finalize the exact loading days and assigned vessels and to exploit the additional sales opportunities that recently arose. We develop a comprehensive mathematical model for maximizing the revenues from additional sales minus the penalty costs associated with deviating from the annual plan. Through a comprehensive numerical study, we analyze the sensitivity of profit on vessel capacity and demand-to-capacity ratio.

5 - Coordination via Pricing in the Reverse Channel

Sila Cetinkaya, SMU, Dallas, TX, United States, sila@smu.edu, Elif Akcali, Yi Zhang

In this paper, we study an extension of the traditional channel coordination problem that arises in the context of a reverse supply chain that is comprised of a collector-remanufacturer pair. We investigate effective pricing mechanisms enhancing the efficiency of collection logistics under a general stochastic return process.

Revenue Management

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Srikanth Jagabathula, NYU Stern School of Business, New York, NY, 10012, United States, sjagabat@stern.nyu.edu

1 - Can Managers Plan Assortments? An Experimental Study

Yulia Vorotyntseva, University of Texas at Dallas, Richardson, TX, United States, Yulia.Vorotyntseva@utdallas.edu, Elena Katok, Dorothee Honhon

Assortment planning can be a very complex problem due to product interaction effects, such as cannibalization and inventory pooling benefits. We want to find out if human decision makers have an intuitive understanding of such effects, and whether they can gain it with practice. To do this, we develop and conduct a behavioral experiment, where the subjects are repeatedly picking assortments in a simplified environment. We find that the subjects perform better when the profit maximizing assortment consists of fewer products and that subjects improve their decisions over time.

2 - Group Conversion: A Better KPI to Compare Stores

Anup Hanamant Walvekar, INSEAD, 1 Ayer Rajah Avenue, PhD Office, Singapore, 138676, Singapore, anup.walvekar@insead.edu, Nils Rudi, Serguei Netessine

Conversion rate is an important KPI for a retail store that captures the fraction of sales opportunity that the store was able to capture. As a group of people shopping together seldom have multiple transactions, the number of groups visiting the store is a more appropriate measure of sales opportunities than the number of individuals. Identifying groups in traffic using video footage is a laborious and expensive task. In this paper, we mathematically model the customer arrival process and derive methods to identify of groups in traffic data obtained from simple counters.

3 - A Model-based Projection Technique for Segmenting Customers

Ashwin Venkataraman, New York University, New York, NY, United States, ashwin@cs.nyu.edu, Srikanth Jagabathula, Lakshminarayanan Subramanian

We consider the problem of segmenting a population of customers into non-overlapping groups with similar preferences, using diverse signals such as purchases, ratings, clicks, etc., over a large universe of items. We propose a model-based projection technique, which transforms the diverse observations into a comparable scale and deals with missing data by projecting the transformed data onto a low-dimensional space. We then cluster the projected data to obtain the customer segments. Our method achieves upto 84% improvement in the accuracy of new movie recommendations on the MovieLens data set and 6% improvement for similar item recommendations algorithm on an offline dataset at eBay.

4 - Building Optimized and Hyperlocal Product Assortments: A Nonparametric Choice Approach

Srikanth Jagabathula, NYU. Stern School of Business, 44 W. 4th St, Kmc Rm 8-74, New York, NY, 10012, United States, sjagabat@stern.nyu.edu, Vivek Farias, Devavrat Shah

Fashion retailers want to "hyper-localize" product assortments, i.e., customize offerings to the preferences of customers visiting each store, to increase sales. The challenge is demand prediction because of the large variety. To address this challenge, we propose: (a) a nonparametric choice modeling technique that uses purchase transactions tagged by customer IDs and (b) an optimization framework that uses our demand predictions to optimally allocate merchandise to different stores. In a controlled experiment at a large US fashion retailer (~$3B annual revenue and ~300 stores), our methods resulted in additional 7% revenue growth (~$200M profit impact) over the current method.

Topics in Entrepreneurship and Innovation

Invited: New Product Development

Invited Session

Chair: Pascale Crama, Singapore Management University, Singapore, 178899, Singapore, pcrama@smu.edu.sg

1 - The When and How of Outsourced Technology Scouting

Sasa Zorc, INSEAD, 1 Ayer Rajah Avenue, PhD Office, Singapore, 138676, Singapore, sasa.zorc@insead.edu, Sameer Hasija, Ilia Tsetlin

A pharmaceutical firm seeks to conduct a search for acquisition opportunities. We consider the decision of whether to outsource this process or do it in-house, and model it in dynamic principal-agent framework. The optimal contract is shown to have a purchase rights structure: agent is paid a retainer plus a bonus each time the principal makes an acquisition based on the agent's lead. The size of this bonus is decreasing in time and depends on probability of finding a suitable opportunity but not on its value. The outsourcing decision is complex and depends on several factors, with information and cost asymmetries being most important. Delaying outsourcing for later parts of search is shown to be optimal.

2 - Breaking the Stalemate: Signaling, Experience, and Value Creation in Technology Licensing

Pascale Crama, Singapore Management University, 50 Stamford Road, Singapore, 178899, Singapore, pcrama@smu.edu.sg, Reddi Kotha, Phillip Kim

We address the question of how signals can be employed to broker technology licensing agreements when information asymmetry prevents risk-averse parties from working together. In our setting, inventors and licensee firms are brought together by licensing managers (LM) to commercialize new technologies. We argue that experienced LM intentionally alter contractual payment structures to signal value creation to the licensee based on ability and need. With experience, LM gain the ability to create value based on selecting promising inventions and matching them to capable licensing partners. In addition, experienced negotiators weaken and amplify signals as needs to address uncertainties vary.

3 - Truth or Funds? Human Behavior under Competition for Resources in R&D

Özge Tüncel, Singapore University of Technology and Design, 8 Somapah Rd, Singapore, tuncel_ozge@mymail.sutd.edu.sg, Niyazi Taneri, Nektarios Oraiopoulos, Jochen Schlapp

Self-interested project managers working on R&D projects compete for their firm's limited resources. This may lead to misreporting of project prospects (adverse selection) and distort both the efforts made by project managers (moral hazard) and the firm's resource allocation decision in the absence of carefully designed incentive mechanisms. We study how human behaviour further complicates this process and suggest remedies to alleviate the problem.

4 - Behavioral Responses in the Multi-armed Bandit Model

Fabian J. Sting, University of Cologne, Albertus-Magnus-Platz, c/o WiSo-Sekretariat Universitaetsstrasse 91, Cologne, 50923, Germany, sting@wiso.uni-koeln.de, Mirko Kremer, Andolhossein (Navid) Ghayazi

How do human decision makers respond to changing business landscapes, e.g., in project portfolio management? Toward answering that question we investigate the well-studied multi-armed bandit model—-yet enriched with disruptions, i.e., changes in the stochastic processes that yield the arms' payoffs. We compare normative results from comprehensive simulation studies with behavioral results from lab experiments.

DEA Methodological Extensions and Applications

Invited: Data Envelopment Analysis

Invited Session

Chair: Mehdi Toloo, Technical University of Ostrava, Czech Republic, VŠB-TU Ostrava, Faculty of Economics, Sokolská tr. 33., Ostrava, 701 21, Czech Republic, m_toloo@yahoo.com

1 - Extended DEA Efficiency Model of Rice Growing Farmers with Undesirable Output and Interval Data

Azizul Baten, Shahjalal University of Science and Technology, Sylhet, Bangladesh, baten_math@yahoo.com

An extended Data Envelopment Analysis model based on Directional Distance Function approach considering undesirable outputs, climatic factors and interval data is developed. The inclusion of these factors enables to represent the actual production environment. The interval data approach is used to model the uncertainties in the production environment and obtain the interval efficiency score of rice farmers who produces undesirable outputs and operates under uncertainty. The optimistic and pessimistic cases are considered to estimate the upper and lower bound of the efficiency score for each farmers as this model cannot be solved in its original form.

2 - Measuring Nursing Home Quality Performance using DEA

Christine Pitocco, Stony Brook University, 6 Essex Drive, Ronkonkoma, NY, 11779, United States, christine.pitocco@stonybrook.edu

A primary concern of consumers as they select a nursing home is the quality of care provided by the home. No single quality measure exists to evaluate nursing home performance; therefore a multidimensional approach is required. We illustrate the use of Data Envelopment Analysis using nine quality indicators to evaluate 589 nursing homes in New York State in 2015.

3 - The Efficiency Measurement of Colombian Higher Education Institutions using Data Envelopment Analysis with Flexible Measures

Sepideh Abolghasem, Universidad de los Andes, Carrera 1 Este #19A-40, Bogota, 11001000, Colombia, ag.sepideh10@uniandes.edu.co, Linas Navas, Felipe Montes, Mehdi Toloo, Andrés Useche, Ricardo Salas, Andrés Medaglia, Roberto Zarama

It is vital to assess the efficiency of universities for effective allocation and utilization of educational resources. This work explores the performance efficiency of higher education institutions (HEIs) in Colombia using a data envelopment analysis (DEA) model. We examine the efficiency of HEIs in terms of their achievement, applicability and research using a variant of DEA where we include flexible measures. To measure efficiency, we consider the results of the national exam after completing higher education studies, graduates' employability rate, the number of published articles, the total number of academic staff, the percentage of PhD and the total number of undergraduate students. The application of DEA enables HEI to identify deficient activities and take appropriate actions accordingly for improvement.

Social Media Analytics for Disaster Management

Invited: Social Media Analytics

Invited Session

Chair: Jun Zhuang, University at Buffalo, SUNY, 317 Bell Hall, Buffalo, NY, 14260, United States, jzhuang@buffalo.edu

Co-Chair: Samiul Hasan, University of Central Florida, Orlando, FL, 32816, United States, samiul.hasan@gmail.com

Co-Chair: Arif Mohaimin Sadri, Purdue University, West Lafayette, IN, 47906, United States, asadri@purdue.edu

1 - Get Insight into Social Media Analysis and Incident Detection

Ying Chen, Northwestern University, 600 Foster St, Evanston, IL, 60208, United States, y-chen@northwestern.edu, Archak Mittal, Hani S.Mahmassani

The feasibility of using social media data for detecting traffic incidents is evaluated. The presented framework consists of three main components, Twitter data mining, location extraction and traffic management. The approach is implemented using data from the Chicago area; using on-line simulation-based traffic estimation and prediction tools, traffic management strategies developed to reduce the impact of incidents are evaluated. The results confirm the potential of Twitter posts to complement and improve the effectiveness of dynamic traffic management approaches for incident conditions.

2 - Crisis Communication and Rumor Management using Social Media During Disasters

Jun Zhuang, University at Buffalo, SUNY, 317 Bell Hall, Buffalo, NY, 14260, United States, jzhuang@buffalo.edu, Bairong Wang

Social media has been used by organizations and private citizens for crisis communication during disasters. However, few research has studied the users' behavior when facing rumors and debunking information. We first study the effectiveness of crisis communication and how re-tweet and mention could help improve crisis information impression. Second, we investigate four cases of rumor responding and corresponding debunking behaviors of Twitter users during Hurricane Sandy in 2012 and Boston Marathon bombings in 2013. Finally, we discuss the optimal debunking strategies dealing with potential rumor information, and the corresponding consequences on the downstream information sharing.

3 - Understanding the Effectiveness of Social Media Communication During Disasters using Twitter Data from Hurricane Sandy

Kamol Chandra Roy, University of Central Florida, Orlando, FL, United States, roy.kamol@Knights.ucf.edu, Samiul Hasan

Rapid communication during a natural disaster is one of the critical aspects of effective disaster management strategies. Online social media provides a tremendous opportunity to communicate information during disasters. In this study, around 52.5 million tweets related to hurricane Sandy have been analyzed to assess the effectiveness of information spreading in social media. Our study reveals that information spreading capacity depends on user follower count, user category, bot score (controlled by human or machine) and activity levels.

4 - Analysis of User-Specific Communication Patterns of Hurricane Sandy using Twitter Data

Arif Mohaimin Sadri, Purdue University, 149 Arnold Drive Apt 12, West Lafayette, IN, 47906, United States, asadri@purdue.edu

Hurricane Sandy was one of the strongest and costliest in the history of hurricanes. Many people used social media to communicate during this period while lacking access to traditional information sources. In this study, we analyzed raw data (~52 M tweets, ~13 M users, Oct 14 -Nov 12, 2012) obtained from Twitter. First, we identify different communities from the subgraphs of Twitter that was active before, during, and after Sandy's landfall. Then, we extract different crisis communication topics evolved in these subgraphs while Hurricane Sandy was approaching.

5 - Revisiting Collaborative Activity and its Impact on Peer-produced Content

Srikar Velichety, University of Memphis, 395 S.Highland Street, Suite 128, Apt#301, Memphis, TN, 38111, United States, svlchety@memphis.edu

We provide a bottom-up view of collaboration in peer-produced content. Using the dictionary definition of collaboration, we identify aspects of collaboration that the present research on online communities does not consider. We introduce and define the concept of implicit collaboration and then identify two dimensions and four possible areas of collaboration. In each area, we identify the relevant social network that captures collaboration. Using customized metrics on these networks that capture various aspects of collaboration in each of the four different areas, we quantify the impact of collaboration on article quality. We also measure the usefulness of these metrics in predicting quality.

Invited Session

Chair: Elena Katok, University of Texas at Dallas, Richardson, TX, 75080, United States, ekatok@utdallas.edu

Co-Chair: Cuihong Li, University of Connecticut, Storrs, CT, 06269, United States, cuihong.li@uconn.edu

1 - The Reference Price Effect of Reserve and Bin Prices

Ernan E.Haruvy, University of Texas-Dallas, School of Management, SM.34 Box 830688, Richardson, TX, 75083-0688, United States, eharuvy@utdallas.edu

Reserve prices and BIN prices can serve as reference prices for bidders and in turn influence bidder entry and willingness to pay. We first quantify the dual impact and implied trade-off of price floors and BINs on the number of bidders and auction revenue. Second, we distinguish the reference price effect of reserve prices from the better known truncation and entry effects of reserve prices. Third, we examine robustness of the reserve price effect to the introduction of BINs and seek to characterize the relative reference pull of a reserve price relative to a BIN on the final price. We find that reserve prices have a smaller impact than BIN on final price and that the impact of reserve price is robust to BINs.

2 - The Influence of Social Media on Charitable Fundraising

Peter T. Popkowski Leszczyc, University of Alberta, 4-30 F Faculty of Business Blg, Edmonton, AB, T6G 2R6, Canada, ppopkows@ualberta.ca

We investigate the combined power of auctions and social media to raise funds for charity. Auctions are uniquely positioned to price unique art, and social media is uniquely positioned to generate demand for that art. We auctioned off artwork created by teams of under-privileged youth with unique stories and goals, and used social media, with a focus on Facebook and Facebook likes to disseminate word of mouth about these auctions. We find that social media increases prices in charity auctions by affecting (1) impressions (i.e., the number of times a Facebook posting displayed) which in turn affect bidding intensity and then price and (2) through Facebook likes which affect price directly.

3 - Procurement Mechanisms with Post-auction Cost-reduction Investigations

George Chen, University of Texas at Dallas, Richardson, TX, United States, georgeqc@umich.edu, Damian Beil, Izak Duenyas

Consider the following procurement setting: After seeing suppliers' bids, the buyer can choose to investigate some suppliers to identify cost-reduction opportunities; the investigated suppliers' costs will decrease by the identified cost-reductions; the buyer then awards the contract. We characterize the optimal first-price sealed-bid mechanism, as well as an optimal mechanism among a wider class of mechanisms. For ex-ante symmetric suppliers, incorporating investigations create an ex ante win-win situation for everyone. The win-win may break down when suppliers are sufficiently asymmetric, but no supplier has the incentive to unilaterally block investigation.

4 - Supplier Cost Reduction: Competition and Endogenous Information Asymmetry

Cuihong Li, University of Connecticut, School of Business, 2100 Hillside Road, Storrs, CT, 06269, United States, cuihong.li@uconn.edu

Consider a hold-up problem in which suppliers exert cost-reduction efforts before the buyer offers contracts. We study the impact of supplier competition and endogenous information asymmetry generated by mixed strategy of suppliers.

Machine Learning & Data Mining

Sponsored: Artificial Intelligence

Sponsored Session

Chair: Ravi Aron, Johns Hopkins University, Baltimore, MD, 21202, United States, raviaron@jhu.edu

1 - Predicting Complex Outcomes using Machine Learning: A Dimensionality Reduction Approach

Praveen Pathak, Warrington College of Business, University of Florida, Gainesville, FL, 32611, United States, praveen.pathak@warrington.ufl.edu

Machine learning techniques are useful in many business domains and specifically to predict outcomes in big data. However big data inherently has a variety of features. The efficacy of machine learning algorithms might be reduced give these many features. But machine learning techniques can be used to do feature selection out of these myriad of features. Such feature selection leads to reduction in dimensionality of features. We use machine learning techniques for dimensionality reduction and show how complex outcomes could be predicted.

2 - Predicting Safe Handoffs, using Data Mining to Determine the Factors that Predict Safer Hand off Behaviors in Inpatient Settings

Phillip Phan, Alonzo and Virginia Decker Professor, Johns Hopkins Carey Business School, Baltimore, MD, 21202, United States, pphan@jhu.edu, Soo-Hoon Lee

This study seeks to discover a multi-level recursive model of organizational and process factors that determine the adoption and use of electronic hand-off tools in clinical settings.

3 - So Far So Good? Predicting Patient State Transition in Chronic Care using Machine Learning

Ravi Aron, Johns Hopkins University, Carey Business School, 100 International Drive, Baltimore, MD, 21202, United States, raviaron@jhu.edu

We address the problem of predicting state transition in chronic diseases. We use techniques drawn from Machine Learning - in specific ensemble learning techniques - to predict a patient's likelihood of state transition. We contrast our approach with traditional estimation models and find that our method based on ensemble learning outperforms these methods.

Social Network Analytics

Invited: Social Media Analytics

Invited Session

Chair: Peng Xie, Georgia Institute of Technology, Atlanta, GA, 30309, United States, peng.xie@scheller.gatech.edu

1 - A Deep Look into Helpful Online Physician Reviews

Lina Zhou, University of Maryland-Baltimore County, 1000 Hilltop Circle, Baltimore, MD, 21250, United States, zhoul@umbc.edu, Nujood Alodadi

Compared with online reviews of other types of products, physician reviews have been much less studied. Much remains to understand what constitutes a helpful online physician review. A few extant studies are focused on analyzing word-level features by leveraging general purposed lexicons. These methods are unable to address domain-specific characteristics of physician reviews such as embedded semantics. They also overlooked social network features of online reviews. This research is aimed to advance our knowledge about helpful online physician reviews by incorporating semantics and social network information.

2 - Revealing Puzzles of the Effect of Online Brand Community Participation on Purchase Frequency

Xuehua Liao, Ph.D, Sun Yat-sen Business School, Guangzhou, China, liaoxueh@mail2.sysu.edu.cn, Kang Xie, Jinghua Xiao

Numerous studies on how online brand community engagement affects purchase generate mixed findings, but slim evidence deep into the contradiction. This study tries to reveal it from perspective of uncertainty reduction theory. Realistic engagement and purchase behavior data are collected to test our hypotheses. Results show that whether users reduce their uncertainty about the firm or product through communication with others plays an important role. This study enriches uncertainty reduction theory by extending its application condition from bilateral to trilateral relation. Also, it puts forward a fresh analytical perspective to shed light on the engagement-purchase effect confusion.

3 - Strategic Information Dissemination in Healthcare Workers Network

Xiaowei Mei, University of Florida, 1454 Union Road, #11, Gainesville, FL, 32603, United States, xmei@ufl.edu

How adoption of new healthcare management practices among healthcare workers can be promoted by disseminating information through their work related network? We examine this phenomenon by studying the adoption of a new medicine in a large hospital in the US. We construct a comprehensive work related network of doctors and other supporting healthcare staff based on their past collaboration over one year period. Then we examine the diffusion of new medicine in this network over time. We find that good health care management practices can be promoted by strategically seeding information about them in the work related network of health care workers.

4 - A Novel Literature Retrieval Model Based on Wisdom of Crowds in the Citation Network

Ruiyun Xu, City University of Hong Kong, Kowloon Tong, Hong Kong, ruiyunxu2-c@my.cityu.edu.hk, Hailiang Chen, J. Leon Zhao

We develop an innovative retrieval model by leveraging the wisdom of crowds embedded in the citation network to enable a fast and comprehensive article search. Instead of keywords, an abstract is used as query input to better capture a user's information need. To assess the relevance between the query and each article in the corpus, we borrow from the research community's aggregate opinion by looking at whether other articles that are topically similar to the query cite the article or not. We conduct experiments on the dataset collected from the three leading IS journals (ISR, JMIS, and MISQ) from 1977 to 2016. Our retrieval model has achieved better performance compared with the baseline models.

5 - Network Structure and Predictive Power of Social Media for the Bitcoin Market

Peng Xie, Georgia Institute of Technology, Room 907, 100 10th Street, Atlanta, GA, 30309, United States, peng.xie@scheller.gatech.edu

Following the recent discovery of social media's predictive power for financial markets, we try to advance the literature by evaluating the role of social media network structure in distinguishing between value-relevant information and noises. Using data from the Bitcoin market, we provide empirical evidence that loosely-connected social media discussion networks are more accurate in predicting future returns. Although social media information linkages cause information free riding and damage the overall network prediction accuracy, they nevertheless serve as landmarks for identifying informed social media participants.

Expertise versus Skill in Human Prediction

Invited: Forecasting and Prediction

Invited Session

Chair: Pavel Atanasov, PhD, New York University, Pytho LLC, 866 President Street, Brooklyn, NY, 11215, United States, pavel@pytho.io

1 - On the Evaluation of Beliefs: A Method for Assessing Credibility in Subjective Probability Judgment

Josh Baker, University of Pennssylvania, Philadelphia, PA, 19103, United States, jbak@sas.upenn.edu

In the face of uncertainty, decision makers must base their choices on subjective beliefs. Consequently, decision making under uncertainty requires decision makers to infer the quality of the beliefs at their disposal. In the absence of an objective criterion, drawing such inferences can be challenging. The purpose of this research was to develop a method for assessing the quality of beliefs when normative benchmarks are unknown. We demonstrate that simple models of belief credibility (individuals vs. wisdom of the crowds) can be used to improve the accuracy of an individual's beliefs ex ante."

2 - The Robust Bayesian Truth Serum

Jens Witkowski, ET.H.Zurich, Rotbuchstrasse 30, Zurich, 8037, Switzerland, jensw@inf.ethz.ch, David C.Parkes

The Bayesian Truth Serum (BTS), due to Prelec (2004), allows the truthful elicitation of private signals (e.g., experiences, or opinions) in regard to a true world state when this ground truth is unobservable. However, BTS ensures proper incentives only in the limit, i.e. as the number of respondents n goes to infinity. We present the Robust Bayesian Truth Serum (RBTS), which is incentive compatible for every $n \geq 3$, taking advantage of a particularity of the quadratic scoring rule. RBTS is the first peer prediction mechanism to provide strict incentive compatibility for every $n \geq 3$ without relying on knowledge of the common prior. Moreover, RBTS is numerically robust and ex-post individually rational.

3 - Identifying Latent Structures in Human Performance Data using COREX

KSM.Tozammel Hossain, USC-Information Sciences Institute, 4676 Admiralty Way #1001, Marina Del Rey, CA, 90292, United States, tozammel@isi.edu

We present an approach to analyzing human performance data using correlation explanation. A key step in our method is to identify latent cognitive factors from users' responses over various psychological, political, and skill tests. The proposed method harnesses these factors to design effective cognitive tests, forecast users' problem-solving performance, and compose optimal team for tackling problems. We demonstrate the effectiveness of our method on forecasters' performance data collected in a geopolitical forecasting tournament for Good Judgement Project.

4 - Small Steps to Prediction Accuracy

Pavel Atanasov, New York University, New York, NY, 10007, United States, pavel@pytho.io

Pavel Atanasov, Pytho, 866 President Street, Brooklyn, NY, 11215, United States, pavel@pytho.io, Jens Witkowski, Barbara Mellers, Lyle Ungar, Philip Tetlock

Under-reaction and over-reaction to new information are the Scylla and Charybdis of belief updating. We show that highly accurate forecasters successfully navigate these hazards by making frequent, small belief updates of their probabilistic estimates. Updating frequency and magnitude were reliable, valid out-of-sample indicators of accuracy across four seasons of a geopolitical forecasting tournament. Frequent updaters tended to consume more news, and scored higher on cognitive reflection, numeracy and fluid IQ tests. Cognitive training caused smaller, more incremental belief updating. Update magnitude may indicate how forecasters process information from multiple sources.

Advanced Analytics Models in Aviation

Sponsored: Aviation Applications

Sponsored Session

Chair: Shervin Beygi, Boeing, Seattle, WA, 98109-2155, United States, shervin@umich.edu

1 - Modeling Crew Itineraries and Delays in the National Air Transportation System

Vikrant Vaze, Dartmouth College, 14 Engineering Drive, Murdough Center, Hanover, NH, 03755, United States, vikrant.s.vaze@dartmouth.edu, Keji Wei

We propose, optimize and validate a methodological framework for estimating the extent of crew-propagated delays and disruptions. We identify factors that influence propagation, and incorporate them into a robust crew scheduling model. We develop a fast heuristic for solving the inverse of this model to generate crew schedules similar to real-world scheduling samples. Extensive out-of-sample validation tests using four large real-world airline networks demonstrate that the crew schedules produced by our approach generate propagation patterns similar to those observed in the real world. Moreover, parameters calibrated for one network are found to perform reasonably well for other networks.

2 - It's Not Just Luck: Evidence of Impact Operational Improvements and Buffers on Performance from the U.S. Airline Industry

Milind Sohoni, Indian School of Business, Ac4 Level 1, Isb Campus Gachibowli Hyderabad 500032, Hyderabad, 500032, India, milind_sohoni@isb.edu, Vinayak V. Deshpande, Chandrasekhar Manchiraju

Amongst others, airline on time performance (OTP) is impacted by three important factors: (i) Factors outside an airline's control such as weather, (ii) passive actions taken by airlines to improve OTP such as schedule padding, and (iii) active actions taken by airlines to improve operations. We analyze how each of these three affect OTP and airline rankings.

3 - Estimating Occupancy Rates at Delta Sky Clubs

Emmanuel Carrier, Delta Air Lines, 5155 Vernon Springs Trl NW, Atlanta, GA, 30327, United States, emmanuel.carrier@delta.com, Keith Becker, Liming Yao

One of the most common complaint about airport lounges is over-crowding. However, many lounge operators do not have accurate estimates of actual occupancy as exits are typically not recorded. In this presentation, we explore how to estimate occupancy rates by leveraging existing data sources such as lounge entry and aircraft boarding scans. Our results show that a more precise estimate of occupancy rates can improve customer satisfaction in two ways: by managing demand across lounges at airports with multiple locations and by increasing revenues through dynamic pricing during off-peak periods.

4 - Competition Policy, Privatization, and Efficiency: Evidence From the Global Airline Industry

Hao Su, University of Maryland-College Park, 3346 Van Munching Hall, College Park, MD, 20743, United States, haosu@rhsmith.umd.edu, Nicola Volta, Davide Scotti, Megersa Abate, Martin E. Dresner

This paper will examine how competition policy and airline privatization affect the efficiency of global airlines. We apply stochastic frontier models to a panel dataset including the largest worldwide airlines in the period 2005-2015. Our results will reveal the impact of state ownership on airline efficiency, as well as how government competition policy, such as open skies, impacts efficiency.

Adversary-focused Military Applications

Sponsored: Military Applications

Sponsored Session

Chair: Brian J. Lunday, Air Force Institute of Technology, Air Force Institute of Technology, WPAFB, OH, 45433, United States, brian.lunday@afit.edu

1 - A Bilevel Programming Model for Integrated Air & Missile Defense Location Planning

Aaron M. Lessin, United States Air Force, 2950 Hobson Way, Department of Operational Sciences, WPAFB, OH, 45433, United States, aaron.lessin@afit.edu, Brian J. Lunday, Raymond R. Hill

The U.S. military must understand antiaccess/area-denial strategies using air defense weapons systems. We propose a bilevel programming formulation to locate weapons systems to maximize the minimum exposure of the aerial penetration path. We compare the result to three alternative metric-specific penetration paths, and illustrate that the proposed asset location strategy is robust with respect to each intrusion metric. A sensitivity analysis is also conducted to examine the effect of several model parameters on solution quality and required computational effort.

2 - Integrated Air and Missile Defense Design via Game Theoretic Models & Heuristics

Brian J. Lunday, Air Force Institute of Technology, 2950 Hobson Way, Department of Operational Sciences, WPAFB, OH, 45433, United States, brian.lunday@afit.edu, Randi Williams, Matthew J.D. Robbins, PhD

We consider a trilevel optimization formulation to locate air defense radars and interceptor batteries, given subsequent (optimal) missile launches by an attacker and interceptor responses by a defender, in direct competition over the expected survival value of targets. Considering the game theoretic view of this two-player, three-stage, extensive form game, we examine its normal-form representation. We test and develop a construction heuristic and tune two variants of an improvement heuristic to identify the best attacker solution, given a defender's best response, and we demonstrate them on a representative scenario.

3 - A Heuristic and Metaheuristic Approach to the Static Weapon Target Assignment Problem

Alexander Kline, Air Force Institute of Technology, Wright Patterson AFB, OH, United States, akline@afit.edu, Darryl K. Ahner, Brian J.Lunday

The problem of targeting and engaging individual missiles (targets) with an arsenal of interceptors (weapons) is known as the weapon target assignment problem and is NP-Complete. We propose and test a metaheuristic having a previously developed heuristic as a subroutine and that iteratively blocks exiting assignments to an initial feasible solution, allowing superior solutions to those that would otherwise be identified via a greedy selection process. We find solutions that are, at worst, within 2% of optimality and, at best, up to 64% better than the solutions reported to be optimal by BARON.

Supply Chain Management

Contributed Session

Chair: Nadezhda Kozlovskaia, Saint Petersburg, Russian Federation, kknn@yandex.ru

3 - Mitigating Contagion Risk under Uncertainty

Alireza Azimian, Lazaridis School of Business and Economics, Unit 103, 55 Hickory St. E, Unit 103, Waterloo, ON, n2j 3j5, Canada, azim9110@mylaurier.ca

Operational failure of a rival can adversely affect an industry. Earlier studies shows that in a planning horizon investing in the safety of unsafe firms by safe firms can mitigate this risk. This study explores whether Gaussian Processes can be applied to create a successful automated safety investment strategy for multiple planning horizons.

4 - Risk Assessment in Sustainable Freight Transportation System

Ravi Shankar, Indian Institute of Technology Delhi, New Delhi, 110016, India, r.s.research@gmail.com, Divya Choudhary

This research aims to identify and prioritize risks involved in sustainable freight transportation system (SFTS). A novel methodology integrating fuzzy set theory, evidential reasoning algorithm and expected utility theory has been used to quantify and prioritize the identified risks. The results of this study provide significant managerial implications for the better management of disruptions in SFTS.

2 - An Empirical Analysis of Supply Chain Finance Adoption

David Wuttke, EBS.Universität, Burgstr. 5, Oestrich-Winkel, 65375, Germany, david.wuttke@ebs.edu, Eve Rosenzweig, H. Sebastian Heese

We empirically test hypotheses derived from the literature on adoption of Supply Chain Finance (SCF). We identify supply chain finance value and supplier size as important drivers of adoption speed. We complement these drivers with institutional pressures. We also derive suggestions for buyers who seek to implement SCF.

1 - The Start-up Remanufacturing Problem

Nadezhda Kozlovskaia, Saint Petersburg State University, 7/9 Universitetskaya nab., Saint Petersburg, 199034, Russian Federation, kknn@yandex.ru, Nadezhda Pakhomova, Knut Richter

A two stage deterministic inventory EOQ model for manufacturing of new products and remanufacturing cores is considered. The supplier is supposed to manufacture new products, delivered to the buyer according to exponential growing demand. He is also capable of remanufacturing used products, returned back by the buyer after some variable time interval T. If the remanufactured products are finished the manufacturing process starts to cover the remaining demand for the time interval. The processes of manufacturing and remanufacturing of the products are instantaneous.

Simulating Complex Service Systems

Sponsored: Service Science

Sponsored Session

Chair: Ashkan Negahban, Pennsylvania State University, Malvern, PA, 19355, United States, anegahban@psu.edu

1 - Using Simulation to Improve Radiology Appointment Schedules and Patient Service Levels

Kayse Lee Maass, Mayo Clinic, Rochester, MN, United States, maass.kayse@mayo.edu, Maria G. Martinez, Mustafa Y. Sir, Kalyan Pasupathy, Michelle Nordland, Stacy R. Schultz, Brian J. Bartholmai

Medical imaging facilities perform a variety of services including diagnostic magnetic resonance imaging, computed tomography, and interventional procedures for a diverse set of patient groups (e.g., pediatric/adult, inpatient/outpatient/emergency). Some equipment may have special capabilities or limitations, and therefore may only serve patients with a particular subset of characteristics. Using data from a large hospital, we developed a simulation model to assess the design of an appointment schedule based on service and patient type, with priority rules for admitting patients into service in real-time. Effects on wait time, on-time starts and equipment utilization are discussed.

2 - Using a Simulation-optimization Approach to Optimize Patients Scheduling- A Table-experiment Approach

Mohammad Dehghanimohammadabadi, Northeastern University, m.dehghani@northeastern.edu, Mandana Rezaeiahari

In this study, a table-experiment framework is used to simulate and optimize patient scheduling at a Breast Cancer Center. The objective of this paper is to sequence the patients such that minimum average flow time is achieved for two types of patients including follow up and consult patients. Each patient type has different service time and follows different care pathways. A semiheuristic framework is developed by integrating MATLAB, SIMIO, and EXCEL to easily perform the table-experiment in a simulation environment. The obtained results from this framework are further analyzed by comparing five heuristic appointment scheduling approaches.

3 - An Incentive-based Rebalancing Scheme for Large Bike-sharing Systems

Ashkan Negahban, Pennsylvania State University, 30 E. Swedesford Road, Malvern, PA, 19355, United States, anegahban@psu.edu, Samarth Patel, Robin Qiu

The goal of this research is to explore the benefits of an incentive-based rebalancing scheme for large bike-sharing systems. In the proposed scheme, riders are offered incentives (such as discounted rates) to drop off their bike at a station other than but close to the original destination that is empty or expected to run out of bikes in the near future. A discrete event simulation model of New York City's CitiBike system is developed to assess the trade-off between bike redistribution cost and reduced profit due to such discounts.

Sponsored: Service Science

Sponsored Session

Chair: Robin Qiu, Pennsylvania State University, Malvern, PA, 19355, United States, robinqiu@psu.edu

1 - Service System Design under Information Uncertainty: Insights from an M/G/1 Model

Juan Ma, Turner Broadcasting System, Inc, Atlanta, GA, United States, juliema1205@gmail.com, Ying Tat Leung, Manjunath Kamath

We consider designing a service system in which the service provider performs an operation on incoming transactions for a client. An important task for the service provider is to decide on the capacity of the service system based on information available. In many cases, some input parameters to the capacity planning problem are uncertain at design time. Nonetheless, violating the service level requirement during actual operation may incur a penalty. We model this problem using a standard M/G/1 queue and analytically derive the optimal capacity under the assumption that transaction arrival rate is only known to a range. Several insights on the impacts of demand information uncertainty are derived.

2 - Understanding Smart Service Systems through Text Mining
Chiehyeon Lim, UC Merced; POSTECH, 790-784, Engineering Building #4-316, San 31, Hyoja-Dong Nam-Gu, Gyungbuk, Korea, Republic of, chlim@unist.ac.kr, Paul Maglio

Despite the widespread application and research on smart service systems, understanding of such systems is limited. We analyze text data related to smart service systems to develop a unified understanding. Using a combination of metrics and machine learning algorithms, we identify important features, 16 research topics, 4 technology factors (connection, collection, computation, and communications), and 13 application areas from 5,378 scientific articles and 1,234 news articles. We also develop conceptual frameworks of smart service system based on the analytics result. Our contribution is to establish common ground for understanding smart service systems based on a data-driven approach.

3 - A Ranking Algorithm for Shipping in the Spot Market
Max R. Biggs, Massachusetts Institute of Technology, Cambridge, MA, 02139, United States, maxbiggs@mit.edu, Georgia R. Perakis

We study a problem in the tramp shipping industry where a broker has to choose from a set of available cargoes but does not know what cargoes will be available for subsequent voyages. Solving the naïve dynamic programming formulation is hard for realistic problem sizes due to the number of available cargo combinations being exponential in nature. Instead we propose a ranking algorithm that is polynomial in the number of cargoes available, and prove this is equivalent to solving the DP optimally. We run simulations to show that the ranking algorithm outperforms the other common heuristics by a minimum of 5% and the current market performance by 4-32%.

Complex Multi-criteria Decision Making Problems 1

Sponsored: Multiple Criteria Decision Making

Sponsored Session

Chair: Murat Mustafa Koksalan, Middle East Technical University, Middle East Technical University, Ankara, 06531, Turkey, koksalan@metu.edu.tr

Chair: Banu Lokman, Middle East Technical University, Middle East Technical University, Ankara, 06800, Turkey, lbanu@metu.edu.tr

1 - Distribution-based Representative Sets for Multi-objective Integer Programs
Banu Lokman, Middle East Technical University, Department of Industrial Engineering, Universiteler Mahallesi, Ankara, 06800, Turkey, lbanu@metu.edu.tr, Sami Serkan Ozarik, Murat Mustafa Koksalan

Finding a set of points that represent the nondominated set for Multi-objective Integer Programs (MOIPs) is an important research area and has many applications. In this study, we search for common properties of the distributions of nondominated points in various MOIPs and show that the distribution of nondominated points may be critical in defining the desired properties of the representative subset. We introduce a density measure and analyze typical distributions of nondominated points for different MOIPs. We categorize the nondominated set into regions based on their estimated densities. We then generate distribution-based representative sets for different MOIPs.

2 - A Web Application for Solving Multi-objective Integer Programming Problems
Gokhan Ceyhan, Middle East Technical University, Orta Dogu Teknik Universitesi, Endustri Muhendisligi Bolumu No 319, Ankara, 06800, Turkey, gokhanceyhan01@gmail.com, Murat Mustata Koksalan, Banu Lokman, Murat Mustata Koksalan

In this study, we will first briefly present our approaches to generate all or representative nondominated points for multi-objective mixed integer linear programming (MOMILP) problems. Then, we will demonstrate our web application where users can input their MOMILP problems, select different solver options based on the type of the output required and use different visualization tools available.

3 - GoNDEF: An Exact Algorithm to Find Non-dominated Solutions of Multi-objective MILP as Points, Line Segments and Facets
Seyyed Amir Babak Rasmi, PhD Student, KOC University, Rumeli feneri st, KOC University, ENG212, Istanbul, 34450, Turkey, srasmi14@ku.edu.tr, Metin Turkay

The Generator of Non-Dominated and Efficient Frontier (GoNDEF) finds exact Pareto solutions represented as points, line segments, and facets consisting of Extreme/non-Extreme Supported/Unsupported Non-dominated solutions for Multi-Objective MILPs. A large group of real-life decision problems involving more than one conflict criterion can be presented as MOMILPs. GoNDEF applies the Screening and the Generative Approaches to extract the non-dominated frontier from a given set of integer solutions and without a given set of integer solutions, respectively.

1 - Deep Reinforcement Learning
Daewoo Chong, Booz Allen Hamilton, Washington, DC,

Machine intelligence is becoming more and more prevalent in our everyday lives. Andrew Ng, a leader in the field, calls it the new electricity. Many of the gains have come from a family of methods including convolutional and recurrent neural networks called deep learning. These methods have become crucial to the improvements in digital assistants, machine translation systems, and self-driving cars, and this seems to be only the beginning. Join this talk on deep reinforcement learning to learn about how using deep convolutional neural networks on games may be able transform the automation industry.

2 - Is Analytics in Professional Sports Making a Difference?
Walter DeGrange, CANA Advisors, Chapel Hill, NC, wdegrange@canallc.com

This presentation covers the impact of analytics on team performance in the top four sports in the United States (Major League Baseball (MLB), National Football League (NFL), National Basketball Association (NBA) and the Nation Hockey League (NHL)) over the past three years. Several analytics projects with professional teams and the issues with implementing solutions are also presented. Projects include developing models for an NHL team and a Major League Lacrosse (MLL) team.

Health Care, Modeling and Optimization

Contributed Session

Chair: Buyannemekh Munkhbat, University of Massachusetts-Amherst, Amherst, MA, United States, bmunkhbat@umass.edu

1 - Characterizing Obstructive Sleep Apnea a Descriptive Analytics Approach
Rupesh Agrawal, Research Assistant, Oklahoma State University, 700 N. greenwood ave., Rm#313, Tulsa, OK, 74106, United States, rupesh.agrawal@okstate.edu, Dursun Delen, Bruce Benjamin

Increasing adoption of EHR/EMR, propagated via affordable healthcare act of 2009, have opened new opportunities to improve health and healthcare outcomes. Obstructive sleep apnea (OSA) is a very common health condition, the existence of which would increase manifestations of deadly diseases such as heart failure. Despite proven adverse effects, the true understanding of the OSA is still in nascent stages. Hence, using a large and feature-rich EHR dataset, this analytics study aimed at characterizing OSA by identifying and analyzing associated comorbidities, and also developing a comprehensive taxonomy of OSA and related health conditions.

2 - The Impact of Health Information Exchange on Patient Mobility and Hospital Competition
Xinxin Guo, Southeast University, 2 Sipailou, Nanjing, 210096, China, bzhmgx@163.com, Haiyan Wang

The potential benefit of health information exchange (HIE) for patients is that reduces the costs patients face to switch providers. This paper examines the impact of the adoption of HIE on health care quality and hospital profits as patients, especially those experienced patients, have the freedom to choose the provider they receive treatment. We develop a two-period duopoly model in which health care quality is differentiated and patients are heterogeneous. We give conditions under which the adoption strategy benefits or hurts providers and social welfare.

3 - Building Multiscale Models for Predicting Spatial Changes between Serial Functional Images of Lung Cancer Patients
Chunyan Duan, Tongji University, Room1114, Tongji Building Block A, No. 1 Zhangwu Road, Shanghai, 200092, China, duanchunyan77@163.com
Chunyan Duan, University of Washington, 1959 NE Pacific St. Box 356043, Seattle, WA, 98105, United States, duanchunyan77@163.com, Stephen R. Bowen, W. Art Chaovalitwongse, Daniel S. Hippe, Daehan Won, Jianxin You, Jianxin You

Lung cancer response varies spatially during therapy. We are modeling serial functional cancer imaging changes from statistically independent regions within lung tumors by cluster analysis and spatial autocorrelation. Features of multiscale cancer regions are trained, cross-validated, and tested in our models to predict spatial changes during and after therapy. This represents a powerful approach to assess local therapeutic efficacy.

4 - Uncertainty Analysis of Species Distribution Models
Xi Chen, University of Texas at Austin, 3500 Greystone Drive, Apt 271, Austin, TX, 78731, United States, carol.chen@utexas.edu

Species distribution models (SDM) are commonly used to predict the geographic distributions of animals or plants species. However, most of SDM methodology produces point estimates. We present two strategies for quantifying the uncertainty of maximum entropy SDM methods: a bootstrap method, and an analytic method. We describe both methods, and compare and contrast their performance on two examples of different sizes. Both Dengue importation probability and Aedes aegypti mosquito suitability examples show that the methods generate comparatively the same results and the novel analytic method we introduce is dramatically faster than the bootstrap method.

5 - A Multi-attribute Optimization Approach for Post-acute Provider Selection
Ashkan Hassani, Texas A&M.University, 4050 ETB, College Station, TX, 77840, United States, ashkanhassani@tamu.edu, Hossein Badri, Maryam Khatami, Mark Alan Lawley

In this study a decision making approach is developed for Post-Acute Care Provider (PACP) selection problem. This approach includes two stages. In the first stage, some quality metrics are used in a TOPSIS method to calculate the closeness coefficients of each candidate PACP to short-stay patient's and long-stay patients. In the second stage, these coefficients are used in a mathematical programming model, along with some other cost and service level metrics to select the best PACP's for both short-stay and long-stay patients. The proposed approach is implemented for PACP selection problem in the city of Houston, TX, and the results are presented and analyzed.

6 - A Multi-dimensional Evolving Contact Network Approach for Modeling Dynamics of Contagious Disease Spread
Buyannemekh Munkhbat, University of Massachusetts-Amherst, 165E Brittany Manor Drive, Amherst, MA, 01002, United States, bmunkhbat@umass.edu, Chaitra Gopalappa, Hari Balasubramanian, Dylan Shepardson, Song Gao

Current simulation models for outbreaks of re-emerging infectious diseases (EIDs) take an individual-level or a population-level approach to modeling contact dynamics. Each modeling technique is a trade-off between increased accuracy versus computational efficiency. We propose a novel Multi-dimensional Evolving Contact Network (MECN) algorithm that combines the attributes of both simulation modeling techniques. Considering the uncertainty in type and origin of future EIDs, our proposed methodology will be suitable for analyses of a range of potential EIDs for an integrated approach to disease prevention in low- and middle- income countries.

Internet of Manufacturing Things

Invited: Invited OR and Advanced Manufacturing

Invited Session

Chair: Hui Yang, Pennsylvania State University, University Park, PA, 16801, United States, huy25@psu.edu

1 - The Internet of Additive Manufacturing Things on IBM Watson
Gayathri Magie, IBM, Kansas City, MO, United States, gayathri@us.ibm.com, Prahalad Rao

Learn about IBM's Watson Internet of Things platform can connect additive manufacturing to the cloud. A road map for implementation at University of Nebraska-Lincoln to register, manage and control the sensor embedded metal additive manufacturing (AM) machine will be revealed. The intent is to send the layer-by-layer sensor data to the cloud, store the data, and use Watson Analytics to detect and predict build failures (currently 1 in 4 parts typically fail to print). This information is used as a repository for part qualification - leading to the certify-as-you-build paradigm in AM.

2 - Parallel Computing and Network Analytics for Fast Industrial Internet-of-things Machine Information Processing and Condition Monitoring
Soundar Kumara, Pennsylvania State University, University Park, PA, 16803-2050, United States, skumara@psu.edu, Chen Kan, Hui Yang

Rapid advancement in sensing and communication brings a new wave of Industrial Internet of Things (IIoT) technology. IIoT integrates a large number of sensors for smart and connected monitoring of machine conditions. However, existing approaches are limited in their ability to extract pertinent knowledge about manufacturing operations from large volumes of IIoT data. This paper presents new parallel algorithms for large-scale IIoT machine information processing, network modeling, condition monitoring, and fault diagnosis. Experimental results show that our algorithm efficiently and effectively characterizes variations of machine signatures for network modeling and monitoring.

3 - Outlier Detection Based on Minimum Spanning Tree and its Application to Manufacturing
Imtiaz Ahmed, Texas A&M.University, College Station, TX, 77843, United States, imtiazavi@tamu.edu, Yu Ding

Outliers are points or clusters of points which lie away from the neighboring points and clusters and inconsistent with the overall pattern of the data. The process of identifying outliers become complicated in absence of the labeled training data. Consequently, a supervised learning cannot be used to learn a rule to classify future observations. Minimum Spanning Tree (MST) is a measure, capable of capturing the relative connectedness of data points/clusters and thus can be utilized to identify the potential outliers of a data set in an unsupervised setting. In this work, an MST based outlier detection algorithm is developed and demonstrated using examples in manufacturing processes.

4 - IIoT Automation or Autonomous Manufacturing
Thomas Paral, TE Connectivity Ltd, Baden-Württemberg, Germany, thomas.paral@te.com

First of all there is no IIoT or Industry 4.0 protocol yet available. There are many initiatives around the globe all speak about IIoT/ Industry 4.0 but most of them are still talking about automation and OEE improvements through transparency not through intelligent autonomous (digital) guided processes along the value chain including life cycle.

Internet of Things: Promises, Challenges and Analytics

Sponsored: The INFORMS Section on Practice

Sponsored Session

Chair: Patricia Neri, SAS Institute, Inc., Cary, NC, 27519, United States, patricia.neri@sas.com

Co-Chair: Anna Olecka, Honeywell, St Petersburg, FL, 33703, United States, annao007@gmail.com

1 - Internet of Things: Promises, Challenges and Analytics
Patricia Neri, SAS.Institute, Inc., 104 Grandtree Ct., Cary, NC, 27519, United States, patricia.neri@sas.com

IoT is a technological innovation taking place in key areas: healthcare, transportation, energy production, smart cities and connected factories to name just a few. IoT is possible because of the decreasing cost of sensors and storage, the Cloud and Analytics. Connected devices gather vast amounts of data, which is analyzed, optimized and turned into insight and information. IoT technology is in early development and multiple challenges must be addressed: data availability and ownership, resistance to adoption, data privacy and data security. In this session we will discuss these challenges and specific IoT applications, as well as, jobs that are being created by IoT and the skills required for those jobs.

Behavioral Operations

Contributed Session

Chair: Matthew Walsman, Rutgers Business School, Berkeley Heights, NJ, United States, mwalsman@business.rutgers.edu

1 - Decision Support for Airport Surface Operations: A Sociotechnical Systems Approach
Elizabeth M. Argyle, Research Fellow, University of Nottingham, Nottingham, United Kingdom, elizabeth.argyle@nottingham.ac.uk, Jason Atkin, Geert De Maere, Robert J. Houghton, Terry Moore, Herve P. Morvan

Demand for airspace capacity is increasing, placing additional pressures both on physical infrastructure and human resources. We present a sociotechnical systems approach for developing a decision support system (DSS) to assist the ground controllers with the complex scheduling and routing tasks at a major European airport. We discuss the role of human behavioral research during the development of search-based algorithms for taxiway routing and departure scheduling and consider the insights that this research has provided into how human operators approach these tasks.

2 - Can Good Jobs be Profitable in Low Cost Services? A Systemic Model and Estimation

Hazhir Rahmandad, Associate Professor, MIT, 100 Main Steet, E62-442, Cambridge, MA, 02142, United States, hazhir@mit.edu

Can profit maximizing firms offer good jobs in low cost services? In a dynamic model of service operations we capture feedbacks, managerial decisions, costs, and benefits related to viability of good jobs. Using data from Borders bookstores and utilizing extended Kalman filtering with latent variables we estimate this model. We find evidence for significant benefits of employee quality and building capabilities as well as notable managerial biases in allocating resources between customer service and capability building. The results point to potential viability of good jobs in low cost services and offers a method for assessing these costs and benefits.

3 - Estimating Customer Spillover Learning of Service Quality

Andres I.Musalem, U. de Chile, Beauchef 851, Santiago, 8370456, Chile, amusalem@dii.uchile.cl, Yan Shang, Jing-Sheng, Jeannette Song

"Spillover" learning is defined as customers' learning about the quality of a service (or product) from their previous experiences with similar yet not identical services. In this paper, we propose a novel, parsimonious and general Bayesian hierarchical learning framework for estimating customers' spillover learning. We apply our model to a one-year shipping/sales historical data provided by a world-leading third party logistics company. Our empirical results are consistent with information spillovers driving customer choices. We also develop policy simulation studies to show the importance of accounting for customer learning when a firm considers service quality improvement decisions.

4 - Investigating the Influencing Factors of Continuous Usage Behavior in Internet Broadcast

Xiaoxi Luan, Tongji University, Shanghai, 200092, China, luanxiaoxi@163.com, Haifeng Zhao

This study aims to investigate what, why and how a cohesive set of factors influence the continuous usage behaviors of Live show users.The model of ECM-IT is applied to the study to help build the Theoretical Model of Continuous Usage Behavior of Internet Broadcast Users. In the model, we set Perceived Usefulness, Perceived Ease of Use, Expectation Confirmation, Perceived Pleasure, and Perceived Trust as independent variables, Satisfaction and Continuous Use Intention as intermediate variables, Continuous Usage Behavior as the dependent variable, and Habit as the regulated variable. We introduce the method of SEM and the technology of AMOS21.0 to analyze the collected data.

5 - Do Advisers Give Bad Advise Experimental Evidence from Consulting

Matthew Walsman, Assistant Professor, Rutgers Business School, 28 Cambridge Dr, Berkeley Heights, NJ, 07922, United States, mwalsman@business.rutgers.edu

In this study, we use a behavioral experiment in a consulting context to investigate the impact of decisions that advisers and clients make and their influence on each other. Specifically, we test the impact of client initiated estimates on their consultant's subsequent recommendations and the resulting client decisions and satisfaction. We test for this effect with both trained and novice clients. We find that when clients interfere with the process by providing their consultants with an initial estimate, expert consultants don't 'take the bait', but instead are more likely to give a differentiated opinion, even when the client's initial input was right.

1 - Joint Pricing and Inventory Management with Strategic Customers

Yiwei Chen, Singapore University of Technology and Design, 8 Somapah Road, Singapore, 487372, Singapore, ywchen@mit.edu, Cong Shi

We consider a model wherein the seller sells a single indivisible product to customers over an infinite horizon. At each time, the seller decides a set of purchase options offered to customers and the inventory replenishment quantity. Each purchase option specifies the price and the product delivery time. Customers stochastically arrive to the system according to a Poisson process. Customer product valuations are randomly drawn from a distribution and are heterogeneous. A customer's arrival time and product valuation are his private information. Customers are forward-looking, i.e., they strategize their purchasing times. A customer incurs delay disutility from postponing to make the purchasing decision and waiting for the product delivery. A customer's delay disutility rate is perfectly and positively correlated with his valuation. The seller has zero replenishment lead time. The seller incurs fixed ordering cost and inventory holding cost. The seller seeks a joint pricing, delivery, and inventory policy that maximizes her long-run average expected profit. We propose a simple policy under which the dominant equilibrium is that customers behave myopically. We show that this policy is asymptotically optimal in the regime wherein customer arrival rate and the seller's fixed ordering cost proportionally grow large. We adopt a mechanism design approach to prove these results.

2 - Posterior Sampling for Markov Decision Processes: Worst-case Regret Bounds

Shipra Agrawal, Columbia University, Industrial Engineering and OR, 423 S. W. Mudd Building, New York, NY, 1002 7, United States, ashipra@gmail.com, Randy Jia

We consider discrete-time communicating Markov Decision Processes (MDP) with finite state space and action space. We present a posterior sampling (aka Thompson sampling) based algorithm for adaptive learning and decision making in such MDPs when the underlying transition matrix is unknown. Our main result is a high probability worst-case regret upper bound of $\tilde{O}(D\sqrt{SAT})$ for this algorithm, for any communicating MDP with finite diameter D, S states, A actions, and $T \geq S^5A$. Here, regret compares the total reward achieved by the algorithm to the total expected reward of an optimal infinite-horizon undiscounted average reward policy, over a time horizon T. This result improves over the best previously known upper bound of $\tilde{O}(DS\sqrt{AT})$ achieved by any learning algorithm in this setting, and closes the crucial gap of S from the known lower bound of $\Omega(DSAT)$ for this problem. Our analysis involves deriving some novel results about the anti-concentration of Dirichlet posteriors, which may be of independent interest.

3 - Ambiguous Risk Constraints with Moment and Unimodality Information

Bowen Li, University of Michigan, Ann Arbor, MI, United States, libowen@umich.edu, Ruiwei Jiang, Johanna Mathieu

Optimization problems face random constraint violations when uncertainty arises in constraint parameters. Effective ways of controlling such violations include risk con- straints, e.g., chance constraints and conditional Value-at-Risk (CVaR) constraints. This paper studies these two types of risk constraints when the probability distribu- tion of the uncertain parameters is ambiguous. In particular, we assume that the distributional information consists of the first two moments of the uncertainty and a generalized notion of unimodality. We find that the ambiguous risk constraints in this setting can be recast as a set of second-order cone (SOC) constraints. In order to facil- itate the algorithmic implementation, we also derive efficient ways of finding violated SOC constraints. Finally, we demonstrate the theoretical results via a computational case study on power system operations.

eBusiness

Sponsored: EBusiness

Sponsored Session

Chair: Jong Seok Lee, PhD, University of Memphis, Memphis, TN, 38152, United States, jslee4@memphis.edu

1 - Modeling Retail and Online Channel Allocation Decisions

Roshanak Mohammadivojdan, University of Florida, 303 Weil Hall, P.O. Box 116595, Gainesville, FL, 32611, United States, rmohammadivojdan@ufl.edu, Joseph Geunes

Consider a retailer who sells items via both a retail store and an online channel. Space limitations in each channel require judicious selection of items and the allocation of these items to the two channels. We model these assortment and channel selection decisions via a stylized mathematical model that accounts for economic inventory replenishment decisions in each channel. The resulting model corresponds to a specially structured two-knapsack problem. Analysis of this problem permits gaining insights on key decision drivers and characteristics of optimal decisions.

2 - The Disruptive Effects of Digital Platform's Entry on Non-high-tech Industry: A Text Mining and Econometric Approach

Sungjin Yoo, University of Memphis, Memphis, TN, United States, syoo3@memphis.edu

In this study, we examined the effect of digital platform entry on the landscape of competition in non-high-tech industry. Using the accommodation industry as our empirical setting, we identify how the incumbents' competitive action portfolio change in response to the entry and how such action differs between the high-end companies and the low-end companies. By analyzing a longitudinal data set of competitive actions of incumbents in the industry, our finding shows that incumbents not only implement more competitive actions but also adapt diverse strategies which are deviant from the industry norm. Furthermore, high-end companies attempt to respond more actively than low-end companies.

3 - Contextually Sensitive Privacy Aware E-commerce Systems

Faruk Arslan, University of Houston Clear Lake, Clear Lake, TX, United States, Arslan@UHCL.edu, Radu Vlas

The purpose of this research is to develop a contextually sensitive solution, which is aimed to reduce the dependency on e-commerce system users to specify and maintain their respective privacy policies for their personal data. To achieve this, we propose a multi-level model to predict whether a certain personal data category (e.g. financial, medical, tastes, etc.) is deemed by the user as personal (or not). We present the application of this model on financial and medical data categories given that the definition of these two data categories as personal, vary across the countries within our sample. Then, we discuss how this predictive model can be embedded into e-commerce systems.

Behavioral Issues in Contracting and Inventory

Sponsored: Behavioral Operations Management

Sponsored Session

Chair: Elena Katok, University of Texas at Dallas, Richardson, TX, 75080, United States, ekatok@utdallas.edu

1 - Project Management under Risk-sharing Contracts

Sina Shokoohyar, The University of Texas at Dallas, 800 W. Campbell Rd SM.30, Richardson, TX, 75080, United States, sxs137430@utdallas.edu, Elena Katok, Anyan Qi

We analyze the risk-sharing contract in which the contractors are paid at the end of the project. We show that for a project with parallel tasks, there exist multiple Pareto-ranked equilibria, where all contractors exert the same efforts, and the worst project delay is observed when the contractors play the secure equilibrium. To mitigate this coordination failure, we propose an information feedback policy, and show that the contractors' efforts in the secure equilibrium increase in the information feedback frequency. To test our theoretical findings, we conduct behavioral experiments, and the result confirms our theoretical findings.

2 - Should Retailers or Suppliers Exercise Effort to Increase Demand?

Anna-Lena Sachs, University of Cologne, Albertus-Magnus-Platz, Cologne, 50923, Germany, anna-lena.sachs@uni-koeln.de, Yingshuai Zhao, Ulrich Thonemann

Demand promotion activities, such as advertisements, enlarge market size and accordingly increase sales profit. In a supply chain, promotion activities can be exercised by any echelon member. We consider a supply chain which is composed of two members, a supplier and a retailer. We investigate whether the supplier or the retailer should exercise the effort of demand promotion activities. We conduct laboratory experiments and compare supply chain performance for retailers or suppliers exercising effort under a Stackelberg game framework or a negotiation framework.

3 - Negotiating Transshipments Prices for Improving Supply Chain Coordination

Sebastian Villa Betancur, University of Los Andes, Bogotá, Colombia, s.villab@uniandes.edu.co, Elena Katok

We use a simplified model of a single-supplier two-retailer supply chain to experimentally understand how retailers simultaneously set transshipment prices and order quantities. We study how these two decisions deviate from the theoretical channel-coordinating benchmarks. Our experiment manipulates two factors: profitability and sequence of decisions. Results show how average order quantities with transshipment are between optimal orders and mean demand (pull-to-center behavior). In addition, participants ignore the critical ratio when they negotiate transshipment prices. Finally, we show how the sequence of decision may affect the probability of agreement between both retailers.

4 - What Can We Learn from Brain Imaging Newsvendors?

Kay-Yut Chen, University of Texas at Arlington, Arkington, TX, United States, kychen@uta.edu, Sridhar P.Nerur, Wendy Casper, Hanli Liu

The current literature on newsvendor behavior relies on "guessing" the underlying cognitive and/or psychological mechanisms from observations, without any direct physical evidence. Functional near infrared spectroscopy (fNIRS) allows researchers to examine brain functions by measuring hemodynamic responses associated with neural activities. We show that newsvendor performances are correlated with neural activations in an area (Brodmann area 43) that has been associated with cognitive effort. In addition, we find negative correlation between neural activations and past profits, which is consistent with satisficing behaviors expected of boundedly rational decision-makers.

Behavioral Topics in Facilitated Modelling

Invited: InvitedBehavioral Aspects of OR

Invited Session

Chair: Vincent de Gooyert, PhD, Institute for Management Research, P.O. Box 9108, 6500 HK, Nijmegen, Netherlands, v.gooyert@fm.ru.nl

1 - Behavioral Factors Affecting Facilitated Modelling of Strategic Issues

Martin Kunc, University of Warwick, WBS.Social Studies Building, Office E1.07, Coventry, CV4 7AL, United Kingdom, martin.kunc@wbs.ac.uk, Kenneth Huh

This study reports in-depth research into the use of resource mapping, within a group based setting, a tool to identify an organization's strategic resources. Specifically, this paper explores the behavioral factors affecting the group dynamic processes through a quantitative and qualitative analysis of different groups' processes. The research identified a number of variables influencing group dynamics: deliberateness, cognitive overload, and cognitive and affective conflicts.

2 - Connecting Community-Based System Dynamics with Collective Impact

Donald R. Greer, Principal, Greer Black Company, P.O. Box 3607, Bozeman, MT, 59772-3607, United States, drgreer@greerblackcompany.com
Donald R. Greer, Principal, Rapid City Collective Impact, 529 Kansas City Street, Suite 207, Rapid City, SD, 57701, United States, drgreer@greerblackcompany.com, Laura Black, Albert Linderman

Collective impact projects seek to improve a region's quality of life through ongoing collaborations across nonprofit, private, governmental and social-service organizations. This paper describes the roles a causal loop diagram played as a shared visual in anchoring, focusing, and connecting nine community work-streams formed during the Rapid City Collective Impact initiative. We propose that causal representations act as effective project-structuring tools in non-traditional projects characterized by ambitious but under-specified outcomes, emergent processes for accomplishing outcomes, diverse resources, and volitional engagement of participants rather than lines of authority.

3 - A Dynamic Theory of the Effect of Facilitated Modeling on Self-efficacy

Vincent de Gooyert, Institute for Management Research, P.O. Box 9108, Nijmegen, 6500 HK, Netherlands, v.degooyert@fm.ru.nl

Previous studies report mixed findings regarding the effect of facilitated modeling (FM) on proximal and distal outcomes, and the responsible mechanisms are not fully known. We focus on the effect of FM on self-efficacy and propose a dual pathway theory. On the one hand, FM can increase self-efficacy when the intervention increases the participant's knowledge about solutions for the problem at hand. On the other hand, FM can decrease self-efficacy when the intervention reveals that the problem is much more complex than initially thought. If multiple FM workshops are held, we expect that over time, firstly the negative pathway will be dominant, and secondly the positive.

4 - Behavioral Analytics: Beginnings of a Body of Work

Martin Kunc, University of Warwick, WBS.Social Studies Building, Office E1.07, Coventry, CV4 7AL, United Kingdom, martin.kunc@wbs.ac.uk, Michael Mortenson

Following the growing interest in analytics and the rise of behavioral approaches in analytical fields (behavioral economics, behavioral OR), this research investigates the development of behavioral analytics, a field at the intersection of these trends. The paper identifies two areas: upstream behavioral analytics, where behavioral patterns act as the stimulus and subject of analytics; and downstream behavioral analytics, where approaches such as visualization are used to give analytics and data science greater influence on the behavior of decision makers. Using a computational literature review, these areas are analysed and compared, and directions for future research are offered.

1 - Operational Strategies for Electrical Car-sharing Systems

Yang Liu, National University of Singapore, Department of Industrial & Systems Engineerin, Singapore, 117576, Singapore, iseliuy@nus.edu.sg, Dong Zhang, Shuangchi He

For one-way electric vehicle (EV) car-sharing model, we proposed two operational strategies to improve its performance.The aim of two operational strategies is to utilize the battery of EVs in a more efficient manner. Two novel network flow models are proposed based on these two strategies, respectively. To satisfy the quick response requirement in the operational level, we further propose an efficient solution algorithm to solve the models. Experimental results reveal that the performance gap between the EV car-sharing system and the traditional car-sharing system can be very small if efficient operational strategies are implemented.

2 - Modeling the Operations of Electric Autonomous Taxis in New York City

Liang Hu, PhD Student, Iowa State University, Ames, IA, United States, lianghu@iastate.edu, Jing Dong

This paper explores the potential of replacing conventional taxis with electric autonomous vehicles (EAVs) in New York City. Customer requests, in terms of pick-up and drop-off locations with time stamps, are extracted from GPS tracked taxi trip data. Local interaction rules are designed to dispatch EAVs to serve customer requests and coordinate their charging activities. The simulation results show that using EAVs can improve taxi operational efficiency and reduce fleet size.

3 - Mobility Pattern Analysis of Free-floating Bike Sharing and Insights on System Operations

Yu Zhang, University of South Florida, Tampa, FL, United States, yuzhang@usf.edu, Aritra Pal

We study historical biking trajectory data of bike sharing users for understanding their mobility patterns and the correlations with environment variables and the interactions of those variables. The outcomes provide insights on system design and operations, e.g. hub regions of bike sharing program, time for conducting static or dynamic rebalancing, and time available for such rebalancing, etc.

4 - Same-day Delivery Planning with Store Fulfillment

Ming Ni, University at Buffalo, The State University of New York, 326 Bell Hall, Buffalo, NY, 14260, United States, mingni@buffalo.edu, Qing He, Jose Luis Walteros, Xuan Liu, Arun Hampapur

This study identifies a seasonal order fulfillment plan for delivering local online orders from nearby retailing stores that minimizes the overall panning and operational costs. It aims to develop optimization models and solution algorithms about store location selection, fleet-sizing for transportation, and inventory planning. Our methodology integrates outer search tree based on mix integer programming and local branching, optimization-based algorithm for initial lifting constraints, with accelerated Benders decomposition method to solve large-scale real supply chain planning problem.

5 - Optimal Design of Urban Taxi Fleet Electrification: A Simulation-Based Optimization Approach

Fang He, Tsinghua University, Shunde Building, N502, Tsinghua University, Beijing, 100084, China, fanghe@tsinghua.edu.cn, Yinghao Jia, Zuojun Max Shen

Transportation management agencies in urban cities are electrifying taxi fleets. How to allocate limited resources to optimize the benefits of taxi fleet electrification deserves thorough investigation. This research gathers the real-time vehicle trajectory data of 39,053 urban conventional taxis and 408 suburban electric taxis in Beijing to extract the customers' travel demand distribution and electric taxi drivers' behavior pattern. We derive a data-driven simulation model to reflect the operations of electric taxi fleet and further propose a simulation-based optimization framework to optimize the deployment of charging infrastructure and the configuration of electric taxi fleet.

8:00 - 8:45 IBM/8:45 - 9:30 Palisade

Invited: Vendor Tutorial

Invited Session

1 - Generic Callbacks in CPLEX, A New Approach

Xavier Nodet, IBM, 1681 Route des Dolines, Valbonne, 06600, France, xavier.nodet@fr.ibm.com

During this tutorial, you will learn how to use a new Generic Callback framework in CPLEX Optimizer. These callbacks allow users to benefit from all the CPLEX features without restriction, and offer a simple API to either get information from CPLEX, or drive CPLEX behavior.

2 - Quantitative Risk Analysis in Excel with @RISK

Rafael Hartke, Palisade Corporation, Ithaca, NY, United States, rhartke@palisade.com

This tutorial will guide you in the use of @RISK for analyzing historical data, and for making forecasts and better decisions in an uncertain business environment. @RISK is part of Palisade's DecisionTools Suite, and runs within the familiar MS Excel environment. It provides all the features you need to quantify and understand risks, along with graphical capabilities and reports to help you present the risk analysis results to a non-technical audience

Energy

Contributed Session

Chair: Yue Zhao, Stony Brook University, Stony Brook, NY, United States, yue.zhao.2@stonybrook.edu

1 - Distributed Transactive Operation of Micro-grid Cluster using a Stochastic Model Predictive Control Algorithm

Yang Chen, University of Illinois at Chicago, Chicago, IL, United States, ychen429@uic.edu, Mengqi Hu

To enable efficient transactive operation among multiple interconnected micro-grids (aka micro-grid cluster), a bi-level distributed decision framework is proposed. A two-stage stochastic optimization model is developed for each micro-grid at the subsystem level with consideration of solar and energy load uncertainties, while a guided particle swarm optimizer is employed at the system level to coordinate transactive operations for all the micro-girds. A stochastic model predictive control algorithm is employed to solve the two-stage stochastic model for real-time operation. A case study of a cluster of four micro-grids is developed to evaluate the effectiveness of the proposed approach.

2 - Multi-period Energy Procurement Policies with Deferrable Demand and Supplementary Uncertain Power Supplies

Tian Wang, Zhongnan University of Economics and Law, Number 182, Nanhu Road, Donghu District, Wuhan, 430073, China, wangtian3261@gmail.com

We analyze a multi-period energy procurement problem for an energy aggregator who is responsible for centralized controlling of energy procurement and consumption. To decide the optimal procurement amount, the aggregator makes trade-offs between two supplies, traditional energy with variable prices vs. free renewable energy with uncertain supplies. We show the optimal procurement policy is to procure traditional energy only when the price is less than a certain threshold, which depends on the statistics of the day-ahead real time prices, the wind energy distribution and the time left to the end of horizon. Numerical studies with real wind data are conducted.

3 - Self Scheduling of a Virtual Power Plant in Energy and Reserve Electricity Markets

Ana Baringo, Universidad de Castilla-La Mancha, Ciudad Real, Spain, Ana.Baringo@uclm.es, Luis Baringo, José Arroyo

We propose an approach for the self scheduling of a virtual power plant that participates in both energy and reserve electricity markets. The virtual power plant comprises flexible demands, a conventional power plant, and a wind-power unit, which participate in the markets as a single entity to optimize the use of their energy resources. Uncertainties in wind-power production and reserve deployment are modeled using confidence bounds, while uncertainties in market prices are modeled using scenarios. This allows us to formulate the self-scheduling problem as an adaptive robust optimization problem, which is efficiently solved using a column-and-constraint algorithm.

4 - A New Approach to Estimate Renewable Energy Potential in a Particular Location

Tunde O.Aderinto, Texas A&M.University-Kingsville, Kingsville, TX, United States, tunde.aderinto@Students.tamuk.edu, Hua Li

The renewable energy potential of a particular location is usually estimated through independent resource assessment of different renewable energy sources.

It may overestimate its potential of the particular location if simply adding up different energy sources' potentials. A new approach is proposed to estimate the renewable energy potential of a particular location by considering the influences among different renewable energy sources during their harvesting processes. The new approach also considers possible option of harvesting different types of renewable energy sources at the same time to seek for the best combination and highest potential of a particular location.

5 - Ex-post Stable and Fair Payoff Allocation for Renewable Energy Aggregation

Yue Zhao, Stony Brook University, 261 Light Engineering, Stony Brook, NY, 11794, United States, yue.zhao.2@stonybrook.edu, Hossein Khazaei

Aggregating statistically diverse renewable power producers (RPPs) is an effective way to reduce the uncertainty of the RPPs. The key question in aggregation of RPPs is how to allocate payoffs among them. In this paper, a payoff allocation mechanism (PAM) with a simple closed-form expression is proposed: It achieves stability (in the core) and fairness both in the "ex-post" sense, i.e., for all possible realizations of renewable power generation. Furthermore, this PAM can in fact be derived from the competitive equilibrium in a market. The proposed PAM is evaluated in a simulation study with ten wind power producers in the PJM interconnection.

Invited Session

Chair: Dong Yoon Song, PhD, Purdue University, School of Civil Engineering, West Lafayette, LA, 47907, United States, song50@purdue.edu

1 - A Two-stage Strategy for Improving the Efficiency of a Traffic Network by Providing Value-added Atis Services

Jingjing Liang, Miss, Tongji University, Room 1413, Tongji Buliding Block A, Zhangwu Road, Shanghai, 200082, China, gina_liang@tongji.edu.cn, Xiaoning Zhang

From the perspective of the traffic management agency, we propose a two-stage strategy for improving the efficiency of a traffic network by providing VATIS services. In the first stage, the traffic management agency selects several ATIS service providers, then offers seed fund to each of them for encouraging VATIS services providing in traffic networks. In the second stage, the traffic management agency announces a fixed target of the total market penetration of VATIS services, and asks service providers to work together to achieve it. If they could complete or partially complete the task, compensations will be paid or partially paid.

2 - Most Reliable Flight Itinerary Problem

Michael Redmond, University of Iowa, Iowa City, IA, 52242, United States, michael-a-redmond@uiowa.edu, Ann Melissa Campbell, Jan Ehmke

With the high amount of uncertainty in airline travel, our research aims to provide airline customers with information about the reliability of their itineraries and help identify the Most Reliable Flight Itinerary (MRFI). We use data from the U.S. Bureau of Transportation to model the distribution of departure and arrival times for flights. We use these distributions to compute the reliability of flight itineraries, which is the likelihood the itinerary will get the passenger to the destination given a start time and travel time budget. We implement a network search algorithm to find the most reliable itinerary and utilize a number of shortcuts in order to find this itinerary in an efficient way.

3 - Quantifying Impacts of Real-time Travel Information on Route Choice Behavior using Psychophysiological Analysis: A Driving Simulator-based Study

Shubham Agrawal, Purdue University, West Lafayette, IN, 47907, United States, shubham@purdue.edu, Irina Benedyk, Dong Yoon Song, Srinivas Peeta

This study develops an analytical framework to quantify the impacts of real-time travel information in driver's route choice decision-making process considering information characteristics (for example, amount, content and source), driver's cognitive state (for example, engagement level and mental workload), situational factors and individual characteristics (for example, age and gender). The driver's cognitive state is estimated by performing psychophysiological analysis based on the data collected using electroencephalogram (EEG), electrocardiogram (ECG) and wearable eye tracking glasses while driving in an interactive driving simulator environment.

4 - Understanding Satisfaction with Travel Experience under Real-Time Travel Information Provision - A Latent Variable Modeling Approach

Dong Yoon Song, PhD Student, Purdue University, West Lafayette, IN, 47907, United States, song50@purdue.edu, Srinivas Peeta

This study investigates travelers' satisfaction with travel experience including the benefits from travel time savings and psychological effects while traveling under real-time travel information provision. A structural equation model is proposed with latent variables for human factor considerations in information perception and multiple dimensions of psychological benefits. Travelers' behavioral data and stated preference data collected through interactive driving simulator experiments and the associated surveys are used to estimate the model.

Food Supply Chain Innovations

Invited: Agricultural Analytics

Invited Session

Chair: Changrui Ren, IBM Research - China, IBM, Beijing, 100193, China, rencr@cn.ibm.com

1 - A Spatiotemporal Approach to Accelerate the Investigation of Food-borne Illness Outbreak using Retail Scanner Data

Kun Hu, IBM.Research, 5224 union ave, San Jose, CA, 95124, United States, khu@us.ibm.com, Shanshan Cao, James Kaufman

Nowadays, foodborne illness caused by salmonella, E. Coli and norovirus is a global challenge due to an altered worldwide food supply chain and increased emergence of new foodborne pathogens. When prevention efforts fail, it is essential to rapidly identify the contaminated product and alert the public. The aim of this study is to demonstrate a new analytic approach that employed big data from retail scanner. After receiving as few as 10 lab confirmed case reports, it is possible to narrow to a subset of 12 suspect products with 90% accuracy for over 80% of food products in the dataset.

2 - Blockchain Enabled Food Supply Chain Traceability and Safety Management

Changrui Ren, IBM.Research - China, Building 19 Zhongguancun Software Park, 8 Dongbeiwang Westroad, Haidian District, Beijing, 100193, China, rencr@cn.ibm.com, Bo Zhang, Dingding Lin, Yongqing Xue, Xin Shi, Mingchao Wan, Miao He

Today's food supply chain is longer and more complex than at any time in history. There is an urgent need for transparency. In our research, we propose a new blockchain enabled approach to construct food supply chain traceability and safety management system. A pilot study has been conducted in China with collaboration from industrial partners, the result of which demonstrate the authenticity, trust and robustness brought by the blockchain technology to the traceability system.

3 - Raw Material Variability in Food Manufacturing

Brian Bourquard, Purdue University, West Lafayette, IN, United States, bbourqua@purdue.edu, Gemma Berenguer, Allan W. Gray, Paul V. Preckel

We characterize the operational decisions of a food manufacturing firm facing raw material variability, that is uncertainty about the characteristics of the raw material inputs to the production process. We link the operational decisions to the firm's strategic decisions, such as supply chain management and firm boundaries. Our goal is to provide managerial insights into how firms facing raw material variability consider and select among their strategic options to improve efficiency and reduce waste. We contribute to the literature by showing that firms facing operational challenges need to consider their strategic options as integral to the manufacturing process.

4 - The Application of Lateral Transshipment to Perishable Inventory Management in Fresh Food Industry

Dilupa Nakandala, Western Sydney University, Paramatta, Australia, D.Nakandala@westernsydney.edu.au, Henry Lau

Product perishability is one of the primary reasons causing more stockouts across the fresh food supply chain and justifies considering lateral transshipment as a managerial response. The proposed model considered the four key cost components of purchasing, backordering, holding, and spoilage costs for minimising the total inventory costs. The optimal balance of lateral transshipment and supplier order can moderate the tendency to over-order. Otherwise, the associated higher level of inventory position to manage any emerging stockout would result in higher spoilage costs as a higher volume of perishable product expires, but without improving the customer service level.

Financial Econometrics

Sponsored: Financial Services

Sponsored Session

Chair: Markus Pelger, Stanford University, Stanford, CA, 94305, United States, mpelger@stanford.edu

1 - Taming the Factor Zoo

Dacheng Xiu, PhD, Chicago Booth, Chicago, IL, United States, Dacheng.Xiu@chicagobooth.edu

The asset pricing literature has produced hundreds of potential risk factors. Organizing this "zoo of factors" and distinguishing between useful, useless, and redundant factors require econometric techniques that can deal with the curse of dimensionality. We propose a model-selection method to systematically evaluate the contribution to asset pricing of any new factor, above and beyond what a high-dimensional set of existing factors explains. Our procedure selects the best parsimonious model out of the large set of existing factors, and uses it as the control in making statistical inference about the contribution of new factors and estimating their price of risk.

2 - Efficient Parameter Estimation for Multivariate Jump-diffusions

Gustavo Schwenkler, Boston University, 595 Commonwealth Ave, Boston, MA, 02215, United States, gas@bu.edu, François Guay

This paper develops an unbiased Monte Carlo estimator of the transition density of a multivariate jump-diffusion process. The coefficient functions are allowed to be state-dependent and non-affine. Our estimator facilitates the parametric estimation of multivariate jump-diffusion models based on discretely observed data. The parameter estimators we propose have the same asymptotic behavior as maximum likelihood estimators as the number of data points grows, but the observation frequency of the data is kept fixed. Our density and parameter estimators are found to be highly accurate and computationally efficient in a numerical study.

3 - Functional Autoregression for Sparsely Sampled Data

Daniel R.Kowal, Cornell University, Ithaca, NY, United States, drk92@cornell.edu

Daniel R.Kowal, Rice University, Houston, TX, United States, drk92@cornell.edu, David S. Matteson, David Ruppert

We develop a hierarchical Gaussian process model for forecasting and inference of functional time series data. The latent process is dynamically modeled as a functional autoregression with Gaussian process innovations. For the dynamic innovation process, we propose a fully nonparametric dynamic functional factor model, with broader applicability and improved computational efficiency over standard Gaussian process models. Extensive simulations demonstrate substantial improvements in forecasting performance and recovery of the autoregressive surface over competing methods. We apply the proposed methods to forecast nominal and real yield curves using daily U.S. data.

4 - Asset Pricing Testing for Many Assets

Markus Pelger, Stanford University, 312 Huang Engineering Center, 475 Via Ortega, Stanford, CA, 94305, United States, mpelger@stanford.edu, Luyang Chen

We derive the asymptotic inferential theory for cross-sectional asset pricing testing when both the number of time observations T and number of assets N are large. After proper normalization the time-series and cross-sectional test statistics are asymptotically normal distributed in contrast to the chi-squared distribution for fixed N. Conventional time-series and cross-sectional tests can lead to contradicting conclusions for large N. Even for moderately sized cross-sections with N = 75 conventional test statistics are strongly biased, while our test statistics have good power and size properties.

Fueling Station Location and Routing Decisions for Alternative Fuel Vehicles

Sponsored: Location Analysis

Sponsored Session

Chair: Ismail Capar, Texas A&M University, College Station, TX, 77843-3367, United States, capar@tamu.edu

Co-Chair: Ibrahim Capar, Bowling Green State University, Bowling Green, OH, 43403, United States, icapar@bgsu.edu

1 - The Recharging Infrastructure Design Problem with Capacitated Recharge Stations and Stochastic Demands

Baris Yildiz, Koc University, Istanbul, 34450, Turkey, byildiz@ku.edu.tr, Evren Olcaytu

We study recharging infrastructure design problem for the urban areas. Considering the investor and consumer viewpoints along with the inherent uncertainty about the recharging demand, we approach to this problem from a broad perspective to obtain significant managerial insights that can help decision makers to shape long term strategies to take advantage of the new opportunities offered by the emerging electric vehicle technologies. We present a branch and cut algorithm to find optimal infrastructure design that minimizes the total investment cost while guaranteeing a target quality of service level that is crucial for the transportation and logistic use of electric vehicles.

2 - Patrol Routing with Hybrid Electric Vehicles

Burcu B. Keskin, University of Alabama, 4138 Meretta Lane, Tuscaloosa, AL, 35406, United States, bkeskin@cba.ua.edu, Mesut Yavuz

In this work, we study highway patrol by state troopers, which differs from police patrol in regards to (i) geographical coverage, (ii) miles traveled by a vehicle, and (iii) the higher probability of involvement in high-speed, long-distance chases. Specifically, for a given mixed patrol fleet consisting of traditional (gasoline or diesel) vehicles and HEVs, we investigate optimal patrol routes to visit time-critical hot spots. Our overall goal is to maximize the visibility of the state troopers while minimizing the costs associated with utilization of troopers. We analyze mathematical properties of the problem to offer analytic solutions or transformations to polynomially-solvable problems.

3 - Random Utility Model for Electric Vehicle Movement with Respect to Multiple Charging Stops

Yudai Honma, The University of Tokyo, Ce405, Komaba 4-6-1, Meguro-ku,, Tokyo, 153-8505, Japan, yudai@iis.u-tokyo.ac.jp, Shigeki Toriumi

This research focuses on the EV-support infrastructure of charging facilities in terms of EV route-decision behavior and multiple charging stops. When considering the movements of long-distance trips, it is very important to incorporate the route of EV movements because there is not only a simple and shortest path from origin to destination, but also several alternative paths. Furthermore, it is also essential to consider an EV's multiple stops at EV-recharging facilities. An elegant mathematical model to analyze the EV-support infrastructure with respect to multiple routes and multiple-charging stops will be discussed.

4 - A Heuristic Method to Solve Large-scale Flow-refueling Location Model

Ibrahim Capar, Bowling Green State University, Department of ASOR, 355 Business Administration Building, Bowling Green, OH, 43403, United States, icapar@bgsu.edu, Ismail Capar

In this research, we propose a new heuristic model for flow-refueling location model for alternative fuel vehicles. One of the challenges many organizations face is using existing exact and heuristic algorithms to solve large scale real-world problems. We present a heuristics approach to solve these larger scale problem consisting of real-world data set obtained from an organization located in Europe. We discuss the heuristic in detail and share the results from numerical experiments.

Joint Session SIM/ OPT under Uncertainty: Sample Average Approximation (SAA): Applications and Methodology

Sponsored: Simulation

Sponsored Session

Chair: Dashi Singham, Naval Postgraduate School, Naval Postgraduate School, Monterey, CA, 93943, United States, dsingham@nps.edu

1 - Sample Average Approximation for Continuous Principal Agent Problems

Dashi Singham, Naval Postgraduate School, 1411 Cunningham Road, Operations Research Department, Monterey, CA, 93943, United States, dsingham@nps.edu, Wenbo (Selina) Cai

We study a sample average approximation for estimating the solution to a continuous-demand principal-agent problem. This approach uses discrete samples from the demand distribution to solve a deterministic demand version of the problem. A special case of the continuous-demand problem where the solution is known motivates the problem. The broader issue is the convergence of functional solutions to SAA problems.

2

- Variance Reduction in Sequential Sampling for Stochastic Programming

Guzin Bayraksan, The Ohio State University, 210 Baker Systems, 1971 Neil Avenue, Columbus, OH, 43210-1271, United States, bayraksan.1@osu.edu, Jangho Park, Rebecca Stockbridge

We investigate the use of variance reduction techniques Latin Hypercube Sampling (LHS) and Antithetic Variates (AV) in sequential sampling for stochastic programming. Sequential sampling takes a sequence of solutions (obtained by any method) and assesses its quality by sequentially increased sample size. We update the theoretical results for LHS and perform computational experiments for both LHS and AV. Our results indicate that the use of AV and LHS in a sequential setting leads to tighter confidence intervals on the solutions obtained with reduced computational effort.

3 - Optimization-based Quantification of Input Uncertainty

Huajie Qian, University of Michigan, Ann Arbor, MI, United States, hqian@umich.edu, Henry Lam

We study the empirical likelihood approach to construct statistically accurate confidence bounds for stochastic simulation under nonparametric input uncertainty. The approach is based on positing distributionally robust optimization problems with suitably averaged divergence constraints to provide asymptotic coverage guarantees. We present the theory giving rise to the constraints and their calibration, and demonstrate how the approach compares to existing methods such as the Bootstrap and the Delta method in terms of computational effort and stability.

4 - Quantifying Uncertainty in Sample Average Approximation via the Empirical Likelihood

Henry Lam, University of Michigan, 1205 Beal Avenue, Industrial & Operations Engineering, Ann Arbor, MI, 48109, United States, khlam@umich.edu, Enlu Zhou

We discuss the use of empirical likelihood in the statistical uncertainty quantification of stochastic objectives and constraints, and its connection to robust optimization. We compare this approach to some classical methods in obtaining performance bounds for stochastic optimization and discuss other recent related works.

Reliant Populations and Disrupted Systems

Sponsored: Transportation Science & Logistics

Sponsored Session

Chair: Elise Miller-Hooks, George Mason University, GMU, Silver Spring, MD, na, United States, miller@gmu.edu

Co-Chair: Jyotirmoy Dalal, Indian Institute of Management Lucknow, Prabandh Nagar, IIM Road, Uttar Pradesh, Lucknow, 226013, India, jyotirmoy.dalal@gmail.com

1 - Real-time Transit Demand Estimation during Disruptive and Emergency Events

Tuan Le, George Mason University, Fairfax, VA, United States, tle34@masonlive.gmu.edu, Vadim Sokolov, Kuilin Zhang, Hubert Ley, James Garner

We present Bayesian models and methods for analyzing transit data in problems of inference about demand for transit system in real time. The goal is to develop short-term (a few hours) forecasts during disruptive events, such as flooding, tornadoes, blizzards and man-made emergencies. In this work, we solve a variant of the origin-destination flow problem. Our models allow for explicit representation of measurement uncertainties and incorporation of prior knowledge about demand patterns, e.g. historically observed origin-destination flows. Historical data is modeled as a prior, and noisy measurements of boardings and alighting are modeled via a likelihood.

2 - Modeling Transit-Communication Interdependencies for Resilience Computation

Neza Vodopivec, George Mason University, Fairfax, VA, United States, nvodopiv@gmu.edu, Elise Miller-Hooks

Resilience to transit disruptions depends not only on a technical system's performance, but also on the ability of individuals to adapt to disruptions. To make well-informed decisions, individuals depend on effective communication. We introduce an integrated socio-technical system model capturing functional dependencies between a system's engineered and social components. We present algorithms used to evaluate component criticality in system performance and identify mechanisms of failure and failure propagation paths.

3 - An Integrated Framework for Assisted Evacuation of Remote Habitats

Jyotirmoy Dalal, Assistant Professor, Indian Institute of Management Lucknow, House No. 422, IIM Lucknow Campus, Lucknow, 226013, India, jyotirmoy.dalal@iiml.ac.in

In the wake of a disaster, automobile based self-evacuation is not always an option for many remote, economically backward population. Even in case of an assisted-evacuation, a lack of proper road infrastructure makes the mass-transit movement unsafe during the disaster. We propose an integrated, centralized, time- and cost-effective mass evacuation and sheltering problem. Given the habitat and shelter locations, our model makes the necessary location, capacity and allocation decisions for a certain number of evacuee-pickup points under various supply and demand side constraints.

Joint Session RAS/Practice: Railroad Machine Learning & Component Failure Analysis

Sponsored: Railway Applications

Sponsored Session

Chair: Roochi Mishra, BNSF Railway Company, Fort Worth, TX, 76131, United States, roochi.mishra@bnsf.com

Co-Chair: Qing He, University at Buffalo, SUNY, Buffalo, NY, 14260, United States, qinghe@buffalo.edu

1 - Data-driven Railway Track Deterioration Model

Qing He, University at Buffalo, SUNY, 313 Bell Hall, Buffalo, NY, 14260, United States, qinghe@buffalo.edu, Amjad Aref

This study proposes an ensemble track deterioration model based on both stochastic mechanics modeling and Big Data machine learning techniques to capture the growth of defects, including both geometry defects and rail defects. The proposed model has been validated by real-world track data from North America Class I railroads.

2 - A Machine Learning Approach to Generate Track Surfacing Plan Based on Geometry Car Test Data

Pooja Dewan, PhD, BNSF Railway, Fort Worth, TX, 76137, United States, pooja.dewan@bnsf.com

In railroad, geometry car provides foot by foot track surface measurements as basic guide line for railway road master to make surfacing plan. Traditionally, we use rule based or threshold based method to indicate the area required to do maintenance. In this presentation, we will present a machine learning based approach to generate track surfacing plan from geometry car test data. Details from data preparation, training data collection to model implementation and deployment will be discussed.

3 - Bearing Failure Analysis

Landon Smith, BNSF Railway, BNSF Railway, Fort Worth, TX, United States, landon.smith@bnsf.com, Hark Braren

In transportation via rail, a roller bearing failure on a car in a train generally leads to catastrophic derailments. For many years, railroads have utilized Hot Box Detectors (HBD) to generate system alerts for bearings that approach a high temperature state. Although this method is somewhat effective, it does not catch ALL failing bearings, and these non-alerted bearings cause various issues impeding smooth operations, such as setouts, service interruptions, and derailments. In this presentation, we will discuss the technology used for timely identification of failing bearings as well as mapping the failure progression modes for different types of bearing failures.

4 - Prediction of Arrival Times of Freight Trafficon US Railroads using Support Vector Regression

Daniel Work, University of Illinois, Chicago, IL, United States, dbwork@illinois.edu, William Barbour

Variability of travel times on the United States freight rail network is very high, which poses operational challenges if the nature of variability is not predictable. This work proposes a data-driven approach to predict estimated times of arrival (ETAs) of individual freight trains based on the properties of the train, network, and conflicting traffic. The problem is posed as a series of location-specific machine learning regression problems and solved using support vector regression trained on over two years of data. We present details on feature engineering, findings on the most predictive factors for ETA, and preliminary ETA improvements exceeding 20% over baseline statistical methods.

Software Tips for the Analytics Classroom

Sponsored: INFORMEd

Sponsored Session

Chair: Thomas G. Groleau, Carthage College, Kenosha, WI, 53140-1994, United States, tgroleau@carthage.edu

1 - Software Tips for the Analytics Classroom

Nilakantan Sundara Raman Narasinganallur, K.J. Somaiya Institute of Management Studies & Research, B 602 Tulip Rachna Garden, Mulund Colony, Mumbai, 400082, India, nilakantan@somaiya.edu

Data analytics has come into limelight especially with voluminous data being generated. Big data requires new techniques in analytics and new softwares. Whether prescriptive or predictive, analytics requires faster integration and implementation. When we teach analytics in the classroom, we need to impart understanding with many shortcuts and tips to make the experience useful and skill-building. The presentation will touch upon the presenter's experience with teaching predictive and prescriptive analytical methods to MBAs in India.

2 - The Role of Simulation Games in the Analytics Classroom

Vincent Hargaden, University College Dublin, School of Mechanical & Materials Engineering, Engineering & Materials Science Centre, Belfield, Dublin 4, Ireland, vincent.hargaden@ucd.ie

We describe the use and impact of an internet based supply chain simulation game to teach topics in analytics to graduate engineering and business school students. This well-known game from Responsive Learning Technologies requires students to apply forecasting, inventory management, transportation and facility location concepts. Using data from 122 student groups since 2011, we compare performance between engineering and business school student cohorts.

3 - Excel is Great – Until it Isn't

Thomas G. Groleau, Carthage College, 2001 Alford Park Drive, Kenosha, WI, 53140-1994, United States, tgroleau@carthage.edu

Microsoft Excel's all-purpose flexibility makes it a commonly used tool for introductory business statistics or other analytics-oriented classes. However it becomes cumbersome for two or more sample inference and large data sets. While we start our business statistics classes with Excel, we transition to dedicated statistics software (SPSS) as the class progresses. This presentation covers when and how we make that transition.

4 - Faculty Resources on the INFORM-ED Website

Michael J. Racer, University of Memphis, 302 Fogelman College of Business, Memphis, TN, 38152, United States, mracer@memphis.edu, Palaniappa Krishnan

The purpose of the website is to provide a resource for faculty members in the operations research are. This website will include several items available for faculty members- sample curriculums to which any member can submit examples, cases, projects, software, etc.

Optimization in Food-Energy-Water Nexus

Sponsored: Energy, Natural Res & the Environment, Energy

Sponsored Session

Chair: Masood Parvania, University of Utah, Salt Lake City, UT, 84112, United States, masood.parvania@utah.edu

Co-Chair: Sauleh Ahmad Siddiqui, Johns Hopkins University, Baltimore, MD, 21218, United States, siddiqui@jhu.edu

1 - Optimizing Water Energy Flexibility in Water Distribution Systems

Masood Parvania, Assistant Professor, University of Utah, 50 S. Central Campus Drive, Room 2110, Salt Lake City, UT, 84112, United States, masood.parvania@utah.edu, Konstantinos Oikonomou

We present a model for optimizing the energy flexibility of water distribution systems (WDS). The water distribution system operators are considered as energy savvy entities, who run the proposed WDS operation model to optimize the operation of water pumps and tanks for minimizing the operation cost of the WDSs, while respecting the hydraulic operating constraints for ensuring deliverability of the WDS energy flexibility. The power system operator, then, optimizes final decisions on the contribution of WDS energy flexibility in power systems operation.

2 - Integrated Modeling to Answer Research Questions at the Intersection of Food-energy-water in Ethiopia

Sriram Sankaranarayanan, Johns Hopkins University, Baltimore, MD, 21218, United States, ssankar5@jhu.edu, Ying Zhang, Benjamin Zaitchik, Sauleh Ahmad Siddiqui

We present an integrated partial equilibrium model for food and energy markets that computes food production and trade volumes in Ethiopia, and models power generation and transmission from hydel and geothermal power stations. Coupling these models though prices and quantities along their supply chains, we asses shifts in welfare under policy scenarios. We run the model under improved irrigation capabilities, crop rotation strategies, and injection of food aid during crop failure.

3 - Opportunities for Energy Water Nexus Planning and Operation

Amro Farid, Dartmouth College, Hanover, NH, United States, Amro.M.Farid@dartmouth.edu

This presentation identifies and motivates several opportunities for integrated operations management and planning of the the energy-water nexus (EWN). First, an exposition of the EWN is given. This discussion focuses on the electric power, potable water, and wastewater distributions systems. Second, the paper shifts to opportunities in integrated operations management highlighted by an energy-water nexus supply-side economic dispatch illustration. Thirdly, the discussion shifts to planning opportunities for the energy-water nexus for the sustainable development of water and energy resources. A concluding section summarizes the policy implications of the identified opportunities.

4 - Optimization of Marine Hydro-Kinetic Devices for Electricity Systems

Alberto J. Lamadrid, Lehigh University, 621 Taylor Street, R451, Bethlehem, PA, 18015-3120, United States, ajl259@cornell.edu

In this work we formulate a proposal for wave farm owners to participate in deregulated electricity markets. Our proposal for the day ahead market allows for a closed form solution of the optimal offer. We establish a mapping between real time prices and profits considering uncertainty, and evaluate the revenue streams for wave energy producers.

Journal of Quality Technology Invited Session

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Fugee Tsung, HKUST, Clearwater Bay Road, Hong Kong, HK, Hong Kong, season@ust.hk

1 - Robust Multivariate Control Chart Based on Goodness-of-fit Test

Nan Chen, National University of Singapore, Department of Industrial and System Eng, 1 Engineering Drive 2, Singapore, 117576, Singapore, isecn@nus.edu.sg, Chen Zhang, Changliang Zou

This paper proposes a distribution-free MSPC chart to detect general distributional changes in multivariate variables. The chart is based on a multivariate goodness-of-fit test, extensible to high dimensional observations. The chart also employs data-dependent control limits to ensure robust charting performance. The proposed chart is exactly distribution-free, and able to operate with unknown in-control distribution or limited reference samples. The chart also has satisfactory OC detection power for general changes without distributional assumptions.

2 - Change Detection in a Dynamic Stream of Attributed Networks

Mostafa Reisi Gahrooei, Georgia Institute of Technology, Georgia Tech, H. Milton Stewart School Of ISYE, Atlanta, GA, 30332-0205, United States, mostafa.reisi@gmail.com, Kamran Paynabar

While anomaly detection in static networks has been extensively studied, only recently, the attention has been focused on dynamic networks. This paper proposes a new methodology for modeling of dynamic attributed networks and for change detection in the network structure. In this methodology, generalized linear models are used to model static attributed network. This model is then combined with a state transition model to capture the dynamic behavior of the system and Extended Kalman filter is used estimate and update network parameters over time. Prediction residuals are then monitored using EWMA. The proposed method is examined through simulations and a case study.

3 - Using Curve-registration Information for Profile Monitoring

Bianca Maria Colosimo, Politecnico di Milano, Via La Masa, 1, Milan, I-20156, Italy, biancamaria.colosimo@polimi.it, Marco Grasso, Alessandra Menafoglio, Piercesare Secchi

The contribution presents a novel approach for profile monitoring, which combines the Functional Principal Component Analysis and the use of parametric warping functions. The key idea is to jointly monitor the stability over time of the registered profiles and the registration coefficients. This allows improving the capability of detecting unnatural pattern modifications, thanks to a better characterization of the overall natural variability.

Systems Modeling Approaches to Energy Analysis

Invited: Energy and Climate

Invited Session

Chair: Benjamin D. Leibowicz, University of Texas-Austin, Austin, TX, 78712-1591, United States, bleibowicz@utexas.edu

1 - The Cost of Policy Uncertainty in Electric Sector Capacity Planning: Implications for Instrument Choice

Benjamin D. Leibowicz, University of Texas-Austin, ETC 5.128D, 204 E. Dean Keeton St. C2200, Austin, TX, 78712-1591, United States, bleibowicz@utexas.edu

The OSeMOSYS energy system optimization model is reformulated as a stochastic program and applied to electric sector capacity planning under climate policy uncertainty in the ERCOT area. Optimal hedging strategies are identified, and the costs of policy uncertainty under carbon taxes, carbon caps, and renewable portfolio standards are compared. Findings clearly indicate that uncertainty considerations favor price-based over quantity-based policy instruments.

2 - Optimal Pathways to Net-zero Emissions: A Study of Austin, Texas

Max Brozynski, University of Texas-Austin, Austin, TX, United States, brozynski@utexas.edu

We develop an integrated systems model of energy supply and demand at the urban scale, and use it to determine optimal decarbonization pathways. Our framework is integrated in that it represents all major energy end-use demands, and captures synergistic linkages among them. Examples of such linkages include electrification of transportation, vehicle-to-grid technologies, combined heat and power, and diverse uses of hydrogen. We apply our model to evaluate decarbonization strategies in Austin, Texas, which recently adopted a goal to achieve net-zero greenhouse gas emissions by 2050.

3 - Improving Solar Integration and Grid Utilization via Residential Cooling Thermal Energy Storage

Thomas Deetjen, University of Texas-Austin, Austin, TX, United States, tdeetjen@gmail.com

This study examines the potential for cooling thermal energy storage (CTES) in the residential sector to provide flexibility to the electric grid. A linear optimization model chooses the capacity and sub-hourly dispatch of chillers and CTES systems in a neighborhood with rooftop solar. The model tests whether CTES can reduce peak electric demand, lessen solar-induced ramp rates, and lower operation costs in the neighborhood and bulk transmission-grid. Results show that CTES operation can improve or worsen these outcomes, depending on how electricity rates have been structured.

4 - Optimal Dispatch and Equipment Sizing of a Community-scale Water Recycling Facility for Electric Demand Flexibility

Scott Vitter, University of Texas-Austin, scott.vitter@gmail.com, Thomas Deetjen, Bruk Berhanu, Michael Webber

This study explored tradeoffs between sizing, operating schedule, and electric load-shifting for a community-scale water recycling facility within a residential area. A mixed-integer linear program was formulated to represent a community system consisting of a batch recycling process, potable water storage, and sewer equalizing storage. Initial results indicate that operating a water recycling facility can reduce overall community costs under certain economic conditions, and that batch processes can be scheduled in response to signals that favor electric demand flexibility. Total water demand, water and sewer pricing, and equipment capital costs strongly influence the optimal solution.

1 - L1-norm Subspace Estimation for Microbiome Data Analysis

Paul Brooks, Virginia Commonwealth Univ, Dept of Stat Sci and OR, P.O. Box 843083, Richmond, VA, 23284, United States, jpbrooks@vcu.edu

DNA from communities of microorganisms can be sequenced to provide a census of the species present. The resulting counts of DNA fragments form profiles that can be explored with clinical data understand host-microbiome interactions in human health. Subspace estimation forms the basis for many tools for discovering important patterns. Using the traditional sum-of-squared error criterion can lead to erroneous conclusions. We demonstrate the performance of a robust subspace fitting procedure in ordination of microbiome samples and as a subroutine in a subspace classification method.

2 - Dynamic Management of Healthcare Queues with Capacity Adjustment Delay Uncertainty

Sara Nourazari, California State University, Long Beach, 1250 Bellflower Blvd-MS.4904, HHS2-118, Long Beach, CA, 90840, United States, sara.nourazari@csulb.edu, Rifat Sipahi, James Benneyan

In spite of the incentives to improve outpatient access, many healthcare systems are still struggling with providing timely access to care, which takes its toll on the patients in need. This work provides a detailed analysis pertaining to Modified Smith Predictor, to develop a robust controller design in queue management problems to regulate queue length despite uncertain demand and delay mismatches between the model and the actual system. By illustrating how flexibility in capacity adjustment can effectively improve patient appointment access, the results of this study demonstrate the value of dynamic modelling in healthcare systems redesign initiatives.

3 - The Efficiency Loss Problem in Social Network Analysis Based on Stochastic Block Model

Peiwen Xu, City University of Hong Kong, 88 Tat Chee Avenue, Hong Kong, Hong Kong, peiwenxu-c@my.cityu.edu.hk, Tsui Kwok Leung

In this paper, we will investigate the efficiency loss for anomaly detection due to the conversion of count data to binary data in social network analysis, based on Stochastic Block Model(SBM), a benchmark for detecting changes of community structure in social network analysis. By applying statistical process control techniques to Stochastic Block Model, the loss of efficiency can be quantified by comparing the average run length (ARL) performance.

4 - Simulation-based Optimization of Prognostics and Health Management enabled Condition-Based Maintenance Policy

Omoleye Taiwo Joel, City University of Hong Kong, Kowloon, Hong Kong, jtomoleye3-c@my.cityu.edu.hk, Kwok Leung Tsui

The practical implementation of condition-based maintenance (CBM) is trailing behind the widespread theoretical benefits in the literature. This necessitates the growing concern about the effectiveness of CBM policy in industries implementing CBM. To overcome this, research is focusing on the value of Prognostics and Health Management (PHM) information in CBM policy. In this paper, simulation-based optimization is used to assess the benefits of PHM-enabled CBM policy under resource dependence. Also, a framework is developed, numerically illustrated, and compared with classic CBM, and traditional maintenance policies using ARENA-based discrete event simulation model.

Design of Logistics Networks

Sponsored: TSL, Freight Transportation & Logistics

Sponsored Session

Chair: Sasha Zhijie Dong, Texas State University, San Marcos, TX, United States, sasha.dong@txstate.edu

1 - A Lagrangian Relaxation Approach to a Multi-Echelon Consolidation of Perishable Products

Christine Nguyen, Northern Illinois University, DeKalb, IL, 60115, United States, cnguyen@niu.edu

Our research focuses on a supply chain of suppliers with low demand for perishable products. By shipping through FTL units, the transportation cost would be less expensive than LTL shipments. The suppliers all ship to a shared consolidation center, where suppliers can experience the advantages of consolidating product. Transportation and inventory decisions are made at suppliers and the consolidation center. This problem is decomposed and solved using a Lagrangian Relaxation approach.

2 - Regional Logistics Network Design with Consider of Roadway Traffic Congestion and Service Decay

Mi Gan, Southwest Jiaotong University, Chengdu, China, taosiyu@swjtu.edu.cn, Si Chen, Siyu Tao

In order to solve the problem that the existed logistics network design models(LND) are lack of consideration on roadway traffic flow. The uncover degree function of logistics facility nodes based on impedance function was built. Then, integrated logistics network design models and corresponding algorithms were proposed on the basis of uncovering degree function. The comparison of general LND models and models we developed by actual case reveals the impact of roadway traffic flow on LND.

3 - Resilient Route Design for Collection of Material from Suppliers
Zhijie Dong, Assistant Professor, Texas State University, San Marcos, TX, 78666, United States, sasha.dong@txstate.edu

As production schedules of manufacturing operations change, the amounts of material to be picked up at individual suppliers can be quite volatile, but it is desirable to have relatively regular route structures in place so that the system can adapt to varying volumes without requiring complete redesign of collection routes every time there is a change in the production schedule at the manufacturing plant. Our model accomplishes this resilient design of routes using a stochastic version of a capacitated clustering formulation. The model is constructed as a two-stage stochastic mixed integer program.

4 - Service Network Design Problem on an Hierarchical Hub-and-Spoke Network for a Major Carrier
Yusuf Secerdin, University of Miami, 1251 Memorial Drive, McArthur Engineering Building, Coral Gables, FL, 33146, United States, yusufsecerdin@miami.edu, Murat Erkoc

In this study, we present mathematical models and solution procedures for the routing and scheduling of the Caribbean air feeder network of a major express cargo service provider. The problem is modeled as a service network design problem on a hierarchical hub-and-spoke network. The proposed solution methodology first executes an initial data processing that involves route generation and elimination in order to contain the size of the solution space for the mathematical model. We consider two versions of the proposed model based on two scenarios: dedicated runs and milk runs. We compare two approaches in terms of operational costs, flight hours, and fleet sizing.

Network Resilience

Sponsored: Transportation Science & Logistics

Sponsored Session

Chair: Yan Deng, Cornell University, Cornell University, 2406 Hasbrouck Apartment, Ithaca, NY, 14850, United States, yd256@cornell.edu

1 - Disaster Induced Traffic Network Analysis using Percolation Theory
Yaoming Zhou, University of Hong Kong, University of Hong Kong, Pokfulam, Hong Kong, Hong Kong, youngme910@hku.hk, Junwei Wang, Jiuh-Biing Sheu

The impact of traffic networks' structure change on operations management during disasters is usually ignored. We propose a stochastic mathematical framework utilizing percolation theory to systematically study how will different magnitude of disasters affect the global and local connectivity of traffic networks. This method also helps find out when and to what extent can the impacts be ignored. The impacts of natural and man-made disasters are compared. We discussed the application of our method to a real-world traffic network with some important insights.

2 - An Optimal Stopping Problem to Mitigate Productivity Losses of a Transportation System Utilizing Hurricane and Storm Surge Forecasts
Rodney Middlebrooks, Graduate Student, North Carolina A&T State University, Greensboro, NC, United States, middlebrooks.r@gmail.com

In the context of a transportation network, a system-wide operational shutdown can be ordered prior to the realization of expected hurricane landfall or storm surge inundation. The decision is binary, with the choice to either continue with routine operations or suspend them, initiating protective measures. The critical infrastructure decision problem is modeled as a finite-horizon optimal stopping problem. The objective is to minimize the loss of productive output of a transportation system, given real-time hurricane and storm surge forecast information.

3 - Vulnerability Assessment and Mitigation of Complementary Transportation Systems under Worst-case Saptially Localized Attacks
Liu Hong, Associate Professor, Huazhong University of Science and Technology, 1037 Luoyu Road, Wuhan, 430074, China, liu.hong@hust.edu.cn, Min Ouyang, Xin Zhong

Spatially localized attacks, caused by natural hazards or malicious attacks, can make serious loss to the transportation systems. This paper proposes an approach to assess and mitigate the vulnerability of complementary transportation systems under worst-case spatially localized attacks. The national level complementary railway and airline systems, and the urban level complementary bus and subway systems, are used as numerical experiments to illustrate the tractability and effectiveness of the proposed method.

4 - Socially Profitable Transport Infrastructure Investment Strategies under Demand Uncertainty: A Real Options Based Approach
Yan Deng, Cornell University, Cornell University, 2406 Hasbrouck Apartment, Ithaca, NY, 14850, United States, yd256@cornell.edu, Oliver Gao

This paper developed a real options based methodology to address the optimal transport investment strategies under travel demand volatility. A socially profitable demand threshold is derived under the market share and competition. The methodology is subsequently applied to the High Speed Rail investment in the United States. The results compared the investment criteria from real options with the NPV valuation approach, and illustrated the investment returns from consumer, producer and environmental surplus. Sensitivity analysis was carried out to examine the characteristics of the optimal transport investment rules and the policy implications under the effects of key parameters.

Diagnostic/Predictive Data Analytics and Data-Driven Decision Making for Smart and Connected Systems

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Raed Al Kontar, University of Wisconsin-Madison, 1513 Mechnaical Engineering Building Room 3255, Madison, WI, 53706, United States, alkontar@wisc.edu

Co-Chair: Shiyu Zhou, University of Wisconsin-Madison, Madison, WI, 53706-1572, United States, szhou@engr.wisc.edu

1 - A Novel Pattern-frequency Tree Approach for Dynamic Transition Analysis
Cheng-Bang Chen, Pennsylvania State University, 310 Leonhard Building, University park, PA, 16802, United States, czc184@psu.edu, Hui Yang, Soundar Kumara

This paper presents a novel methodology of pattern-frequency tree for transition analysis in dynamic nonlinear systems. First, we propose Hyperoctree State space Aggregation Segmentation to delineate the high-dimensional dynamic processes in a continuous state space. Then, we develop a pattern-frequency tree to characterize and model the pattern distribution. Finally, we leverage pattern-frequency distribution information to develop a k-Maximin deviation algorithm for e ective and e cient detection of process anomalies. Experimental results show that the proposed method performs better than the conventional methods in multi-sensor settings and high-dimensional environments.

2 - Contamination Source Identification Based on Sequential Bayesian Approach for Water Distribution Network with Stochastic Demands
Chao Wang, University of Wisconsin-Madison, Rm. 3255, ME building 1513 University Ave., Madison, WI, 53706, United States, cwang436@wisc.edu, Shiyu Zhou

The contamination source identification problem in the water distribution network is studied under the Bayesian framework. Simulations for the contamination propagation are conducted, where sensor alarms are recorded to establish the observation probability distributions. Then, the posterior probability of each possible source can be calculated. Finally, the contamination source is identified based on the ranking of the posterior probability. The contribution of this work is that the observation probability distributions are organized into hierarchical tree structures and the challenge of combinatorial explosion is avoided. The effectiveness of this method is verified by a case study.

3 - Active Learning for Gaussian Process Classification using a Data-based Kernel
Hang Li, Pennsylvania State University, University Park, PA, 16803, United States, hul180@psu.edu, Enrique del Castillo, George Runger

Active learning and semi-supervised learning are important techniques in the machine learning field, especially when the labeled instances are very difficult, time-consuming or expensive to obtain. In this presentation we discuss a Gaussian Process Classification (GPC) model with a data-based kernel that exploits the manifold structure hidden in the labeled and unlabeled data. Based on the GPC model, we develop an uncertainty-based active learning scheme which queries the most informative instances to label. We also investigate the hyperparameters learning problem by maximizing the likelihood of labeled data. Promising experimental results are presented for synthetic data and real world classification problems.

4 - Nonparametric Prognostics using Convolution Processes: An Alternative Approach Based on Transfer Learning

Raed Al Kontar, University of Wisconsin-Madison, 1513 University Avenue, Room 3255, Madison, WI, 53706, United States, alkontar@wisc.edu, Shiyu Zhou

In this paper, an alternative view on modeling condition monitoring (CM) signals is proposed. This view draws its roots from multitask learning and is based on treating each CM signal as an individual task. Each task is then expressed as a convolution of a latent function drawn from a Gaussian process (GP), and the transfer of knowledge is achieved through sharing these latent functions between historical and in-service CM signals. As a result, all task are represented through a functional graphical model. Aside from being non-parametric, the individualistic approach in our model is able to account for heterogeneity in the data and automatically infer the commonalities between different signals.

Joint Session QSR/ENRE Electricity: Data-driven Systems Engineering Approaches in Wind Power Systems

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Eunshin Byon, University of Michigan, 1205 Beal Avenue, 1205 Beal Avenue, Ann Arbor, MI, 48109, United States, ebyon@umich.edu

Co-Chair: Hoon Hwangbo, Texas A&M University, College Station, TX, 77840, United States, hhwangbo@tamu.edu

1 - Contextual Bayesian Ascent Algorithm for Cooperative Wind Farm Control

Jinkyoo Park, jinkyoo.park@kaist.ac.kr

We discuss a probabilistic optimization method for identifying the joint optimal operational conditions of wind turbines in a wind farm for varying wind condition. We developed a Contextual Bayesian Ascent (CBA) algorithm, an extended version of Bayesian Optimization (BO) that can find an optimum of a target function through the iterative learning and sampling procedure. CBA takes into account context information that modifies the target function and restricts the searching space so that it can rapidly find an optimum. The results from simulation studies using an analytical wind farm power function show that the CBA algorithm can achieve an almost optimum control policy.

2 - Assessment of Wind Parameter Sensitivity on Ultimate and Fatigue Wind Turbine Loads

Latha Sethuraman, National Renewable Energy Laboratory, National Wind Technology Center, 15013 Denver West Parkway, Golden, CO, 80401, United States, Latha.Sethuraman@nrel.gov, Amy Robertson

Wind turbines are designed using a set of simulations to ascertain the structural loads that the turbine could encounter, but the only probabilistic variable considered is the mean wind speed. Other wind parameters, such as turbulence spectra, sheer, veer, spatial coherence, and component correlation are deterministic values that in reality could vary vastly in time and between sites and have a significant effect on the loads. This paper seeks to assess the sensitivity of different wind parameters on the resulting turbine ultimate and fatigue loads during normal operational conditions. Eighteen different wind parameters are screened using an Elementary Effects approach with radial points.

3 - Wake Effect Parameter Calibration in Wind Power Systems

Bingjie Liu, bingjiel@umich.edu, Matthew Plumlee, Eunshin Byon

In design and operations in wind power systems, physical interactions among wind turbines, called wake effects, is one of the significant factors that affect power generation performance. Among several wake modeling approaches, physics-based engineering models have been widely used due to its simplicity. The accuracy of engineering wake models, however, highly depends on the parameters. This talk proposes a calibration approach for estimating the relationship of wake parameters and environmental factors.

4 - Multivariate Power Curve Estimation an Adaptive Kernel Method Reflecting the Domain Knowledge

Hoon Hwangbo, Texas A&M.University, 522 Southwest Parkway, Apt A, College Station, TX, 77840, United States, hhwangbo@tamu.edu, Yu Ding

Accurate estimation of wind turbine power curve improves wind power prediction and hence economic assessment of existing or potential wind energy projects as well as operational controls and condition monitoring of turbines. Deviating from the predominant practice of univariate power curve modeling, a recent study introduced a multivariate power curve model utilizing additive multivariate kernels, which significantly improves the prediction accuracy. In this study, we further strengthen the multivariate power curve model by allowing adaptive bandwidths and enhancing the additive structure maintained between the multivariate kernels that ultimately reflect the domain knowledge better.

Learning and Optimization for Resilient Power Grids

Sponsored: Energy, Natural Res & the Environment Environment & Sustainability

Sponsored Session

Chair: Yury Dvorkin, New York University, Seattle, WA, 98115, United States, dvorkin@nyu.edu

Co-Chair: Yu Zhang, University of California, Santa Cruz, Albany, CA, 94706, United States, zhangy@ucsc.edu

1 - T&D Integration: Value of Learning about Consumers

Yury Dvorkin, Assistant Professor, New York University, 5 Metrotech Center, New York, NY, 11201, United States, dvorkin@nyu.edu

We will present a modeling framework to analyze techno-economic interactions between transmission and distribution electrical grids. This framework intends to allocate flexibility of distributed energy resources between transmission and distribution grid support services. Since availability of some distributed energy resources is constrained by socio-economic behavior of electricity consumers, we will use a learning-compatible approach to account for behavioristic aspects that cannot be considered using formal models. The usefulness of the proposed framework will be illustrated on benchmark transmission and distribution systems.

2 - Learning through Power Distribution Grid Probing

Vassilis Kekatos, Virginia Tech, Blacksburg, VA, United States, kekatos@vt.edu

Although power distribution grids are challenged by limited observability, many nodes are equipped with smart meters collecting voltage and power injection readings. The key idea here is to engage the smart power electronics to probe the grid and infer non-metered loads. Probing can be accomplished by commanding inverters to fluctuate their (re)active power injections. Recording the incurred voltages at actuated and metered nodes can unveil injections at non-metered nodes. It is analytically shown that probing over two time instances is successful if and only if non-metered nodes can be matched to metered nodes through vertex-disjoint paths as numerically corroborated using actual data too.

3 - Modeling and Optimization of Complex Buildings with Deep Neural Networks

Yuanyuan Shi, University of Washington, Seattle, WA, United States, yyshi@uw.edu, Yize Chen, Baosen Zhang

Buildings are responsible for 40% of the global energy consumption and aroused serious economical and environmental concerns. Previous model-based optimization and control methods for building energy management either involves tedious modeling processes or cannot fully capture the exact dynamics of sophisticated buildings. Here we propose an alternative approach which is model-free and data-driven. By utilizing high volume of data coming from advanced sensors, we train a deep neural network which could accurately represent the operation dynamics of buildings. The trained network is then directly fitted into a constrained optimization problem to find the optimal control strategies.

4 - Black Start Allocation for Power System Restoration

Georgios Patsakis, University of California Berkeley, 1460 Cedar St, Berkeley, CA, 94702, United States, gpatsakis@berkeley.edu, Deepak Rajan, Shmuel S.Oren

Extended blackouts of the power system, even though rare, can have a very high cost impact. System operators use heuristically predefined sequences for restoring the grid back to its initial state, based on units with the ability to start autonomously, called Black Start (BS) units. Recent literature tries to optimize over such candidate sequences. In light of pending BS unit retirements, we instead aim to optimally allocate BS units on the grid, while also extending current optimization models to include grid considerations. Scenarios corresponding to partial outages of the grid are considered and a decomposition algorithm is utilized to solve the problem. A test case is simulated.

Big Data

Contributed Session

Chair: Anushka Chandrababu, International Institute of Information Technology, Bangalore, Bangalore, India, anushka.babu@iiitb.org

1 - IoT Security

Michael Chuang, SUNY New Paltz, 1 Hawk Drive, New Paltz, NY, 12561, United States, mikeychuang@gmail.com

Internet of Things, a global infrastructure enabling services by interconnecting physical and virtual things based on interoperable information and communication technologies, has emerged in business applications in various industrial areas, and will reshape tomorrow's business and technology development.

2 - Individual Social Behavior and Intraday Patterns in Market Movements

Keli Xiao, Stony Brook University, College of Business, Stony Brook, NY, 11794, United States, keli.xiao@stonybrook.edu, Gaoshan Wang, Gaoshan Wang, Jishun Wang, Feiran Li, Xiaoyan Ding

In this study, we investigate the intraday patterns of individual investors' social behavior and the stock market dynamics with several new technical attempts including (1) developing an investor engagement index (IEI) using stock forum activity data based on the customer engagement theory, and (2) proposing a multi-source forecasting framework that combines both time series models and machine learning algorithms. With the IEI and transaction data of each stock, the relationship between IEI and stock movement is investigated and discussed. Based on the data collected from a famous Chinese stock forum, we benchmark the performance of our approach with several classic baselines.

3 - The Sequence Effects of Customer Experiences on Customer Perceived Value in Wellness-centric vs. Standard Hotel Stays: A Structural Econometric Analysis

Min Kyung Lee, Clemson University, 100 Sirrine Hall, Clemson, SC, 29634, United States, minl@g.clemson.edu, Aleda Roth, Bernardo F. Quiroga, Rohit Verma

We explore emerging market trend of wellness industry that provides service offerings or products reactively to healthy people to make them feel even healthier. Our work specified a structural econometric model to explore the theoretical importance of the service process sequencing for wellness-centric rooms versus exactly similar standard rooms. Specifically, we account for customers' experiences from hotel check-in to room stay to check-out on their satisfaction and likelihood to recommend for both wellness-centric rooms and standard rooms. We demonstrate that the wellness-centric service offering produces more perceived customer value added, when benchmarked against identical rooms.

4 - Neural Network Predictions of NYC Traffic Collisions

Anirudh Madhusudan, Graduate Student, University of Illinois-Urbana Champaign, 909S.Fifth Street, 120A Sherman Hall, Champaign, IL, 61820, United States, anirudh2@illinois.edu, Harshad Rai

The NYPD Motor Vehicle Collision dataset offers information on the traffic collisions and fatalities that have occurred in NYC since 2012. Also since 2012, the Vision Zero initiative has been trying to incorporate road-safety measures to reduce traffic incidents. This projects uses several visualizations and machine learning algorithms including Logistic Regression and Neural Network to learn and predict the occurrences of collisions and fatalities usings the dataset. The project also studies the impact of the treatments offered by Vision Zero to alleviate the condition of New York traffic.

5 - Dependency Discovery and Quality Improvement in Multistage Manufacturing Processes

Andi Wang, Georgia Institute of Technology, Atlanta, GA, United States, andi.wang@connect.ust.hk, Hao Yan, Jianjun Shi

Many modern fabrication processes such as semiconductor fabrication involve a large number of stages. Massive data are generated from each stage for quality improvement. Although the correlation structure between stages can be very complex, existing methods either analyze the data acquired from each stage independently or apply a state-space model that only captures the dependency of subsequent stages. In this research, we aim at detecting and modeling the complex dependency structure of data from multi-stages processes, which will provide great opportunity for further quality improvement.

6 - Convex Model Database – An Extension to Transportation Networks

Anushka Chandrababu, PhD Candidate, International Institute of Information Technology, Bangalore, 26/C, Electronic City, Bangalore, India, anushka.babu@iiitb.org, Srinivasa Prasanna

We present our extensions to the Convex Model Database (CmdB) suitable for summarizing structured or unstructured big-data and used for answering queries for convex optimization problems. We will specifically show how the database can be used to solve problems pertaining to one of the largest railway networks in the world. The database will store data as polytopes derived from historical and apriori structural relationships and compresses the infinite possibilities of train arrival or departure, into a very compact representation. We will show how the database can answer business use cases such as conflicts in train schedules through relational algebraic operations on the polytopes.

1 - Global Optimization with Surrogate Approximation of Constraints

Juliane Mueller, Lawrence Berkeley National Lab, 2453 Bonar Street, Berkeley, CA, 94702, United States, juliane.mueller2901@gmail.com, Joshua Woodbury

We introduce GOSAC, a global optimization algorithm for problems with computationally expensive black-box constraints and cheap objective functions. GOSAC first finds a feasible point by solving a multi-objective optimization problem in which the constraints are minimized simultaneously. Subsequently, GOSAC aims at improving the feasible solution. We use cubic radial basis function surrogate models to approximate the constraints. We iteratively select sample points by minimizing the cheap objective function subject to the constraint function approximations. We assess GOSAC's efficiency on cheap test problems with integer and continuous variables and two environmental applications.

2 - A Lagrangian Search Method for the P-median Problem

Jiming Peng, University of Houston, Houston, TX, United States, jopeng@Central.uh.edu

In this talk, we present a new method for the P-median problem. We first recast the P-median problem as a global optimization problem over the set of Lagrangian multipliers. Then we present a stochastic search method to find the Lagrangian multipliers corresponding to the optimal solution of the original P-median problem. Numerical experiments show that our method can effectively find a global optimal or very good suboptimal solution to the underlying P-median problem, especially for P-median problems with a large gap between the original problem and its Lagrangian relaxation.

3 - Strong Valid Inequalities for Boolean Logical Pattern Generation

Hong Seo Ryoo, Professor, Korea University, 145 Anam-Ro, Seongbuk-Gu, Seoul, 02841, Korea, Republic of, hsryoo@korea.ac.kr, Kedong Yan

0-1 multilinear programming (MP) captures the essence of pattern generation in Logical Analysis of Data (LAD). This paper utilizes graph theoretic analysis of data to discover useful neighborhood properties among data for data reduction and multi-term linearization of the common constraint of an MP pattern generation model in a small number of stronger valid inequalities. This means that, with a systematic way to more efficiently generating Boolean logical patterns, LAD can be used for more effective analysis of data in practice. Mathematical properties and the utility of the new valid inequalities are illustrated on small examples and demonstrated with 12 real-life data mining datasets.

1 - Clinic Appointment Scheduling for Integrated Practice Units

Pengfei Zhang, The University of Texas at Austin McCombs School of Business, Austin, TX, 78731, United States, pz@utexas.edu, Douglas Morrice, Jonathan F.Bard

Clinic appointment scheduling is very important for clinic management because it affects the providers' time usage and patients waiting time. It is important that we have a schedule that can balance providers' time usage and patients' waiting. We consider a clinic appointment scheduling problem with multiple types of providers and two types of patients. The objective is to minimize the clinic closing time while restrain the patients' waiting time to be within a certain range. We propose a new model for the problem, and develop heuristic method to solve it.

2 - Probabilistic Power Dominating Set Problem

Ou Sun, University of Arizona, 827 E Drachman St, Tucson, AZ, 85719, United States, suno@email.arizona.edu, Neng Fan

Power dominating set problem is widely used in power system. An important application in this area is the minimum Phasor Measurement Unit (PMU) Placement Problem which has zero-injection bus property. However, after sensor placement, there may be some unexpected failures occur on PMUs or transmission lines, which can affect the function of whole power system. Starting from this idea, we propose two methods to formulate the probabilistic coverage model under uncertainty of PMUs and lines given covering probability of each bus. One is changing the chance constraint into logarithm, another is calculating the covering probability of each bus in the network design graph.

3 - Optimization of Microgrid Operations with Renewable Energy Integration

Jose L.Ruiz Duarte, University of Arizona, Tucson, AZ, 85721, United States, jlruizduarte@email.arizona.edu, Neng Fan

The development and integration of new technologies to the traditional power grid are transforming it into a smart grid capable of responding to electricity demand growth and integration of renewable energy sources. Microgrids are important part of this approach. In this presentation, a mixed integer linear program is developed for operations of a microgrid, including unit commitment decisions, line connectivity decisions with network topology, power trade with main grid, islanding operations, energy storage systems, and solar energy integration. The uncertainty of solar power is captured by robust optimization, and problem is solved by Column-and-Constraint Generation algorithm.

Ethics in AI and OR

Invited: Operations Research and the Future of Computing

Invited Session

Chair: Tae Wan Kim, PHD, Carnegie Mellon University, Posner #243, 500 Forbes Avenue, Pittsburgh, PA, 15213, United States, twkim@andrew.cmu.edu

1 - Autonomous Machines are Ethical

John Hooker, Carnegie Mellon University, Tepper School of Business, Pittsburgh, PA, 15213, United States, jh38@andrew.cmu.edu

While many see the prospect of autonomous machines as threatening, autonomy may be exactly what we want in a superintelligent machine. There is a sense of autonomy, deeply rooted in the ethical literature, in which an autonomous machine is necessarily an ethical one. Development of the theory underlying this idea not only reveals the advantages of autonomy, but it sheds light on a number of issues in the ethics of AI. It helps us to understand what sort of obligations we owe to machines, what obligations they owe to us, and whether to assign responsibility to machines or their creators.

2 - The Missing Ingredient in Robotics and Artificial Intelligence: Intrinsic Values

Thomas Donaldson, PhD, The Wharton Schoo
l, University of Pennsylvania, Philadelphia, PA, United States, donaldst@wharton.upenn.edu

The rise of robotics and AI will force management organizations to take intrinsic values more seriously. Intrinsic values are non-derivative, impartial and synoptic. Non-intrinsic values, in contrast, are derivative, meaning that they derive either from mere postulation or from the perceptions of individual agents. New AI/robotics challenges frustrate traditional analyses that tend to use non-intrinsic values.

3 - Ethics and Accountability of Algorithms

Kirsten Martin, PhD, George Washington University, martink@email.gwu.edu

Recent headlines warn against the hidden and unchecked biases of algorithms used in advertising, sentencing, hiring, lending, etc. Hiding behind the apron of these headlines is a series of critical decisions about the design of the algorithm and the role of algorithms in decision making. The goal of this presentation is to explore how algorithms, which are developed, used, and sold by firms, can be biased and unjust, perform an important role in ethical decisions, and have implications for accountability in corporate responsibility. This paper offers a framework to examine the value-laden decisions when utilizing an algorithm to augment organizational and individual decision-making.

4 - Algorithmic Transparency, a Right to Explanation and Placing Trust

Tae Wan Kim, Tepper School of Business, Carnegie Mellon University, 5000 Forbes Avenue, Pittsburgh, PA, 15213, United States, twkim@andrew.cmu.edu, Bryan Routledge

A growing number of researchers and governmental bodies have called for algorithmic accountability. European Parliament and Council adopted General Data Protection Regulation, which will come into force in 2018. Authors debate whether GDPR, in addition to a right to be forgotten, grants EU residents another novel kind of protection, a so-called "right to explanation." Here we articulate a tripartite structure of the right, justify it, and explore possible models of an ex post explanation that companies can provide to data subjects. Since we explore the moral or ethical, not legal, foundations of a right to explanation, the implications of our work are beyond the European context.

1 - Distributed Spectral Clustering and Applications

Shahzad Bhatti, University of Illinois at Urbana Champaign, 104 S Mathews Ave, Urbana, IL, 61801, United States, bhatti2@illinois.edu, Carolyn L.Beck

Clustering is fundamental to machine learning. Most clustering algorithms are tailored for data stored on a central machine and are inappropriate for large data distributed across machines. The scale of the data may also prohibit moving it to a central machine. Our approach employs two phases: 1) individual machines generate a set of representative points for local data and communicate these to a central machine; 2) the central machine performs spectral clustering on the representatives and communicates cluster assignments to the distributed machines. We have explored various algorithms to generate representatives and compared results. Our algorithm is easily cast in the MapReduce framework.

2 - An Extended Formulation of the Convex Recoloring Problem on a Tree

Minseok Ryu, University of Michigan, 1535 Pine Valley Boulevard, Apt 212, Ann Arbor, MI, 48104, United States, msryu@umich.edu, Sunil Chopra, Bartosz Filipecki, Kangbok Lee, Sangho Shim, Mathieu Van Vyve

We introduce a strong extended formulation for the convex recoloring problem on a tree, which has an application in analyzing phylogenetic trees. The extended formulation has only a polynomial number of constraints, but dominates the conventional formulation and the exponentially many valid inequalities introduced by Campelo et al. The solution time using the extended formulation is much smaller than that with the conventional formulation. Moreover, the extended formulation solves all the problem instances attempted in Campelo et al. (2016) and larger-sized instances at the root node of the branch-and-bound tree without branching.

3 - Automated Conjecturing for Integrality Gap Bounds

Craig Larson, Virginia Commonwealth University, VA, United States, clarson@vcu.edu

We explain how the open source CONJECTURING program can be used to generate conjectures for the integrality gap for IP problems. The conjectures are in the form of upper or lower bounds; these bounds are functions of user-input invariants that may come from the problem being modeled. We use the k-partite Balanced Tree Problem as an example of what is possible. The problem is to partition the vertices of a tree into k sets so that the number of edges with endpoints in different partitions is minimized. We present a variety of conjectured bounds, in terms of the order n, the size m, and other invariants, and discuss an iterative process of investigation—-which is applicable to any similar optimization problem.

5 - Balanced Tree Partitioning

Paul Brooks, Virginia Commonwealth Univ, Dept of Stat Sci and OR, P.O. Box 843083, Richmond, VA, 23284, United States, jpbrooks@vcu.edu

In this talk, we present two integer programming formulations for the k-Balanced Partitioning problem for trees. One is an adaptation of a formulation for all tree partitions. The other is a novel flow-based formulation with a smaller integrality gap. We describe solution strategies and present computational results comparing the formulations.

Algorithms for Structured Optimization Problems II

Sponsored: Optimization, Nonlinear Programming

Sponsored Session

Chair: Shiqian Ma, Chinese University of Hong Kong, Shatin, Hong Kong, sqma@se.cuhk.edu.hk

Co-Chair: Yunan Zhou, University of Southern California, 2707 Portland Street, Apt 111, Los Angeles, CA, 90007, United States, yunanzho@usc.edu

1 - On the Pervasiveness of Difference-convexity in Optimization and Statistics

Maher Nouiehed, University of Southern California, Los Angeles, CA, United States, nouiehed@usc.edu, Jong-Shi Pang, Meisam Razaviyayn

This paper establishes the dc property of many well-known functions that appear in diverse engineering and statistical problems. Motivated by a quadratic programming (QP) based recourse function, we show that the (optimal) value function of a copositive QP is dc on the domain of finiteness of the program when the objective function's quadratic term matrix and the constraint matrix are fixed. We prove this using a dc decomposition of a piecewise LC1 function (function with Lipschitz gradient). Moreover, we show that many composite statistical functions in risk analysis, including expectation/value-at-risk (VaR)/conditional value-at-risk (CVaR)-based random deviation functionals, are all dc.

2 - Proximal Quasi Newton Methods for Convex Optimization

Hiva Ghanbari, PhD Candidate, Lehigh University, Bethlehem, PA, 18015, United States, hig213@lehigh.edu, Katya Scheinberg

In this work, we analyze the global convergence rate of proximal quasi-Newton algorithm for composite optimization problems, both in the exact and inexact setting, in the case when the objective function is strongly convex. We also investigate a practical variant of this method by establishing a simple stopping criterion for the subproblem optimization. Furthermore, we consider an accelerated variant, to the proximal quasi-Newton algorithm.

3 - On the Resolution of L0-minimization Problems via Alternating Lagrangian Schemes

Yue Xie, Pennsylvania State University, 445 Waupelani Dr, Philadelphia, PA, 16801, United States, yux111@psu.edu

We consider minimization of an objective function that contains l0-norm over a polyhedral set. This problem can be equivalently formulated as a mathematical program with complementarity constraints (MPCC). We prove that weak constraint qualifications hold at feasible points of MPCC, and KKT conditions are sufficient under suitable assumptions. The smooth MPCC formulation are resolved via an ADMM scheme and an augmented Lagrangian scheme. Despite the overall nonconvexity, each ADMM subproblem can be solved efficiently recognizing a hidden convexity property. Moreover, the limit point of both schemes satisfy KKT conditions. Preliminary numerics indicate that these approaches are promising.

4 - Stochastic Game with Chance Constraints: Lagrange Method

Yunan Zhou, University of Southern California, Los Angeles, CA, 90007, United States, yunanzho@usc.edu

In this paper, we study one algorithm for solving a non-cooperative game with expected value function in the constraints via a Lagrange formulation as a min-max game. The algorithm consists of 2 iterative loops. In the outer loop, an approximal point method is applied. And in the inner loop, the Lagrange method is used to relax constraints and then using sample average approximation method, we solve the problem iteratively. The convergence results of both loops are established in almost surely sense.

Decision Diagrams for Optimization

Sponsored: Optimization, Integer and Discrete Optimization

Sponsored Session

Chair: Thiago Serra, Carnegie Mellon University, Pittsburgh, PA, United States, tserra@cmu.edu

1 - Postoptimality of Mixed-integer Programs with Decision Diagrams

Thiago Serra, Carnegie Mellon University, 527-1/2 Gettysburg Street, Pittsburgh, PA, 15206, United States, tserra@cmu.edu, John Hooker

We consider what-if analyses on the set of near-optimal solutions of a mixed-integer linear program. For example, to determine the objective function impact of changing a variable or to find the combinations of assignments that define near-optimal solutions. In particular, we look at the role that decision diagrams can can play to operationalize MILP postopimality, since the required data can be compiled more concisely and then efficiently retrieved for different queries.

2 - A Binary Decision Diagram Based Algorithm for Solving a Class of Integer Two-stage Stochastic Programs

Leonardo Lozano, Clemson University, 423 Lindsay Road, Apt 104, Clemson, SC, 29631, United States, llozano@g.clemson.edu

We consider a class of two-stage stochastic integer programming problems with binary variables appearing in both stages and a set-covering structure in the second stage. Our approach uncovers strong dual formulations to the second-stage problems by transforming them into dynamic programming (DP) problems parameterized by first-stage variables. These DPs can be formed by use of binary decision diagrams (BDDs), which then yield traditional Benders inequalities. Moreover, we limit the size of the resulting BDDs using concepts related to the minimization of branchwidth on hypergraphs. We demonstrate the efficacy of our approach on a set of stochastic vertex cover problems.

3 - Novel Dynamic Programming Techniques for Discrete Multiobjective Optimization

Andre Augusto Cire, University of Toronto-Scarborough, Department of Management, UTSC, 1265 Military Trail, Toronto, ON, M1C-1A4, Canada, acire@utsc.utoronto.ca, David Bergman, Merve Bodur, Carlos Cardonha

In this talk we present a novel dynamic programming (DP) methodology for addressing discrete multiobjective optimization problems. Our technique applies typical decision-diagram operations to remove dominated solutions from the state-transition graph of a DP model, while exploiting its underlying recursive structure to derive more efficient labeling techniques. We apply this concept to enumerate the pareto frontier in multiobjective variants of the knapsack, set covering, and set partitioning problems, exhibiting orders of magnitude improvements over state-of-the-art general-purpose multiobjective optimization algorithms.

4 - An MDD-based Lagrangian Approach to the One-to-one Multi-commodity Pickup-and-delivery TSP

Margarita Paz Castro, University of Toronto, 5 King's College Road, Toronto, ON, Canada, mpcastro@mie.utoronto.ca, Andre Augusto Cire, Chris Beck

We address the one-to-one multi-commodity pickup and delivery traveling salesman problem (mPDTSP), a variant of the TSP that includes the delivery of a fixed set of commodities by a capacitated vehicle. We propose an approach that uses a discrete relaxation based on Multivalued Decision Diagrams (MDDs) to better represent the combinatorial structure of the problem. We enhance our relaxation by using the MDDs as a subproblem of a Lagrangian relaxation technique, leading to significant improvements both in bound quality and run time performance. Experimental results show that our approach outperforms state-of-the-art methodologies, closing 27 open instances from the literature.

Joint Session OPT/Practice: Recent Progress in Optimization Software I

Sponsored: Optimization, Computational Optimization and Software

Sponsored Session

Chair: Hans Mittelmann, Arizona State University, Tempe, AZ, 85287-1804, United States, mittelmann@asu.edu

1 - Performance Improvements and New Features in the Gurobi Optimizer

Robert E. Bixby, CSO, Gurobi Optimization, Inc., 3733-1 Westheimer Road, Box 1001, Houston, TX, 77027, United States, bixby@gurobi.com

This talk will cover the latest developments in the Gurobi Optimizer, especially performance improvements on MIP and LP, such as new and improved cutting planes, presolve reductions, heuristics and symmetry handling.

2 - Recent Improvements in IBM ILOG CPLEX Optimizer

Andrea Tramontani, IBM.Italy, Via Martin Luther King, 38/2, Bologna, 40132, Italy, andrea.tramontani@it.ibm.com

This talk will cover the latest developments in the CPLEX Optimizer. We will present some of the new features and algorithmic techniques recently added to CPLEX, and we will give benchmark results to assess the performance improvements achieved in the latest CPLEX version.

3 - Stronger Relaxations for Bilinear Terms using Linear Constraints
Benjamin Mueller, Zuse Institute Berlin, Takustr 7, Berlin, 14195, Germany, benjamin.mueller@zib.de, Ambros Gleixner, Felipe Serrano

One of the most important techniques for relaxing nonconvex quadratic constraints are the well-known McCormick inequalities, which describe the convex envelope for a single bilinear term over a rectangular domain. However, it might not be the best choice when taking additional (e.g., linear) constraints into account. Following this line of thought, we use linear programming to obtain inequalities from the problem formulation that can be used to improve the McCormick relaxation of a bilinear term. We use the constraint integer programming framework SCIP to show the impact of the tighter relaxations on instances of the MINLPLib2.

4 - Latest Benchmarks of Optimization Software
Hans Mittelmann, mittelmann@asu.edu

We will report on selected of our benchmarks including on discrete problems and for both open source and commercial software.

Decomposition Approaches for Power Systems Planning under Uncertainty

Sponsored: Energy, Natural Res & the Environment Electricity

Sponsored Session

Chair: Lim Gino, ginolim@central.uh.edu

Co-Chair: Aida Khayatian, University of Houston, Houston, TX, 77057-3197, United States, aida.khayatian@gmail.com

1 - Policymaking for Microgrid Expansion Planning in Electric Power Systems under Uncertainty
Aida Khayatian, University of Houston, 1801 Bering Dr, Apt 736, Houston, TX, 77057-3197, United States, aida.khayatian@gmail.com, Masoud Barati, Gino J. Lim

This paper integrates microgrid expansion planning with generation and transmission planning to study the potential advantages of the grid-connected microgrid. This planning problem faces several challenges such as the competitiveness of power investor companies, environmental restrictions, rural electrification, and uncertainty. To address these challenges via integrating microgrid, this study proposes long-term planning policies. These policies are established based on evaluating the performance of the microgrid in terms of the planning criterions. Computational results from two IEEE 6 and 118-bus test systems are presented to analyze the effectiveness of the proposed policies.

2 - Managing Stored Energy in Microgrids via Multistage Stochastic Programming
Arnab Bhattacharya, University of Pittsburgh, 6236 5th Avenue, Apt 102A, Pittsburgh, PA, 15232, United States, cfcarnabiitkgp@gmail.com, Jeffrey P. Kharoufeh

Energy storage systems can mitigate adverse effects of renewable sources in a microgrid where procurement and storage decisions are made under uncertain demand, renewable supply and prices. A multistage stochastic linear programming model is formulated to minimize the expected total costs in a microgrid, subject to power flow, storage capacity and supply-demand balance constraints. To improve computational tractability, a new regularized stochastic dual-dynamic programming (SDDP) algorithm is employed to obtain high-quality solutions within a reasonable time. A computational study highlights significant cost reductions and computational benefits.

3 - Power Management in Micro Grids with Renewable Source and Storage
Natarajan Gautam, Texas A&M.University, Dept of Industrial and Systems Engineering, Room 4012 Emerging Technologies Building, College Station, TX, 77843-3131, United States, gautam@tamu.edu, Soongeol Kwon

We consider a micro-grid scenario where a significant amount of energy is generated in-house from renewable sources. To combat uncertainty in demand, supply and smart pricing, we consider managing power consumption by the usage of storage devices, energy market and demand response. We formulate and solve a stochastic optimization problem.

Dynamic Programming/Control

Contributed Session

Chair: Xin Wang, University of Wisconsin-Madison, Middleton, WI, United States, xin.wang@wisc.edu

1 - Dynamic Expediting of an Urgent Order with Uncertain Progress
Luca Bertazzi, University of Brescia, Contrada Santa Chiara, 50, Brescia, 25122, Italy, luca.bertazzi@unibs.it, Riccardo Mogre

A supplier manages an urgent order with uncertain progress for which her client has set a deadline. The supplier observes in real time the order progress and chooses dynamically the effort level to expedite the order. The problem is to identify expediting policies to minimize the expected cost. We formulate a discrete stochastic dynamic programming problem. By conducting a worst-case analysis, we show that decreasing the level of flexibility may lead to a large increase in the cost. Then, we model the case in which the supplier takes into account the negative effects of late order completion. Finally, we compare the two policies using a computational study based on a car seat assembly case.

2 - Accurately Approximating the Value Function in Stochastic Dynamic Programming with Neural Networks
Kyle Perline, Cornell University, Ithaca, NY, 14850, United States, krp73@cornell.edu, Christine A.Shoemaker

In Approximate Dynamic Programming the value function can be approximated with neural networks. We develop a Unimodal Approximation Optimization (UAO) algorithm to tune the neural network architecture more efficiently than existing methods to create a more accurate value function approximation. In general, UAO can be applied to computationally expensive discrete domain optimization problems with noisy objective functions that have a unimodal, but not necessarily convex, mean. We demonstrate on hydropower control problems that this approach yields more accurate control solutions.

3 - How a Cities Open Data Portal Helps Drive the Local Economy
Abdulrahman Habib, Student, University of North Texas, 1404 Sombre Vista Dr, Denton, TX, 76205, United States, abdulrahmanhabib@my.unt.edu, Victor Prybutok

This study explores how the flow of information in smart cities improves the local economy. An open data portal allows municipalities to publish data for public and private analysis that drives decision making. The results of this study also provide insights into why providing data to citizens creates economic opportunity.

4 - Dynamic Pricing with Demand Learning and Reference Price Effect
Nenggui Zhao, University of Science and Technology of China, Jinzhai, He Fei, China, zhaoneng@mail.ustc.edu.cn, Cao Ping, Xiaoming Yan

In this paper, we consider a retailer selling a durable product over a finite horizon, with the objective of maximizing the expected total discounted revenue. In this problem, the customers' arrival rate is unknown and will be learned in a Bayesian way. Moreover, arriving customers' purchase behavior is affected by reference price. First, we analyze the structural properties of the optimal revenue function and the optimal pricing policy. Second, we find that the problem can be simplified in the case of sufficient inventory. Third, we investigate the value of market size and the effect of reference price. Finally, we conduct several numerical examples to justify our theoretical results.

5 - Dynamic Pricing in a Bike Sharing System
Mikhail Gordon, University of Pittsburgh, 241 Mervis Hall, Pittsburgh, PA, 15260, United States, m.gordon@pitt.edu

A bike sharing system is subject to rebalancing daily to keep each station operating at its potential. The use of dynamic pricing allows for incentives to be given to consumers for their starting and ending locations to be altered to lessen the amount of rebalancing necessary for a system.

6 - Optimal Pricing Strategy for Electric Vehicle Sharing Fleet
Xin Wang, University of Wisconsin-Madison, 8916 Red Beryl Drive, Middleton, WI, 53562-4278, United States, xin.wang@wisc.edu, Yuguang Wu

We investigate a dynamic pricing decision problem for an electric vehicle (EV) sharing system who faces time varying stochastic customer demand and electricity price. Demand in each time period reacts to the announced price (like Uber Surge Pricing), while the EV fleet operations and charging decisions are optimized to gain revenue. An approximate dynamic programming based algorithm is proposed to derive the optimal decision policy.

1 - An Elasticity Model for Joint Gas-grid Expansion Planning Optimization

Pascal Van Hentenryck, University of Michigan, 1813 IOE Building, 1205 Beal Avenue, Ann Arbor, MI, 48108-2117, United States, pvanhent@umich.edu, Russell Bent, Seth Blumsack

Recent trends in gas-fired power plant installation has increased the connections between the electric power and natural gas industries. As a result, undesired situations may arise, such as those experienced by both systems during the winter of 2013/2014 in the northeastern US. This talk considers these challenges and present a Combined Electricity and Gas Expansion (CEGE) planning model. The CEGE model minimizes the cost of meeting gas and electricity demand during high-stress conditions and introduces an elasticity model for analysis of gas-price volatility caused by congestion. We conduct an in-depth analysis on a case-study that include the New England area.

2 - Merchant Storage Investment in a Deregulated Electricity Industry

Afzal Siddiqui, University College London, Department of Statistical Science, Gower Street, London, WC1E 6BT, United Kingdom, afzal.siddiqui@ucl.ac.uk
Afzal Siddiqui, Stockholm University, Stockholm, Sweden, afzal.siddiqui@ucl.ac.uk, Ramteen Sioshansi, Antonio J. Conejo

We develop a bi-level programming model of an imperfectly competitive electricity industry with electricity generation and storage operations at the lower level and storage investment at the upper level. Our analytical results demonstrate that a relatively high (low) amount of market power by generators leads to low (high) storage capacity adoption by a profit-maximising merchant relative to a welfare-maximising ISO. Using a charge on generation ramping between off-peak and peak periods, we illustrate how to incentivise socially optimal storage investment even with a merchant.

3 - Stochastic Programming for Fuel Supply Planning of Combined Heat and Power Plants

Daniela Guericke, Technical University of Denmark, Kgs. Lyngby, Denmark, dngk@dtu.dk, Ignacio Blanco, Henrik Madsen, Juan M. Morales

The consumption of biomass to produce power and heat has increased due to the carbon neutral policies. Combined heat and power (CHP) plants often combine biomass with other fuels, e.g., natural gas. The negotiation process for supply contracts involves many uncertainties due to the long planning horizon. The demand for biomass is uncertain, and heat demand and electricity prices vary during the planning period. We propose a method using stochastic optimization to support the biomass and natural gas supply planning for CHP plants including short-term decisions for optimal market participation.

4 - An Integrated Market for Electricity and Natural Gas Systems with Stochastic Power Producers

Christos Ordoudis, Technical University of Denmark, Technical University of Denmark, Lyngby, Denmark, chror@elektro.dtu.dk, Pierre Pinson, Juan Miguel Morales

Gas-fired power plants can serve as a flexible component to ensure security of supply in energy systems with high shares of fluctuating renewables. In view of a tighter coupling between electricity and natural gas systems, we propose an integrated model that jointly optimizes their operation under uncertain power supply by applying two-stage stochastic programming. We use a formulation that properly models the dynamics of the natural gas system, which is essential in short-term operations to take full advantage of the flexibility of the integrated energy system. Our analysis shows the efficiency of the proposed model in accommodating high shares of renewables in a realistic case study.

Chance-Constrained, Stochastic and Robust MIP and Applications

Sponsored: Optimization, Optimization Under Uncertainty

Sponsored Session

Chair: Kibaek Kim, Argonne National Laboratory, 9700 South Cass Avenue, Lemont, IL, 60439, United States, kimk@anl.gov

1 - Cardinality Constrained Robust MIP and Submodular Polyhedron

Seulgi Joung, Korea Advanced Institute of Science & Technology, Daejeon, Korea, Republic of, sgjoung22@gmail.com, Sungsoo Park

We consider valid inequalities for the cardinality constrained robust knapsack problem, which can be used to solve the cardinality constrained robust mixed 0-1 programming problems. We define valid inequalities using submodularity of the cardinality constrained robust knapsack set function. We prove that these inequalities define the convex hull of robust continuous knapsack problem with a single continuous variable. In addition, the most violated inequality can be separated in polynomial time using a greedy algorithm. The computational experiments on the robust binary knapsack problem and the robust knapsack problem with continuous variables exhibit the effect of proposed inequalities.

2 - Parallel Dual Decomposition with Branch-and-Bound Method

Kibaek Kim, Assistant Computational Mathematician, Argonne National Laboratory, 9700 South Cass Avenue, Building 240, Lemont, IL, 60439, United States, kimk@anl.gov

We present a parallel dual decomposition that decouples a large-scale MIP problem into tractable smaller subproblems by the Lagrangian relaxation of coupling constraints in the problem. On top of it, we also develop a branch-and-bound method that ensures integer feasibility with respect to the primal integer variables. Unlike the one in Caroe and Schultz, our method branches on the primal integer variables characterized in the Dantzig-Wolfe decomposition space. Computational results are presented for various problem instances.

3 - A Stochastic Optimization Approach to Maintenance Turnaround Planning in Integrated Chemical Sites

Sreekanth Rajagopalan, Carnegie Mellon University, 5000 Forbes Avenue, Doherty Hall 4200, Pittsburgh, PA, 15213, United States, sreekanth@cmu.edu, Nikolaos Sahinidis, Satyajith Amaran, Scott Bury

An integrated chemical site is a network of processing plants that consume and produce a variety of chemical products. A maintenance turnaround is a capital and resource intensive maintenance project that requires a long planned outage. We investigate enterprise-wide approaches to plan turnarounds in an integrated chemical site on a medium-term horizon; specifically, we propose a stochastic optimization model that incorporates production reliability for simultaneous production and turnaround planning. We compare different policies for heuristics within a decomposition scheme.

4 - A Hybrid Constraint Removal Scheme in Scenario Approach for Chance-constrained Programs

Roya Karimi, University of Arizona, 1725 N.park Ave, #1E, Tucson, AZ, 85719, United States, royakarimi1993@email.arizona.edu

In this talk, we consider the constraint removal method in the scenario approach for solving chance constrained programming problems.We introduce two constraint removal schemes: one model-free and the other model-based, as well as the ideas behind them. Furthermore, to show the strength of our proposed methods, a comparison with other existing approaches is provided in an extensive numerical study on a semidefinite optimization problem in control theory.In addition, the proposed methods can be applied to solve a wide range of practical problems.

Optimization and Learning in Decision Processes

Sponsored: Optimization, Optimization Under Uncertainty

Sponsored Session

Chair: Mahshid Salemi Parizi, Seattle, WA, 98105, United States, msalemip@uw.edu

Co-Chair: Archis Ghate, University of Washington, University of Washington, Shoreline, WA, 98155, United States, archis@u.washington.edu

1 - Weakly Coupled Markov Decision Processes with Parametric Uncertainty

Mahshid Salemi Parizi, 3801 Brooklyn Ave NE, Apt M304, Seattle, WA, 98105, United States, msalemip@uw.edu

We consider a class of stochastic dynamic programs where multiple, otherwise independent, subproblems are linked via constraints. This problem class is known as weakly coupled Markov decision processes (MDP). We consider the case where transition probabilities for each subproblem are unknown to the decision maker. The decision maker thus attempts to balance learning (exploration) with reward maximization (exploitation). Tractable approximate dynamic programing methods rooted in the Bayesian learning framework will be presented.

2 - Backward ADP with Hidden Semi-Markov Information Models

Joseph L.Durante, Princeton University, Princeton, NJ, United States, jdurante@princeton.edu, Juliana Nascimento, Bolong Cheng, Warren B.Powell

We consider an energy storage problem involving a wind farm with a forecasted power output, a power demand, an energy storage device, and a connection to the larger power grid (with associated electricity prices). The stochastics are modeled using a novel hidden semi-Markov model which accurately replicates both forecast error distributions and the periods of time for which a process stays above or below its forecast. We derive near-optimal time-dependent policies using a technique we call backward approximate dynamic programming, which overcomes the computational hurdles of classical (exact) backward DP, and achieves higher quality solutions than the more familiar forward ADP methods.

3 - Optimal Learning with General Nonlinear Belief Models

Xinyu He, Princeton University, Princeton, NJ, 08544, United States, xinyuhe@princeton.edu, Warren B.Powell

We consider the problem of optimizing an unknown function over a multidimensional continuous space, where function evaluations are noisy and expensive. We assume that a globally accurate model of the function is not available, but there exist some parametric models that can well approximate the function locally. We propose an algorithm, using local approximation technique and optimal learning policies, to quickly learn the shape of the function and find the optimal design. Experiments on both synthetic problems and a real materials science application show the strong performance of our algorithm.

Joint Session OPT/Practice: Stochastic Inventory Management

Sponsored: Optimization, Optimization Under Uncertainty

Sponsored Session

Chair: Xiting Gong, The Chinese University of Hong Kong, Hong Kong, xtgong@se.cuhk.edu.hk

1 - Dynamic Inventory Management under Stockout Substitutions

Tianxiao Chen, The Chinese University of Hong Kong, ERB615, CUHK, Shatin, Hong Kong, chentx@se.cuhk.edu.hk, Xiting Gong

In this paper, we consider a periodic-review inventory control problem with two products which can be substituted if one of them is out of stock. We formulate the problem as a two-dimensional dynamic program and characterize the structure and asymptotic bounds of the optimal policy under a wide range of parameter settings.

2 - Dynamic Pricing and Inventory Management under Network Externalities

Renyu Zhang, Assistant Professor, New York University Shanghai, 1555 Century Avenue, Shanghai, 200122, China, renyu.zhang@nyu.edu, Nan Yang

We study the impact of network externalities on a firm's joint pricing and inventory policy under demand uncertainty. A customer's willingness-to-pay and, thus, the potential demand are increasing in the past sales of the product. We show that the presence of network externalities gives rise to the tradeoff between generating current profits and inducing future demands, thus having several important operational implications. For example, network externalities prompt the firm to provide better services to customers. We also propose a dynamic look-ahead heuristic policy with optimality gaps decaying exponentially in the forward-looking time length.

3 - Analysis of Ordering Strategies under Market Competition and Capacity Constraint

Weili Xue, Southeast University, Hankou Road 22, Nanjing, China, weili@seu.edu.cn

In this paper, we consider a supply chain with a manufacturer and two retailers, in which the two retailers compete in the same consumer market and the manufacturer has capacity constraint. Each manufacturer can order before or after demand uncertainty realization. We characterize the equilibrium ordering strategies and show that an asymmetric equilibrium may exist even for the symmetric setting when the supplier's capacity is constrained and the wholesale prices are exogenously determined. We further extend our result to the case when the capacity is unlimited and when the wholesale prices are endogenously determined.

■ Monday Plenary

Hilton- Ballroom of Americas, Level 2

Optimization: Past, Present, Future

Plenary

Invited Session

1 - Sports Scheduling Meets Business Analytics

Bob Bixby, Gurobi

For the vast majority of business applications, optimization means linear and mixed-integer programming. Beginning with Dantzig's simplex method in 1947, optimization experienced a slow, uneven period of development into the mid 1980s. Then, beginning in the late 1980s, developments ensued that completely transformed optimization and its applications, driven by truly remarkable performance improvements in the underlying solvers. What's coming next may be even more exciting. Driven by an explosion in available business data, a new broad corporate focus on extracting value from that data, increased computing power, and the continually expanding power of optimization solvers, optimization promises to become an indispensable tool in managing the modern enterprise.

Risk Attitudes

Sponsored: Decision Analysis

Sponsored Session

Chair: Andrea Hupman Cadenbach, University of Missouri-St. Louis, St Louis, MO, 63121, United States, cadenbach@umsl.edu

1 - Risk Attitudes in Disaster Planning

Vicki Bier, University of Wisconsin, Madison, WI, United States, vicki.bier@wisc.edu

This talk discusses some implications of risk attitudes (specifically, risk aversion) for disaster planning. Surprisingly, if we take risk aversion seriously, it may mean that we are being overly protective against radiation-induced fatalities following nuclear incidents. However, "psychic numbing" may make it difficult to use risk aversion to encourage preparedness.

2 - Risk Attitude Modeling in Homeland Security Decisions

Ali E. Abbas, University of Southern California, OHE 310R, 3650 McClintock Ave, Los Angeles, CA, 90089, United States, aliabbas@usc.edu

Decision Analysis is a normative approach for making decisions in the face of uncertainty, and can be applied to a variety of decisions. The field of utility theory is often misused and replaced by other non-normative approaches under the umbrella of decision analysis. This talk will discuss an application of utility theory in homeland security decisions and discuss some widely used (and flawed) approaches.

3 - New Results on Risk Attitudes in Operations Decisions
Andrea Hupman Cadenbach, University of Missouri-St. Louis, 211 Express Scripts Hall, 1 University Boulevard, St Louis, MO, 63121, United States, cadenbach@umsl.edu

Previous results in the literature have shown that in repeated newsvendor decisions, the optimal ordering policy for a risk averse decision maker is approximately the same as for a risk neutral decision maker. These results, however, are based on an assumption of independent demand from one period to the next. In this talk, we present new results that show that in the presence of demand dependence, the optimal ordering policy for a risk averse decision maker differs from the optimal risk neutral policy. These results are extended to a general sequential decision making scenario.

4 - Theory of Generalized Risk Attitudes
Janne Gustafsson, Ilmarinen Mutual Pension Insurance Company, Porkkalankatu 1, Helsinki, 00018, Finland, janne.gustafsson@gmail.com

This paper develops a theory of risk attitudes that is based on the premise that a risk neutral decision maker (DM) is indifferent between a lottery and the average (in terms of preference) of the outcomes obtained from infinite repetition of the lottery. We show that a risk neutral DM seeks to maximize the expectation of measurable value. The results suggest that (i) the DM's risk attitude in expected utility theory is related to the transformation between the measurable value function and the von Neumann-Morgenstern utility function and (ii) the applicability of the conventional definitions of risk attitudes is limited to settings in which the DM's measurable value function is linear.

Beliefs in Environmental Decision-making Processes

Sponsored: Decision Analysis

Sponsored Session

Chair: Melissa A Kenney, University of Maryland, College Park, MD, 20740, United States, kenney@umd.edu

1 - Finding Common Ground when Experts Disagree: Energy and the Environment
Erin Baker, University of Massachusetts-Amherst, MIE, 220 Elab, Amherst, MA, 01003, United States, edbaker@ecs.umass.edu, Ahti Salo, Valentina Bosetti

We address the problem of decision making under "deep uncertainty," introducing an approach we call Robust Portfolio Decision Analysis. We derive a set of portfolios that are non-dominated across beliefs; and then identify robust individual alternatives from the non-dominated portfolios. The process allows us to synthesize multiple expert- or model- based beliefs by uncovering the range of alternatives that are intelligent responses to the range of beliefs. We show that this method encompasses many of the robustness concepts in the literature. We illustrate our approach using a problem in the climate change and energy policy context: choosing among clean energy technology R&D portfolios.

2 - Effect of Decision Rules on Chemical Alternatives Assessment
Michael Gerst, University of Maryland, 1337 Meridian Place NW, Washington, DC, 20010, United States, mgerst@umd.edu, Melissa A.Kenney, Brett Howard

Alternatives assessment (AA) is an overarching term for the process of identifying, comparing, and selecting safer alternatives to chemicals that might pose a risk to humans or the environment. To date, many methods have been produced, each with foci that largely align with the discipline producing the method. We demonstrate the efficacy of a multi-criteria approach in an AA of 14 paint stripper chemicals by showing its flexibility compared to other decision rules.

3 - Characterizing the Evolution of Global Ground-water Stress
Roshanak Nateghi, Characterizing Global Ground Water Storage Trends, Purdue University, West Lafayette, IN, 47906, United States, rnateghi@purdue.edu, C. Bayan Bruss, Benjamin Zaitchik

Groundwater is a key element of global access to water resources; and has important implications for political stability, economic growth and public health in every society. Recent rapid population growth, and increased rates of urbanization have led to groundwater stress. Identifying the national-scale drivers of groundwater storage trends is the key first step for understanding water availability and devising sustainable water management policy in a changing climate. In this research we have conducted extensive data analyses to find the key predictors of the observed groundwater storage trends using agricultural, climate, demographic, land-use and economic variables in 81 countries.

4 - Decision Analysis Approach to Environmental Model Interpretation
Melissa A. Kenney, Associate Research Professor, University of Maryland, 5825 University Research Court, Suite 4001, College Park, MD, 20740, United States, kenney@umd.edu, Eva D. Regnier, Michael Gerst

Bayesian reasoning - asking what model output we ought to expect as a function of the possible realities - is rarely applied to the interpretation of the output from mechanistic models. Specifically, our framework treats the model as an evidence-generating process from which the analyst considers the joint relationship between reality and model output. This process yields a likelihood function that (i) serves to guide what questions should be asked in the model building and validation process and (ii) how insights should be updated given prior information and model outputs. To illustrate the approach, we discuss physical climate models and integrated assessment models.

Humanitarian Logistics

Invited: Tutorial

Invited Session

Chair: Jiming Peng, University of Houston, Houston, TX, 77204, United States, jopeng@Central.uh.edu

Co-Chair: Rajan Batta, University at Buffalo (SUNY), 410 Bell Hall, Buffalo, NY, 14260, United States, batta@buffalo.edu

1 - Humanitarian Logistics
Bahar Yetis Kara, Bilkent University, Ankara, Turkey, bkara@bilkent.edu.tr, Sinem Sava er

Many incidents requiring humanitarian assistance, which can be categorized mainly as disasters and long term crises, have taken place in the recent years. Humanitarian logistics play a crucial role in managing these events because of the response time constraints, limited resource amounts and high levels of uncertainty. Therefore, it is apparent that the challenges faced in humanitarian logistics differ from the conventional challenges encountered in commercial logistics applications such as having conflicting goals for different parties, funding and political issues. In this tutorial, we provide an introduction to humanitarian logistics by defining its characteristics, application areas and challenges. Then, we analyze and synthesize relief logistics and development logistics literature based on Operations Research (OR) problems encountered in disaster management cycle while putting emphasis on the last 10 years. For various disaster management stages; namely preparedness and response phases, certain case studies will be discussed using a real life dataset from Kartal region of Istanbul. Moreover, for development logistics, a case study on providing healthcare in rural areas will be evaluated.

Grand Ballroom A

Cloud Computing and Data Centers in Applied Probability I

Sponsored: Applied Probability

Sponsored Session

Chair: Alexander Stolyar, University of Illinois at Urbana-Champaign, Urbana, IL, 61801, United States, stolyar@illinois.edu

1 - On TTL Caching in Content Delivery Networks
Sanjay Shakkottai, University of Texas-Austin, ENS.437 ECE Department, Austin, TX, 78712, United States, shakkott@austin.utexas.edu, Soumya Basu, Aditya Sundarrajan, Javad Ghaderi, Ramesh Sitaraman

We study TTL caching in content delivery networks (CDNs). Using a stochastic approximation approach, we develop algorithms that adapt the time-to-live parameter to current workloads, and demonstrate performance gains over the state-of-art.

2 - Control of Parallel Server Systems with Learning
Yuan Zhong, University of Chicago, Booth School of Business, Chicago, IL, 60637, United States, Yuan.Zhong@chicagobooth.edu, Jean Walrand

We consider parallel server processing systems, where the service rates have dependence on both the job class and the server, and we are interested in control policies that do not assume knowledge of system parameters. First, we show that the classical max-weight policy, modified under certainty equivalence, is not throughput optimal, hence the necessity of forced learning. Then, we propose two classes of control policies that incorporate learning in different ways and prove that both classes are throughput optimal.

3 - Mixing Time and Structural Inference for Bernoulli Auto-regressive Processes
R. Srikant, UIUC, Urbana, IL, United States, rsrikant@illinois.edu, Carolyn Beck, Dimitris Katselis

We introduce a multivariate random process called a Bernoulli Autoregressive Process (BAR). A BAR process models a discrete-time vector random process where the components of the vector are represented by the nodes in a graph. We show that the BAR process mixes rapidly, by proving that the mixing time is O(log p). For a network with p nodes, where each node has in-degree at most d<<p, we provide a greedy algorithm that can efficiently learn the structure of the underlying directed graph with a sample complexity proportional to the mixing time of the BAR process.

4 - Large-scale Join-idle-Queue System with General Service Times
Alexander Stolyar, University of Illinois at Urbana-Champaign, Urbana, IL, United States, stolyar@illinois.edu, Sergey Foss

A parallel server system with n identical servers is considered. Customer service times are i.i.d. with finite mean 1/mu. Join-Idle-Queue routing algorithm is studied, under which an arriving customer is sent to an idle server, if such is available, and to a randomly uniformly chosen server, otherwise. We consider the asymptotic regime where n goes to infinity and the customer input rate is lambda n. Under the condition lambda/mu<1/2 we prove that the sequence of (appropriately scaled) stationary distributions concentrates at the natural equilibrium point, with the fraction of occupied servers being constant equal lambda/m. In particular, the steady-state probability of waiting vanishes.

Trade-offs in Revenue-driven Marketplaces

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Yonatan Gur, Stanford University, Stanford, CA, 94305, United States, ygur@stanford.edu

1 - Revenue Management with Repeated Interactions
Dragos Florin Ciocan, INSEAD, Street 1, Fontainebleau, France, florin.ciocan@insead.edu, Andre Du Pin Calmon, Gonzalo Romero

We consider a revenue management problem where a platform interacts with a set of customers over a number of epochs. Unlike traditional network revenue management, we consider customers who maintain state over the epochs - their state depends on the quality of their past service with the platform. There is thus a non-trivial trade-off between the platform myopically maximizing short term revenues, versus maximizing the long term goodwill of its customers. We develop policies that are good approximations of the optimal for this problem.

2 - Revenue Loss under Constrained Allocations in Centralized Marketplaces
Xavier Warnes, Stanford University, Stanford, CA, United States, xwarnes@stanford.edu, Yonatan Gur, Dan Andrei Iancu

In many online marketplaces where consumers are assigned to providers, a centralized planner aims to maximize instantaneous revenue while accounting for various considerations that may impact long run sustainability. We formulate a broad class of constraints that includes fairness and discrimination among providers, and study the efficiency loss associated with these constraints.

3 - Revenue-maximizing Rankings for Online Platforms with Quality-sensitive Consumers
Nicolas Stier-Moses, Universidad Torcuato Di Tella, Buenos Aires, Argentina, nstier@utdt.edu, Pierre L'Ecuyer, Patrick Maille, Bruno Tuffin

When keywords are searched in search engines, classified ads websites, or online retailers, platforms can return any permutation of results. Two extreme rules are to use rankings based on estimated relevance (which improves customer experience in the long run because of quality) or on expected immediate revenue (which improves short-term revenue). A key question is what middle ground between them should be chosen. We introduce stochastic models that combine both strategies, anticipating that the rate of user visits depends on the quality provided by the ranking policy, and propose effective solution methods to compute rankings that optimize long-term revenues.

4 - Dynamic Collateral Management for a Prime Brokerage
Vivek Farias, MIT, 100 Main Street, Cambridge, MA, 02142, United States, vivekf@mit.edu, Eli Gutin

Ever since the 2008 financial crisis, collateral management for secured lending has assumed an important place in financial markets. In this work, we study the collateral management problem (CMP), faced by a prime brokerage, through the lens of multi-period stochastic optimization. We show that a simple dual price based algorithm is not only asymptotically optimal, but has constant additive loss relative to an optimal algorithm. We back-test the method on data from a prime brokerage and find material increases in revenue.

MSOM Special Speaker: David Simchi-Levi

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Tunay Tunca, Unversity of Maryland, 8803 Courts Way, Silver Spring, MD, 20910, United States, ttunca@rhsmith.umd.edu

1 - Online Resource Allocation with Applications to Revenue Management
David Simchi-Levi, Massachusetts Institute of Technology, Dept of Civil and Environmental Engineering, 77 Massachusetts Avenue Rm 1-171, Cambridge, MA, 02139, United States, dslevi@mit.edu

Online resource allocation is a fundamental problem in OR and CS with applications such as offering products to customers, distributing jobs to candidates, assigning advertisers to ad slots, and matching drivers to passengers. These problems can be abstracted as follows: there are fixed resources, each of which can be sold at multiple known prices. These resources must be allocated on-the-fly, without assuming anything about future demand. In this talk we cover the CS and OR literature on the problem and in particular focus on two techniques: exploration and exploitation methods, as well as competitive analysis.

Sustainable Food Supply and Food Waste

Sponsored: Manufacturing & Service Oper Mgmt, Sustainable Operations

Sponsored Session

Chair: Elena Belavina, University of Chicago Booth School of Business, Chicago, IL, 60637, United States, elena.belavina@chicagobooth.edu

1 - Design of Sales Force Compensation Schemes to Reduce Product Waste
Arzum E. Akkas, Boston University, 100 Memorial Drive, 8-11C, Cambridge, MA, 02142, United States, aakkas@bu.edu

We empirically examine sales-force compensation schemes of manufacturers that impact expiration of consumer-packaged-goods (CPG) at retailers to identify incentive-aligning compensation schemes. Using sales commission data from a CPG manufacturer, we investigate the impact of counterfactual schemes on manufacturer's profit and product waste based on our model of sales-force decision process.

2 - Dynamic Staffing of Volunteer Gleaning Operations
Erkut Sonmez, Boston University, 1496 Beacon St, Apt 4, Brookline, MA, 02446, United States, sonmez@bu.edu, Baris Ata, Deishin Lee

Gleaning programs organize volunteer gleaners to harvest leftover crops that are donated by farmers for the purpose of feeding food-insecure individuals. Thus, the gleaning process simultaneously reduces food waste and food insecurity. However, the operationalization of this process is challenging because gleaning relies on two uncertain sources of input: the food and labor supplies. We develop a model to capture the uncertainties in food and labor supplies and seek a dynamic volunteer staffing policy that maximizes the long run average volume of food gleaned.

3 - Economically Motivated Adulteration in Farming Supply Chains: the Role of Supply Chain Dispersion and Traceability
Somya Singhvi, MIT, 235 Albany Street, Cambridge, MA, 02139, United States, ssinghvi@mit.edu, Retsef Levi, Yanchong Zheng

We develop a game-theoretic analytical model to study the effects of quality uncertainty, supply chain dispersion, traceability, and testing accuracy on economically motivated adulteration (EMA) in a farming supply chain with a distributed network of farmers. We further analyze the manufacturer's optimal investment in traceability and testing frequency to satisfy a risk constraint while minimizing costs. We leverage the analysis of our model to derive important and new insights that can inform both policy makers and commercial entities in food supply chains to address EMA risks. We also use data from real world case studies to calibrate our model and highlight its 'predictive' power.

4 - Food Waste in Grocery Retail

Elena Belavina, University of Chicago Booth School of Business, 5807 S.Woodlawn Ave, Chicago, IL, 60637, United States, elena.belavina@chicagobooth.edu

Food waste is a major contributor to carbon emissions (as big as road transport). Identifying and influencing market conditions that can decrease food waste is thus important to combat global warming. We build and calibrate a stylized two-echelon perishable-inventory model to capture grocery purchases and expiration at competing stores and households in a market. We examine how the equilibrium waste in this model changes with store density. Our analysis shows that higher density reduces food waste up to a threshold density; it leads to higher food waste beyond this threshold. Put differently, in so far as food waste is concerned, there exists an optimal store density.

Analytics in Medical Decision Making and Population Health

Sponsored: Health Applications

Sponsored Session

Chair: Turgay Ayer, Georgia Institute of Technology, Atlanta, GA, 30332, United States, ayer@isye.gatech.edu

Co-Chair: Anthony Bonifonte, Georgia Institute of Technology, Austell, GA, 30106, United States, ABonifon@gatech.edu

1 - Analytics in Blood Pressure Management: From Data to Decisions

Anthony Bonifonte, Georgia Institute of Technology, 5940 Water Oaks Dr, Austell, GA, 30106, United States, ABonifon@gatech.edu, Turgay Ayer, Ben A.Haaland, Ben A.Haaland

Antihypertensive drug treatment can control elevated blood pressure (BP) and reduce the risk of cardiovascular disease. We propose data-driven models that capture heterogeneity in BP progression and combine stochastic optimization and statistics to identify the optimal thresholds for initiating treatment and for increasing the treatment dosage. We analytically characterize the expected value and variance of the hazard ratio, which enables us to easily compute the optimal treatment decisions, and capture different attitudes towards risk (e.g. risk neutral or risk averse). Our findings may help guide future RCT design for hypertension treatment.

2 - Prioritizing Hepatitis C Treatment in U.S. Prisons

Turgay Ayer, Georgia Institute of Technology, School of Industrial and Systems Engineering, Groseclose 417, Atlanta, GA, 30332, United States, ayer@isye.gatech.edu, Can Zhang, Anthony Bonifonte, Jagpreet Chhatwal, Anne Spaulding

Prison systems offer a unique opportunity to control the hepatitis C virus (HCV) epidemic. New HCV treatments are very effective, but providing treatment to all inmates is prohibitively expensive. We propose a restless bandit modeling framework to support HCV treatment prioritization decisions in U.S. prisons. Parameterized by real-world data, we derive a closed-form index policy and demonstrate the improvement in our policy over current practice and benchmark policies. Our results shed light on several controversial health policy issues in HCV treatment prioritization in the prison setting and have important policy implications, such as needing to consider more than health state of inmates.

3 - Dynamically Consistent Home Health Care Routing and Scheduling

Seyma Guven-Kocak, Georgia Institute of Technology, Atlanta, GA, United States, seymaguven@gatech.edu, Pinar Keskinocak, Alejandro Toriello, Aliza R.Heching

This work addresses a real-world home health care routing and scheduling problem (HHCRSP) faced by a home care agency in the U.S. In home health care scheduling, there is a desire to retain consistency with respect to the aides servicing each patient, which is referred to as continuity of care. In order to handle continuity of care, we propose a dynamic approach and introduce the dynamically consistent home health care routing and scheduling problem (D-Con-HHCRSP). We present solution methods to address HHCRSP and D-Con-HHCRSP, where the goal is to be able to quantify and control the deviation from the existing schedule in place, so that some of the existing assignments may be retained in the new schedule.

4 - Short-term Mortality Prediction in a Cohort of Cancer Patients

Ying Zhuo, Massachusetts Institute of Technology, 70 Lincoln Street, Unit L612, Boston, MA, 02111-2670, United States, zhuo@mit.edu, Dimitris Bertsimas, Colin F. Pawlowski, John M. Silberholz, Alexander M. Weinstein, Eddy Chen, Aymen Elfiky

As cancer patients often receive aggressive and potentially unnecessary care at the end of life, there is significant need to accurately predict mortality. We obtained 11 years of electronic health records (EHR) from a large cancer center and engineered 401 features: demographics, genomics, vitals, lab tests, etc. We identified 23,983 patients who initiated 46,646 anti-cancer regimens. We fitted state-of-the-art machine learning models to predict 60-, 90- and 180-day mortality and achieved out-of-sample AUCs of 0.90, 0.89, 0.87, respectively, significantly higher than existing models.

Health Policy Modeling, Analysis, and Insight

Sponsored: Health Applications

Sponsored Session

Chair: Pooyan Kazemian, PhD, Harvard Medical School, Boston, MA, 02114, United States, pooyan.kazemian@mgh.harvard.edu

1 - Flexible FDA Approval Policies

Taylor Corcoran, University of California-Los Angeles, 110 Westwood Plaza, Los Angeles, CA, 90024, United States, taylor.corcoran.1@anderson.ucla.edu, Elisa Frances Long, Fernanda Bravo

Current U.S. FDA approval standards require pharmaceutical companies to demonstrate drug efficacy at a 0.05 significance level using clinical trial outcomes. This policy ignores heterogeneity in disease characteristics, such as the severity and prevalence, the level of research and development taking place, and the number of alternative drug treatments available for patients. We develop a queueing framework to analyze the drug approval process that incorporates such factors. We derive optimal approval policies and conduct a numerical study for three diseases (HIV, hypertension, and breast cancer).

2 - Same-day Follow-up Appointments, Spoilage, and Continuity of Care: An Empirical Investigation

Xiaoxu Tang, University of Minnesota, Minneapolis, MN, United States, tangx238@umn.edu, Diwakar Gupta, Yichuan Ding

We use a proprietary dataset (2M+ records) to study follow-up appointments in outpatient clinics. We propose methodologies to tag episodes of care and measure continuity of care and appointment-slot spoilage (late cancellation or no-show). We find that same-day follow-up (SDFU) appointments (those booked on the day the prior appointment occurred) have greater continuity of care and higher spoilage rate while controlling for patient, physician, and clinic characteristics. Counterfactual analysis is performed to evaluate SDFU appointments as a strategy for managing follow-ups.

3 - Robust Optimization Framework to Account for Prediction Errors for Cancer Diagnosis

Selin Merdan, University of Michigan, 1640 McIntyre Street, Ann Arbor, MI, 48105, United States, smerdan@umich.edu, Brian T.Denton

In the early detection and diagnosis of disease, multiple diagnostic tests are often available in discriminating between diseased and nondiseased individuals; however, how best to use these tests to render a diagnosis is challenging because there is often a tradeoff between the benefits of an accurate diagnosis of the anticipated disease and harms and costs associated with the diagnostic tests themselves. The motivation for our work in this research is to combine multiple diagnostic tests into an optimal composite diagnostic testing, which will provide a good balance between unnecessary testing and missed cases with higher sensitivity and specificity in the context of prostate cancer detection.

4 - Optimizing Monitoring Policies under Unknown Patient Adherence

Zhenhuan Zhang, University of Minnesota, 425 13th Ave SE Apt.1001, Minneapolis, MN, 55414, United States, zhan4490@umn.edu, Diana Maria Negoescu

In most instances of disease management, adherence to treatment is crucial to treatment success. However, measurements of patient adherence are often noisy and adherence behavior is unknown to physicians prior to treatment initiation. We optimize HIV Viral Load (VL) monitoring policies in this setting, and assess the total costs and quality-adjusted life years achieved by different policies.

5 - Estimating the Economic Cost of Physician Burnout in the United States

Shasha Han, NUS.Business School, Biz 2 Building B1, 1 Business Link, PhD office, NUS.business school, Singapore, Singapore, shashahan@u.nus.edu, Tait D. Shanafelt, Christine A. Sinsky, Karim Awad, Joel Goh

Importance: Even though physician burnout is known to be associated with negative clinical and organizational outcomes, the costs of burnout are poorly understood. Consequently, leaders of healthcare institutions cannot properly assess the benefits of initiatives to remediate physician burnout.Objective: To estimate the annual cost associated with physician burnout in the United States and to develop a methodology for individual healthcare institutions to estimate their institution-level costs associated with physician burnout.

Modeling of Pharmacy Operations

Sponsored: Health Applications

Sponsored Session

Chair: Bryan A Norman, University of Pittsburgh, Pittsburgh, PA, 15261, United States, banorman@pitt.edu

1 - Determining Optimal Policies for Medication Dispenses to In-patient Units

Anna Svirsko, University of Pittsburgh, 4200 Fifth Avenue, Pittsburgh, PA, 15260, United States, ACS167@pitt.edu, Bryan A. Norman, Seth Hostetler

While many hospital pharmacies have seen drastic improvement in their service due to technological improvements such as automated dispensing cabinets (ADCs) and pharmacy robots, these systems continue to faces challenges with how best to use these technologies. We have created a math programming model which reduces the number of missing medications and the system cost by identifying a standard pathway through which medications are dispensed to patients with considerations for the medication ordered, the dose type, the unit, and the forecasted demand for the medication. Key findings are illustrated through reviewing the results of the math program on the in-patient units of a local health system.

2 - Locating an Automated Central Filling Pharmacy for a Community Pharmacy Network

Hamdy Salman, University of Pittsburgh, Pittsburgh, PA, United States, hgs6@pitt.edu

Community pharmacies play an important role in providing patient safety by providing Medication Therapy Management (MTM). One of the strategies to provide more MTM in a community pharmacy is to use an automated Central Fill. An automated central fill offloads part of the pharmacy's prescription filling process. Our research focuses on locating a central fill that can provide relief for multiple pharmacies under stochastic demands. We provide a chance constrained capacitated facility location model when pharmacy demands are variable. The results include a comparison between using a chance constraint model and using a simpler policy to determine the central fill location.

3 - Automated Dispensing System Inventory Policy

Vera Tilson, University of Rochester, 3-343 Carol Simon Hall, W.E. Simon Graduate School of Business, Rochester, NY, 14627, United States, Vera.Tilson@simon.rochester.edu, Gregory Dobson

We discuss ILP formulation for computing inventory policy parameters for an Automated Medication Dispensing System.

4 - Modeling Clinical and Operational Workflows in Community Pharmacies

Kathryn Smith, NCSU, 2051 Trexler Court, Raleigh, NC, 27606, United States, knsmith4@ncsu.edu, Julie Simmons Ivy

As healthcare moves from fee-for-service to outcomes-based performance, community pharmacies are providing enhanced clinical services such as comprehensive medication reviews (CMRs). Through CMRs, pharmacists identify potential drug therapy problems that may interfere with patient adherence or cause adverse outcomes. This information facilitates communication between clinicians and pharmacists and can improve care. We developed a discrete event simulation of the clinical and operational workflows of multiple community pharmacies to evaluate patient wait times, prescription flow times, and staff utilization.

Funding Opportunity Notice: "The project described was supported by Grant Number 1C1CMS331338 from the Department of Health and Human Services, Centers for Medicare & Medicaid Services."General Disclaimer: "The contents of this publication are solely the responsibility of the authors and do not necessarily represent the official views of the U.S. Department of Health and Human Services or any of its agencies."

The Supply Side of Organ Transplantation Systems

Sponsored: Health Applications

Sponsored Session

Chair: Burhaneddin Sandikci, University of Chicago, Chicago, IL, 60637, United States, burhan@chicagobooth.edu

Co-Chair: Sait Tunc, University of Chicago, Chicago, IL, 60637, United States, Sait.Tunc@chicagobooth.edu

1 - Allocative Efficiency and New Supply in Kidney Exchange

Mohammad Akbarpour, Stanford University, Stanford, CA, United States, mohamwad@stanford.edu

We present a simple model of matching in stochastic networks and discuss the role of "timing" in the efficient allocation of kidneys in organ markets. We will show that, under some conditions, creating market thickness is highly valuable. Nevertheless, even the most efficient matching policies are constrained with the fundamental thickness of the market, which is the arrival of donors to the system. We will , therefore, ask a new question: What are the ways we can increase the arrival rate of donors? We will discuss two radical solutions: Creating a global exchange market, and removing the problem of double-coincidence of wants through a "token" system.

2 - Jumping the Line, Charitably: Analysis and Remedy of Donor-priority Rule

Tinglong Dai, Johns Hopkins University, 100 International Dr, Baltimore, MD, 21202, United States, dai@jhu.edu, Ronghuo Zheng, Katia P. Sycara

The ongoing shortage of organs for transplantation has generated an expanding literature on organ allocation. By contrast, organ donation has been little explored. In this paper, we develop a parsimonious model of organ donation to analyze the donor-priority rule, which grants registered organ donors priority in receiving organ. In view of the potentially undesirable social-welfare consequences, we propose a freeze-period remedy.

3 - Expanding the Donor Pool: the Use of Marginal Organs for Transplantation

Sait Tunc, University of Chicago, Chicago, IL, United States, sait.tunc@chicagobooth.edu, Burhaneddin Sandikci

Despite the efforts to increase the supply of donated organs for transplantation, organ shortage keeps increasing as the demand outpaces supply. We study the use of marginal organs for transplantation, which has been receiving increased attention in the medical community to alleviate the burden of shortages, in a queueing theoretic framework. In particular, we examine the equilibrium impact of offering marginal organs to patients who have low access to high quality organs, and conduct welfare analysis to understand the effect of individuals' decisions on social welfare. We provide policy incentives to increase the utilization of marginal organs while improving the social welfare.

4 - The Effects of Patient Portals on Kidney Allocation and Transplant Outcomes

Yeongin Kim, University of Texas-Dallas, Richardson, TX, Yeongin.Kim@utdallas.edu, Mehmet U.S. Ayvaci, Srinivasan Raghunathan, Bekir Tanriover

The recent healthcare reform promotes the use of information technology, such as patient portals, to provide patients better access to information source. Motivated by the kidney transplant decision, we empirically analyze the impact of the patient portals adoption on outcomes including time to transplant and time to drop out of the transplant waiting list. We show that the adoption of a patient portal is positively associated with the probability of receiving a deceased-donor kidney and negatively associated with the probability of receiving a living-donor kidney. The probability of drop-out from the waiting list due to worsened health conditions decreases with the adoption of a patient portal.

Improving Healthcare Operations

Sponsored: Health Applications

Sponsored Session

Chair: Claudia Rosales, Michigan State University, East Lansing, MI, 48824, United States, Rosales@broad.msu.edu

1 - On the Relations between Operational Focus, Operating Experience, and Operational Performance: Evidence from Patient Discharges in Cardiology Operating Units

David Zepeda, PhD, Northeastern University, 214 Hayden Hall, 360 Huntington Avenue, Boston, MA, 02115, United States, d.zepeda@northeastern.edu, Gilbert N. Nyaga, Gary J. Young

Operational focus is of much interest in health care where a long standing debate has existed over advantages/disadvantages of general vs specialty hospitals. However, there has been relatively little research in the OM literature that considers the intersection of operational focus and operating experience. Using patient discharge records from 294 California hospitals over a five-year period, we empirically evaluated the inter-relationship between operational focus and operating experience in cardiology operating units. Findings suggest that the effects of operational focus and operating experience on operational performance are complementary, but the benefits come at a cost to payers.

2 - Service Outsourcing Emphasis and Hospital Performance
Sachin B. Modi, Wayne State University, Rm 300.07, Detroit, MI, 48202, United States, ge3918@wayne.edu, Saurabh Mishra, Peter Salzarulo

Hospitals often face the decision of delivering services by relying on contracted providers versus utilizing internal resources. Such an emphasis on outsourcing to service providers can allow for better financial performance, but can also lower patient outcomes. Relying on data from US hospitals over a 14 year period, this study investigates the influence of service outsourcing emphasis of hospitals on patient length of stay and operating margins. Further, the study also highlights key boundary conditions in these relationships. The results provide important guidelines for hospital administrators, regarding their service outsourcing strategy.

3 - Managing Physician Preferred vs. General Medical Supplies – The Use of Consignment Inventory
Claudia Rosales, Michigan State University, N350 N.Business Complex, East Lansing, MI, 48824, United States, Rosales@broad.msu.edu, Anand Nair

In healthcare medical devices and materials represent the largest cost after labor. Hospitals spend significant resources purchasing and managing general as well as specialty medical supplies typically called physician preferred items. One of the ways hospitals seek to reduce the cost of medical supplies is by the use of inventory consignment. We analyze the impact of the use of consignment inventory for general and physician preferred medical supplies. Our models capture both the potential benefits that could be obtained with the use of consignment and the system conditions that can result in increased costs. Results are compared to real hospital data.

4 - The Effects of Health Information Technology and Communication Quality on Medical Malpractice Lawsuits
Luv Sharma, University of South Carolina, Columbia, SC, United States, Luv.Sharma@moore.sc.edu, Carolyn Queenan

This paper uses data from 168 acute care hospitals in Florida to study the impact of HIT and caregiver-patient communication quality on the number of medical malpractice lawsuits filed against the hospital. Results demonstrate a direct impact of communication quality and an indirect impact of HIT in influencing lawsuits.

Empirical Research in Service Operations

Sponsored: Manufacturing & Service Oper Mgmt, Service Operations

Sponsored Session

Chair: Ruomeng Cui, Bloomington, IN, 47401-7739, United States, cuir@indiana.edu

1 - Impact of Unexpected and Expected Breaks on Worker Productivity
Pradeep Kumar Pendem, University of North Carolina-Chapel Hill, 110 Mistywood Circle, Apt S, Chapel Hill, NC, 27514, United States, pradeep.pendem@gmail.com

Using harvesting worker productivity data from a U.S based agricultural firm, we evaluate effects of two types of breaks (expected versus unexpected), and two distinct forms of unexpected breaks, and find that unexpected breaks can, under certain conditions, yield immediate post-break performance increases. We supplement our findings by a conceptual laboratory replication showing that unexpected breaks lead to increased performance when they allow people to maintain attention on the focal task. Our results have implications on design of operational systems and need for emphasis on studying the break type prior to taking any corrective action.

2 - How Local Economic Factors Affect Retail Inventory Liquidation Value
Nathan C. Craig, 630 Fisher Hall, 2100 Neil Avenue, Columbus, OH, 43210, United States, craig.186@osu.edu, Ananth Raman

Retailers close stores for many reasons, from changes in strategy to bankruptcy. When closing a store, most retailers liquidate the store's inventory in place via the process of store liquidation. We collect data from an asset disposition firm about 2,000 store liquidations involving 31 retailers and $4B of inventory. We observe that inventory liquidation values vary substantially across store closings, even for a single retailer. We combine the proprietary data with store-level economic data and identify factors that significantly affect inventory liquidation value.

3 - The Importance of Operational Efficiency for Promotional Inventory Campaigns: Empirical Evidence
Ioannis Stamatopoulos, University of Texas at Austin, McCombs School of Business, 2110 Speedway B6000, Austin, TX, 78705, United States, yannis.stamos@mccombs.utexas.edu

We use the adoption of an innovative tracking and monitoring technology by a brick and mortar retail chain in the US to causally identify the impact of operational execution on the effectiveness of promotional inventory campaigns. Our findings suggest that the potential gains from increasing operational efficiency in this setting are economically significant.

4 - Operational Transparency Increases Trust in and Engagement with Government
Ryan Buell, Harvard Business School, Morgan Hall 429, Boston, MA, 02163, United States, rbuell@hbs.edu, Ethan Porter, Michael Norton

We propose that revealing the "submerged state," by making sure that citizens can see the often-hidden work that government performs, enhances both perceptions of government and engagement with it. Three studies, comprised of original experimental and new municipal data, support this proposition.

Robust Optimization in Operations Management

Sponsored: Manufacturing & Service Oper Mgmt, Service Operations

Sponsored Session

Chair: Chaithanya Bandi, Northwestern University, Evanston, IL, 60208, United States, c-bandi@kellogg.northwestern.edu

1 - Sustainable Inventory with Robust Periodic-affine Policies
Eojin Han, Northwestern University, Evanston, IL, United States, EojinHan2020@u.northwestern.edu, Chaithanya Bandi, Omid Nohadani

We extend the work of Van Mieghem and Rudi (2002) to multi-period settings with uncertain and correlated demands. The approach leaps beyond the distributional assumption and models uncertainties via polyhedral sets. We formulate the inventory problem as a multi-stage robust optimization problem. We then develop periodic-affine policies, which require less information about past demands. We show theoretically and numerically that our framework guarantees worst-case performance, while reducing the computation. Our results are applied to the ordering policy of a pharmaceutical retailer in India.

2 - Robust Dual Sourcing Inventory Management: Optimality of Dual Index Policies
Jan Van Mieghem, Professor, Northwestern University, Evanston, IL, 60208, United States, VanMieghem@kellogg.northwestern.edu, Jiankun Sun

We provide a robust optimization model for inventory management with two supply sources with general leadtimes for which we show that a dual index, dual base-stock policy is optimal, even in a non-stationary setting. In an extensive stationary simulation study, this robust dual sourcing policy performs as well as, and can even outperform each of, the best heuristics presented in the stochastic inventory literature.

3 - Pricing the Service Level Guarantees in the Amazon AWS Spot Market
Chaithanya Bandi, 1987, 2001 Sheridan Rd, 566, Evanston, IL, 60208, United States, c-bandi@kellogg.northwestern.edu, Siva Theja Maguluri

In this paper, we combine tools from robust queueing theory and mechanism design to design polcies for pricing spot market instances.

4 - Design of a Robust Stroke Network: Personalized Patient Transportation Policies
Amir Ardestani-Jaafari, McGill University, Montreal, QC, Canada, amir.ardestanijaafari@mail.mcgill.ca, Beste Kucukyazici

In the diagnosis and treatment of acute stroke, the timely medical intention is increasingly critical. However, transporting the patients to the closest hospital may not be the best solution. This often causes congestion in some hospitals, while the stroke beds are underutilized in others. We study the patient allocation and transportation protocols to optimize the coordination between emergency medical services and designated stroke hospitals. Specifically, we study the trade-off between minimizing transportation time to the hospital and minimizing the congestion experienced by the patient at the hospital using robust optimization.

Health Care, Processes

Contributed Session

Chair: Alireza E. Vandi, Virginia Tech, Blacksburg, VA, United States, alvandi@vt.edu

1 - Synthesis of 12 Lead Electrocardiogram using a Single Lead and its Application in Hand-held ECG Devices

Kahkashan Afrin, Graduate Student, Texas A&M.University, 1201 Harvey Rd., Briarwood Apts,, Apt 3, College station, TX, 77840, United States, afrin@tamu.edu

Recent advancements in the sensor technology has led to the development of handheld ECG devices and facilitated remote healthcare monitoring. However, its inability to give contiguous 12 leads, essential for diagnosing cardiac disorders has made it unacceptable for the clinical use. In this work, we artificially synthesize clinically equivalent 12 lead ECG using a single channel ECG with more than 90% accuracy.

2 - Resolving Payment Denial Issues by Nursing Facilities: Role of Upper Echelon, Institutional & Market Factors

Ajit Appari, University of Texas Health Science Center at Houston, 1200 Pressler Street, RAS.W-310, School of Public Health, Houston, TX, 77030, United States, ajit.appari@uth.tmc.edu

Quality of care at nursing facilities is a major issue plaguing the US health care system. I propose and evaluate a conceptual framework reflecting deviant behavior based on institutional and upper echelon theories to understand the sluggishness of nursing facilities in resolving payment denial related deficiencies. There were 3147 denials of durations 3 to 1213days across all facilities during 2011-2016. A multilevel mixed-effects ordered logistic model with Heckman correction is used to identify what type of facilities in what institutional/market conditions take longer to resolve such denial deficiencies [Moderate (91-120days) or Laggard (>120days) Vs Early resolution (1-90days)].

3 - Comparing the use of Partial Least Squares and Covariance Based Structural Equation Modeling in an Ehealth Information Model

Anh Ta, University of North Texas, Denton, TX, 76201, United States, Anh.Ta@unt.edu, Gayle Prybutok, Victor R. Prybutok

Covariance-based Structural Equation Modeling (CB-SEM) is a common methodology used by researchers in behavioral science. Although partial least squares SEM (PLS-SEM) is sometimes considered "a silver bullet" for examining the relationships among constructs, critics claim PLS is flawed and an inappropriate methodology. This study compares the value and use of both methods in the context of eHealth information seeking behavior.

4 - Risk Factors for High Infant Mortality Rate

Alireza E. Vandi, Virginia Tech, 1311 Perry Street, Room 236, Blacksburg, VA, 26505, United States, alvandi@vt.edu, Niyousha Hosseinichimeh

Infant mortality rate (IMR) has declined over the past decade in the U.S.; however, it still has one of the highest IMR among developed countries. IMR varies substantially across states which provides the opportunity to study the state level factors associated with IMR. In 2015, IMR in MA was 4.2 per live births while it was over 9 per 1000 in MS. We gathered a state-level panel dataset for all 50 U.S. states from 2001 to 2015 and used a first differencing regression model to investigate the main factors contributing to the high infant mortality and the disparity among different states. Initial analyses show that drug abuse, and percentage of babies born low birthweight explains some of the variations in IMR.

Predictive Analytics and Healthcare Operations

Sponsored: Manufacturing & Service Oper Mgmt, Healthcare Operations

Sponsored Session

Chair: Retsef Levi, MIT, Cambridge, MA, 02142, United States, retsef@mit.edu

1 - Predictive Models for Heart Failure Admissions

Jazmin Furtado, Massachusetts Institute of Technology, Cambridge, MA, 02140, United States, jazminf@mit.edu, Mariam Al-Meer, Retsef Levi, Ana Cecilia Zenteno Langle, Gregory Lewis, James Januzzi, Ryan Thompson

Heart failure (HF) is a chronic condition that results in the impairment of the ventricle's ability to fill with or eject blood. The American Heart Association predicts that there will be ~10 million HF patients in the US by 2037, with total hospitalization costs exceeding $70 billion. We propose a predictive model which identifies with high confidence patients at greatest risk of a first hospital admission following encounters with their primary care providers and/or cardiologists in any given year. Significant predictors include demographic characteristics, medication history, and proxies for socio-economic status.

2 - Valuing and Optimizing Non-facetime Work to Inform Physician Compensation

Michael Hu, MIT, 70 Pacific St., Apt 332, Cambridge, MA, 02139, United States, hum@mit.edu, Karen Carlson, Joseph Doyle, Stephanie Eisenstat, Annie Huppert, Retsef Levi

Primary care physicians (PCPs) have traditionally been paid according to activities-based compensation models. Health systems are now moving to patient panel-based payments. This requires methods to determine the workload associated with different patient panels. Until now, panels have been evaluated using "risk scores", which measure clinical complexity. However, risk scores do not capture non-facetime work (NFTW), such as visit documentation, which consumes a substantial amount of PCP time. We demonstrate that risk scores do not accurately measure the workload of patient panels. We then create prediction models that reliably estimate the workload required to manage different patients.

3 - Predictive Analytics to Manage Hospital Discharges

Retsef Levi, Massachusetts Institute of Technology, Cambridge, MA, United States, retsef@mit.edu, Peter Dunn, Kyan Safavi, Jonathan Zanger, Ana Cecilia Zenteno Langle

We present a surprisingly accurate predictive model to predict upcoming discharges in hospitals. The model is incorporated into a new process to drive earlier discharges and significantly improved management of the hospital bed capacity.

4 - Impacts of Staffing Patterns on Patient Length of Stay

Kimia Ghobadi, MIT, 100 Main Street, E62-459, Cambridge, MA, 02142, United States, kimiag@mit.edu, Andrew Johnston, Retsef Levi, Peter Dunn, Walter O'Donnell

Staffing pattern in resident teams of Internal General Medicine effect patients' wait-time for beds in the Emergency Department, as well as their hospital length of stay once they are on the floor. We identify a natural randomized control setting to quantify the impacts of care-team hand-offs for general medicine patients and analyze the effects for various admitting diagnosis.

Supply Chain Risk

Sponsored: Manufacturing & Service Oper Mgmt, Supply Chain

Sponsored Session

Chair: Juan Serpa, McGill University, juan.serpa@mcgill.ca

1 - Inventory in Times of War

Andres F. Jola-Sanchez, Indiana University, Bloomington, IN, United States, ajolasan@indiana.edu, Alfonso J. Pedraza-Martinez, Juan Serpa

How does war affect firms' inventory? We study this question by cobbling together a unique data panel from the Colombian civil war (battled by two guerrilla groups). We glean: (i) operational-level metrics from 38,916 firms; (ii) war-level metrics from all 1,122 Colombian municipalities; and (iii) the at-fault armed group for each attack. To obtain causal estimates, we use a difference-in-difference model that hinges on the 2012-peace process between the government and one of the two guerrilla groups. We find that war leads to lower inventory. However, proximity to trade centers moderates this response: firms far from trade centers hold more inventory in times of war.

2 - Quality Control under Noisy Signals

Ahmet Colak, Northwestern University, Chicago, IL, United States, a-colak@kellogg.northwestern.edu

Combining public and private auto industry data sets, I derive novel defect variables that influence quality improvement decisions. Accounting for various product characteristics and spillover effects relating to quality, I study a panel data that span from 2004 to 2017. I examine how signal volatility impacts quality decisions. Particularly, I develop an empirical framework that assesses how much a standard deviation increase in signal variability lowers consumer and firm welfare. Finally, I consider various managerial policies to mitigate such negative effects.

3 - Strategic Inventory and Supplier Encroachment

Huiqi Guan, University of Miami, 417 Jenkins Building, School of Business Administration, Coral Gables, FL, 33146, United States, h.guan@umiami.edu, Haresh B.Gurnani, Xin Geng, Yadong Luo

We study the combined effect of strategic inventory and supplier encroachment in a two-period model. The buyer may withhold excess inventory and the supplier can introduce a direct selling channel in the second period. We find that irrespective of the buyer's unit holding cost, strategic withholding may occur and the supplier's encroachment strategy is distorted.

4 - A Quasi Experimental Study of Environmental Benefits of Craigslist

Suvrat Dhanorkar, Pennsylvania State University, 466 Business Building, University Park, PA, 16802, United States, ssd14@psu.edu

Matching platforms such as Craigslist can facilitate the creation of C2C closed loop supply chains (CLSCs) for used goods, which can enhance product reuse and limit reliance on recycling and disposal alternatives.We use a quasi-experimental setup to examine how Craigslist's entry into various U.S. geographic markets impacts environmental outcomes.

Inventory Management

Contributed Session

Chair: Zhongjie Ma, Purdue University, West Lafayette, IN, United States, zhongjiema@purdue.edu

1 - A Reinforcement Learning Approach for Perishable Product Supply Chain with Markov-modulated Demand

Ahmet Kara, Erciyes University, Erciyes University, Department of Industrial Engineering, kayseri, 38039, Turkey, ahmet.kara@erciyes.edu.tr, brahim Do an

Inventory management of perishable products with limited shelf life is different than the classical inventory management. The inventory control of perishable products requires different ordering policies that consider both the quantity and the age of the stocks. This study analyzes a two-echelon supply chain model for perishable inventory management with Markov-Modulated Demand. We examine different ordering policies to emphasize the importance of the age information. The problem has been formulated using a reinforcement learning model.

2 - Newsvendor Problems with Demand Forecast Updating and Supply Constraints

Meimei Zheng, Shanghai Jiao Tong University, Shanghai, 200240, China, meimeizheng2009@gmail.com, Kan Wu, Yan Shu

This study investigates an extension of the newsvendor model with demand forecast updating under supply constraints. A retailer can postpone order placement to obtain a better demand forecast. However, the manufacturer would charge the retailer a higher cost for a shorter lead time and set restrictions on the ordering times and quantities. Two supply modes are investigated: supply mode A, which has a limited ordering time scale, and supply mode B, which has a decreasing maximum ordering quantity. For supply mode A, it can be proven under justifiable assumption that a retailer should order either as early or as late as possible. For supply mode B, an algorithm is proposed to simplify the ordering policy.

3 - Optimal Order and Shipment Policies on Classic Periodic-review Two-echelon Distribution Models

Youyi Feng, Professor, Business School, Sichuan University, Wangjiang Campus, Sichuan University, Wuhou District, Chengdu, Sichuan, China, Chengdu, China, yyfeng@live.com, Lei Xie

We characterize optimal dynamic inventory policies for the classic single-item periodic-review two-echelon distribution inventory models over a finite planning horizon. Consisting of a warehouse and a number of retailers, the system periodically procures inventory from an outside supplier to replenish the warehouse and delivers on-hand inventory from the warehouse to the downstream retailers. We innovate the computing procedures of linear complexity to obtain optimal order/shipment quantities respectively. Infinite-horizon models with discounted cost and long-term average cost criteria are also explored.

4 - Multi Season Production Planning under Sales Quota

Tianxiao Chen, The Chinese University of Hong Kong, ERB615, CUHK, Shatin, Shatin, Hong Kong, chentx@se.cuhk.edu.hk, Xiting Gong, Qing Li, He Xu

Motivated by the export quota in international trading, we study a periodic-review multi-season production planning problem where the total sales quantity in each season is restricted by a sales quota. By formulating the problem as a dynamic program, we characterize the structure of the optimal production policy and exam the impact of sales quota.

5 - Dynamic Coordination in a Supply Chain with Production Capacity Uncertainty

Zhongjie Ma, Purdue University, 403 W. State Street, West Lafayette, IN, 47906, United States, zhongjiema@purdue.edu, Qi Feng, J. George Shanthikumar

We study the effect of upstream supply uncertainty on the inventory decisions in a two-stage supply chain under both centralized and decentralized controls. Applying the concept of directional concave ordering and extending the notion of stochastic linearity, we develop a concave transformation of the problem for a general class of stochastic supply functions, which allows us to analyze the dynamic problem and characterize the optimal policy. Furthermore, we discuss the mechanism to dynamically coordinate the decentralized systems when the upstream and downstream make the ordering decisions based on self-interest.

Queueing Models in Applied Probability

Sponsored: Applied Probability

Sponsored Session

Chair: Baris Ata, University of Chicago, Chicago, IL, 60637, United States, Baris.Ata@chicagobooth.edu

Co-Chair: Xiaoshan Peng, University of Chicago, Booth School of Business, Chicago, IL, 60637, United States, x-peng@chicagobooth.edu

1 - Managing Service Platforms with Self-scheduling Agents and Impatient Customers

Rouba Ibrahim, University College London, MS& I.department, UCL, Gower Street, London, WC1E 6BT, United Kingdom, rouba.ibrahim@ucl.ac.uk

We study the operational management of service platforms with self-scheduling agents and impatient customers. Since the customer impatience distribution plays an important role, we propose controlling it using delay announcements, and characterise the interaction between three controls at the manager's disposal: the staffing level, the compensation offered to agents, and the announcements made to customers.

2 - A Constrained Optimization Problem for a Two-Class Queueing Model

Mark E. Lewis, Cornell University, School of Ops Research & Information Engin., 221 Rhodes Hall, Ithaca, NY, 14853, United States, mark.lewis@cornell.edu, Cory Girard, Linda Vogel Green, Jingui Xie

We discuss dynamic server control in a two-class service system under a constraint on the number of high-priority customers. A class of randomized threshold policies is defined, and is proven to contain an optimal policy in the case without abandonments. The proof of optimality is then used to construct heuristic policies for the case of low-priority abandonments, which we test numerically. The experiments we run suggest that, even when abandonments are introduced, these classes of policies outperform priority policies, and, in some cases, are near-optimal.

3 - Delay Predictability Tradeoffs in Reaching a Secret Goal

Kuang Xu, Stanford Graduate School of Business, Stanford, CA, United States, kuangxu@stanford.edu, John N.Tsitsiklis

We formulate a model of dynamic decision-making to study an agent's predictability as she attempts to reach a final goal through a sequence of intermediate actions, while watched by an adversary who tries to predict the goal before it is reached. We are motivated by the increasing ubiquity of large-scale data collection infrastructures capable of predicting an agent's intentions and future actions, in juxtaposition with an agent's desire for privacy. We show the predictability of the agent's goal can be made inversely proportional to the time she spends reaching it, and that this is the best possible. This characterization does not depend on the structure of the agent's state space beyond the diameter.

4 - Managing the Callback Option under Arrival Rate Uncertainty

Xiaoshan Peng, Indiana University, Kelley School of Business, Bloomington, IN, 47405, United States, xp1@iu.edu, Baris Ata

We study how to manage the callback option effectively to mitigate congestion due to temporary surges in the arrivals to a call center. When a customer arrives, the call center manager decides whether to keep him in the online queue or to offer the callback option. Some customers may reject the callback offer. We show that a modified lookahead policy that looks into the future arrivals and service completion times for the next p/h time units and uses the current number of customers in the system who previously rejected a callback offer is pathwise optimal among the complete foresight policies.

Asymptotic Methods in Financial Mathematics

Sponsored: Applied Probability

Sponsored Session

Chair: Jose Figueroa-Lopez, Washington University, St. Louis, MO, figueroa-lopez@wustl.edu

1 - Utility Maximization Problems in a Regime Switching Market Model

Adriana Ocejo Monge, Assistant Professor of Statistics, University of North Carolina-Charlotte, Fret 335G, 9201 University City Blvd., Charlotte, NC, 28223, United States, amonge2@uncc.edu

We present utility maximization problems where an agent builds her portfolio by investing in a bond and a risky asset whose price dynamics follow a diffusion process with regime-switching coefficients, modeled by a finite-state Markov chain. We consider the class of iso-elastic utility functions, which includes the power utility. We show how to explicitly compute the value function using Laplace transforms and present the optimal trading strategy.

2 - Optimal Thresholding of Truncated Realized Variations

Jose E.Figueroa-Lopez, Washington University-St Louis, One Brookings Drive, St Louis, MO, 63130, United States, figueroa-lopez@wustl.edu, Cecilia Mancini

We consider a univariate semimartingale model for (the logarithm of) an asset price, containing jumps having possibly infinite activity. We aim at optimally selecting the threshold of truncated realized variations by minimizing the conditional mean square error of the estimator. A parsimonious asymptotic characterization of the optimum is established, which turns out to be asymptotically proportional to the Levy's modulus of continuity of the underlying Brownian motion. Moreover, minimizing the cMSE enables us to propose a novel implementation scheme for the optimal threshold sequence. Monte Carlo simulations illustrate the superior performance of the proposed method.

3 - Short Maturity Asian Options in Local Volatility Models

Lingjiong Zhu, PhD, Florida State University, FL, United States, lz465@nyu.edu

We present a rigorous study of the short maturity asymptotics for Asian options with continuous-time averaging, under the assumption that the underlying asset follows a local volatility model. The asymptotics for out-of-the-money and at-the-money cases are derived, and explicit formulas are given in the cases of Black-Scholes model, square-root model and CEV model. We present an analytical approximation for Asian options prices, and demonstrate good numerical agreement of the asymptotic results with the results of Monte Carlo simulations and benchmark test cases. This is based on the joint work with Dan Pirjol.

4 - Price Dynamics in a Limit Order Market under Time Dependent Order Flow

Johnathan A. Chavez-Casillas, University of Calgary, Calgary, AB, Canada, jonathan.chavezcasil@ucalgary.ca

In this talk we will, briefly, introduce Limit Order Books and explain the intricate dynamics between the order flow and the price process. We will discuss some efforts to describe the price dynamics and how they have been generalized to capture some empirical properties observed in the data. We will then introduce a model that considers a time-dependent order flow and, under some assumptions, characterize the price process within this model. We will then finish by describing how this model fit some particular data under the given assumptions.

1 - Stochastic Models to Optimize Biomanufacturing Operations

Tugce Martagan, Eindhoven University of Technology, Eindhoven, Netherlands, t.g.martagan@tue.nl

We develop an inter-disciplinary framework to reduce biomanufacturing costs and lead times. The proposed framework consists of several Markov decision models that dynamically control and optimize protein purification operations. We partition the state space into decision zones, and propose a novel zone-based decision making approach to quantify the business risks and costs. We develop guidelines that are easy to implement in practice. Industry implementation indicates 20% reduction in protein purification costs and timelines.

2 - Beyond Product Functionality

Tian Chan, Emory University's Goizueta Business School, 1300 Clifton Road, Atlanta, GA, 30322, United States, tian.chan@emory.edu

Products combine function and form. We focus on form. We combine clustering techniques with experimental validation to identify styles (groupings of designs of similar form) among the over 350,000 US design patents granted from 1977 to 2010. Thus we compile a dataset of styles that can serve as an empirical platform to study the role of product form in NPD. Using the data, we find that (i) style turbulence (the unpredictability of changes in a style's prevalence) follows a U-shaped relationship with respect to function turbulence and (ii) style turbulence increases over time.

3 - Corporate Predictions Markets: Evidence from Google, Ford and Firm X

Bo Cowgill, Columbia Business School, 3022 Broadway, Uris Hall 702, New York, NY, 10583, United States, bo.cowgill@gmail.com

We examine data from prediction markets run by Google, Ford Motor Company and an anonymous conglomerate (Firm X). We find these markets are relatively efficient and improve expert forecasts at all 3 firms by as much as a 25% reduction in mean squared error. The most notable inefficiency is an optimism bias in the markets at Google. The few inefficiencies that appear become smaller over time. Experienced traders and those with higher past performance trade against the identified inefficiencies.

4 - Value Creation and Capture in a World of Bottlenecks

Douglas Hannah, University of Texas at Austin, Austin, TX, United States, dph@utexas.edu

Ecosystems are settings in which firms depend on one another to provide the components that together comprise valuable products. Research has identified effective collaboration as central to firms' ability to create value in ecosystems, but a gap exists with respect to when and for whom different types of collaboration are effective. I address this gap with a game theoretic model that compares two archetypal strategies, and thus contribute to research on ecosystems and collaborative strategy.

5 - Digital Platforms and Product Innovativeness: Towards an Understanding of Innovationat the Device Layer

Hyunwoo Park, The Ohio State University, Columbus, OH, 30309, United States, park.2706@osu.edu

The infusion of digital capabilities into physical products is an increasingly pervasive phenomenon. This prolific combination of "bits" and "atoms" necessitates a deeper understanding of the association between logical capability and physical machinery innovation. This chapter frames that digital platforms represent "areas" in technology design space that enable innovative recombination of technological components. It also proposes a novel and extensible index for quantifying innovativeness.

Predictive Analytics for Advancing Personalized and Evidence-based Medicine

Invited: InvitedHealthcare Systems and Informatics

Invited Session

Chair: Eva Lee, Georgia Tech, Atlanta, GA, 30332-0205, United States, evakylee@isye.gatech.edu

1 - Machine Learning: Multi-site Evidence-based Best Practice Discovery

Eva Lee, Georgia Tech, Industrial & Systems Engineering, Ctr for Operations Research in Medicine, Atlanta, GA, 30332-0205, United States, evakylee@isye.gatech.edu, Yuanbo Cody Wang

This work is joint wih Care Coordination Institute. We invesigate best practice characteristics among 737 clinical sites that covers 2.7 million patients. Data interoperabiity is established via non-redundancy graph mapping onto standardized medical/lab/pharma terminologies. Next, unsupervised learning is performed to uncover treatment outcome patterns. Supervised learning via a classification model ((DAMIP) is then applied to uncover discriminatory characteristics that can predict the quality of treatment outcome. We will present results for diabetic patients. The patterns identified provide clinical practice guidelines for "rapid learning" across all clinical sites.

2 - Outcome-driven Personalized Treatment Design for Managing Diabetes

Xin Wei, Georgia Institute of Technology, Atlanta, GA, United States, xwei36@gatech.edu, Eva Lee

This work is joint with Grady Memorial Hospital. The management of gestational diabetes mellitus(GDM) focuses on close monitoring of a patient's blood glucose level while the clinician experiments with dosing strategy based on some clinical guidelines and his/her own experience. We propose a drug-effect-based personalized approach to improve treatment outcome for GDM patients. Specifically, a predictive model based on pharmacokinetic and pharmacodynamic(PK/PD) analysis of drug dosage and blood glucose level is proposed to uncover personalized treatment effect and then incorporated in a planning model for optimal dosing strategy. Results for GDM patients will be presented.

3 - A Supervised Biclustering Approach for Personalized Medicine

Milad Zafar Nezhad, Wayne State University, Detroit, MI, United States, m.zafarnezhad@wayne.edu, Kai Yang

Traditional medicine typically applies one-size-fits-all treatment for the entire patient population whereas precision medicine develops tailored treatment schemes for different patient subgroups. The fact that some factors may be more significant for a specific patient subgroup motivates researchers to develop new approaches to subgroup analysis, which is an effective strategy to personalize treatment. In this study, we propose a novel patient subgroup detection method, called Supervised Biclustring (SUBIC) using convex optimization and apply our approach to detect patient subgroups in a vulnerable demographic subgroup at the high risk of cardiovascular disease.

Mechanism Design, Networks, and New Markets II

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Santiago Balseiro, srb43@duke.edu

Co-Chair: Ozan Candogan, University of Chicago, Chicago, IL, 27708, United States, ozan.candogan@chicagobooth.edu

1 - Strategic Dynamic Pricing with Network Externalities

Azarakhsh Malekian, University of Toronto, Toronto, ON, Canada, azarakhsh.malekian@rotman.utoronto.ca

We study the optimal pricing of a monopolist selling goods in a dynamic pricing game with multiple rounds. Customers are forward-looking and experience a (positive) network externality. The seller commits to a price sequence and strategic buyers play a perfect Bayesian equilibrium. We fully characterize the optimal pricing policy and show that it is linearly increasing in time, where the slope of the price path is described by a single network measure: sum of the entries of the inverse of network externality matrix, termed network effect. We also study the effect of price discrimination and establish that in the earlier rounds the price offered to more central buyers is lower.

2 - Facilitating the Search for Partners on Matching Platforms: Restricting Agent Actions

Yash Kanoria, Columbia Business School, New York, NY, 10027, United States, ykanoria@columbia.edu, Daniela Saban

Two-sided matching platforms, such as those for labor, accommodation, dating, and taxi hailing, control many aspects of the search for partners. We consider a dynamic model of search by strategic agents with costly discovery of pair-specific match value. We find that in many settings, the platform can mitigate wasteful competition in partner search via restricting what agents can see/do. If agents on one side have a tendency to be more selective (due to smaller screening costs or greater market power), the platform should disallow agents on the less selective side from reaching out. This forces agents on the more selective side to reach out and improves the welfare of agents on the less selective side.

3 - Temporal Microstructure of Surge Pricing

Bin Hu, UNC Chapel Hill, McColl Building CB3490, Kenan-Flagler Business School, Chapel Hill, NC, 27599, United States, bin_hu@unc.edu, Ming Hu, Han Zhu

Ride-sharing platforms such as Uber and Lyft contingently increase prices (known as Surge Pricing) to modulate surges of rider requests and attract drivers. However, in managing unpredictable demand shocks with Surge Pricing, an important feature neglected in the existing literature is that supply (drivers) reacts much slower than demand (riders) to price changes. We model this feature and the resulting rider and driver strategic behaviors, and show that neglecting this feature can lead to significantly distorted and underperforming decisions.

4 - Markov Chain Models for Controlling the Exposure Frequency Distribution of Online Advertising

Ali Hojjat, University of New Hampshire, Durham, NH, United States, ali.hojjat@unh.edu, John G.Turner

Recent trends in online advertising show that explicit reach and frequency specifications are preferred over aggregate impression or budget goals. We propose two Markov chain models for serving ads that can achieve a desired frequency distribution for an online ad campaign. We characterize the necessary and sufficient conditions on the arrival distribution that must hold for a feasible ad serving policy to exist, and characterize the publisher's impression assignment rule in closed form. Extensions of our framework to multi-advertiser and multi-audience-segment settings are also presented.

Pricing, Information Sharing, and Other Decisions in RM Applications

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Ramandeep Randhawa, University of Southern California, Los Angeles, CA, 90089, United States, ramandeep.randhawa@marshall.usc.edu

1 - Markdown Policies for Demand Learning and Strategic Customer Behavior

N. Bora Keskin, Duke University, Fuqua School of Business, 100 Fuqua Drive, Durham, NC, 27708-0120, United States, bora.keskin@duke.edu, Hongfan Chen

Consider a firm selling a product to a finite population of myopic and strategic customers with heterogeneous valuations. The firm faces uncertainty about the market size and how strategic customers are. We develop guidelines for designing asymptotically optimal markdown policies for demand learning in the presence of strategic customers.

2 - Contingent Stimulus in Crowdfunding

Longyuan Du, Rotman School of Management, University of Toronto, 105 St George St, Toronto, ON, M5S.3E6, Canada, Longyuan.Du14@Rotman.Utoronto.ca, Ming Hu, Jiahua Wu

We consider a model where backers arrive sequentially at a crowdfunding project. Upon arrival, a backer makes her pledging decision by taking into account the expected project success rate. We characterize the dynamics of a project's pledging process. To boost success, we propose and characterize three contingent stimulus policies, i.e., seeding, feature upgrade and limited-time offer. We show that the benefit of contingent policies is greatest in the middle of crowdfunding campaigns. Testing with the data set of Kickstarter, we obtain empirical evidence that the projects' success rates improve by 14.6% on average with updates in the middle of the campaign and when the pledging progress is lagging.

3 - Bayesian Persuasion on Networks

Kimon Drakopoulos, University of Southern California, drakopou@marshall.usc.edu, Ozan Candogan

In the presence of misinformation, platforms face a tradeoff between customer engagement and quality of shared information. In this paper we explore this tradeoff and discover the optimal information revelation mechanism. The amount of information provided to each agent according to this mechanism turns out to relate to a novel centrality measure that we further analyze and relate to existing notions of centrality.

4 - Information Sale in Competitive Markets

Kostas Bimpikis, Stanford University, kostasb@stanford.edu, Alireza Tahbaz-Salehi, Davide Crapis

We study the strategic interaction between a seller of information and buyers that compete in a downstream market. Our analysis illustrates that the nature and intensity of competition are key in determining the optimal strategy. In particular, we show that when the customers' action are strategic complements, it is to optimal to offer the most accurate information to all customers. In contrast, when actions are strategic substitutes, it is optimal to either (i) restrict the overall supply of the information product, or (ii) offer a product of inferior quality. We also show that the incentive to restrict the supply or quality of information intensifies in the presence of information leakage.

Customer Choices and Pricing

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Hongmin Li, Arizona State University, Tempe, AZ, 85287, United States, hongmin.li@asu.edu

1 - Pricing under the Generalized Extreme Value Models with Homogeneous Price Sensitivities

Heng Zhang, University of Southern California, Los Angeles, CA, 90007, United States, hengz@usc.edu, Paat Rusmevichientong, Huseyin Topaloglu

We study multi-product pricing problems under generalized extreme value models and homogeneous price sensitivity parameter for all products. First, we consider the unconstrained problem, and show that the optimal prices of different products have a constant markup over costs, and give an explicit formula for optimal markups. We next study the pricing problem subject to the convex inventory constraints, the formulation of which includes the deterministic approximation for the dynamic pricing problems over a network of resources. We show the problem can be transformed into a convex problem with purchase probabilities as the decision variables, and solved efficiently.

2 - Consumer Choice and Market Expansion: Modeling, Optimization and Implementation

Ruxian Wang, The Johns Hopkins Carey Business School, 100 International Dr, Baltimore, MD, 21202, United States, ruxian.wang@jhu.edu

We incorporate market expansion effects into consumer choice models and investigate the revenue management and pricing problems.

3 - Analysis of Discrete Choice Models: A Welfare-based Framework

Xiaobo Li, University of Minnesota, 1006 27th Avenue SE,, APT.'E', Minneapolis, MN, 55414, United States, lixx3195@umn.edu, Guiyun Feng, Zizhuo Wang

In this paper, we study the relation between several well known classes of discrete choice models, namely the random utility model (RUM), the representative agent model (RAM) and the semi-parametric choice model (SCM). Using a welfare based model as an intermediate, we show that the RAM and the SCM are equivalent. Furthermore, we show that both models as well as the welfare based model strictly subsume therandom utility model when there are three or more alternatives, while the four are equivalent when there are only two alternatives. Thus, this paper presents a complete picture on the relation between these choice models. We also study substitutability and complementarity properties in choice models.

4 - Product Design under Multinomial Logit Choices: Optimization of Costly Attributes and Prices in an Evolving Product Line

Gwangjae Yu, Arizona State University, 300 E.Lemon St, BA 451G, Tempe, AZ, 85281, United States, gjyu@asu.edu

We study a product-line design problem in which customers' choice among multiple products is given by a multinomial logit (MNL) model. A firm determines product attributes and prices in an evolving product line to maximize profit. In particular, given the prices and attributes of products that already exist in a product line, the firm optimizes prices and/or attributes of the new products to be added to the same product line.

Control and Optimization Techniques for Power Systems I

Invited: Energy Systems Management

Invited Session

Chair: Richard Y Zhang, UC Berkeley, Berkeley, CA, 94720, United States, ryz@berkeley.edu

1 - Inner Approximations of Power Flow Feasibility Sets

Konstantin Turitsyn, Massachusetts Institute of Technology, Cambridge, MA, 02139, United States, turitsyn@mit.edu, Krishnamurthy Dvijotham, Hung Nguyen

Inner approximations of power flow feasibility sets have a variety of applications for example operational security. While the outer approximations can be naturally constructed via convex relaxations, the problem of constructing inner approximations is generally hard. This talk will introduce a new strategy of constructing inner approximations for general power flow equations not restricted to any topologies and bus types. The framework is based on the adaptive bounding of nonlinearities and certification of the self-mapping of the convex set as required by the Brouwer fixed point theorem. The proposed framework is scalable to large cases and covers most of the feasible region in practice.

2 - Value of Flexible Wind Dispatch in Stochastic Unit Commitment

Georgios Patsakis, UC Berkeley, Berkeley, CA, 94720, United States, gpatsakis@berkeley.edu, Shmuel S.Oren

We explore the expected benefit on social welfare from integrating in power systems the flexibility to dispatch the wind lower than its available output. Initially, we provide motivation for instances when wind spilling could prove beneficial. We then utilize a stochastic unit commitment approach for a reduced California power system. Two decomposition techniques are used to solve the problem. The first one is based on recent literature and utilizes global cuts and Lagrangian penalties to reach an optimal solution, for a small number of scenarios. The second one is a heuristic combination of progressive hedging with scenario reduction.

3 - Pricing in Multi-interval Real-time Markets

Bowen Hua, University of Texas at Austin, 1650 West Sixth Street, Apt D, Austin, TX, 78703, United States, bowenhua90@gmail.com, Ross Baldick

A multi-interval real-time market bases itself on a look-ahead economic dispatch problem implemented in a model predictive control fashion. Under the current pricing structure in the multi-interval real-time market of CAISO and NYISO, generators may have incentive to deviate from the ISO's dispatch. We propose a pricing method that mitigates this incentive problem by explicitly considering historical loss. Numerical tests show that our method improves price signal and reduces out-of-market payments.

4 - Spurious Critical Points in Power Systems State Estimation

Richard Y Zhang, UC Berkeley, Berkeley, CA, 94720, United States, ryz@berkeley.edu, Javad Lavaei, Ross Baldick

The power systems state estimation problem computes the set of complex voltage phasors given quadratic measurements using nonlinear least squares. Even in the absence of measurement errors, local search algorithms can become "stuck" at local minima, which correspond to nonsensical estimations. In this talk, we observe that local minima cease to be an issue as redundant measurements are added. Posing state estimation as an instance of the quadratic recovery problem, we derive a bound for the distance between the true solution and the nearest spurious local minimum, in order to show that they become increasing rare and far-away from the true solution with the addition of redundant information.

Efficiency and Productivity – YR

Invited: Data Envelopment Analysis

Invited Session

Chair: Ole Bent Olesen, University of Southern Denmark, University of Southern Denmark, Odense, 5230, Denmark, ole@sam.sdu.dk

1 - Shape Constrained Kernel-weighted Least Squares

Daisuke Yagi, Texas A&M.University, College Station, TX, United States, d.yagi@tamu.edu, Yining Chen, Andrew L. Johnson, Timo Kuosmanen

Nonparametric estimation methods avoid functional form misspecification which is caused by parametric assumptions. However, the flexibility of nonparametric methods often cause difficulties in interpreting results in many applications of productivity analysis. However, microeconomic theory provides additional structure for modeling a production or cost function which can be interpreted as shape constraints. We propose nonparametric shape constrained estimators that combine the advantage of avoiding functional misspecification with improving the interpretability of estimation results relative to unconstrained nonparametric methods.

2 - Direction Selection in Stochastic Directional Distance Functions

Kevin Layer, Texas A&M.University, College Station, TX, United States, kevin.layer@tamu.edu, Andrew L. Johnson, Robin C. Sickles

A stochastic directional distance function (SDDF) allows for noise in potentially all input and output variables; however when estimated, the direction selected will affect the functional estimates. This paper addresses the question, how should the direction be selected to improve the estimates of the underlying production behavior. From Monte Carlo simulations we find two main guidelines: picking a direction orthogonal to the region where most of the data lies and a direction that is consistent with the noise in the DGP. Finally we confirm the analysis with an application on a cost function for hospital production in the U.S.

3 - The Measurement of Revenue Inefficiency Over Time: An Additive Perspective

Samah Jradi, samah.jradi@kedgebs.com,
Tatiana Bouzdine Chameeva, Juan Aparicio

In this paper, we introduce a Luenberger-type indicator based on the weighted additive distance function defined in [Aparicio et al. 2016] to measure revenue inefficiency change over time. The weighted additive distance function endows the well-known weighted additive model in data envelopment analysis (DEA) with a structure of distance function that allows to determine values related to the performance of points located in both the interior and exterior of the reference production possibility set. We consider an application to French wine production.

Leaders on Twitter

Invited: Social Media Analytics

Invited Session

Chair: Sung Won Kim, University of Illinois at Urbana Champaign, Champaign, IL, 61820, United States, swk@illinois.edu

1 - Leaders and Lemmings on Twitter: Examining the Role of Cognitive and Heuristic Persuasion

William Obenauer, Rensselaer Polytechnic Institute, Troy, NY, United States, Obenaw@rpi.edu

Social networking sites (SNS) are a rapidly growing global force of influence. SNS are unique in that they restrict the use of communication tools such as body language and voice inflection, while giving users unfettered access to their audience, thus allowing for new types of leaders to emerge. We examine this dynamic by collecting data during a 14-day period of the 2014 Indian Parliamentary elections using Twitter's streaming API 1.1 with a keyword filter limiting our data capture to Tweets relevant to the election. Our final data set includes 3.87 million Tweets which we analyze to identify behavioral trends that result in the emergence of leaders within SNS.

2 - Recruiting Members of Underrepresented Groups: What Women-in-Tech Meetups do Differently

Jessica Clark, University of Maryland Smith School of Business, College Park, MD, 20742, United States, jclark@stern.nyu.edu

Recruiting members of underrepresented groups into technology jobs is a major challenge for organizations. The goal of this work is to understand how various aspects of such organizations' public faces affect their ability to attract diverse membership. Using data gathered from meetup.com, we compare general technology-themed Meetups to those explicitly targeting female members. We characterize members' propensity to join and become active members of each Meetup using its textual description, events, reviews, and discussion board communications, among other aspects.

3 - The Impact of Short-term Introductory Incentives on Newmembers: Evidence from Online Health Communities

Wei Chen, University of Arizona, 1130 East Helen Street, McClelland Hall 430, Tucson, AZ, 85721, United States, weichen@email.arizona.edu, Xiaofei Zhang, Bin Gu, Xitong Guo

Many online communities deploy short-term extra incentive policy to motivate user contributions, especially for the new members. However, whether the communities can benefit from this policy is unclear. We draw on a policy change in a leading online health platform to answer this question. We find that even though the short-term extra incentives increase contribution quantity during the policy window, but decrease contribution quantity significantly after the policy window. The policy also does harm to the platform by decreasing contribution quality, but can help to increase user survival. Moreover, the impacts of the short-term extra incentives are contingent on users' professional titles.

4 - How Corporate Sponsors can Shift Donations in Philanthropic Crowdfunding Markets

Lauren Rhue, Wake Forest University, 1834 Wake Forest Rd, 212 Farrell Hall, Building 60, Winston-Salem, NC, 27106, United States, rhuela@wfu.edu

This study examines if corporate sponsorship affects donations to disadvantaged recipients and if corporate sponsorship "crowds-in" or "crowds-out" individual donations on a philanthropic crowdfunding platform. Using data from DonorsChoose and a matched sample technique, I find that corporate sponsorship can "crowd-out" individual donors but "crowd-in" local donations to the highest poverty recipients and mitigate the conflict between "home bias" and donations to highest need recipients. There are managerial implications for platforms and corporate social programs as well as societal implications based on the potential of philanthropic platforms to reduce poverty and/or inequality.

Correlated and Interdependent Valuations in Mechanism Design

Invited: Auctions

Invited Session

Chair: Michael Albert, Duke University, Durham, NC, malbert@cs.duke.edu

1 - The Value of Side Information for Revenue Extraction

Hu Fu, University of British Columbia, Vancouver, BC, Canada, fu.hu.thu@gmail.com

Suppose we have some side information regarding a single bidder to whom we try to sell a single item, does it matter if we reveal the information to the buyer? We show that the answer is yes, and give nontrivial sufficient conditions under which the revenue loss caused by revealing the information is bounded by a small factor. We also derive implications for revenue optimal auctions with multiple correlated bidders, via a Bayesian extension of Ronen's lookahead auction.

2 - Optimal Procurement with Quality Concerns

Giuseppe Lopomo, Duke University, FSB, P.O. Box 90120, Durham, NC, 27708, United States, glopomo@duke.edu

We characterize optimal procurement mechanisms in environments where each supplier's privately known type affects both its production cost and the buyer's willingness to pay for its product. We restrict attention to mechanisms that satisfy both incentive compatibility and individual rationality ex post. We show that when the affiliation among the suppliers' types is low, it is optimal for the buyer to randomly select the winner if its willingness to pay is sufficiently large, and not trading at all otherwise. If instead the affiliation is high, a standard second-price auction, possibly with a reserve price, is optimal.

3 - Mechanism Design with Correlated Valuations: How Much Correlation is Necessary?

Michael Albert, Duke University, 308 Research Drive, Durham, NC, 27708, United States, malbert@cs.duke.edu

In a setting where bidders' values are correlated, an auction designer can extract the full social surplus as revenue. However, this result strongly relies on the assumption of a common prior distribution between the mechanism designer and the bidders. We show that if a bidder's distribution is one of a countably infinite sequence of potential distributions that converges to an independent private values distribution, then there is no mechanism that can guarantee revenue more than greater than the optimal mechanism over the independent private value mechanism, even with sampling. This suggests that a high degree of correlation is essential in the application of correlated mechanism design.

Machine Learning in Physiological Data Analytics

Sponsored: Artificial Intelligence

Sponsored Session

Chair: Hong Lin, linh@uhd.edu

1 - An ACT-R Model for Blog Users' Negative Emotion Generation in Crises

Jingjing Zhang, Nanjing University of Science & Technology, Jiangsu, China, zjingjing1202@163.com, Peng Wu, Yao Cai

The purpose of this paper is to study the Blog users' negative emotion generation in crises (Blog users'-NEGC). We develop an Adaptive Control of Thought Rational (ACT-R) model to represent the Blog users'-NEGC (the ACT-R-NEGC model). This model is based on two cognitive facts: memories have emotional effect restricted to the contextual part of activation, goals and confidence change over crises. An experimental study was conducted to test the efficiency of this model by using data retrieved from Sina Weibo and Twitter on food safety crises. This model strongly supported the Blog users'-NEGC, and this paper shows a way to model emotion within cognitive architecture in the context of real life crises.

2 - Understanding Reasons for Medication Nonadherence: An Exploration in Social Media using Sentiment-enriched Deep Learning Approach

Jiaheng Xie, University of Arizona, 1130 E. Helen Street, Tucson, AZ, 85721, United States, xiej@email.arizona.edu, Xiao Liu

Medication nonadherence (MNA) refers to the behavior when patients do not fill prescriptions at pharmacies. To take proactive measures, the stakeholders need to understand patients' reasons for MNA. Current studies attempt to provide one-size-fits-all solutions to the "average patients." To address this issue, we develop a semantically enhanced deep learning approach to detecting patient and drug-specific reasons for MNA using health social media data. Our model reached a precision of 86.43%, a recall of 92.53%, and an F1-score of 89.38%. This study contributes to information systems and health IT by designing a deep-learning-based framework for detecting tailored reasons for MNA.

3 - A Process Mining Framework for Analyzing Learning Clickstream Data

Kexin Yin, University of Delaware, Newark, DE, United States, yinkexin@udel.edu, Harry Wang

Learning analytics is an emerging field of research that aims to utilize a wide range of educational data to establish a deep understanding of the learning processes and learner behavior. In this paper, we propose a process mining framework for analyzing large-scale learning clickstream data collected from a major US university's learning management system. We address a number of modeling and analysis challenges from a process mining perspective and propose new concepts for process-centric learning analytics. Based on the process mining results, we conduct an experiment to see how social influence affects learning processes and results.

Studying Social Issues with Social Media

Invited: Social Media Analytics

Invited Session

Chair: Jessica Clark, NYU Stern School of Business, Brooklyn, NY, 11217, United States, jclark@stern.nyu.edu

1 - Diffusion of Ineffectual User Innovation

Vidya Haran, University of Illinois Urbana-Champaign, 1206 South Sixth Street, 350 Wohlers Hall, Champaign, IL, 61822, United States, vharan@illinois.edu, Sung Won Kim

We examine why ineffectual user innovations diffuse and persist in online communities. We investigate the case of 'tweaking', an ineffectual yet popular user innovation, on babycenter.com. Tweaking is the use of enhancing digital pictures to determine the results of a pregnancy test earlier than using the test as instructed. Though the tweaked results are not considered valid by the scientific community, the tweaking community continues to grow. We analyze online discussion to posit that psychological safety, anxiety, desirability bias, source credibility and social proof are the important factors that keep ineffectual user innovations from getting rejected.

2 - Gender Inequalities in Online Doctor Ratings

Aishwarya Shukla, PhD, University of Maryland Smith School of Business, College Park, MD, United States, adshukla@rhsmith.umd.edu, Michelle Dugas, Gordon (Guodong) Gao, Ritu Agarwal

Despite findings that female physicians are, on average, more patient-centered and effective than male physicians, evidence that patients are more satisfied with female physicians is equivocal. We sought to further clarify the relationship between physician gender and patient satisfaction with a unique dataset of online doctor reviews from India. To this end, we examined differences in the rates of positive and negative recommendations for male and female physicians, and explored moderating factors such as gender match. We also conducted text analysis of the reviews for further insights. Implications for physician care and consumer decision-making are discussed.

3 - Can You Pay My Bills? Crowdfunding as Supplemental Income

Lauren Rhue, Wake Forest School of Business, 1834 Wake Forest Rd, 212 Farrell Hall, Building 60, NC, 27106, United States, rhuela@wfu.edu

This study examines the role of crowdfunding in supplementing individuals' income by using data from GoFundMe. Regional differences in opportunities, political leanings, and income inequality influence the crowdfunding goals and the campaigns' success rate. Areas with fewer resources may experience more campaigns per capita and lower success because there is greater need for extra income yet there are fewer affluent potential contributors. Also, because personal social connections are critical in fundraising, we investigate the use of social media as well as the linguistic and image elements of the campaigns.

INFORMS Korea Chapter

Sponsored: INFORMS Special Sessions

Sponsored Session

Chair: Chang Won Lee, Hanyang University, School of Business, 17 Haengdang Dong, Seoul, 133-791, Korea, Republic of, leecw@hanyang.ac.kr

1 - Humanitarian Supply Chain Management: Research Opportunities and Implementation Issues

Chang Won Lee, Hanyang University, School of Business, 17 Haengdang Dong, Seoul, 133-791, Korea, Republic of, leecw@hanyang.ac.kr

This study is to explore research opportunities and Implementation issues in Humanitarian Supply Chain Management (HSCM). This study is to review some issues on social impact of HSCM consequences. Implication perspectives in SCM in non-profit sector are not reviewed well compared to those in SCM for-profit contexts so that this study provides the cases of challenges and research opportunities.

2 - Effects of Hospital Occupancy on Patient Length of Stay and Patient Outcome

Yunsik Choi, Clemson University, 100 Sirrine Hall, Clemson, SC, 29634-1305, United States, yunsikc@g.clemson.edu, Lawrence Fredendall, Aleda Roth, Babur De Los Santos, Michael Makowsky

We examine the effect of hospital occupancy on time from admission to procedure start (segment 1) and the time from procedure end to discharge (segment 2). We investigate the effect of hospital occupancy on the completion of time segment 1 and 2 and effects of the completion time on 30-days readmission.

3 - Designing Energy Supply Chains for Energy Food and Flood

Kwon Gi Mun, Fairleigh Dickinson University, Fort Lee, NJ, United States, kgmun@fdu.edu, Yao Zhao, Raza Ali Rafique

The interconnected issues of Energy, Food, and Flood are among the most formidable challenges faced by developing countries. The development of hydropower has the potential to address all these issues in the same time. We identify the unique features, economies, and trade-offs in the hydro system development. We also provide the end-to-end and dynamic perspectives.

Air Traffic Flow Management

Sponsored: Aviation Applications

Sponsored Session

Chair: Guglielmo Lulli, g.lulli@lancaster.ac.uk

1 - Strong IP Models for Ground Delay Program Planning

Alexander Estes, University of Maryland-College Park, College Park, MD, United States, aestes@math.umd.edu, Michael O. Ball

The Federal Aviation Administration uses ground delay programs to manage congestion at an airport when the capacity of that airport to accept incoming flights has been impacted by some external factor. We present a multi-stage integer programming model for planning ground delay programs. This model has a strong LP relaxation, and we can show that every constraint of the formulation is facet-defining for the convex hull of integer programs. We also present computational results.

2 - A Passenger-centric Approach to Air Traffic Flow Management

Alexandre Jacquillat, Carnegie Mellon University, Heinz College, 5000 Forbes Avenue, Pittsburgh, PA, 15213, United States, ajacquil@andrew.cmu.edu

Existing Air Traffic Flow Management (ATFM) approaches are based on aircraft-centric objectives. However, the ultimate impact of flight delays and cancellations on aviation stakeholders are amplified by passenger misconnections on one-stop or two-stop itineraries. We present a novel model of network-wide ATFM operations that considers simultaneously flight delay costs and passenger disruption costs. Results suggest that passenger disruptions can be greatly reduced through no, or limited, increases in flight delays, thus making the outcomes of ATFM initiatives more consistent with airline and passenger preferences. Implications for implementation are discussed.

3 - Secondary Landing Slot Allocation Mechanisms for Ground Delay Programs

Jackie W. Baek, MIT, 77 Massachusetts Ave, Bldg E40-103, Cambridge, MA, 02139, United States, baek@mit.edu, Hamsa Balakrishnan

When congestion is expected at an airport, the Federal Aviation Administration issues a Ground Delay Program (GDP) to allocate landing slots in accordance with the predicted arrival capacity. Once these slots are initially allocated, there is a Collaborative Decision Making step in which airlines can swap slots among their own flights, and also decide cancellations. There has been limited literature on secondary slot allocation mechanisms for the inter-airline trading of slots. We analyze the effectiveness of various secondary slot allocation methods with respect to cost savings, fairness, and incentive compatibility to different airlines.

4 - Mining Alternative Flight Trajectories from Data Repositories: An Application to the European Airspace

Luigi De Giovanni, University of Padua, 63 via Trieste, Dipartimento di Matemtica "Tullio Levi Civita", Padova, I-35121, Italy, luigi@math.unipd.it, Giovanni Andreatta, Lorenzo Capanna, Luca Righi

Optimization models for Air Traffic Flow Management aim at determining flight trajectories that reduce congestion of both airports and en-route sectors, and maximize the efficiency of the Air Traffic Management system. To select suitable trajectories, models should consider many factors, such as length, time, en-route charges, fuel consumption, aircraft specifications, airspace users' preferences etc.,that are not always fully known. We present a data driven approach to mine alternative 2D, 3D or 4D trajectories from the historical flight records stored in the Eurocontrol DDR2 data sources, in order to develop and feed mathematical models for the optimization of trajectory based operations.

Supply Chain Management

Contributed Session

Chair: Lorena Pradenas, Universidad de Concepcion, Concepcion, Chile, lpradena@udec.cl

1 - The Impact of Product Variety on Subassembly Inventory and Strategic Assembly Sequencing

Jeonghan Ko, Ajou University, Suwon-si, Korea, Republic of, jeonghan@umich.edu

Jeonghan Ko, University of Michigan, Ann Arbor, MI, 48105, United States, jeonghan@umich.edu, Heng Kuang

This paper identifies the impact of product variety on the safety inventory of subassemblies in serial assembly processes when limited component commonality exists among products. We derive a measure to relate the levels of the product variety and safety inventory. We show that the measure can be used to optimally sequence assembly processes to reduce subassembly inventory levels. We extend the results as a prioritized sequencing principle for more generalized cases.

2 - Field Study of Supply Chain Management Practices of Small-and-medium Enterprise (SME) Retailers

Shardul Phadnis, Malaysia Institute for Supply Chain Innovation, 2A, Persiaran Tebar Layar, Seksyen U8, Shah Alam, 40150, Malaysia, sphadnis@misi.edu.my

This study describes the nature of supply chain management practices of small-and-medium enterprise (SME) retailers in an emerging market, based on a multi-method field study. Our findings suggest that constrained supply of key resources, specifically operating cash and management skills, influences the retailers' strategies for procuring the merchandise, warehousing and transporting the goods, and operating the retail stores. We contrast the observed practices with the best practices advocated in the literature, assess the suitability of both sets of practices to the operating environment, and provide normative guidelines for improving the performance of the supply chain practices.

4 - Big Data for Integrated Supply Chain Design

Gang Wang, Assistant Professor, University of Massachusetts Dartmouth, 285 Old Westport Rd, Room 214, North Dartmouth, MA, 02747, United States, gwang1@umassd.edu

This paper considers a big-data driven, integrated supply chain design, with the focus on efficient supply chain design analytics. The supply chain is three-echelon consisting of contracted suppliers, capacitated processing centers, and demand points. It first presents a methodology for identifying potential locations for the processing centers using sales data in ERP and GIS data. Then a mixed-integer linear programming model is to determine the optimal number of processing centers, along with efficient algorithm and computational testing.

3 - Recruitment Stocking Problems

Anh Tuan Ninh, William & Mary, 1604 Queens Crossing, Williamsburg, VA, 23185, United States, ninhtuananh@gmail.com

We explore a general class of inventory control problem - the recruitment stocking problem, which can be found in clinical trials, marketing research/new product launch, as well as inventory management for end-of-life-cycle products. Both exact and approximation methods to measure key performance metrics for the system will be presented.

6 - Prediction of Consumption of Materials with Artificial Neural Networks

Lorena Pradenas, Universidad de Concepcion, Casilla 160-C Correo 3, Concepcion, 4030000, Chile, lpradena@udec.cl, Camila Flores

This study focuses on the use neural networks to effectively predict the consumption of multiple materials and spare parts of a forestry company and compare the results obtained with those achieved through traditional methods. Today, company analysts must manually assign the forecasting model that best suits the behaviors of each of the more than 100,000 materials coded.. In addition to this, there are hardware limitations, which do not allow the analysis of information in a consolidated way to make global decisions. Clustering methods and unconventional forecasting models were used to obtain predictions with better performance.

Analytics and OR for Cloud Computing and Internet of Things (IoT)

Sponsored: Service Science

Sponsored Session

Chair: Aly Megahed, IBM Research - Almaden, San Jose, CA, 95123, United States, aly@gatech.edu

1 - A Stochastic Programming Approach for Cloud Elasticity

Aly Megahed, IBM.Research - Almaden, 150 Palm Valley Blvd Apt 2066, San Jose, CA, 95123, United States, aly.megahed@us.ibm.com, Mohamed Mohamed, Sameer Tata, Chelliah Sriskandarajah, Jon Stauffer

Vertical elasticity in cloud applications is the ability of increasing or decreasing computing resources to handle incoming queries. This is commonly achieved is via increasing or decreasing deployed application instances. Determining the optimal number of instances for a given horizon is challenging, because of the random number and type of incoming queries. There is also a trade-off between deploying too many instances (paying unnecessary deployment costs) and deploying too few of them (penalties for delaying query execution). We propose a stochastic programming method for this problem.

2 - Optimizing Metric Monitoring Frequencies in Resource-constrained IoT Applications

Jennifer A. Pazour, Assistant Professor, Rensselaer Polytechnic Institute, 110 8th street, CI I.5217, Troy, NY, 12180, United States, pazouj@rpi.edu, Aly Megahed, Ahmed Nazeem, Samir Tata, Mohamed Mohamed

We formulate a mixed integer program to determine the optimal monitoring start time and interval frequency for multiple metrics in resource constrained Internet of Things (IoT) environments. The optimization model is used for adaptive monitoring and resolved when triggered based on monitored values or environmental events. Given solution time is critical, application-specific solution approaches are developed and tested, including reformulation, valid inequalities, and column generation procedures.

3 - Stabilizing Consumer Electrical Demand

Ray Strong, IBM, San Jose, CA, United States, hrstrong@us.ibm.com, Ralphael Arar, Kevin Roche, Sandeep Gopisetty

We discuss managing and stabilizing power consumption in a smartly-connected private home or office using a controlled system of IoT devices. Each IoT device is closely associated with an electrical power consuming element, a set of circuit switches, a rechargeable battery, an independent source of power, or the local connection to a public electrical power utility. Stabilizing consumption will tend to produce a win for both consumer and utility.

Complex Multi-criteria Decision Making Problems II

Sponsored: Multiple Criteria Decision Making

Sponsored Session

Chair: Murat Mustafa Koksalan, Middle East Technical University, Ankara, 06531, Turkey, koksalan@metu.edu.tr

Co-Chair: Banu Lokman, Middle East Technical University, Ankara, 06800, Turkey, lbanu@metu.edu.tr

1 - Interactive Approaches for Bi-objective UAV Route Planning in Continuous Space

Hannan Tureci, Middle East Technical University, çi Blokları Mah. 1427.Cad. 1508.Sok., Ankara, Turkey, hannantureci@gmail.com, Murat Mustafa Koksalan, Diclehan Tezcaner Ozturk

In this study, we consider the route planning problem of unmanned air vehicles (UAVs). We use two objectives; minimizing total distance traveled and minimizing total radar detection threat. We consider routing in a 2-D continuous terrain, in which we have infinitely many efficient trajectories between target pairs. We develop interactive algorithms that find the most preferred solution of a route planner, who has either of the underlying preference function structures: linear or quasiconvex. To implement the algorithms to problems, we use approximated nondominated frontiers of the trajectories between targets. We demonstrate the interactive algorithms on illustrative examples.

2 - An Interactive Approach for Product and Process Design Parameter Optimization under Model Uncertainty

Melis Ozates, Middle East Technical University, Industrial Engineering Dept, Office Room 318, Ankara, 06800, Turkey, mozates@metu.edu.tr, Gulser Koksal, Murat Mustafa Koksalan

We develop an interactive approach for the two-response product and process design optimization problem, considering DM's preferences under model uncertainty. We involve the problem analyst (PA) in the searching procedure to help the DM converge to his/her preferred solutions quickly. The PA systematically searches the relevant solution space at each iteration by converting DM's verbal preferences into mathematical expressions.

3 - Real Time Bicriteria Route Planning for Unmanned Air Vehicles

Murat Mustafa Koksalan, Middle East Technical University, Industrial Engineering Department, Ankara, 06531, Turkey, koksalan@metu.edu.tr
Murat Mustafa Koksalan, Georgetown University, Washington DC, DC, United States, koksalan@metu.edu.tr, Diclehan Tezcaner Ozturk, Nail Karabay

Distance and threat minimization are important criteria in the route planning of unmanned air vehicles. In this study, we consider these criteria and acknowledge that the conditions keep changing during the trip. We develop an approach that keeps modifying the route in real time. We assume that the route planner has a linear value function of the two criteria which we know partially. We demonstrate the approach on several example problems.

4 - Using Bilevel Programming to Solve Multiobjective Optimization Problems

Serpil Sayin, Koc University, College of Admin Sciences and Economics, Rumeli Feneri Yolu Sariyer, Istanbul, 34450, Turkey, ssayin@ku.edu.tr, Gokhan Kirlik

We propose a bilevel programming formulation that is capable of delivering an efficient solution of a multiobjective optimization problem that maps into a given set, provided that one exits. If the Decision Maker's preferences are known a priori, they can be used to specify the given set. Alternatively, the bilevel program can be used to obtain a representation of the nondominated set. This requires a thorough search of the outcome space. While building a discrete representation, the algorithm also generates an approximation of the nondominated set within the specified error factor. We illustrate the approach on a multiobjective linear programming problem and discuss its strengths and weaknesses.

5 - Interactive Evolutionary Approaches to Multi-objective Feature Selection

Muberra Ozmen, University College London, Level 38, 1 Canada Square, London, E14 5AA, United Kingdom, muberra.ozmen.16@ucl.ac.uk, Gulsah Karakaya, Murat Mustafa Koksalan

In feature selection problems, the aim is to select a subset of features to characterize an output of interest. In characterizing an output, we may want to consider multiple objectives such as maximizing classification performance, minimizing number of selected features or cost, etc. We develop a preference-based approach for multi-objective feature selection problems. Finding all Pareto optimal subsets may turn out to be a computationally demanding problem and we still would need to select a solution. Therefore, we develop interactive evolutionary approaches that aim to converge to a subset that is highly preferred. We test our approaches on several instances and demonstrate they work well.

Innovative Technologies

Cluster: Analytics

Sponsored Session

1 - Crowd-Sourcing Analytics with Datasplash

Lorens Helmchen, George Washington University, Washington, DC, United States, helmchen@gwu.edu

We introduce Datasplash, a new web-based analytics application that allows anyone to load, explore, and share their data quickly, easily, and securely on any device anywhere — without downloading and installing software or learning a programming language. We show how even users with no analytics training can spot salient and significant associations, assess model fit, and compute predictions. We also show how Datasplash can be used to recognize and remedy more advanced model-fitting challenges, such as non-linearities, outliers, confounding, and collinearity. We illustrate these features by applying them to case studies from the hospitality and health care industries.

2 - Communicating with the New Machine: Human Insight at Machine Scale

Kris Hammond, Narrative Science, Chicago, IL, United States, khammond@narrativescience.com

In this talk, I will outline what we are with regard to data analytics and how the technology of automatic narrative generation from data plays the crucial role of bridging the gap between the Big Data world of numbers and symbols and our need for understandable insights. I will dive into use cases from business, education and everyday life to show how the power of automatically generated narratives can provide us all with the insights that are still trapped in the wealth of data we now control.

Daniel H. Wagner Prize Competition I

Invited: Daniel H. Wagner Prize Competition

Invited Session

Chair: Patricia Neri, SAS Institute, Inc., 104 Grandtree Ct., Cary, NC, 27519, United States, patricia.neri@sas.com

1 - The Inmate Assignment and Scheduling Problem and its Application in the PA Department of Corrections

Tamás Terlaky, Lehigh University, 200 W. Packer Ave, Bethlehem, PA, 18015, United States, terlaky@lehigh.edu, Mohammad Shahabsafa, Chaitanya Gudapati, Anshul Sharma, Louis J. Plebani, George R. Wilson, Kristofer B. Bucklen

The inmate assignment project, in close collaboration with the PA Dept. of Corrections, took five years from start to successful implementation. Our novel Inmate Assignment Decision Support System (IADSS) is designed with the main goal of simultaneously, and system-wide optimally, assigning the inmates to the correctional institutions. IADSS includes a new hierarchical multi-objective MILO model, which accurately describes the inmate assignment problem. This is the first time that OR methodologies have been used to optimize the operations, and built into the routine business practice, of a correctional system, thus it opens a rich and untouched area for the application of OR.

2 - Forecasting and Optimization Models for Audience Targeting on Television

Wes Chaar, Turner Broadcasting System, Inc., 106 N.Denton Tap Road, # 210-273, Coppell, TX, 75019-2148, United States, wscemail2002@yahoo.com, J. Antonio Carbajal, Peter Alexander Williams

At Turner, we have developed and implemented innovative, integrated forecasting and optimization models that forecast audiences in the 24/7 programming schedule, generate media plans across all Turner's networks, and schedule commercials holistically. These methods power Turner's audience targeting solutions: TargetingNOW and AudienceNOW, which have produced significant sales and advertisement efficiencies for Turner and its clients, and moved the industry forward in the emerging audience targeting landscape.

Health Care, Modeling and Optimization

Contributed Session

Chair: Danielle Ripsman, Waterloo Ontario, ON, Canada, daripsman@uwaterloo.ca

1 - Joint Optimization of Appointment and Real-time Schedule in the Presence of Walk-ins, Waiting Time Targets and No-shows

Xingwei Pan, Shanghai Jiao Tong University, No. 800 Dongchuan Road,Minhang District, Shanghai, 200240, China, 1103951776@sjtu.edu.cn

Clinics give the highest priority to appointed patients, incurring long waiting of walk-ins. To balance the waiting between the appointed and walk-ins, this paper jointly optimizes the appointment and real-time schedule by considering appointed patients' waiting time target (WTT) and no-shows. A finite horizon Markov Decision Process model is proposed to establish structural properties of the optimal control policy. Appointment schedule is gained by combining a stochastic programming model and local search. Numerical tests show the impact of WTT and efficiency of the approach. Key words: appointment; real-time schedule; waiting time target; Markov Decision Process; Stochastic Programming

2 - Policy Design for Online Scheduling with Heterogeneous Patients and Doctors

Shan Wang, Shanghai Jiao Tong University, 1954 Huashan Road, Shanghai, 200030, China, wangshan_731@sjtu.edu.cn, Huiqiao Su, Guohua Wan

How to design the patients scheduling policy for the heterogeneous patients and doctors is a problem in health care management. We study the process of outpatient clinic service in China and find there exit problems in outpatient scheduling. In this paper, we show how to model this problem as an online scheduling problem, and demonstrate how to solve this scheduling problem by applying the Markov Decision Process. We design the numerical experiments to compare the performances of our policy and two policies employed in practice by simulating various scenarios; the numerical results show that our policy has the best performance under all scenarios, especially when the system has a heavy workload.

3 - Nurse Scheduling with Shift Preferences using Goal Programming

Esra Agca Aktunc, Kadir Has University, Kadir Has Cd. Cibali, Istanbul, 34083, Turkey, esra.agca@khas.edu.tr, Elif Tekin

Fair workload and job satisfaction should be taken into account in nurse scheduling to improve the quality of healthcare. In this study, a monthly nurse scheduling model is developed based on labor regulations, hospital management requirements, and nurse preferences. A multi-objective integer program is formulated and solved as a goal programming model to avoid disproportional shift assignment, improve job satisfaction of nurses, and reduce medical errors caused by fatigue. Resulting schedules for various shift preference scenarios are compared to show the improvement in the schedule quality in terms of performance measures such as distribution of preference violations among nurses.

4 - A Polynomial-time Approximation Scheme for Sequential Batch-testing of Series Systems

Yaron Shaposhnik, Assistant professor, University of Rochester, Simon Business School, CS.H.3-343, 500 Joseph C. Wilson Blvd., Rochester, NY, 14627, United States, yaron.shaposhnik@simon.rochester.edu, Danny Segev

We study a recently-introduced generalization of the classic sequential testing problem for series systems, consisting of multiple stochastic components. The conventional assumption in such settings is that the overall system state can be expressed as a boolean function, defined with respect to the states of individual components. However, unlike the classic setting, rather than testing components separately, we allow aggregating multiple tests to be conducted simultaneously, while incurring an additional set-up cost. We devise a PTAS for the sequential batch testing problem, thereby significantly improving on the constant-factor approximation of 6.829+eps due to Daldal et al.

5 - Personalized Fatigue-aware Scheduling of Physical Activity using Stochastic Programming

Alla Kammerdiner, New Mexico State University, 7474 Sierra Luz Dr, Las Cruces, NM, 88012, United States, alla@nmsu.edu

Sedentary people benefit from physical activity. Yet, overexertion from an activity induces fatigue, which can discourage the following physical activity and long-term adherence to exercise. In this study, we develop and formulate new stochastic programming problems for scheduling bouts of physical activity in sedentary people to maximize its health benefit while limiting overexertion. The models are formulated to maximize the time or amount of activity while constraining the chance of exercising past fatigue onset, which could have a negative impact on adhering to exercise. We present the solution algorithms and illustrate the application of the developed optimization problems on real data.

Additive Manufacturing – Data Analytics and OR I

Invited: Invited OR and Advanced Manufacturing

Invited Session

Chair: Alaa El Wany, Texas A&M University, TAMU, College Station, TX, 77843, United States, elwany@tamu.edu

1 - Characterizing the Geometric Accuracy of Additively Manufactured Components

Mojtaba Khanzadeh, PhD Student, Mississippi State University, McCain Engineering, Starkville, MS, 39759, United States, mk1349@msstate.edu, Linkan Bian, Prahalada Rao

The objective of this work is to quantify the geometric deviations of additively manufactured parts from a large dataset of laser-scanned coordinates using a type of neural network called self-organizing map (SOM). The central hypothesis is that clusters recognized by the SOM correspond to specific types of geometric deviations, which in turn are linked to certain additive manufacturing process conditions. This hypothesis is tested on parts made using the Fused Filament Fabrication AM process. This is an important research; although AM processes can make parts with complex geometries, a major barrier preventing use of AM in mission-critical applications, is the lack of geometric accuracy of parts.

2 - Forward Uncertainty Quantification Analysis via Polynomial Chaos Expansion of an Additive Manufacturing Selective Laser Melting Thermal Model

Alaa Elwany, Texas A&M.University, College Station, TX, 77843, United States, elwany@tamu.edu, Gustavo Tapia

Thermal models of Additive Manufacturing SLM processes help gain understanding by calculating thermal histories that the material undergoes given a combination of processing parameters, and can be employed in quality assessment of the build by melt pool characterization. Nevertheless, these models normally depend in many physical inputs whose values might vary according a probability distribution. This study presents a Forward UQ approach using PCE to quantify the variation in the outputs of the model given those of the inputs. The analysis benefits users to identify specific parameters and decide if more control over them should be applied if variations of melt pool dimensions are excessive.

3 - The Impact of 3D Printing on Manufacturer Retailer Relations

Mohammad Ebrahim Arbabian, PhD Student, University of Washington, 4120 Brooklyn Ave NE unit 503, #503, Seattle, WA, 98105, United States, me.arbabian@gmail.com, Michael R.Wagner

We consider the impact of 3D printing, or additive manufacturing, on a supply chain, consisting of a manufacturer and retailer, where either the manufacturer or retailer can adopt 3D printing. The firms utilize a wholesale-price contract and serve stochastic customer demand. We also study government subsidies of the 3D printer cost.

4 - Multiple-Objective Optimization of Additive Manufacturing Processes

Linkan Bian, Mississippi State University, Industrial and Systems Engineering Department, P.O. Box 9542, Mississippi State University, MS, 39762, United States, bian@ise.msstate.edu

We propose a novel approach for improving geometry accuracy of Additive Manufacturing parts in a systematic manner. Initial experimental data show that different geometric characteristics of part may not be possible to optimize simultaneously. The developed method targeted minimizing deviations within parts major Geometric Dimensioning and Tolerancing characteristics. Efficiency of proposed method is validated using simulation studies coupled with a real world case study for geometry accuracy optimization of parts fabricated by the Fused Filament Fabrication system. The results show that optimal designs are achieved by fewer numbers of experiments compared with existing methods.

Humanitarian and Developing Country Operations

Sponsored: Public Sector OR

Sponsored Session

Chair: Jon M. Stauffer, Texas A&M University, College Station, TX, 77843, United States, jstauffer@mays.tamu.edu

1 - The Impact of Crop Minimum-support-prices on Farmers' Sowing Decisions and Product Availability

Prashant Chintapalli, UCLA Anderson School of Management, Los Angeles, CA, 90095, United States, prashant.chintapalli.1@anderson.ucla.edu, Christopher S. Tang

We analyze the impact of crop minimum-support-price (MSP) program on the sowing decisions of farmers in emerging markets. We consider the case of 2 crops and when farmers have heterogeneous production costs. We assume that a fraction of farmers are strategic. We show that though the number of strategic farmers growing a crop can reduce with an increase in the crop's MSP, the total availability of the crop is always increasing. Due to this, improper execution of MSP can hurt the society. While the returns of farmers can be negatively affected, bad MSPs can skew product availability.

2 - Mobile Money Agent Inventory Management

Karthik Balasubramanian, Harvard Business School, Boston, MA, United States, kbalasubramanian@hbs.edu, David F. Drake, Douglas Fearing

Mobile money agents exchange cash for electronic value and vice versa, forming the backbone of an emerging electronic currency ecosystem in the developing world. We model the agent's inventory problem, develop policy recommendations, and evaluate these policies with East African data.

3 - Global Vehicle Supply Chains in Humanitarian Operations: A Network Analysis Approach

Jon M. Stauffer, Texas A&M.University, 4217 TAMU, College Station, TX, 77843, United States, jstauffer@mays.tamu.edu, Alfonso J.Pedraza-Martinez, Lu Yan, Luk N. Van Wassenhove

Using 4WD vehicle supply chains, we test the common assumption that development program supply is independent of disaster supply in humanitarian operations. We utilize Exponential Random Graph Models to empirically test hypotheses and then use simulations to study the impact of the empirical results. We find that development program supply decreases due to disaster supply, which increases the preference for centralized supply chains.

4 - Operational Drivers of Stock-outs in Reproductive Health Care Supply Chains: An Empirical Study

Amir Karimi, University of Minnesota Twin Cities, Minneapolis, MN, 55455, United States, karim100@umn.edu, Karthik Natarajan, Kingshuk K. Sinha

Despite the widespread prevalence of contraceptive stock-outs in practice, very little is known about the drivers of stock-outs and this forms the motivating context for our study. Utilizing data from service delivery points in developing countries, we investigate the relationship between the stock-outs of contraceptive products and factors such as product variety, inventory management practices, and a facility's geographic location. This study sheds light on the operational drivers of stock-outs in global humanitarian health delivery settings, thereby highlighting the potential mitigation mechanisms that can be leveraged by facilities to minimize the likelihood of stock-outs.

Marketing

Contributed Session

Chair: Jacob Do-Hyung Cha, Seoul National University, Gwanak-gu, United States, research.dohyung@gmail.com

1 - Subscription Selling: the Role of Consumer Valuation Uncertainty and Competition

Qiaohai (Joice) Hu, University of Missouri-St. Louis, St Louis, MO, United States, joice.hu@gmail.com, Yimin Yu, Xiaobei Shen

As subscription becomes increasingly popular, it is important to understand when it is more profitable than traditional selling. The literature offers the following explanation: subscription benefits firms because it enables them to price-discriminate among heterogeneous consumers. This study reveals two new drivers of subscription: an intertemporal pooling effect in the presence of consumer valuation uncertainty and a competition softening effect.

2 - The Evil Necessity: the Role of Surge Pricing in Sharing Economy

Xinying Hao, PhD Student, The University of Texas at Austin, 3500 Greystone Dr., # 262, Austin, TX, 78731, United States, xinying.hao@mccombs.utexas.edu

Using prices as signals to equilibrate supply and demand, Uber's surge pricing fits economics theory perfectly. Yet, surge pricing still faces popular and harsh criticism. In this paper, we examine the consumer's skepticism and psychological resistance to this mandatory charge. We propose a reference price model to empirically investigate how surge pricing (in price and time dimensions) can affect consumers' behavior. We aim to provide implications for platforms in sharing economy via three natural experiments: (1) No surge pricing. (2) Optional surge pricing, which would allow riders to opt-in to surges and be expedited to the front of the queue at a premium cost. (3) Mandatory surge pricing.

3 - Characterizing Customer Choice from Sales Transaction Data for Introducing Niche Products

Elham Nosratmirshekarlou, Wayne State University, 2200 Fuller Ct, Apt 809B, Ann Arbor, MI, 48105, United States, fo7573@wayne.edu, Ratna Chinnam, Evrim Dalikran, Satyendra Rana

We exploit promising non-parametric customer choice modeling methods to identify major customer segments and subsequently rely on parametric models for identifying demand for promising niche products within segments.

4 - When Marketing Strategy Meets Capital Markets: Marketing Spending and Market Feedback from Securities Analysts

Jacob Do-Hyung Cha, Seoul National University, Room 313, 58-dong, Seoul National University, Gwanak-gu, 150-742, Korea, Republic of, research.dohyung@gmail.com, Hye-Jin Cho

This study examines the role of securities analysts in the context of marketing intensity, a largely neglected issue in the extant literature. The results of a large-scale, cross-industry research suggest that capital markets' feedback - proxied by the earnings forecasts of financial analysts - leads to reduce marketing intensity. We propose that top managers tend to cut marketing spending when they are under pressure to meet analysts' performance targets. We further argue that analyst coverage can serve as an external monitoring mechanism to help contain this agency problem. We test these hypotheses with data from a sample of U.S. manufacturing firms during the period of 1979 to 2014.

WORMS: Female Professional Development

Sponsored: Women in OR, MS

Sponsored Session

Chair: Dorothee Honhon, University of Texas at Dallas, Richardson, TX, 75080, United States, dorothee.honhon@utdallas.edu

1 - Worms Panel Session on Professional Development for Women in OR/MS

Dorothee Honhon, University of Texas at Dallas, 800 West Campbell Road, SM30, Richardson, TX, 75080, United States, dorothee.honhon@utdallas.edu

In this panel session, successful male and female academics will discuss the topic of professional development for women in the OR/MS world. In particular they will address questions such as how women can make themselves heard in meetings, how to negotiate and apply for promotion, how to select the best service jobs and decline excessive requests, how to dress to succeed, etc. Panelists will also discuss what steps can be taken to make the OR/MS academic field more women-friendly and fair. Bring a male colleague along to attend the session and both of you get a free WORMS coffee mug!

2 - Panelist

Scheduling VII

Invited: Project Management and Scheduling

Invited Session

Chair: Alessandro Agnetis, Universita Di Siena, Siena, 53100, Italy, agnetis@dii.unisi.it

Co-Chair: Federico Della Croce, Politecnico di Torino, Torino, 10129, Italy, federico.dellacroce@polito.it

1 - Exact Algorithms for the Equitable Traveling Salesman Problem

Frits C.r. Spieksma, Catholic University of Leuven, Brussels, Belgium, frits.spieksma@kuleuven.be

Given a weighted graph G = (V, E) , the Equitable Traveling Salesman Problem (ETSP) asks for two perfect matchings in G such that (1) the two matchings together form a Hamiltonian cycle in G and (2) the absolute difference in costs between the two matchings is minimized. The problem is shown to be NP-Hard, even when the graph G is complete. We present two integer programming models to solve the ETSP problem and compare the strength of these formulations. One model is solved through branch-and-cut, whereas the other model is solved through a branch-and-price framework. We conduct computational experiments on different types of instances, often derived from the TSPLib, and we report our findings.

2 - Scheduling with Variable Time-of-use Costs

Bo Chen, University of Warwick, Coventry, United Kingdom, Bo.Chen@wbs.ac.uk

We address a class of problems of scheduling a set of independent jobs onto a single machine that charges each job for its processing under variable time-of-use (ToU) tariffs. We consider a range of regular scheduling criteria as constraints with the objective of minimizing the total ToU cost. For each of the problems in the class, we establish its computational tractability. For those tractable we provide an efficient algorithm, while for those intractable we provide a pseudo-polynomial-time algorithm or a polynomial-time approximation scheme.

3 - LPT Rule for Identical Parallel Machines Revisited

Federico Della Croce, Politecnico di Torino, Corso Duca degli Abruzzi 24, Torino, 10129, Italy, federico.dellacroce@polito.it, Rosario Scatamacchia

Consider the well known LPT rule for scheduling jobs on identical parallel machines. It requires to sort the jobs in non-ascending order and then to assign one job at a time to the machine whose load is smallest so far. We consider an alternative approach that splits the sorted jobset in tuples of m consecutive jobs (1,...,m - m+1,...,2m etc.) and sorts the tuples in nonincreasing order of the difference (slack) between the largest job and the smallest job of the tuple. Then a list scheduling is applied to the set of sorted tuples. This approach strongly outperforms LPT on benchmark literature instances. The approximation ratio of a procedure combining LPT and the proposed approach is also discussed.

4 - The Price of Fairness in a Two-agent Single-machine Scheduling Problem

Alessandro Agnetis, Universita Di Siena, Dipartimento Ingegneria, Dell'Informazione Universita Di Siena, Siena, 53100, Italy, agnetis@dii.unisi.it

In this talk we investigate the concept of price of fairness applied to scheduling problems. We consider two agents (players), each having a set of jobs to perform, that compete for using a single machine. We investigate the situation in which one agent aims at minimizing total completion time of his/her jobs, while the other is concerned with minimizing tardiness with respect to a common due date. We propose a definition of utility and discuss both max-min and proportionally fair solutions, giving bounds on the price of fairness.

Mobile Commerce, Apps, and Services

Sponsored: EBusiness

Sponsored Session

Chair: Keum Seok Kang, PhD, Florida International University, Miami, FL, 33199, United States, kskang@fiu.edu

1 - A Net Diffusion Model of Mobile Application: Considering Self-referencing, with in-category Dependency, and Drop-out Process

Youngsok Bang, Chinese University of Hong Kong, bangyoungsok@baf.cuhk.edu.hk, Dong-Joo Lee, Kunsoo Han, Sang Won Kim

Modeling the diffusion of mobile apps is practically important, as the mobile app market has become a significant economy. Furthermore, the diffusion process of mobile application has several distinctive features, which makes the modeling work theoretically meaningful. Considering distinctive features of mobile app diffusion—assimilation gap, self-referencing, and within-category dependency—, we develop a flexible diffusion model of mobile apps. Using the large-scale data, we evaluate the model fit of competing models across multiple apps. The analysis results suggest the appropriate diffusion model for a specific app type.

2 - Consumer Search, Producer Entry, and Product Variety: Theory and Evidence from a Digital Product Market

Michael (Zhan) Shi, Arizona State University, Tempe, AZ, United States, zmshi@asu.edu, Raghu Santanam, Zhongju (John) Zhang

Many digital goods markets are characterized by large product space, functionality and design heterogeneity, and low cost of entry for producers. We examine the influence of incumbent digital products distribution on consumer search, entry of new products into different niche locations and market performance. The producers in the market strategically choose to enter different niche locations according to their capability. We analyze the entry pattern and sales distribution that emerge endogenously as part of the equilibrium market structure, and how product variety changes the equilibrium.

3 - A Dynamic Location Based Advertisement Delivery Problem

Keumseok Kang, Assistant Professor, Florida International University, 11200 S.W. 8th Street, Miami, FL, 33199, United States, kskang@fiu.edu

Location Based Advertisement (LBA) enables physical stores to attract customers more effectively than ever by sending location-aware advertisements through customers' mobile devices. In spite of increasing attention in practice, LBA has attracted little attention in the literature. We study a dynamic advertisement delivery problem in a push-based LBA from the perspective of an intermediary advertiser that is sending advertisements to prospective customers on behalf of stores.

4 - Exploring Mobile Technologies in the Hospitality Industry: The Antecedents and Differential Impacts of using Mobile Devices on Hotel Employees' Outcomes

Minwoo Lee, Assistant Professor, Conrad N. Hilton College of Hotel & Restaurant Management, University of Houston, Houston, TX, United States, mlee37@Central.uh.edu

This study attempts to identify smart-computing functions of Smartphone use at the workplace and to examine the impact of using smart-computing functions on employees' managerial roles and overall performance improvement in the hospitality industry. Findings of this study indicate that user's Smartphone dependence and perceived critical mass lead to using smart-computing functions. Using smart-computing functions is positively associated with Mintzberg's three managerial role performance, resulting in overall performance improvement. Discussions and suggestions for future research are provided.

5 - Air Matters: the Impact of Searching Air Quality Information

Sang Pil Han, Arizona State University, BA 301D, Tempe, AZ, 85287, United States, sangpil.han@asu.edu, Ki-Kwang Lee, Youngki Park, Hyuncheol Kim

More than 90% of the world's population lives in areas where air pollution exceeds safety thresholds, according to the World Health Organization. We investigate whether meaningful use of information technologies can help individuals mitigate the risk of environmental hazards such as air pollution by having immediate access to information about ambient air quality. We find that information search for air quality index such as Particulate Matter 10 (PM 10) is most helpful to individuals when the air quality condition is not evident to naked eyes without checking the exact PM10 level online.

Managerial Judgment and Decisions

Sponsored: Behavioral Operations Management

Sponsored Session

Chair: Brent Moritz, Penn State University, University Park, PA, 16802, United States, bmoritz@psu.edu

1 - How To Benefit from Supplier-retailer Negotiations: An Example of the Buyback Contract

Michael Becker-Peth, RSM.- Rotterdam School of Management, AlbertuBurgemeester Oudlaan 50s-Magnus-Platz, Erasmus University Rotterdam, Rotterdam, 3062, Netherlands, michael.becker-peth@uni-koeln.de, Elena Katok, Ulrich Thonemann

A standard way to test newsvendor contracts in the lab is to have the supplier propose a contract and the retailer place an order to maximize the expected profit. We show that when this process is used with human decision makers, coordinating contracts do no emerge. Human retailers place sub-optimal order quantities and exhibit inequity averse behavior, i.e., reject unfair offers. We show that allowing the player to negotiate can improve the profits of both players when negotiation is successful, especially when parties negotiate over the order quantity in addition to the contract parameters.

2 - Integrating Managerial Insight and Optimal Algorithms

Blair Flicker, University of Texas-Dallas, 800 W. Campbell Road, Mailstop AD23, Richardson, TX, 75208, United States, bflicker@utdallas.edu

A nearly universal finding in behavioral operations management is that human decision-makers suffer from biases that erode firm profits. But humans can gather information that is not available to standard optimization routines (macroeconomic developments, local trends, consumer sentiment). If humans have superior information, their decisions might actually be "superoptimal." Human newsvendors endowed with superior demand information fail to improve profitability when placing orders directly due to poor decision-making. However, a novel approach to automatically convert subjects' demand forecasts into insight-informed order quantities does substantially improve profitability.

3 - Judgment Forecasting for Multiple Demand Sources

John Aloysius, University of Arkansas, Supply Chain Management Department, Wcob 204, Fayetteville, AR, 72701, United States, aloysius@uark.edu, Marat Davletshin, Siqi Ma, Enno Siemsen

Managers often forecast demand for different distribution channels (e.g., online vs in-store), geographical regions, and store formats. There may be different systematic variation between these different demand sources (e.g., growing online demand and shrinking in-store demand). We experimentally study characteristics of situations where aggregated forecasting is advantageous over disaggregated forecasting.

4 - Impact of Capacity and Fixed Costs on Routine Sourcing Decisions under Demand and Supply Uncertainty: An Experimental Investigation

Arunachalam Narayanan, University of Houston, Dept of Decision and Information Sciences, Mail Stop 6021, University of Houston, Houston, TX, 77204, United States, anarayanan@bauer.uh.edu, Nickolas K. Freeman, Brent Moritz

We consider a procurement manager who sources raw materials from two suppliers. One of the supplier is perfectly reliable and expensive, while the other is cheaper but unreliable, failing to deliver with some positive probability. The buying firm has limited capacity to process the order and may be subjected to a fixed costs, like labor and utilities, regardless of whether they produce or not in that period. We first show theoretically that the capacity is an influencing factor when making sourcing decisions, forcing the manager to choose a more reliable supplier, while the sunk cost has no effect on these decisions. We evaluate these theoretical findings in an experimental setting.

Behavioural OR in Healthcare

Invited: InvitedBehavioral Aspects of OR

Invited Session

Chair: Sally C. Brailsford, University of Southampton, Southampton, S017 1BJ, United Kingdom, s.c.brailsford@soton.ac.uk

Co-Chair: Paul Harper, Cardiff University, United Kingdom, harper@cardiff.ac.uk

1 - Overdiagnosis Risk in Breast Cancer Screening: Incorporating Adherence Behavior and Racial Disparity

Mahboubeh Madadi, Assistant Professor, Louisiana Tech University, Ruston, LA, United States, madadi@latech.edu, Wesley Wilkes

Although known to be the primary method for early detection of breast cancer, mammography screening exposes patients to the risk of overdiagnosis, which is defined as the detection and subsequent treatment of a breast cancer that would not present clinically in a patient's lifetime. In this study, we develop a Markovian model to estimate the risk of overdiagnosis under various screening policies while incorporating patient's adherence behavior. We also provide personalized estimations for overdiagnosis risk taking into consideration different factors such as racial disparity in cancer incidence and progression as well as patient's age.

2 - Operating Theatres Scheduling Optimization by Integrating Efficiency with Patients Satisfaction

Xue Yang, Xi'an Jiaotong University, Xi'an, China, yxueyx@outlook.com, Wentian Cui, Zhen Shang, Yang Wang, Yang Zhang

We building a mixed integer programming model for the operating theatres scheduling problem in a specialized hospital in China. In this model, we use a multinomial logit choice model to characterize patients satisfaction. The efficiency of operating theatres is measured by the linear combination of the number of finished surgeries and overtime. From extensive experimental analysis, we find interesting phenomena and propose valuable suggestions to healthcare managers.

3 - Are Patients Rational Decision-makers?

Sally C.Brailsford, University of Southampton, School of Management, Southampton, S017 1BJ, United Kingdom, s.c.brailsford@soton.ac.uk

In traditional OR models, it is typically assumed that there is a single, rational decision-maker, or a group of rational decision-makers who seek a compromise solution in the absence of a solution that is optimal for all. For example, health economists seek to maximize quality adjusted life years, and public health physicians (and insurance companies) take a population-level perspective. But how does the individual patient, or their family, take decisions regarding their own health? Are patients always rational, and if not, how can we model their behavior?

Modeling and Analysis of Emerging Mobility Services III

Sponsored: TSL, Urban Transportation

Sponsored Session

Chair: Yang Liu, National University of Singapore, Singapore, 117576, Singapore, iseliuy@nus.edu.sg

Co-Chair: Yu Nie, Northwestern University, Evanston, IL, 60208, United States, y-nie@northwestern.edu

1 - Multi-cycle Optimal Taxi Routing with E-hailing

Xinlian Yu, University of Massachusetts Amherst, 130 Natural Resources Road, Amherst, MA, 01003, United States, xinlianyu@umass.edu, Song Gao, Hyoshin (John) Park, Xianbiao Hu

An optimal taxi routing problem is investigated for a single taxi that accounts for multiple cycles of pick-up and drop-off into the future. Practical implementations are proposed to solve the multi-cycle optimal taxi routing problem in a reasonable time. The solution will be compared with observed searching behaviors from GPS trajectories in a mega city to demonstrate the advantage of the multi-cycle approach.

2 - Equilibrium and Ridesharing Payment Policies for Heterogeneous Dynamic Ridesharing Travelers in Morning Commute

Rui Ma, University of California, Davis, 2041 Academic Surge, University of California, One Shields Avenue, Davis, CA, 95616, United States, drma@ucdavis.edu, Michael Zhang

We formulate a dynamic ridesharing problem for a single bottleneck in morning commute. Travelers' choices of departure-time and ridesharing modes as groups with heterogeneous values of travel time are captured at the dynamic equilibrium. An equivalent differential complementarity system is then established and solved numerically. Dynamic parking pricing strategies to achieve the system optimum at the free-flowing condition are discussed. The results suggest that the ridesharing payment policies should be properly designed to achieve the social, economic and environmental goals.

3 - Recognizing Taxi Driver Search Strategies using Sparse Subspace Clustering

Kenan Zhang, Northwestern University, Evanston, IL, United States, KenanZhang2020@u.northwestern.edu, Yu Nie

The rapid expansion of Transportation Network Companies (TNC) has revived the interest in understanding the search behaviors of traditional taxi drivers. Using a taxi GPS trajectory dataset collected in Shenzhen, China, this study explores taxi drivers' search strategies in the urban area. Customer search behaviors are represented by features including searching distance and the characteristics of origin and destinations. A sparse subspace clustering (SSC) model is applied to classify taxi driver search strategies into major groups. Compared to conventional clustering algorithms (e.g. K-means), SSC better addresses the issue of nonlinear and high-dimensional nature of human behavior.

4 - Equilibrium Analysis of Urban Road Networks with Ride-sourcing Services

Zhengtian Xu, University of Michigan, Ann Arbor, MI, 48105-2540, United States, xzt@umich.edu, Yafeng Yin

The surge of ride-sourcing services in recent years has reshaped travelers' mode choices for intra-city trips. As outcomes of the interactions between service operators and travelers, a substantial portion of vehicular trips in ride-sourcing services are spent searching and meeting travelers other than fulfilling their requested orders. These accessory trips, however, are missing ingredients in the current network equilibrium analysis methodology. Therefore, this study aims to propose a new model that describes the mixed equilibrium between the occupied vehicular trips that directly serve passenger demands and the accessory trips made by vacant ride-sourcing vehicles.

5 - Identifying Malevolent Users in Free-floating Bike Sharing Systems

Aritra Pal, USF, 2210 Fitness Club Way, Apt 202, Tampa, FL, 33612, United States, aritra1@mail.usf.edu, Yu Zhang

The purpose of this study is to extract and identify users who are deliberately mishandling or damaging bikes in a (free-floating) bike sharing system based on its historical data. We propose a four step method to solve this problem and illustrate its usage with "Share-A-Bull Bikes" free-floating bike sharing system as our case study.

Sponsored Session

Chair: Zhe Zhang, University of Texas at Dallas, jameszhangzhe@utdallas.edu

1 - Towards Better Social Advertising

Shaojie Tang, UT Dallas, Richardson, TX, United States, sxt146930@utdallas.edu

Social advertising has the potential to general a significant cascade of adoption through influence in the online social networks. The goal of this work is to optimize the ad allocation such that the expected cascade can be maximized.

2 - Equilibrium Distribution of Mobile App Quality and Privacy

Jiali Zhou, Hong Kong University of Science and Technology, Hong Kong, Hong Kong, zhoujiali90@163.com, Kai Lung Hui

Mobile APPs bring consumers great convenience but raise privacy concerns because of the collection and use of customer data. We examine the equilibrium distribution of mobile APP quality and data requests. Consumers have heterogeneous preferences for APP quality and privacy. APP developers strategically choose quality and data requests to maximize profits. Our theoretical analysis suggests that the equilibrium data requests and hence consumer privacy follow a power law distribution. APP quality decreases monotonically, with high quality APPs requesting more personal data but also earning more market share. Preliminary empirical evidence from leading APP platforms support our analysis.

3 - Organizing for Disaster Management Across Many Districts
Barrie Nault, University of Calgary, Calgary, AB, Canada, nault@ucalgary.ca, Hong Guo, Yipeng Liu

We examine districts' choice of whether to centralize in a setting with more than two districts. Districts face interoperability challenges and convex costs in deciding their investment in disaster management assets, where these assets can be shared across districts. We derive conditions for cost sharing that maximize social welfare where some, but not all, districts decide to centralize.

4 - Devising Management Response Strategies in a Competitive Market
Mingwen Yang, The University of Texas at Dallas, Richardson, TX, 75080, United States, mxy131030@utdallas.edu, Vijay Mookerjee, Eric Zheng, Hongyu Chen

We address a practical question of when a firm should respond to customer reviews in a competitive market, where consumers' purchasing decisions are influenced by the reviews of the focal and the competing firms. Factoring in competition is essential for a firm to derive an optimal response strategy to effectively manage online WOM and subsequently influence sales. Our study extends the literature by 1) designing an optimal response strategy to online reviews, 2) prescribing the relationship between firm response and sales and 3) considering competition. We develop a Stochastic Differential Equation (SDE) model that captures the data generating processes and estimate the model using real data.

Energy

Contributed Session

Chair: Adam Ng, National University of Singapore, Singapore, isentsa@nus.edu.sg

1 - Welfare Effects of Pricing Schemes for Non-Convex Markets
Jacob Mays, Northwestern University, 2145 Sheridan Road, Room C230, Evanston, IL, 60208, United States, jacob.mays@u.northwestern.edu

A major goal of competitive electricity markets is encouraging optimal investment in generation capacity, demand response capabilities, and energy efficiency measures. For market-integrated buyers and sellers, these investments are guided by prices announced by system operators. However, the usefulness of these prices has been called into question due to the proliferation of zero-marginal-cost wind and solar resources, the influence of out-of-market supports, and the presence of non-convex technical constraints. This work investigates the influence of price formation decisions on welfare in electricity markets.

2 - Robust Design of Energy Consumption Subsidies Reform
Hossein Mirzapour, University of Montreal (HEC School of Business), 920-6275 Northcrest, Montreal, QC, H3S.2N3, Canada, hossein.mirzapour@hec.ca, Amir Ardestani-Jaafari

To raise the necessary public support for any energy subsidies reform, a prevalent recommendation is to redistribute its revenue among the most affected households/industries. However, the main challenge to design an effective redistribution mechanism is how to reach those needy entities, particularly in the presence of some uncertain side-effects such as the price inflation of non-energy goods. We study the problem of a social planner. The goal is to minimize the gap between the local subsidized price and its international level, while expecting a minimum purchasing power for the most affected entities. We show the value of a flexible distribution mechanism in such reforms.

3 - Energy and Reserve Co-optimization – Reserve Availability, Lost Opportunity and Uplift Compensation Cost
Ivan Pavic, Research Associate, University of Zagreb, Faculty of Electrical Engineering and Computing, Unska 3, Zagreb, 10000, Croatia, ivan.pavic@fer.hr, Hrvoje Pandzic, Yury Dvorkin

In a deregulated power systems, energy and reserve are often co-optimized to decrease costs payed by end-users. Generating companies can still encounter monetary losses caused by the provision of reserve. Currently, compensation of these losses is based on ex-post calculations which do not adequately factor real costs and create distortions in market prices. Proposed algorithm run energy and reserve co-optimization with an explicit consideration of two compensation mechanisms, i.e. lost opportunity and uplift payments. The problem is structured as a bi-level and converted to single level using strong duality equation. The case study shows that the proposed model increases market efficiency.

4 - A Computable General Equilibrium Model for Power Interruption Contracts
Lakshmi Palaparambil Dinesh, University of Cincinnati, 601 McAlpin Avenue, Apt 5, Cincinnati, OH, 45220-1539, United States, lakshmi603@gmail.com, Dr. Kenneth Skinner, Dr. Uday Rao

Energy demand response programs change the energy consumption behavior of consumers with changes in price and demand. Our supply demand integrated cost minimization model shows that demand response lowers overall costs for suppliers and promotes energy savings for customers. In addition to the cost savings for the supplier, we also look at the societal welfare using a Computable General Equilibrium (CGE) model that will aid the energy policy regulators. This model helps to understand the generation costs and activity levels at equilibrium, the tax rates needed to float demand response and the amount of capital that can be saved by demand response.

5 - Energy-economic Recovery Resilience with Input-output Linear Programming Models
Adam Ng, National University of Singapore, 10 Kent Ridge Crescent, Singapore, 119260, Singapore, isentsa@nus.edu.sg, Peijun He, Bin Su

We develop a novel input-output linear programming model to study the energy-economic resilience of an economy by analyzing the relationships between energy disruption, impacts on production and demands, and post-disruption recovery efforts. The model evaluates the minimum level of recovery investments required to restore production levels so that economic impacts are acceptable over the post-disruption duration. The optimization model is solved using a cutting plane method which involves computing a small sequence of mixed integer programs. A case study using China input-output data is performed to demonstrate the model's ability to uncover critical inter-sectoral dependencies.

Advancements in Detecting and Modeling Traffic Flow

Sponsored: TSL, Intelligent Transportation Systems (ITS)

Sponsored Session

Chair: Wei-Hua Lin, University of Arizona, Tucson, AZ, 100190, United States, whlin@email.arizona.edu

1 - Transportation Network Traffic Detector Error Estimation
Han Yang, UCDavis, 1 Shield Ave, Davis, CA, 95616, United States, cnhyang@ucdavis.edu, Yudi Yang, Yueyue Fan

One of the main challenges regarding traffic sensor data is how to assess its quality, as empirical works have shown inconsistency from a large portion of road sensors even they are not labelled as "broken" by major traffic data providers. This paper aims to address the problem of identifying the malfunctioned sensors and correcting systematic error using a network modelling based statistical approach. The measurement error is defined conditionally on the true flow which is unobservable. Network flow balance is assumed to be preserved among traffic flows. We provide two different estimators based on moment matching and maximum likelihood respectively to estimate the systematic error ratio.

2 - Multi-class Support Vector Machines Based Traffic Pattern Detection
Sayyid Vaqar, King Fahd University of Petroleum and Minerals, P.O. Box 983, Dhahran, 312600, Saudi Arabia, savaqar@kfupm.edu.sa

The traffic jam detection problem is formulated as a pattern recognition problem with scarce data utilizing Principal Component Analysis and Multiclass Support Vector Machines. The collected data is viewed as a snapshot of traffic flow condition on the road. For each time step this data will provide snapshots of driving conditions for the node of interest. With proper analysis these snapshots can be used in predicting traffic jam conditions on the freeways.The model is tested under assumption of different levels of vehicles equipped with Mobile Ad hoc network communication capability. The trained MSVMs are then used to predict traffic conditions for unlabeled test data.

3 - A Generalized Theory of Mixed Traffic Flow Based on Behavioral Assumptions
Jia Li, Research Associate, University of Texas at Austin, 7630 Wood Hollow Dr, Apt 251, Austin, TX, 78731, United States, lijia.ust@gmail.com

This research proposes a generalized theory of mixed traffic flow. Most existing mixed traffic flow models are descriptive in nature and lack sound behavioral interpretations. Towards filling this gap, a theory is developed from natural behavioral assumptions and explicitly addresses factors such as lane and information access. The stationary and dynamic behaviors of mixed traffic flow in several application scenarios, including mixed connected/automated and regular traffic, will be discussed.

4 - Traffic Equilibrium in a System with Interactions Between Drivers and Traffic Control

Wei-Hua Lin, Associate Professor, University of Arizona, Systems and Industrial Engineering, Tucson, AZ, 85721, United States, whlin@email.arizona.edu

We will assess how traffic pattern would change in response to a traffic control system in which the interaction between traffic control and individual drivers is made possible. Both short-term and long-term effects will be evaluated. Properties associated with the traffic equilibrium resulting from the interaction will be examined.

Application of Geospatial and IoT Data in Agriculture

Invited: Agricultural Analytics

Invited Session

Chair: Siyuan Lu, IBM, IBM, Yorktown Heights, NY, 10598, United States, lus@us.ibm.com

1 - Thoreau: A Fully Buried Wireless Sensor Network for Soil and Plant Science

Supratik Guha, PhD, University of Chicago, Chicago, IL, 60637, United States, guha@uchicago.edu, William Kent, Xufeng Zhang, Arseniy Andreyev, Cristina Negri, Monisha Ghosh, Jacob Gold

I will describe our research that has led to an end-to-end fully buried wireless sensor network for monitoring soil properties as a function of time on the University of Chicago campus in Hyde Park, Chicago. The network, named Thoreau, uses commercial sensors for monitoring temperature, volumetric water content, water potential and electrical conductivity as representative examples that are integrated into low power sensor packages (including the microprocessor unit, radio and antenna) that are buried 6-14 inches below the ground. A SigFox low power IoT wireless network is used for connectivity and the wireless signal path includes subterranean transmission followed by refraction into the air above ground. All data is curated on the Cloud and available via thoreau.uchicago.edu in open access mode. We will describe our experiences with Thoreau over the past 9 months, and we argue that scalable, affordable, ubiquitous subterranean sensing networks are within reach and will have significant impact on agriculture, the environment, and our understanding of soil and plant science.

2 - Advances in Agricultural Analytics

Joshua Woodard, Cornell University, Ithaca, NY, United States, jdw277@cornell.edu

By 2050, the population will approach 10 billion people, placing enormous strain on the Earth's resources, and food security is at increased risk from climate change. Meanwhile, the increased availability of high resolution geospatial, environmental, biophysical, and economic data—coupled with the expansion of computational capacity—is creating new opportunities for data-driven scientific discovery. This talk will discuss recent advances in the emerging fields of digital agriculture and agricultural analytics, including applications in policy analytics and risk assessment.

3 - Digital Agriculture and the Future of Farming

Raj Khosla, Colorado State University, Fort Collins, CO, United States, Raj.Khosla@colostate.edu

Precision Agriculture has been around for over two decades. The first decade had a strong focus on quantifying spatial variability in soils, the second decade spent significant time on science and technology of precision management of nutrients. Now with increasing adoption of Precision Ag there is interest in harnessing the power of data for making management decision based on evidence. The success of future farming practices, output, efficiency and sustainability, would rely on "farming the data" as much as "farming the ground". This presentation will empower audience with research based information on how agriculture is embracing information technologies to feed the growing population.

Chair: Lingfei Li, Chinese University of Hong Kong, Shatin, N T, Hong Kong, lfli@se.cuhk.edu.hk

Co-Chair: Qi Wu, Chinese University of Hong Kong, Shatin, Hong Kong, qwu@se.cuhk.edu.hk

1 - Dynamic Mean CVaR Portfolio Selection and Time Consistency Induced Term Structure of CVaR

Duan Li, The Chinese University of Hong Kong, Faculty of Engineering, Dept of Systems Engineering & Engineering Mgmt. Shatin, Hong Kong, dli@se.cuhk.edu.hk

We derive in this research optimal dynamic mean-CVaR portfolio policy for general incomplete discrete-time markets. As the dynamic mean-CVaR problem formulation is time inconsistent, how to update investor's VaR level and the trade-off between the mean and CVaR measures dynamically and adaptively is an important issue to address. We provide a complete answer to this question by deriving analytically the time-consistency induced term structure of CVaR in this research.

2 - Dark Pool Trading a Hawkes Process Approach

Xuefeng Gao, Chinese University of Hong Kong, William M.W. Mong Engineering Building,, Room 606, Shatin, Hong Kong, xfgao@se.cuhk.edu.hk, Lingjiong Zhu, Xiang Zhou

Dark pools are automated trading facilities which do not display bid and ask quotes to the public. In this talk, we use the Hawkes process to model the clustered arrival of trades in a dark pool and analyze various performance metrics including time-to-first-fill, time-to-complete-fill and the expected fill rate of a resting dark order.

3 - Negative Term Structure via Density Splitting

Shingfan Chan, Chinese University of Hong Kong, William M.W. Mong Engineering Building, Rm 507, Shatin, NT, Hong Kong, qwu@se.cuhk.edu.hk, Qi Wu

Persistent low interest rate environment demands a term structure model to have high conditional probabilities near zero point. We construct a "density splitting" technique to model this "sticky" behavior of yield curves. By breaking the continuity of conditional densities of risk factors that many existing models assume, we gain control of how much probability mass is allocated at a particular level. The method is flexible in that it applies to existing models, and allows sticky behavior at both negative and positive region. We apply this approach to the Nelson-Seigel family and calibrate to ECB and JPY curves. We found that bond and swap data prefer our model over existing shadow rate models.

4 - Analysis of Markov Chain Approximation for Option Pricing and Hedging: Grid Design and Convergence Behavior

Lingfei Li, Chinese University of Hong Kong, 608 William M.W. Mong Engineering Building, Shatin, N.T, Hong Kong, lfli@se.cuhk.edu.hk, Gongqiu Zhang

Continuous time Markov chain (CTMC) approximation is an intuitive and powerful method for pricing options in general Markovian models. This paper analyzes how grid design affects the convergence behavior of barrier and European options in general diffusion models. We obtain sharp estimates for the convergence rate of option price, delta and gamma. Based on our theoretical results, we propose a novel class of non-uniform grids, which enable the CTMC approximation method to price and hedge a large number of options with different strikes fast and accurately. Applicability of our results to jump models is discussed through numerical examples.

Fueling Station Location and Routing Decisions for Alternative Fuel Vehicles II

Sponsored: Location Analysis

Sponsored Session

Chair: Ismail Capar, xas A&M University, College Station, TX, 77843-3367, United States, capar@tamu.edu

1 - Supply Chain Planning in a Cross-Dock Environment

Manoj Vanajakumari, Texas A&M.University, 4318 Toddington Ln, College Station, TX, 77845, United States, manojuv@tamu.edu, Chelliah Sriskandarajah, Haoying Sun

We consider a supply chain planning problem via efficient cross-docking for an oil field services Company. The supply chain problem involves minimizing the total inbound and outbound transportation costs and the inventory management costs at the cross-docking facility and the plants. We analyze two problems: (i) the company ships all products bound to each plants periodically, and (ii) the company outsources the delivery of each product to a 3PL, on an individual basis, to the plants. We develop a decision support systems for the company.

2 - Evaluation Model of Traffic Network Utilizing Geographical Divergence Degree of Multiple Routes
Motoki Tajima, The University of Tokyo, Tokyo, Japan, m-tajima@iis.u-tokyo.ac.jp, Yudai Honma

In the research, we try to evaluate the traffic network in terms of geographical tolerance. Especially, we consider multiple alternate routes, and focus on divergence of them to calculate the robustness of networks. We firstly search alternate routes by adopting K shortest path routing algorithm. Next, we define several local factors which show the robustness quantitatively, then expand them to the whole network.

3 - Robust Design of Refueling Station Locations for Alternative Fuel Vehicles with Driving Range Constraint
Samuel Labi, Purdue University, 550 Stadium Mall Drive, West Lafayette, IN, 47907, United States, labi@purdue.edu, Mohammad Miralinaghi

his study develops a multi-period framework to investigate the optimal refueling locations for alternative fuel vehicles (AFVs) under travel demand uncertainty and driving range limitations. AFVs are classified by their driving range, and the uncertainty of travel demand in each AFV class is duly factored through a multi-class robust discrete optimization model. An algorithm is developed to solve the decision model for a large network.

Parallel Simulation Optimization

Sponsored: Simulation

Sponsored Session

Chair: Jie Xu, George Mason University, Fairfax, VA, 22030, United States, jxu13@gmu.edu

1 - An Efficient Fully Sequential Selection Procedure Guaranteeing Probably Approximately Correct Selection
Sijia Ma, PhD Student, Cornell University, 292 Rhodes Hall, Cornell University, Ithaca, NY, 14853, United States, sm2462@cornell.edu, Shane Henderson

Ranking and Selection procedures are designed for selecting the best among a finite set of systems using stochastic simulation. Instead of assuming a known lower bound on the difference between the best and others, we consider the probably approximately correct selection (PAC) formulation. We present a new fully sequential selection procedure, called the Envelope Procedure (EP), which delivers PAC guarantee. A particular sampling rule that achieves good efficiency is proposed. We compare the efficiency of the EP with some existing procedures in numerical experiments, and the results show that the EP saves considerable computational effort in many problem configurations.

2 - Challenges in Parallel Ranking and Selection
Susan R. Hunter, Purdue University, School of Industrial Engineering, Grissom Hall, 315 N. Grant Street, West Lafayette, IN, 47907-2023, United States, susanhunter@purdue.edu, Barry L. Nelson

We discuss the current state of the art in R&S for large problems solved on parallel computing platforms. We provide a new stylized model for representing parallel R&S procedures, and discuss the mathematical and computational formulations of existing R&S procedures under the stylized model. We also speculate on the future of parallel R&S procedures.

3 - Simulation Based Optimization Towards High Performance Computing
Haobin Li, Institute of High Performance Computing, A*STAR.Singapore, 1 Fusionopolis Way, #16-16 Connexis, Singapore, 138632, Singapore, lihb@ihpc.a-star.edu.sg, Giulia Pedrielli, Loo Hay Lee

This talk provides a brief introduction on how to speed up the simulation based optimization towards high computational performance. Specifically, three areas are to be explored, namely 1) designing a Pareto-efficient configuration for various computational infrastructures; 2) adapting the optimization algorithms to the parallel environment, e.g., OCBA algorithm with GPU computing; and 3) developing a modelling paradigm that could systematically distribute the computational effort to parallel cores, such as the modularized O2DES framework. The motivation for the three areas of studies is to be discussed, and preliminary results will be illustrated to show the potential in each area.

4 - A Structured Approach for Parallel Simulation Optimization Implementation
Ji Xu, George Mason University, Fairfax, VA, 22205, United States, jxu13@gmu.edu, Scott Rosen

In this talk we present our framework for performing parallel simulation optimization that involves a library of simulation optimization techniques and a guidance system to assist the general analyst in using the library. We also present parallel adaptations of two simulation optimization algorithms: Industrial Strength COMPASS and Empirical Stochastic Branch and Bound. After presenting these algorithms we provide numerical performance results under a case study involving a large-scale, real-world simulation. In addition performance of these algorithms, with respect to speed and quality of the final solution, is compared to a metamodel-based optimization procedure.

1 - Hidden Figures Panel Discussion
Karen T.Hicklin, University of North Carolina at Chapel Hill, B-24 Hanes Hall, Chapel Hill, NC, 27599-3260, United States, khicklin@email.unc.edu

The movie Hidden Figures (2016), based on the book by Margot Lee Shetterly, is a depiction of the untold story of black women mathematicians at NASA whose integral roles played a major part in some of America's historical space achievements. In this session, we celebrate the achievements of black women and their contributions to advancements in operations research. The panel features women at different points in their careers and will highlight their work as operations researchers with the goal of encouraging diversity.

Quality Monitoring and Analysis in Complex Manufacturing Processes

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Weihong Guo, Rutgers, The State University of New Jersey, Piscataway, NJ, 08854, United States, wg152@rutgers.edu

1 - Software Reliability Modeling with Considering Randomness of Environmental Factors
Mengmeng Zhu, Rutgers University, 1920 Aspen Court, Piscataway, NJ, 08854, United States, mengmeng.zhu@rutgers.edu, Hoang Pham

Software reliability gains more attention from the researchers and practitioners in the past few decades. Lots of environmental factors defined by many studies can affect software reliability during the development process. However, most existing software reliability models have not incorporated these environmental factors. We propose a theoretic software reliability model with considering the fault detection rate is a stochastic process due to the randomness of the environmental factors. Examples are included to demonstrate the effectiveness and predictive power of the proposed model.

2 - Ensemble Modeling of in Situ Variables for Printed Electronics Manufacturing with in Situ Process Control Potential
Hongyue Sun, University at Buffalo, Buffalo, NY, United States, hongyues@buffalo.edu, Yifu Li, Ran Jin

Aerosol jet® printing is a printed electronics process that is capable to print various materials with fine features. In this paper, an ensemble model strategy is proposed to quantify the effect of the process setting variables on the in situ variables, and the effect of the in situ variables on the product quality in a two-level hierarchical way. By identifying significant in situ variables as responses for the process setting variables, as well as significant predictors for the product quality in a joint model estimation problem, the proposed model has a hierarchical variable relationship to enable in situ process control. A case study is used to demonstrate the advantages of the proposed method.

3 - Optimize Wind Farm Development with Hybrid Wind Biorefinery Renewable Energy System in Micro Grid Community
Qing Li, Rutgers University, Piscataway, NJ, United States, ql78@scarletmail.rutgers.edu, Honggang Wang

As one of the most promising renewable energy sources, wind power has been widely applied to meet the ever growth of energy consumption. Energy production varies due to wind fluctuation, thus constantly meeting community's demand while maintaining cost efficiency is not always the case. In this study, the food waste from local community serves as energy recovery source in biorefinery to produce baseline energy. Computational models and optimization methods are developed for optimal development of wind farm in hybrid wind-biorefinery energy system to meet community demand. Two-stage optimization framework is proposed to search and improve the optimal number and placement of turbines.

4 - Nonparametric Change-point Detection for Process Monitoring and Prognostics in Advanced Manufacturing
Weihong Guo, Rutgers, The State University of New Jersey, 96 Frelinghuysen Rd, CoRE Rm 220, Piscataway, NJ, 08854, United States, wg152@rutgers.edu, Shenghan Guo

It is essential to detect significant changes to the production processes. In this study, we develop a monitoring and prognostics method that implements non-parametric change-point detection methods on non-stationary time series data collected from a real automobile manufacturing system. For offline change-point detection, we integrate three non-parametric methods: LASSO, threshold TLASSO, and wild binary segmentation (WBS); for online change-point detection, we implement the modified sequential change-point detection and multivariate adaptive regression splines. These nonparametric methods are compared in case studies with real manufacturing data.

Energy and Climate VI

Invited: Energy and Climate

Invited Session

Chair: Murat Erkoc, University of Miami, Hialeah, FL, 33015, United States, merkoc@miami.edu

1 - A Multi-objective Energy Management Model for Operation Planning in Smart Grids

Haluk Damgacioglu, PhD Candidate, University of Miami, 1251 Memorial Drive McArthur Engr. Bldg. Room 280, Coral Gables, FL, 33156, United States, haluk.damgacioglu@miami.edu, Nurcin Celik

The efficient utilization of distributed generation resources and demand side management (DSM) play a crucial role in satisfying and controlling electricity demand in smart grids. DSM programs make the operation planning problem more difficult with the additional objective of customer stakeholder. Here, we model the operation planning problem considering three conflicting objectives, minimizing the total operation cost and GHG emission, and maximizing the customers' satisfaction. The multi-objective model is implemented on a generic smart grid and solved using augmented epsilon contraint method.

2 - A Multi-objective Mathematical Model for Integrated Electricity and Natural Gas Pipeline Network Problems

Ahmet Akgun, Wichita State University, Wichita, KS, United States, axakgun@shockers.wichita.edu, Mehmet Bayram Yildirim

A multi-period multi-objective mathematical model for integration of electricity expansion planning and natural gas pipeline network problem is proposed. The proposed model is formulated as MINLP and it optimizes the costs, greenhouse gas emissions and foreign dependency for both electricity and natural gas pipeline networks simultaneously. This paper aims to determine what kind of generation units to be built, where and when to build generation units. The proposed model is tested on a 22-node electricity and 24-node Belgium natural gas network to determine the optimum investment strategy.

3 - A Zero Carbon Multi-site Production Model under Stochastic Demand and Intermittent Power

An Pham, Graduate Research Assistant, Texas State University, San Marcos, TX, United States, a_p276@txstate.edu, Tongdan Jin, Jin Qin, Fei Sun

We investigate whether is it economically viable and technically feasible to operate zero carbon manufacturing, transportation and warehouse using onsite wind and solar power. A big data analytics method is developed to characterize the renewables yield based on 11-year meteorological data. We show that zero carbon is achievable if the wind capacity factor is 0.3 or the photovoltaic capacity factor reaches 0.4. Our study facilitates manufacturing industries to become a "prosumser" who actively participate in demand responses as a green energy producer under smart grid paradigm.

4 - Load Shifting and Energy Storage in the Smart Grid

Murat Erkoc, Associate Professor, University of Miami, 1251 Memorial Drive, Coral Gables, FL, 33146, United States, merkoc@miami.edu, Eyad M.Al-Ahmadi

We study load-shifting and energy storage in an electricity market composed of a single energy provider and multiple customers via a Stackelberg game setting. The provider acts as the leader and decides on price discounts across a finite time horizon. The consumers follow and decide if and how they shift their consumption from their nominal demand. In terms of energy storage, we consider and compare two cases. In the first case, the consumers make the energy storage decisions. In the second, the energy provider manages the client storage devices at consumer sites. We investigate the joint impact of price discounts and storage option on player incentives and peak-to-average ratios.

2 - B2B Marketing Campaign Recommendation: A Social and Temporal Perspective

Jingyuan Yang, Rutgers University, Newark, NJ, United States, jingyyan@rutgers.edu

The buying processes of Business to Business (B2B) customers involve series of various marketing campaigns providing multi-faceted product/service information. To better guide B2B customers through dynamic and complex buying processes, we propose a unified view of social and temporal modeling for B2B marketing campaign recommendation. Specifically, we first construct temporal graph as the knowledge representation of each B2B customer's buying process. The recommender system is then built in a low-rank graph reconstruction framework using probabilistic graphical models. We also incorporate the business community relationship as the social factor to further improve overall performance.

3 - Diagnostics and Treatment of Chronic Disease with Artificial Intelligence

Bo Jin, Dalian University of Technology, Dailian, China, jinbo.dlut@gmail.com

Parkinson's disease (PD) is a chronic disease that develops over years and varies dramatically in its clinical manifestations and overall prognosis. It is challenging to compute similarity due to patient data collected from longitudinal clinical trials often consists of multiple modalities and presents temporal dynamics. To provide scalable solutions that can accurately identify similarity from the complex patient data, we propose a deep model that directly learns patient similarity from longitudinal and multi-modal patient data with an RNN architecture that can encode the similarity between two sequences and dynamically match temporal patterns inpatient data.

Green Vehicle Routing

Sponsored: TSL, Freight Transportation & Logistics

Sponsored Session

Chair: Mesut Yavuz, University of Alabama, myavuz@cba.ua.edu

1 - Managing Electric Vehicle Charging Station Congestion under Uncertainty

MD Abdul Quddus, Mississippi State University, 319 North Jackson Street, Apt 3E, Starkville, MS, 39759, United States, mq90@msstate.edu, Mohammad Marufuzzaman, John Usher, Mesut Yavuz

This study incorporates a non-linear cost term in the objective function to capture the congestion effect at charging stations. We propose a hybrid decomposition algorithm that combines Constraint Generation algorithm with a Sample Average Approximation with an enhanced Progressive Hedging algorithm. A case study is conducted by considering road network of Washington, D.C. area. The results of the analysis indicate that incorporating congestion factor encourage larger capacity charging stations opening decisions, increase the number of batteries storing decisions, and higher congestion cost decreases the number of charging stations opening decisions.

2 - Green Location-routing Problem

Okan Dukkanci, Bilkent University, Ankara, Turkey, okan.dukkanci@bilkent.edu.tr, Bahar Kara, Tolga Bektas

This talk will introduce the Green Location-Routing Problem, an extension of the classical Location-Routing Problem that explicitly accounts for fuel consumption and emissions, the amount of which is measured by a widely used comprehensive modal emission model. The objective is to minimize a total cost function comprising depot, fuel and emission costs. The talk will present a mixed integer programming formulation of the problem with a set of valid inequalities, and describe solution approaches. Computational results on realistic data sets will be presented.

3 - An Integrated Fleet Management Model Introducing Alternative Fuel Trucks into Existing Diesel Long-haul Fleets

Ilke Bakir, Georgia Institute of Technology, H. Milton Stewart School of ISyE, Atlanta, GA, 30332, United States, ilkebakir@gatech.edu, Alan Erera

We address the challenge of smoothly introducing alternative fuel trucks (AFTs) into an existing long-haul trucking fleet while making necessary structural changes and maintaining feasible operations during the transition. We develop an integrated fleet management model, which incorporates the decisions for (i) opening new maintenance/fueling facilities, and (ii) assigning trucks to travel routes for ensuring demand satisfaction, into a fleet replacement framework. Additionally, in order to obtain optimal (or good feasible) solutions for realistically sized problem instances, we propose a Benders' decomposition framework and a local search based heuristic.

4 - An Iterated Beam Search & Column Generation Hybrid Solution to the Green Vehicle Routing Problem

Mesut Yavuz, The University of Alabama, Alston Hall Box 870226, Tuscaloosa, AL, 35487, United States, myavuz@cba.ua.edu, Isil Koyuncu

This talk addresses the routing problem of a homogeneous fleet of green vehicles, where each vehicle has a finite driving range before it must visit a refueling station, and all vehicles must return to the depot by end-of-day. We develop a column generation algorithm based on optimally routed customer sets. An iterated beam search algorithm is developed to generate the customer sets. The talk discusses static and dynamic strategies to integrate the two algorithms. Computational evaluation of the proposed algorithm is also presented.

School Bus Routing and Scheduling

Sponsored: Transportation Science & Logistics

Sponsored Session

Chair: Dimitris Bertsimas, Massachusetts Institute of Technology, 77 Massachusetts Avenue, E40-147, Cambridge, MA, 02139, United States, dbertsim@mit.edu

1 - Solving Multi-school Bus Routing and Scheduling Problem

Zhongxiang Wang, Graduate Student, University of Maryland, 406 Ridge Rd, Apt 7, Greenbelt, MD, 20770, United States, zxwang25@umd.edu, Ali Shafahi, Ali Haghani

School bus routing and scheduling is usually treated as two separated problems. Such separation will lead to a worse solution than solving them together with respect to the number of buses and travel time. The key point connecting routing and scheduling problem - trip compatibility - is thus deeply studied. A Mixed Integer Programming model is proposed along with a School Decomposition Algorithm. The model and algorithm are tested on eight sets of randomly-generated mid-size problems in comparison to the existing models. The results show that the proposed model and algorithm can find a better solution using up to 30% fewer buses than the best traditional models in a reasonable amount of time.

2 - Dynamic Electric Buses Scheduling under Stochastic Traffic Conditions

Xindi Tang, Tsinghua, Beijing, China, txd16@mails.tsinghua.edu.cn, Fang He, Xi Lin

Our research proposes a dynamic electric bus scheduling model under pre-determined timetable which effectively handles the subsistent stochasticity of traffic conditions and range limitation of electric vehicles. To expeditiously solve the problem which suffers from exponential expansion of variables, we embed it into a branch and price framework. We conduct numerical experiments based on real data in Beijing, simulate potential scenarios with delay propagation considered, and do sensitivity analyses, proving effectiveness of our models and performances of our algorithms.

4 - To School and Back Again an Optimization Approach to Large Scale School Bus Routing

Dimitris Bertsimas, Massachusetts Institute of Technology, 77 Massachusetts Avenue, E40-147, Cambridge, MA, 02139, United States, dbertsim@mit.edu, Arthur J. Delarue, Sebastien Martin

We present a novel optimization-based methodology for the School Bus Routing Problem (SBRP) that maximizes bus re-use between schools, in order to minimize overall costs to the city. Our method is tractable at the scale of a large city, simultaneously optimizing routes for 200 schools and 25,000 students, in a network with tens of thousands of edges. In the real-world setting of the Boston Public Schools (BPS) district, we show that our method reduces the overall number of buses needed each day by 18%, the total daily driving distance by 40%, and the total daily driving time by 37%.

Computer Experiments and Uncertainty Quantification

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Ying Hung, Rutgers State University of New Jersey, Piscataway, NJ, 08854-8019, United States, yhung@stat.rutgers.edu

1 - A Generalized Gaussian Process Model for Computer Experiments with Binary Time Series

Chih-li Sung, Georgia Institute of Technology, Atlanta, GA, United States, csung33@gatech.edu, Jeff Wu

Conventional analysis for computer experiments is based on Gaussian process (GP) models. Non-Gaussian observations such as binary responses are common in some computer experiments, but the extensions of GP models to these cases have received scant attention in the literature. Motivated by the analysis of a class of cell adhesion experiments, we introduce a generalized Gaussian process model for binary responses. The methodology is applied to study two different cell adhesion mechanisms, which were conducted by computer simulations. The fitted models reveal important biological differences between the two mechanisms in repeated bindings, which cannot be directly observed experimentally.

2 - Sequential Learning of Deformation Models in Additive Manufacturing through Calibration of Simulation Models.

Tirthankar Dasgupta, Rutgers, Piscataway, NJ, United States, tirthankar.dasgupta@rutgers.edu

Successful prevention of geometric shape deformation of products manufactured by additive manufacturing depends on building predictive deformation models. However, resource constraints impose restrictions on the number of test shapes of a particular type, making the use of meta models inevitable. To build meta models of deformation with good predictive power, calibration of existing models with data from physical experiments is necessary. We propose a sequential procedure for designing physical experiments and calibrating an ensemble of existing simulation models with data obtained from such experiments.

3 - Active Subspaces: Emerging Ideas for Dimension Reduction in Computational Science and Engineering Models

Paul Constantine, Colorado School of Mines, Golden, CO, 80401, United States, paul.constantine@colorado.edu

Engineers use simulations to study relationships between a model's inputs and outputs. However, thorough parameter studies (e.g., UQ) are challenging when the simulation is expensive and the model has several inputs. The engineer may try to reduce the dimension of the model's input parameter space. Active subspaces identify important directions in the input parameter space. I will (i) describe computational methods for discovering active subspaces, (ii) propose strategies for exploiting the reduced dimension, and (iii) review results from engineering applications. Visit activesubspaces.org

Functional Data, Image and Shape Analysis: Methodology and Applications

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Hao Yan, Atlanta, GA, 30319, United States, yanhao@gatech.edu

Co-Chair: Kamran Paynabar, Georgia Institute of Technology, Atlanta, GA, 30332-0205, United States, kamip@umich.edu

1 - An Image Data Based Manifold Learning Approach for Online Diagnosis of Additive Manufacturing Processes

Chenang Liu, Virginia Tech, Blacksburg, VA, 24060, United States, lchenang@vt.edu, Zhenyu Kong

Online quality monitoring and control is one of the major challenges in additive manufacturing (AM). A potential effective approach for online quality control of AM is based on image analysis. This work proposes an online manifold learning based classification method for analyzing real-time image data collected by digital microscopes embedded in the AM machine. The resulting system can diagnose the surface quality status, i.e., to identify the type and severity of the printing defects, in a real-time manner. The case study shows that the proposed method is very effective and it can also be integrated into an online closed-loop control system.

2 - Sparse Subspace Learning of Dynamic Multivariate Functions

Hao Yan, Georgia Institute of Technology, 3525 Highgrove Way

NE, Atlanta, GA, 30319, United States, yanhao@gatech.edu, Chen Zhang, Jianjun Shi

This paper presents a dynamic subspace learning method for multivariate functional data modeling. We assume different functions come from different disjoint subspaces, and only functions of the same subspace have cross-correlations with each other. These subspaces can be learnt as a sparse regression problem. By allowing but regularizing the regression change over time, we can further describe cross-correlation dynamics. The model can be efficiently estimated by the fast iterative shrinkage-thresholding algorithm, and the features of every subspace can be extracted using the smooth multi-channel functional PCA. Numerical studies demonstrate the efficiency of the proposed methodology.

3 - Minimizing Negative Transfer of Knowledge Through Scalable and Regularized Cokriging Models

Raed Al Kontar, University of Wisconsin-Madison, 1513 University Avenue, Room 3255, Madison, WI, 53706, United States, alkontar@wisc.edu, Shiyu Zhou

Multivariate Metamodeling and the estimation of functional data is specifically challenging due to the large number of parameters to be estimated, high computational complexity and the negative transfer of knowledge which may occur if different functional output have no commonalities. In this paper, we present a scalable approach to simultaneous estimation of functional data based on the multivariate Gaussian process. Specially, we introduce a regularized process which allows sequential estimation of parameters and minimizes the negative transfer of knowledge between uncorrelated outputs.

4 - Point Cloud Data Analysis for Process Modeling and Optimization

Hao Yan, 3525 Highgrove Way NE, Atlanta, GA, 30319, United States, yanhao@gatech.edu, Kamran Paynabar, Massimo Pacella

Advanced 3D metrology technologies such as Coordinate Measuring Machine (CMM) and laser 3D scanners have facilitated the collection of massive point cloud data, beneficial for process monitoring, control and optimization. However, due to their high dimensionality and structure complexity, modeling and analysis of point clouds is a challenge. In this paper, we utilize techniques developed in multilinear algebra and propose a set of tensor regression approaches to model the variational patterns of point clouds and link them to process variables. The performance of the proposed methods is evaluated through simulation and a real case study of turning process optimization.

11:00 - 11:45 Simio/11:45 - 12:30 AMPL

Invited: Vendor Tutorial

Invited Session

1 - 11-11:45 Simio

Renee Thiesing, Simio LLC, Louisville, KY, United States, rthiesing@simio.com

Simio is a premier simulation and scheduling software that allows you to expand traditional benefits of simulation to improve daily operations. In this tutorial, we will demonstrate Simio's 3D rapid modeling capability to effectively solve real problems. Explore how a single tool can be used to not only optimize your system design, but also provide effective planning and scheduling. Come explore the Simio difference and see why so many professional and novice simulationists are changing to Simio.

2 - Developing Optimization Applications Quickly and Effectively through Algebraic Modeling in AMPL

Robert Fourer, AMPL.Optimization Inc., 2521 Asbury Ave, Evanston, IL, 60201, United States, 4er@ampl.com

Can you negotiate the complexities of the optimization modeling lifecycle, to deliver a working application before the funding runs out or the problem owner loses interest? Algebraic languages streamline the key steps of model formulation, testing, and revision, while offering powerful facilities for incorporating models into larger systems and deploying them to users. This presentation introduces algebraic modeling for optimization by carrying a single illustrative example through multiple contexts, from interactively evolved formulations to scripted iterative schemes to embedded applications. We feature the new Python API for AMPL, and the QuanDec system for creating web-based collaborative applications from AMPL models.

Data Mining

Contributed Session

Chair: Safak Yakti, Binghamton University, Binghamton, NY, United States, syakti1@binghamton.edu

1 - A Classification Based Method to Detect Epilepsy using EEG Signals

Eda Karacaoglan, Erciyes University, Kayseri, Turkey, edakaracaoglan@erciyes.edu.tr, Mahmut Tokmakci, Fatma Uysal

It is important to diagnosis epilepsy correctly. Because EEG signals are dynamic and nonstationary, it is very hard to diagnosis epilepsy exactly. In literature there are some studies to detect epilepsy with the help of data mining methods. In this study, it has been tried to detect epilepsy by classifying Electroencephalogram (EEG) signals. For this purpose a new method is developed and applied on test data. The results are presented.

2 - A Classification Based Method to Detect Stress using ECG Signals

Fatma Uysal, Research Assistant, Erciyes University, Engineering Faculty, Biomedical Engineering Department, Kayseri, 38039, Turkey, fatmauysal@erciyes.edu.tr, Mahmut Tokmakçı, Eda Karacao lan

Stress is one of the serious factors for inducing many physical illnesses such as heart attacks, cognitive dysfunctions and depression. Electrocardiogram signal (ECG) which reflects the electrical activity of the heart ensures useful information in detection human stress. This work consists of five steps including stress-inducing test, data collection, signal preprocessing, feature extraction and classification. The aim of this study is to classify the stress using feature extraction algorithms and machine learning algorithms.

3 - Could Wellness Programs Help Decrease the Health Costs?

M. Gabriela Sava, Clemson University, College of Business, 145 Sirrine Hall, Clemson, SC, 29634, United States, msava@clemson.edu, Lawrence Fredendall, Kristin Scott

To reduce their total healthcare costs, private companies are starting to invest more in preventive care. Wellness programs are one strategy to try to minimize the total healthcare costs. We use data from one wellness program to analyze how employees' life style characteristics could predict future healthcare costs faced by the employer.

4 - Can Analytics Help Improve the Implementation of Preventive Care Programs?

M. Gabriela Sava, Clemson University, College of Business, 145 Sirrine Hall, Clemson, SC, 29634, United States, msava@clemson.edu, Luis G. Vargas, Jerrold H. May, James G. Dolan

In order to improve public health and to reduce healthcare costs, the U.S. Preventive Task Force has developed preventive programs for chronic diseases, such as colorectal cancer. We suggest how analytical methods might be used to help increase the level of implementation of preventive screening for colorectal cancer, by improving healthcare providers' understanding of patients' preferences with respect to the set of screening options available. Improved understanding enables healthcare providers to propose "personalized" medical paths that should increase the likelihood of patients' compliance.

5 - Data-driven Patient Scheduling on Asthma Intervention Considering Air Pollution

Luo Li, Professor, Sichuan University, Business School, Chengdu, 610064, China, luolicc@163.com, Fengyi Zhang, Wei Zhang

The aim of this study is to provide a framework of data-driven asthma patient scheduling on intervention with minimized readmissions . We first identified corresponding factors (especially on air pollution) that affect readmission and discharge process by accessing health insurance database; then we figured out the Markov transition process of readmission and discharge under each circumstance; finally, we constructed a MDP (Markov decision process) model, in which the penalties of Markov states are non-monotonic.Due to the fact that the optimality only exits under certain conditions, we proposed heuristics to achieve near-optimal and analyzed their performance.

6 - Mortality Risk Prediction for Atrial Fibrillation Patients

Safak Yakti, PhD Candidate, Binghamton University, Binghamton, NY, United States, syakti1@binghamton.edu, Mohammad T.Khasawneh, Serkan Saygi

Atrial Fibrillation (AF) is the most common heart rhythm disorder worldwide according to CDC. AF affects more than 3 million Americans and causes 130,000 death per year. Aim of this research is to identify the factors that influence mortality caused by AF and to compare between the prediction models namely Logistic Regression, Decision Trees, and Alternating Decision Tree methods. Performance measures are used to evaluate performances of the models. These models are utilized by using two different datasets; first one imbalanced dataset (7,796 patients), and second under-sampled dataset (2,350 patients) with AF diagnosis who were referred between 2012 and 2014.

Sponsored Session

Chair: Christos Maravelias, PhD, University of Wisconsin - Madison, Madison, WI, United States, christos.maravelias@wisc.edu

1 - Integer Programming Approaches for Appointment Scheduling with Random No-shows and Service Durations

Ruiwei Jiang, University of Michigan, 1205 Beal Ave., Ann Arbor, MI, 48109, United States, ruiwei@umich.edu, Siqian Shen, Yiling Zhang

We consider an appointment scheduling problem with random no-show and service duration. We propose a distributionally robust optimization model and derive computationally tractable reformulations based on integer programming approaches. Numerical results demonstrate that the proposed approach yields better out -of-sample performance, especially when the randomness is misspecified.

2 - Closing the Gap NNAC Optimal Power Flow by Strengthening the Convex QC Relaxation using Parallel Computing

Gabriel Hackebeil, hackebeg@umich.edu

An important problem in power systems is finding optimal operating conditions for transmission systems, which are governed by the non-convex AC power flow equations (AC-OPF). In this work, we apply global optimization strategies, such as optimality-based range reduction and spatial branch-and-bound, in an HPC setting to close the optimality gap on many of the AC-OPF test cases from NESTA. We use the convex QC relaxation as a subproblem and employ linearization techniques to avoid numerical issues with solving this SOCP in practice, allowing for faster and more robust subproblem solves. Our implementation is built on the open-source AML Pyomo.

3 - An MINLP Model and Solution Methods for Blend Scheduling Problems

Christos T. Maravelias, University of Wisconsin-Madison, 1415 Engineering Drive, Engineering Hall 2024, Madison, WI, 53706, United States, maravelias@wisc.edu, Yifu Chen

We propose a new mixed integer nonlinear programming (MINLP) model for integrated blending and scheduling problems in oil refineries. Unlike existing approaches, the model considers crude oil operations, intermediate processing and final product blending simultaneously. To solve the proposed model efficiently, we develop preprocessing techniques based on propagation of product demands and property specifications, and propose three families of tightening constrains. We present computational results showing the effectiveness of these methods.

4 - Exploiting Integrality in the Global Optimization of Mixed-integer Nonlinear Programming Problems with Baron

Nikolaos Sahinidis, Swearingen Professor, Carnegie Mellon University, Department of Chemical Engineering, 5000 Forbes Avenue, Pittsburgh, PA, 15213, United States, sahinidis@cmu.edu, Mustafa Kilinc

We present recent developments in the global optimization software BARON to address problems with integer variables. A primary development was the addition of mixed-integer linear programming relaxations to BARON's portfolio of linear and nonlinear programming relaxations. We describe BARON's dynamic strategy for deciding under what conditions to activate integer programming relaxations in the course of branch-and-bound. We also describe primal heuristics for finding good solutions of mixed-integer nonlinear programs. Finally, we report extensive computational results to analyze the impact of each technique in the solution process.

1 - Finding Central Clique Clusters in Graphs

Foad Mahdavi Pajouh, University of Massachusetts Boston, Boston, MA, Foad.Mahdavi@umb.edu, Maciej Rysz

We propose a solution algorithm for identifying the most central cliques in graphs and examine its effectiveness when the centrality measure is defined by betweenness. Numerical experiments demonstrating the computational performance of the proposed method are conducted and compared with results obtained from solving an equivalent mixed integer programming representation.

2 - Extreme-point Search Methods for Solving Fixed-charge Generalized Networks

Angelika Leskovskaya, Southern Methodist University, Caruth Hall 3145 Dyer Street, Suite 372, Dallas, TX, 75275, United States, aleskovs@lyle.smu.edu, Richard Barr

While researchers have studied generalized networks flow problems extensively, the powerful addition of fixed charges on arcs has received scant attention. This work describes network-simplex-based algorithms that efficiently exploit the quasi-tree basis structure of the problem relaxations and presents computational comparisons with commercial solution alternatives.

3 - Finding Groups with Maximum Betweenness Centrality

Oleg Prokopyev, University of Pittsburgh, Pittsburgh, PA, 15261, United States, droleg@pitt.edu, Alexander Veremyev

In this talk we consider the problem of identifying the most influential (or central) group of nodes (of some predefined size) in a network. Such a group has the largest value of betweenness centrality or one of its variants, for example, the length-scaled or the bounded-distance betweenness centralities. We demonstrate that this problem can be modelled as a mixed integer program (MIP) that can be solved for reasonably sized network instances using off-the-shelf MIP solvers. We also present extensive computational experiments with different types of real-life and synthetic network instances to illustrate the effectiveness and flexibility of the proposed framework.

1 - The Traveling Salesman Problem with Road Distances

William J. Cook, University of Waterloo, Combinatorics and Optimization, Waterloo, ON, N2L.3G1, Canada, bico@uwaterloo.ca

Following Dantzig, Fulkerson, and Johnson, we show that a certain tour of 49,603 sites in the US is shortest possible, measuring distance with point-to-point routes obtained from Google Maps. We highlight a cost-refinement technique that allows the cutting-plane method to generate lower bounds on the tour length without explicit knowledge of the full distance matrix. The talk is based on joint work with Daniel Espinoza, Marcos Goycoolea, and Keld Helsgaun.

2 - Redistricting with Optimal Minority Representation

Boris Brimkov, PhD, Rice University, Houston, TX, United States, bb19@rice.edu

Redistricting is the process of partitioning geographic regions and population groups into electorates for municipal and state legislatures. In states with diverse populations, districts in which minority demographic groups comprise voting majorities can help prevent minority vote dilution. While other aspects of the redistricting problem have been thoroughly investigated by the combinatorial optimization community, the formation of minority-majority districts has not yet received an adequate treatment. This talk will discuss several theoretical and computational investigations aimed at producing redistricting plans that are optimal with respect to minority representation.

3 - A Hybrid Metaheuristic for Finding Near Optimal Target Sets in Consensus Models

Derek J.Mikesell, Rice University, P.O. Box 1892, MS-134, Houston, TX, 77005, United States, djm13@rice.edu

Given a network, we consider the problem of selecting a subset of nodes A of a fixed size K such that the average hitting time to A is minimized. This study is motivated by modeling communication models as a random walk on a weighted loopless directed graph, where the desired information is observed when a random walk reaches the chosen set. In general, this problem is NP-hard. In this paper we observe near-optimal solutions to this problem by considering a hybrid metaheuristic. This hybrid metaheuristic is formed from a discrete version of a simplified Cuckoo Optimization Algorithm and a Greedy Randomized Adaptive Search Procedure (\textit{GRASP}). Additionally, the restricted candidates for this method are chosen based on a spectral decomposition of the network - taking advantage of a random walks likelihood of staying within a cluster. Results show that better-than-greedy solutions can be obtained in a small number of iterations.

4 - Regression-Style Learning by Column Generation

Ai Kagawa, Rutgers University, 100 Rockafeller Road, Building A, Piscataway, NJ, 08854, United States, ai.kagawa@gmail.com

REPR (Rule-Enhanced Penalized Regression) is a column generation method to predict a scalar response from numerical observations. It enhances a penalized L1 or L2 regression model with new variables indicating whether observations lie inside certain multidimensional boxes. The column generation subproblem is the NP-hard RMA (Rectangular Maximum Agreement) problem, which we solve by parallel branch and bound. We empirically compare REPR to various alternatives and discuss accompanying data discretization techniques and tactics for reducing the computational load of the subproblems.

Interactions of Optimization and Statistical Learning I

Sponsored: Optimization, Nonlinear Programming

Sponsored Session

Chair: Ethan Xingyuan Fang, Pennsylvania State University, University Park, PA, 16802, United States, xxf13@psu.edu

1 - Sample Complexity Analysis for Low-order Optimization Algorithms

Shuzhong Zhang, University of Minnesota, 111 Church Street, Department of Industrial and Systems Engineer, Minneapolis, MN, 55455, United States, zhangs@umn.edu

In this talk we study sample complexities for various zeroth-order algorithms for (stochastic) convex optimization. Essentially, the analysis is meant to understand how many times one will need to call the (stochastic) zeroth-order oracle in order to get an ϵ optimal solution in expectation. Such algorithms and analysis are important for various Bayesian optimization models and applications arising from revenue management. We shall also extend our discussions to include certain non-convex models.

2 - Dynamic Factorization and Partition of Complex Networks

Mengdi Wang, Princeton University, 226 Sherrerd Hall, Princeton, NJ, 08544, United States, mengdiw@princeton.edu

Finding the reduced-order structure is critical to understanding complex networks. Existing approaches are applicable only when the full network is explicitly observed. We focus on online factorization and partition of implicit large-scale networks based on observations from an associated random walk. We propose an efficient nonconvex stochastic gradient algorithm that processes dependent data dynamically generated by the underlying network and learn a low-dimensional representation. Using a diffusion approximation analysis, we show that the algorithm achieves nearly optimal performance in both sample and space complexity. The proposed approach is experimented on Manhattan taxi data.

3 - Tuning-free Heterogeneity Pursuit in Massive Networks

Jinchi Lv, University of Southern California, IOM.Department, Marshall School of Business, Los Angeles, CA, 90089, United States, jinchilv@marshall.usc.edu, Yingying Fan

Heterogeneity is often natural in many contemporary applications involving massive data. While posing new challenges to effective learning, it can play a crucial role in powering meaningful scientific discoveries through the understanding of important differences among subpopulations of interest. In this paper, we exploit multiple networks with Gaussian graphs to encode the connectivity patterns of a large number of features on the subpopulations. To uncover the heterogeneity of these structures across subpopulations, we suggest a new framework of tuning-free heterogeneity pursuit (THP) via large-scale inference, where the number of networks is allowed to diverge. In particular, two new tests, the chi-based test and the linear functional-based test, are introduced and their asymptotic null distributions are established. Under mild regularity conditions, we establish that both tests are optimal in achieving the testable region boundary and the sample size requirement for the latter test is minimal. Both theoretical guarantees and the tuning-free feature stem from efficient multiple-network estimation by our newly suggested approach of heterogeneous group square-root Lasso (HGSL) for high-dimensional multi-response regression with heterogeneous noises. To solve this convex program, we further introduce a tuning-free algorithm that is scalable and enjoys provable convergence to the global optimum. Both computational and theoretical advantages of our procedure are elucidated through simulation and real data examples.

4 - Understanding Best Subset Selection and Relatives

Rahul Mazumder, Massachusetts Institute of Technology, Sloan School of Management, 100 Main Street, Cambridge, MA, 02139, United States, rahulmaz@mit.edu

Sparsity plays a key role in linear statistical modeling and beyond. In this talk I will discuss the best subset selection problem and recent computational techniques relying on integer optimization and first order optimization methods, that enable us to obtain high-quality, near-optimal solutions for best-subsets regression, for sizes well beyond what was considered possible. This sheds interesting new insights into the statistical behavior of subset selection problems vis-a-vis popular, computationally friendlier methods thereby motivating the design of new statistical estimators with better statistical and computational properties.

Discrete and Combinatorial Optimization

Sponsored: Optimization, Integer and Discrete Optimization

Sponsored Session

Chair: Gerdus Benade, Carnegie Mellon University, Carnegie Mellon University, Pittsburgh, PA, 15213, United States, jbenade@andrew.cmu.edu

1 - A Matrix Selection Problem

Zeyang Wu, University of Minnesota, 609 Southeast Oak St Apt 2-12, Minneapolis, MN, 55414-2922, United States, wuxx1164@umn.edu, Qie He

Consider a discrete-time dynamic system xk+1 = Mk xk among time horizon k = 0,1,2,...,T. The matrix Mk can be chosen as one of the given two matrices A or B. The matrix selection problem is defined as follows: given an initial vector x0, select matrices M1, M2, M3, ... MT, such that a linear function over the states x1, x2, x3, ... xT is minimized. This problem is motivated by various applications, e.g. cancer treatment planning, antibiotics design. We formulate this problem as a mixed-integer linear program and derive several families of facet-defining inequalities for the resulting formulation.

2 - Preference Elicitation for Participatory Budgeting
Gerdus Benade, Carnegie Mellon University, 6235 Fifth Avenue, Apt B17, Pittsburgh, PA, 15232, United States, gerdusbenade@gmail.com, Swaprava Nath, Ariel Procacci a, Nisarg Shah

Participatory budgeting is a practical variant of the knapsack problem which enables the allocation of public funds by collecting and aggregating individual preferences; it has already had a sizable real-world impact. Making the most of this new paradigm requires a rethinking of some of the basics of computational social choice, including the very way in which individuals express their preferences. We analytically compare four preference elicitation methods through the lens of implicit utilitarian voting, and find that threshold approval votes are qualitatively superior. This conclusion is supported by experiments using data from real participatory budgeting elections.

3 - The Replenishment Schedule to Minimize Peak Storage Problem
Dorit Simona Hochbaum, University of California-Berkeley, Dept of IEOR, 4135 Etcheverry Hall MC 177, Berkeley, CA, 94720-1777, United States, hochbaum@ieor.berkeley.edu, Xu Rao

The replenishment storage problem is to determine the integer timing of orders of items, each of given size, and each order is depleted within a given number of days (cycle time), so that the peak storage capacity is minimized. The problem is known to be NP-hard. We demonstrate here that RSP is weakly NP-hard for constant joint cycle length (the least common multiple of all individual cycles) and strongly NP-hard for non-constant joint cycle length. For constant joint cycle discrete-RSP, we present a pseudo-polynomial optimization algorithm and the first FPTAS for identical cycles.

4 - Ranking Students using Noisy Self-generated Questions
Nam Ho-Nguyen, Carnegie Mellon University, 5000 Forbes Avenue, Pittsburgh, PA, 15213, United States, hnh@andrew.cmu.edu, Gerdus Benade, Wolfgang Gatterbauer, R. Ravi

We consider the question of evaluating students based on student-generated questions. Unlike teacher-generated questions, student-generated questions are more unreliable and can misleading, i.e., unable to distinguish between strong and weak students. We explore several novel methods for this problem which are scalable, robust to misleading questions and missing responses, and capable of identifying ill-posed questions. We perform a comprehensive computational study to compare our methods against traditional parametric frameworks.

Joint session OPT/Practice: Recent Progress in Optimization Software II

Sponsored: Optimization, Computational Optimization and Software

Sponsored Session

Chair: Hans Mittelmann, Arizona State University, Tempe, AZ, 85287-1804, United States, mittelmann@asu.edu

1 - The SAS MILP Solver: Current Status and Future Developments
Philipp M. Christophel, SAS.Institute Inc., Maria-Sibylla-Merian-Str. 36, Mainz, 55122, Germany, Philipp.Christophel@sas.com, Imre Polik, Menal Guzelsoy, Amar Kumar Narisetty

We give an overview of the current status of the SAS mixed integer linear programming (MILP) solver. The focus will be on describing recent implementation efforts for the MILP solver as well as future development directions.

2 - Recent Progress in the Xpress Solvers
Michael Perregaard, Xpress Developer, FICO, Birmingham, United Kingdom, MichaelPerregaard@fico.com

We will present some of the recent advances in the FICO Xpress solvers. The emphasis will be on how we can bring in different technologies, such as interior point solvers, in order to improve MILP performance.

3 - Matlab Optimization Update
Mary Fenelon, MathWorks, 3 Apple Hill Drive, Natick, MA, 01760, United States, Mary.Fenelon@mathworks.com, Steve Grikschat

The MATLAB Optimization Toolbox has solvers for linear, quadratic, mixed-integer linear and nonlinear optimization problems. Recent improvements to these solvers will be presented along with their application to building prescriptive analytics applications with MATLAB.

4 - Recent Improvements in SCIP 4
Robert Lion Gottwald, Zuse Institute Berlin, Rubensstr. 102, Berlin, 12157, Germany, robert.gottwald@zib.de

SCIP is a branch-and-cut based solver for mixed-integer-nonlinear programming (MINLP) problems. Its extensible design makes it particularly well suited for research and it is currently one of the fastest solvers available in source code. We will present improvements in the latest release of SCIP and give a prospect of new features such as presolving methods for the sparsification of the constraint matrix and enhancements in the cutting plane separation.

Deterministic and Stochastic Optimization for Electric Power Systems

Sponsored: Energy, Natural Res & the Environment Electricity

Sponsored Session

Chair: Andy Sun, Georgia Institute of Technology, Atlanta, GA, 30312, United States, andy.sun@isye.gatech.edu

1 - Market-based Transmission Expansion Planning using an Area and Unit Decomposition Approach
Philipp Hartel, Fraunhofer IWES, Konigstor 59, Kassel, 34119, Germany, philipp.haertel@iwes.fraunhofer.de

Motivated by future offshore grid connections in the North Sea region, a market-based TEP model with a particular focus on long-term operational flexibility in multiple market areas of the energy system in Europe is presented. While accounting for interactions of power, heat, and transport sectors in the future, aggregated formulations of hydro-thermal units are used to capture short- to long-term power market dynamics. To solve the problem with a planning horizon of a full consecutive year, a solution strategy involving an area and unit decomposition for the resulting large-scale convex linearly-constrained non-smooth problem is pursued using a doubly stabilized proximal bundle algorithm.

2 - Valid Inequalities for Hydro Genco Self-scheduling Optimization
Minseok Ryu, University of Michigan, msryu@umich.edu, Antonio J. Conejo, Ruiwei Jiang

We focus on a self-scheduling optimization problem for a hydro generation company that manages a set of interconnected hydro reservoirs. We consider a class of key physical and operating characteristics of hydro reservoirs and generators in practical settings, including the prohibited operating zones and the nonlinear and nonconvex performance curves. We employ a mixed-integer linear programming (MILP) approach to approximate these characteristics. The MILP approach facilitates the use of many efficient computational tools, e.g., optimization solvers and valid inequalities. Finally, numerical experiments are conducted based on a real-world case study.

3 - Leveraging Predictive Analytics to Control and Coordinate Operations Scheduling and Maintenance
Murat Yildirim, Georgia Institute of Technology, Atlanta, GA, United States, murat@gatech.edu, Andy Sun, Nagi Gebraeel

Penetration of the renewable sources, distributed generation, and market dynamics increase the congestion and volatility in modern power grids, leading to frequent on-off cycles and stringent production requirements on power plants that significantly affect their lifetime. This presentation proposes a unified analytics framework that integrates i) a stochastic degradation model to provide accurate sensor-driven predictions of the remaining life distribution for power plants operating under varying loading conditions, with ii) an adaptive optimization model that finetunes the loading on the power plants by determining the optimal maintenance and operational decisions.

4 - Multistage Stochastic Unit Commitment with SDDIP
Andy Sun, Georgia Institute of Technology, 755 Ferst Drive, Atlanta, GA, 30312, United States, andy.sun@isye.gatech.edu

Unit commitment is one of the key operational problems in power systems. We propose a new type of decomposition algorithm based on Stochastic Dual Dynamic Integer Programming (SDDiP) to solve a dynamic programming formulation of a multistage stochastic unit commitment (MSUC) problem. We propose a variety of computational enhancements to adapt SDDiP to MSUC, and conduct extensive computational experiments to demonstrate that the proposed method is able to handle elaborate stochastic processes and can solve MSUCs with a huge number of scenarios that are impossible to handle byexisting methods.

5 - Techniques to Assess Performance of Electricity System Operation in the Presence of Ex Post Pricing
Tuong Nguyen, The New Zealand Electricity Authority, Level 7 - 2 Hunter Street, Wellington, 5024, New Zealand, manhtuong@yahoo.com

This paper examines an approach for the analysis of the system operator's real-time dispatch performance. In the New Zealand electricity system, generators are economically dispatched every five minutes in real time based on a real-time dispatch schedule. Computation of this schedule takes account of offers to supply, network topology, and demand forecasts. Market settlement prices are determined for each 30-minute trading period the following day using the final pricing schedule. The paper discusses the major causes of the differences between the real-time dispatch schedule and the final pricing schedule, and describes various options to measure system operation performance.

1 - Research on Diabetes Screening Strategies in China using Agent Based Simulation Model

Bowen Pang, Tsinghua University, Tsinghua Univ. Zijing 14#, Beijing, 100084, China, pzkaixin@foxmail.com, Xiaolei Xie, Yan Li, José A. Pagán

Diabetes is one of the major chronic diseases in China with a prevalence rate of more than 10%. Screening is an effective way to recognize diabetes at early stage in order to control and reduce relative costs. However, considering the large population with high variety, screening without sound strategy often incurs considerable amount of costs. Therefore, it is significant and challenging to make policies on diabetes screening. An agent based model (ABM) is developed and validated to simulate the status quo in order to provide policy implications for nation-wide screening strategy, which is currently lacking.

2 - Determinants of Older Patient Choice of Medical Service Provider in China

Yi Chu, PhD Student, Industrial Engineering, Beijing, China, chuy14@mails.tsinghua.edu.cn, Xie Xiaolei, Zuojun Shen

It is crucial to understand factors influencing health service choice to manage patient flow on a national level. We aim at finding the determinations of medical service provider choice between older patients in China. We use conditional logit model to analyze nationwide data from China Health and Retirement Longitudinal Study and local yearbooks in 2013. Outpatient and inpatient choice patterns in different regions are also compared. Our research shows that policy makers should design a flexible policy and pay attention to important factors, such as regional effect.

3 - Impact of Affordable Care Act (ACA) on Patient Choices and Care

Sarah Berkin, California State University, Hayward, CA, United States, sberkin@horizon.csueastbay.edu, Philip Cole-Regis, Kimberly Reyes, Balaraman Rajan, Surendra Sarnikar

We analyze the impact of the Affordable Care Act (ACA) on healthcare coverage in the United States. Rollout of the plans, protections, and mandates began in 2010, progressing until full implementation in 2015. There has since been a notable decrease in uninsured citizens. To assess the quality of healthcare, we focus on: number of, type, and cost of emergency room visits including wait times and appointment availability. We also look at the impact on preventive care through different indicators.

1 - Reducing Degradation in Batteries used for Frequency Regulation via Nonlinear Control

Johanna Mathieu, University of Michigan, 1301 Beal Avenue, EECS.Building, Ann Arbor, MI, 48109, United States, jlmath@umich.edu, Joshua Adam Taylor

Batteries can be used to provide frequency regulation to electric power systems; however, a battery's energy storage capacity degrades as it consumes and produces power. We extend an existing nonlinear battery model, pose the battery control/management problem as a tracking control problem, and develop several nonlinear controllers. In simulation, we show how the controllers enable us to easily tradeoff tracking accuracy and battery life, and how explicitly considering nonlinear battery dynamics in the controllers improves performance.

2 - Task-based End-to-end Model Learning in Stochastic Optimization

Priya L. Donti, Carnegie Mellon University, Pittsburgh, PA, 15213, United States, pdonti@cs.cmu.edu, Brandon Amos, J. Zico Kolter

While prediction algorithms commonly operate within some larger process, the criteria by which we train these algorithms often differ from the criteria on which we actually evaluate them: the performance of the full "closed-loop" system on the ultimate task at hand. For instance, instead of merely predicting electricity demand in a standalone setting, one may want to use these predictions within planning and control tasks such as power generator allocation in the presence of energy storage. We propose an end-to-end approach for learning probabilistic machine learning models in stochastic programming that directly capture the objective of the task for which they will be used.

3 - Collaborative Demand-response Planner for Smart Buildings with Storage

Juan A. Gomez, Polytechnique Montréal, 3190 Boul. Edouard Montpetit 104, Montreal, QC, QC H3T.1K2, Canada, juan.gomez@polymtl.ca, Miguel F.Anjos

We present a collaborative scheme for the end-users in a smart building with multiple housing units. This approach determines a day-ahead operational plan that provides demand-response services by taking into account the amount of energy consumed per household, the use of storage and solar panels, and the amount of shifted load. We use a biobjective optimization model to trade off total user satisfaction versus total cost of energy consumption. Experimental results and a sensitivity analysis validate the performance of the proposed approach and help to clarify its strengths, its limits, and the requirements for ensuring the desired outcome.

Interdependent System Modeling – The Nexus of Power, Natural Gas, and Water Systems

Sponsored: Energy, Natural Res & the Environment, Energy

Sponsored Session

Chair: Andrew Lu Liu, Purdue University, West Lafayette, IN, 47907, United States, andrewliu@purdue.edu

1 - Quantifying the Effect of Natural Gas Price Uncertainty on Economic Dispatch Cost Uncertainty

Dan Hu, Iowa State University, 422 Stonehaven Dr. Unit 17, Ames, IA, 50010, United States, danhu@iastate.edu, Sarah M. Ryan

In competitive electricity markets, vulnerability in gas supply to electricity generators creates a risk of high electricity prices. We propose an hourly economic dispatch model that accounts for natural gas availability and cost from both contracts and the spot market. With probabilistic inputs estimated from historical data, we use Monte Carlo simulation to generate the resulting distributions of electricity dispatch cost both with and without gas price uncertainty. The effect of gas price uncertainty is assessed in terms of distance between the distributions.

2 - An Economic Equilibrium Model for the Integrated Electricity Market

Lihui Bai, University of Louisville, Dept. of Industrial Engineering, J.B. Speed School Of Engineering, Louisville, KY, 40292, United States, lihui.bai@louisville.edu, Andrew Lu Liu, Qipeng Zheng

We consider an equilibrium model for an integrated electricity market system consisting of electricity consumers, power generators, grid owners, coal producers, natural gas producers, marketers and pipeline owners. In the equilibrium model, each individual player optimizes its own subsystem while market-clearance conditions are satisfied wherever players interact with each other. Numerical results will be reported including validation with the EIA's published data.

3 - Joint Optimization of Power and Water Systems through Distributed Algorithms

Andrew Lu Liu, Purdue University, 315 North Grant Street, School of Industrial Engineering, West Lafayette, IN, 47907, United States, andrewliu@purdue.edu

There has been an increasing interdependence between the power and water sector. Meeting growing electricity demand would require more fresh water for power plants' cooling, causing tension on water systems. While co-optimization of all the inter-linked systems may reach the most efficient solutions, it is impossible to do so with regulatory and computational constraints. We propose a provably-convergent distributed algorithm so that through each sector's individual optimization and information sharing, the joint-systems-wide optimal solution can be reached.

4 - Robust Defense Strategy for Gas-electric Systems Against Malicious Attacks

Feng Qiu, Argonne National Laboratory, Lemont, IL, United States, fqiu@anl.gov, Cheng Wang, Jianhui Wang

This talk proposes a methodology to identify and protect vulnerable components of connected gas and electric infrastructures from malicious attacks, and to guarantee a resilient operation by deploying valid corrective actions, while accounting for the interdependency of gas pipeline network and power transmission network. The proposed mathematical formulation gives rise to to a tri-level optimization problem. Case studies on two test systems demonstrate the effectiveness and efficiency of the proposed methodology.

Chair: Hamed Rahimian, Ohio State University, Columbus, OH, 43210, United States, rahimian.1@osu.edu

1 - Wasserstein Distributional Robustness and Regularization in Statistical Learning

Rui Gao, Georgia Institute of Technology, Atlanta, GA, 30332, United States, rgao32@gatech.edu, Xi Chen, Anton J.Kleywegt

A central question in statistical learning is to design algorithms that generalize to new data. We tackle this problem by formulating a Wassestein distributionally robust stochastic optimization (DRSO), and establish its connection with gradient-norm regularization. Such connection has several important implications. (i) It provides new interpretations for problems involving regularization, including many machine learning problems and discrete choice models. (ii) It enables a new way to derive generalization error bounds for statistical learning problems using tools from DRSO. (iii) It suggests a systematic approach to regularize problems in deep learning (e.g. training of GANs).

2 - Decomposition Algorithms for Distributionally Robust Optimization using Wasserstein Metric

Sanjay Mehrotra, Northwestern University, Dept of I.E./M.S.C246 Tech Inst, 2145 Sheridan Road, Evanston, IL, 60208-3119, United States, mehrotra@iems.northwestern.edu, Fenqiao Luo

We study distributionally robust optimization (DRO) problems where the ambiguity set is defined using the Wasserstein metric. We show that this class of DRO problems can be reformulated as semi-infinite programs. We give a central cutting-surface method for the convex objective, assuming that we have a separation oracle. We used a distributionally robust generalization of the logistic regression model (DRLR) to test our algorithm. Numerical experiments on the DRLR models show that the number of oracle calls are typically $20\sim 50$ to achieve 5-digit precision. The solution found by the model is generally better in its ability to predict with a smaller standard error.

3 - Data-driven Distributionally Robust Chance-constrained Programming with Wasserstein Metric

Ran Ji, Assistant Professor, George Mason University, 4400 University Dr. MS.4A6, Fairfax, VA, 22031, United States, rji2@gmu.edu, Miguel A.Lejeune

We investigate a class of distributionally robust chance-constrained (DRCC) optimization problems with Wasserstein metric. We develop a reformulation and algorithmic framework to solve the problem. We formulate a series of new DRCC models for portfolio optimization problems, including some widely used reward-risk ratios in finance. The computational study shows the applicability and scalability of the proposed framework.

4 - Distributionally Robust Newsvendor Problems with Variation Distance

Hamed Rahimian, The Ohio State University, 1971 Neil Avenue, 210 Baker Systems Building, Columbus, OH, 43210, United States, rahimian.1@osu.edu, Guzin Bayraksan, Tito Homem-de-Mello

We use distributionally robust stochastic optimization to model a general class of newsvendor problems. We form the ambiguity set by all demand distributions that their variation distances are bounded by a level of robustness-from a nominal distribution. For this problem: (1) we derive closed-form expressions of the optimal solution as a function of the level of robustness, (2) we determine the regions of demand that are critical to the optimal cost, and (3) we establish quantitative relationships between the distributionally robust model and the corresponding risk-neutral and classical robust optimization models. Our study can guide decision makers to choose an appropriate level of robustness.

Sponsored Session

Chair: Anna Timonina-Farkas, EPFL, RAO, Anna.farkas@epfl.ch

1 - Distributionally Robust Location-routing Problem

Dimitri Papadimitriou, Nokia Bell Labs, Rue du Charme 24, Brussels, 1190, Belgium, dimitri.papadimitriou@nokia-bell-labs.com

In Distributionally Robust Optimization (DRO), model data is represented as random variable over a family of probability distributions. The motivation of using this technique for the solving location-routing problems stems from the ambiguity characterizing the probability distribution of demands in space (origin) and size driving location and allocation-dependent routing decisions. For this propose, we propose a data-driven DRO model which produces decisions that are robust with respect to the ambiguity set of all demand distributions that satisfy prescribed statistical hypothesis tests.

2 - Optimizing Crashing Decisions in Project Management Problem with Disruptions

Haoxiang Yang, Northwestern University, 2145 Sheridan Road, Room C151, Evanston, IL, 60208, United States, haoxiangyang2019@u.northwestern.edu, David Morton

We consider the problem of crashing a PERT network to accelerate project completion under a small number of disruptions. When a disruption occurs, the duration of an activity, which has not started, can change. The magnitude of that change, and the timing of the disruption, can both be random. We formulate this problem as a stochastic mixed integer program (SMIP). We propose a branch-and-bound algorithm to solve the SMIP and evaluate the computational performance of our approach.

3 - Information Theoretic Learning in MDPs with Hierarchical Parametric Uncertainty in Transition Probabilities

Peeyush Kumar, B14, Industrian and Systems Engineering, MEB, University of Washington Seattle, Seattle, WA, 98195-2650, United States, agaron@uw.edu, Archis Ghate

This research extends the recent work on Information Directed Policy Sampling (IDPS) to hierarchical MDPs. IDPS provides a way for decision maker to simultaneously balance the effect of exploration and exploitation. We consider MDPs where uncertainty in transition probabilities comes from two levels. The top level uncertainty corresponds to the decision-maker's uncertainty about the system model. The bottom-level uncertainty is rooted in the decision-maker's knowledge about the model parameters. This research extends IDPS to hierarchical MDPs and provides analytical performance bounds as well as numerical analysis on Response Guided Dosing.

4 - Robust PageRank: Stationary Distribution on a Growing Network Structure

Anna Timonina-Farkas, EPFL, RAO, Rue Saint-Laurent 33, Lausanne, Switzerland, anna.farkas@epfl.ch

PageRank is a challenging and important network ranking algorithm, which plays a crucial role in information technologies and numerical analysis due to its huge dimension and wide range of possible applications. Recently, a robust formulation of the PageRank model has been proposed for the case, when links in the network structure may vary influencing the transportation matrix defined by the network structure. In this work, we make a further step forward, allowing the network to vary not only in links, but also in the number of nodes. We propose a new robust formulation of the PageRank problem for uncertain networks with fixed growth rate.

Stochastic Mixed-Integer Programming and Applications

Sponsored: Optimization, Optimization Under Uncertainty

Sponsored Session

Chair: Semih Atakan, University of Southern California, Los Angeles, CA, 90089-0193, United States, atakan@usc.edu

1 - Error Bounds for Inexact Cutting Plane Techniques for Stochastic Mixed-integer Programming Problems

Ward Romeijnders, University of Groningen, Nettelbosje 2, Groningen, 9747 AE, Netherlands, w.romeijnders@rug.nl

We derive error bounds for a class of inexact cutting plane techniques for stochastic mixed-integer programming problems. These error bounds converge to zero if the total variations of the probability density functions of the random variables in the model converge to zero. Moreover, we show several numerical experiments, illustrating the actual error of using these inexact methods.

2 - Solving Stochastic Mixed-Integer Programs using a Generalized Value Function

Onur Tavaslioglu, University of Pittsburgh, 7171 Buffalo Speedway, Apt 1934, Houston, TX, 77025, United States, ont1@pitt.edu, Oleg A.Prokopyev, Andrew J. Schaefer

We introduce the generalized value function of a mixed-integer program, which is simultaneously parameterized by its objective and right-hand side. We describe its fundamental properties, which we exploit through three algorithms to calculate it. We then show how this generalized value function can be used to reformulate two classes of very difficult mixed-integer optimization problems: two-stage stochastic mixed-integer programming and multi-follower bilevel mixed-integer programming. For both of these problem classes, the generalized value function approach allows the solution of instances that are significantly larger than those solved in the literature.

3 - Subgradient Methods for Stochastic Mixed-Integer Programs

Cong Han Lim, University of Wisconsin-Madison, Madison, WI, United States, clim9@wisc.edu, Jeff T.Linderoth, James Luedtke, Stephen J.Wright

We present our work on improving the subgradient method for solving the Langrangian dual of a stochastic mixed-integer program (SMIP). Our techniques include subsampling and asynchronicity, and leads to methods that have similar guarantees as the full subgradient method. The algorithms run effectively on both large-scale distributed platforms and multi-core servers. We present computational results on some classic SMIP problems.

4 - PH-BAB Applications in Power Systems Planning

Semih Atakan, University of Southern California, 3715 McClintock Ave, GER.240, Los Angeles, CA, 90089-0193, United States, atakan@usc.edu, Suvrajeet Sen

Progressive Hedging (PH) has been used as a heuristic optimization method for many SMIP problems. In this talk, we briefly describe our framework (PH-BAB) for using PH to compute optimal solutions to stochastic mixed-integer convex programs (SMICPs). We, then, present an algorithm within this framework for specially-structured SMICPs. The performance of the algorithm will be demonstrated on academic benchmark instances and stochastic Unit Commitment problems.

Monday, 12:30 - 2:30PM

■ Monday Poster

Monday Poster Session

Poster Session

1 - Weighted Networks: Edge-splitting Procedure in Centrality Computations

Ivan Belik, Dr., Norwegian School of Economics, Helleveien 30, Bergen, 5045, Norway, ivan.belik@nhh.no

The analysis of social network's centralities has a high-level significance for many real-world applications. The variety of game and graph theoretical approaches has a paramount purpose to formalize a relative importance of nodes in social networks. In the given research, we present a formalized symbiotic graph theoretical and game theoretical algorithm for the centrality computation in the domain of weighted networks. The given algorithm calculates network centralities for weighted graphs based on the proposed edge-splitting procedure. The approach is tested and illustrated based on different types of network topologies.

2 - Managing Volunteer Convergence at Disaster Relief Centers

Hussain Abualkhair, North Carolina A&T.State University, 614 Eagle Road, Apt 2C, Greensboro, NC, 27407, United States, hfabualk@aggies.ncat.edu

Disaster Relief center managers face uncertainty in both the timing and quantity of donations, as well as the number of spontaneous volunteers. Volunteer convergence is one of the biggest challenges for relief center managers. To better understand this phenomenon and find effective management strategies, we develop an agent-based simulation model consisting of donors providing relief items, beneficiaries in need of relief items and random arrivals and departures of volunteers. We investigate volunteer assignment policies that reduce donor beneficiary waiting time under given changes in volunteer capacity, available inventory, and beneficiary's arrival rates.

3 - Budgeting Dredging Projects to Improve Resilience of the Inland Waterway Network

Khatereh Ahadi, PhD Candidate, University of Arkansas, 4207 Bell Engineering Center, Fayetteville, AR, 72701, United States, kahadi@uark.edu

We consider the problem of selecting a budget-limited subset of maintenance actions to maximize the expected tonnage of commodities that can be transported through the inland waterway system. Uncertainty in our model is the budget required at each district for emergency dredging arises from unpredictable conditions. Thus, our main decision is allocating budget to each district to cover the cost of reactive dredging. We model this problem as a stochastic programming model, develop solution approaches, and analyze computational results.

4 - Robust Synthetic Control

Muhammad J. Amjad, Massachusetts Institute of Technology, 235 Albany Street, Suite 3121A, Cambridge, MA, 02139, United States, mamjad@mit.edu, Devavrat Shah, Dennis Shen

Abadie et al introduced the idea of using "synthetic control" for comparative case studies, where the control unit is a convex combination of unaffected (donor) units. We present "robust" synthetic control where we propose a generic latent variable model which subsumes the classical method. Algorithmically, we first "de-noise" the observations and then learn the linear synthetic control allowing us to do away with needing preprocessing "expert" knowledge or covariate information to identify a good subset of donor units. Additionally, our algorithm is asymptotically consistent in MSE and robust to missing and/or noisy observations.

5 - Predicting Power Price Profile in the Electricity Market by Solving a Bi-level Optimization Problem

Maliheh Aramon, Applied Researcher, 1QBit, Unit 403, 1461 Harwood Street, Vancouver, BC, V6G 1X7, Canada, maliheh.aramon@1qbit.com

In this project we address a practical bi-level optimization model in the electricity market. By considering market data for a particular operating horizon, our goal is to find an hourly price profile incentivizing global production levels that closely match the market demand. To solve the problem, a two-stage heuristic algorithm is developed. An initial price profile is first found and a sequence of steps then iteratively perturbs the price profile closer to an optimal price profile. The designed heuristic algorithm can also be solved using disruptive hardware such as a quantum annealer. Our numerical results on a real data set illustrate a close match between supply and demand for 95% of the hours.

6 - Interdicting Layered Physical and Information Flow Networks

Nail Orkun Baycik, Rensselaer Polytechnic Institute, 110 8th Street Center for Industrial Innovation, Suite 5015, Troy, NY, 12180, United States, baycin@rpi.edu

We study the interdiction of layered networks that involve a physical flow and an information flow network. The objective of the defender is to maximize the physical flow and the objective of the attacker is to minimize this maximum amount. There exist interdependencies between the networks which leads to a network interdiction problem with a discrete inner problem. By using duality, we reformulate the problem and obtain a single-level model. We apply this technique to the application of combating illegal drug trafficking and protecting cyber infrastructures, and present computational results.

7 - Optimal Operation of Large Scale Flexible Hydrogen Production in Constrained Transmission Grids with Stochastic Wind Power

Espen Flo Bødal, PhD Candidate, Norwegian University of Science and Technology, O.S.Bragstads Plass 2E, Trondheim, 7030, Norway, espen.bodal@ntnu.no

The focus of this work is on developing and assessing the value of using a stochastic model when planning the operation of the flexible hydrogen production in a region with large wind power potential and constrained transmission grids, and how it affects storage strategies. Specific situations when the stochastic model is superior to a deterministic model based on the expected value is identified and analyzed in detail. The effects from stochastic wind power production on the optimal size of storage is also investigated by conducting an analysis of the dual variables of the storage constraints.

8 - Best Subset Selection of Factors Affecting Influenza Spread using Multi Objective Optimization

Aigerim Bogyrbayeva, graduate Student, University of South Florida, 4202 E. Fowler Avenue, Tampa, FL, 33620, United States, aigerimb@mail.usf.edu, Hanisha Tatapudi, Walter Silva, Hadi Charkhgard

Influenza ranks among the most common viral infections. It is extremely contagious and fatal for senior adults and children. Influenza is treated by pharmaceutical interventions (i.e. vaccines) and non-pharmaceutical interventions (i.e. quarantines). Due to the nature of the disease and its viral mutations, creating vaccines for every Influenza strain is time consuming. Hence, Non-Pharmaceutical Interventions (NPIs) have been successfully used in the past. We study the impact of NPIs on the spread of the disease and recommend the best subset selection of NPIs. We used a bi-objective optimization approach for accurately predicting the infection attack rate and minimizing the number of NPIs.

9 - Will the High-speed Passenger Railway Line Operation Affects on Regional Logistics System

Mi Gan, Southwest Jiaotong University, Jinniu District, 111 N.1st Erhuan Road, Chengdu, 610031, China, migan@swjtu.cn, Xi Huang

An applied STIRPAT model has been applied to estimate the impacts of high speed passenger railway line operation on regional logistics system. The regional freight volume from 2014-2016 has been selected to represent the status of logistics system, the number of passenger of each stations of high speed passenger railway line has been selected as the independent variable. The analysis result shows high-speed rail operation has positive effects on regional logistics system.

10 - An Optimization Model for Resilient Service Systems

Jing Gong, Jinan University, School of Public Administration, Guangzhou, China, tgongjing@jnu.edu.cn

A service system in our research has two-fold meaning: 1)to meet the demand; 2)to be delivered by a directed graph. Recent catastrophic events precipitate a wide range of impacts so that public awareness continues to grow of resilience as an important means of characterizing the ability to deal with them. Taking resilience into account will raise the following questions: How can we represent the resilience of a service system? How can managers tradeoff between a cost minimum system and a resilience maximum system? This paper proposes a linear piecewise recovery function and applies it to the decision-making processes of improving a service system's resilience to disasters.

11 - Educational Efficiency Distance in Secondary Schools of SãO Paulo Municipalities

Maria Cristina Gramani, Professor, INSPER.Institute of Education and Research, Rua Quatá 300, Sao Paulo, 04546-042, Brazil, mariacng@insper.edu.br

This study analyzes the performance of secondary schools in Brazil according to two indicators: (i) "gap of the school", which measures the real distance of performance between schools in national ranking and, (ii) "discipline bias", which investigates whether schools with better educational performance are those with a higher tendency to score better in certain fields. We found that, high level of students in Mathematics consists on the determinant of efficiency of schools with a higher socioeconomic level, and the lower number of students with low level in Human science is the efficiency determinant of schools with lower socioeconomic status.

12 - Determining Decoupling Points in a Supply Chain Associated with Different Design Preferences

Lin Guo, University of Oklahoma, Norman, OK, United States, lin.guo@ou.edu, reza alizadeh, Janet Katherine Allen, Farrokh Mistree

In this research, we propose an approach using exploration of the solution space of a multi-goal compromise Decision Support Problems model to determine the decoupling points of a three-echelon supply chain. Facing different design preferences of the supply chain, the goals should be satisfied in different degree, and the change of the design preference may take place rapidly, which requires the decoupling points flexible enough to be moved through the supply chain.

13 - Bus Ranking Method for Robust Optimization

Amandeep Gupta, Cornell University, 316 Highland Road, Ithaca, NY, 14850, United States, ag729@cornell.edu, Lindsay Anderson

Interest in efficient and flexible stochastic methods for unit commitment has been growing steadily in answer to increasing renewable energy resources on the grid. This work describes a statistical bus ranking methodology that identifies the most critical buses based on criteria such as economic dispatch cost, or ramping needs to provide a robust unit commitment solution. The method is illustrated via a case study on the IEEE 30-bus system and compared to other established approaches to demonstrate the efficacy of obtained solutions. Results show that the bus ranking method performs as well as the best of these methods, with the provision of additional flexibility and potential for parallelization.

14 - Optimal Step-stress ALT under Interval Monitoring and Progressive Type-I Censoring

David Han, University of Texas at San Antonio, Management Science & Statistics, College of Business, San Antonio, TX, 78249-0632, United States, david.han@utsa.edu

A step-stress ALT under progressive Type-I censoring was considered when a continuous monitoring of failures is infeasible but inspections at certain time points is possible. In addition to the accelerated failure time model, a general scale family of distributions was considered for flexible modeling. The MLE of scale parameters and their conditional densities could be derived explicitly. Using the exact distributions of the estimators, confidence intervals for the parameters were obtained and numerically assessed.

15 - Views and Subscriptions: Which One Matters to a Youtuber's Monetization Success?

Bo Han, Texas A&M.University-Commerce, 2600 S.Neal, Commerce, TX, 75428, United States, bo.han@tamuc.edu

The critical factors to a monetization success have gained a tremendous interest from YouTubers and social media entrepreneurs. However, there has not been a rigorous study testing the effects of the view factors and subscription factors on a YouTuber's revenues. We introduce a new empirical model to address this knowledge gap. Validating our model by a panel data of 116 most viewed YouTuber channels, we find that the new daily views, the daily view growth rate, and the existing total views of a YouTuber's videos are significantly positively associated with her daily revenue. The subscription variables do not directly contribute to a YouTuber's daily revenue.

16 - Server Behaviours in Queueing Systems

Paul Harper, Cardiff University, School of Mathematics, Cardiff, CF24 4AG, United Kingdom, harper@cardiff.ac.uk

In the classical queueing theory literature, a server is commonly assumed to work at a constant speed. Motivated by observations from healthcare applications, in particular within Emergency Departments, a study is made to explore the nature of the relationship between service times and workload in order to assess and quantify any workforce (server) behaviours. An analytical model is presented in which service time depends on queue length. The research helps to demonstrate the importance of more accurately capturing server behaviours in workload-dependent environments, and the impact this has on the overall system performance.

17 - Optimization of Emergency Evacuations Through Exit Allocation and Risk Analysis

Elizabeth Hooper, Texas A&M.University-Kingsville, Kingsville, TX, United States, elizabeth@alumni.purdue.edu

Exit locations and evacuation procedures facilitate occupant safety during emergencies. This research aims to optimize building exit locations and analyze risk during building evacuations. Nonlinear programming and queueing theory are used to optimize exit locations and determine egress times. A risk analysis with risk matrix and flow chart for emergency evacuation are also created. Lastly, this paper discusses an application of smart building technology for building evacuations during emergencies. The results show that the use of optimization techniques and risk analysis allow better planning and response during emergencies.

18 - Decision Pattern Mining in Chronic Disease

Praowpan Tansitpong, Mahidol University International College, 999 Bhuddamonthn 4 Rd., Nakon Pathom, 73170, Thailand, praowpan.tan@mahidol.ac.th

This study utilizes electronic medical records (EMRs) to evaluate diversity in standard of care from prescription decision in multiple clusters and identify "high cost" segment by using health benefit differentiation, brick-and-mortar Pareto classification, and Hierarchical clustering.

19 - Natural Language Processing Techniques for Patent Analysis in Management Research

Mike Horia Teodorescu, Doctoral Candidate, Harvard Business School, Wyss House, Boston, MA, 02163, United States, miketeod@hbs.edu

As legal instruments, patents do not follow the linguistical assumptions expected in a natural language. Direct application of standard linguistic tools does not capture the intricacies of the patent corpus. I present a novel corpus model, modified measures of textual similarity, and applications of patent text processing to knowledge flows within and across firms.

20 - Optimization of Scheduling Malleable Tasks on Single-stage Non-identical Machines

Qing Wang, Northeastern University, Heping District, 3-11 Wenhua Road, Liaoning, 110819, China, qwang@mail.neu.edu.cn

This paper considers a special manufacturing environment of make-to-order quartz processing enterprise. The tasks for scheduling are malleable and each has a due date with penalty for tardiness. The considered production stage is the bottleneck factor of order tardiness in the whole manufacturing process, and there are several equipments or machines in common function at the stage. Each equipment or machine has distinctive processing efficiency and processing costs. The study aims to minimize the total costs in two aspects of the processing costs and the tardiness penalties to find the optimal schedule solution.

21 - An Artificial Neural Network Based Decision Framework for VRPTW

Bochen Wang, Shanghai University, Shanghai, China, websterchen@163.com

This paper proposes an improved technique for VRPTW decision framework by using the Cplex solution to train the BP neural network. Through tunning parameters, the trained network can get the near optimal solution of VRPTW. The numerical result shows the improved method can reduce computing time efficiently.

22 - Cranes Scheduling in Frame Bridges Based Automated Container Terminals

Wencheng Wang, Shanghai University, Shanghai, China, 194716297@qq.com

This paper investigates crane scheduling problems for a new type of automated container terminal system, which is based on multi-storey frame bridges. For this new design concept, this paper studies how to schedule two types of cranes, i.e., quay cranes and bridge cranes that transfer containers between different storeys. The schedules of these two types of cranes impact the operation efficiency of the terminal system. Mathematical models are proposed for the two scheduling problems. Meta-heuristics are developed to solve them. Numerical experiments are conducted to validate the effectiveness of the proposed models and the efficiency of the proposed solution method.

23 - Forecasting Environmental Life Cycle Impacts (FELCI) for U.S. Army Material Selection

Matthew D. Wood, U.S. Army Engineer Research and Development Center, ERDC - US.Army Corps of Engineers New England, 696 Virginia Road, Concord, MA, 01742, United States, matthew.d.wood@usace.army.mil, Taylor E.Rycroft, Jeffrey Cegan, Igor Linkov

Managers of military training ranges require approval from environmental regulators and other interests when proposing changes to training activities (e.g., new materials, operating procedures). Regulators bias toward requiring all possible environmental tests, however, information gained tends to decrease logarithmically as time/dollar cost increases. We introduce the FELCI tool, a portfolio model built on top of UNEP/SETAC's USEtox 2.0 model. It recommends the optimal portfolio(s) of fate, exposure, and effects tests that minimize uncertainty in predicted ecotoxicological impacts while adhering to program cost and time constraints.

24 - Multi-parametric Sensitivity Analysis of Integer Programming: A Comparison of Two Optimization Algorithms

Hsin Pin Wu, National Tsing Hua University, No. 101, Section 2, Kuang-Fu Road, Hsinchu, Taiwan 30013, R.O.C., Hsinchu, 30013, Taiwan, newstephanie90404@gmail.com, Yu Ching Lee, Chor Yiu Sin

This study develops multi-parametric sensitivity analysis theorems for integer programs from two different algorithms: column generation and the iterative dual method proposed by Shapiro (1977). We develop post-optimality analysis theorems which indicate that the optimal solution will remain optimal if the sum of the negative reduced cost is not less than a threshold. Then, we carry out numerical experiments with multi-parameter costs perturbation problem using two proposed theorems separately and compare the results and computational tractability.

25 - Store Brand Introduction Strategy under Retailer Stackelberg Leadership Supply Chain

Hongming Xu, Doctoral Candidate, Tongji University, School of Economics and Management, 1239 Siping Road, Shanghai, China, shyiming2013@gmail.com, Yongrui Duan, Jiazhen Huo

We study store brand introduction strategies in a market channel composed of one national brand manufacturer and two retailers which, each, carry a national brand product and may sell its own brand product. We use a game theoretic model to analyze interactions between retailers' store brand decision and channel leadership structures which contained both vertical level (between manufacturer and retailers) and horizontal level (between retailers) with retailers as leader . As a result, retailers will be easier to introduce a store brand in a retailer stackelberg leadership structure.

26 - Measuring Nursing Home Efficiency using PCA-DEA Approach

Fangzheng Yuan, Upper Great Plains Transportation Institute, 1340 Administration Ave, Fargo, ND, 58108, United States, Fangzheng.yuan@ndsu.edu, Yongshin Park

This study employs a robust approach to measure the efficiency of the nursing homes in Fargo-Moorhead Metropolitan area using two stage analysis consisting of principal component analysis (PCA) and data envelopment analysis (DEA). The objective is to improve discriminatory power of the DEA by reducing the dimensionality of data set when there is an excessive number of inputs and outputs compared to the number of decision-making units (DMUs). The performance of each DMUs is ranked and a benchmarking target is provided to improve the efficiency score in this study. The result demonstrates that using PCA can noticeably improve the discrimination of DEA models.

27 - Multimodal Emergency Medical Transportation Network Design for Trauma Patients

Nasibeh Zanjirani Farahani, University of Missouri, E3437 Thomas and Nell Lafferre Hall, Columbia, MO, 65211, United States, nzqpc@mail.missouri.edu, James Noble, Moein Enayati

Parallel usage of different modes of transportation in the design of healthcare transportation network provides the chance of full demand coverage for trauma patients' services. Ambulances and helicopters should work together to achieve the highest rate of survival. This paper presents a mathematical model to reach the minimum commuting time.

28 - Liner Ship Deployment Considering Transshipment, Fuel Cost and Port Capacity

Lu Zhen, Shanghai University, Room 469, 599 Shangda Road, Shanghai, 200444, China, mmshan@shu.edu.cn, Hu-Chen Liu, Jianxin You, Jianxin You, Mengmeng Shan

This paper investigates a liner ship deployment problem, which can help a liner shipping company to decide the suitable number of ships deployed on each route as well as the suitable arrival time at each port of call on each route in the company's shipping network. Different from the related literature, this paper considers some more comprehensive and realistic factors such as the container transshipment in the network, ships' fuel consumption cost affected by their sailing speed, capacity limitations at ports with respect to the resources of berths

29 - Flexible Design under Uncertainties

K.Jo Min, Iowa State University, 3004 Black Engineering, Department of Industrial &, Ames, IA, 50011-2164, United States, jomin@iastate.edu, John Jackman, Chung-Hsiao Wang, Joe Eilers

In this poster, we examine the economic value of various flexibilities in the design of products, processes, and systems based on simple principles of stochastic optimal control. We show how such a value determines strategic decisions relevant to design, and discuss the economic implications and managerial insights.

30 - Applying a Pythagorean Model for NFL Playoff Analytics

Tung Cu, Bloomsburg University of Pennsylvania, 400 E. Second Street, Bloomsburg, PA, 17815, United States, tcu@bloomu.edu, Carolyn Lamacchia, Ty Rohrbach

Sport analytic topics have been received a large attention by both professional and academic communities. However, previous research on predictive modeling of National Football League (NFL) games only focuses on one-for-all models for an entire season. Since competitions in regular season much differ from that in playoffs, previous models are not robust. Strategic moves in a regular season are for the best conference position while playoffs present a win-at-all-cost situation. The result of the playoffs is much more uncertain than regular season games. The current study proposes a Pythagorean model to predict the NFL playoffs since playoff games lead to the coveted championship.

31 - New Data for Representing Irrigated Agriculture in Economy-wide Models

Kirby Ledvina, MIT.Joint Program on the Science and Policy of Global Change, 77 Massachusetts Avenue, Building E19-411, Cambridge, MA, 02139, United States, kledvina@mit.edu, Niven Winchester, Kenneth Strzepek, John Reilly

The paper develops a framework to represent irrigated land's crop production value and expansion potential within economy-wide models. Production values are calculated at a high spatial resolution, and a global dataset of evaluation metrics identifies the regions and crops where there are large differences in irrigated production value shares based on direct calculation and approximated by output volumes. Separately, the paper quantifies irrigated land's expansion potential through regional supply curves based on water availability and the costs of irrigation infrastructure. Altogether, the paper enables a deeper exploration of the impacts of water availability on economic activity.

32 - Measuring Climate Resilience of Hong Kong's Transportation System

Xinying Huang, University of Hong Kong, Pokfulam Road, Haking Wong Building, Hong Kong, Hong Kong, xinying@hku.hk

Transportation plays an important role in a society's daily operation. Under the background of global warming, there are more extreme weather events, such as tropical cyclone, rainstorm, etc. Almost all modes of Hong Kong's transportation will be affected by these events. The impact reflects on the decrease in road capacity, the increase in transportation time, etc. Resilience is the ability of a system to maintain its main function when disaster or emergency happens. This research uses stochastic programming to model a multi-modal transportation network under adverse weather condition for Hong Kong and does analysis on network resilience.

33 - Cloud-based Inventory Optimization Solution for Retail

Dmitry Pechyony, Microsoft, Cambridge, MA, United States, dmpechyo@microsoft.com, Chenhui Hu, Hong Lu, Praneet Singh Solanki, Ilan Reiter

We present a cloud-based inventory optimization solution. It can be deployed in Azure cloud from https://aka.ms/invopt and customized to business goals and constraints of retailers. Our solution has a flexible, scalable and extensible architecture. Operations researchers and developers can use it to define optimization problems of new inventory management policies, operationalize them and track their performance. We use Azure Data Lake to store unlimited data volumes and Azure Batch to solve optimization problems in parallel. Furthermore, many free and commercial solvers can be plugged into our solution using Pyomo interface. The source code and documentation are at https://aka.ms/invdoc .

34 - Information Overload's Hidden Impact – the Response to a Rising Tide of Information.

William D. Senn, Dr., Texas Woman's University, 8808 Cassidy Lane, Aubrey, TX, 76227, United States, wsenn1@twu.edu

As information load increases, decision accuracy also increases up to an undefined point after which decision accuracy decreases. This turning point is where information overload begins, according to (Eppler & Mengis, 2004). This study looks at how knowledge managers perceive information overload. It investigates the impact of fake news and big data on these perceptions. In a world of ever increasing information flow people are bombarded with information. This research provides insight into the information overload response function.

35 - Ranked Constraint Reconciliation for Price Optimization

Jagdish Ramakrishnan, Data Scientist, Walmart Labs, 1000 National Ave, Unit 214, San Bruno, CA, 94066, United States, jagdish.ram@gmail.com, Matyas Sustik

Given a set of ranked infeasible constraints, generate a new feasible set of constraints. In the context of price constraint reconciliation, merchants provide local constraint information (e.g., item price bounds, pack sizes) that together are impossible to meet. We would like to avoid violations on high priority constraints and allow some violations on low priority constraints. The proposed method processes constraints by rank and repeatedly solves optimization subproblems using slack variables. We implemented a python module that takes in ranked linear constraints and outputs a set of feasible constraints. It enables maintainability and flexibility compared to lengthy logic-based code.

36 - Biological Restoration of Fragmented Landscapes for Connectivity and Intactness

Denys Yemshanov, Research Scientist, Natural Resources Canada, 1219 Queen street East, Sault Ste. Marie, ON, P6A2E5, Canada, denys.yemshanov@canada.ca, Robert G. Haight, Frank H. Koch, Marc-André Parisien, Tom Swystun, Quinn Barber, Salimur Choudhury, Fabio Campioni, Cole Burton

Maintaining habitat connectivity for endangered wildlife is critical for successful restoration of fragmented landscapes. We propose a maximum flow, multigraph connectivity formulation with connected area requirements and budget constraint to address landscape restoration. The MIP model is scenario-based, with an objective of determining restoration strategies that maximize habitat area accessible to wildlife in a fragmented landscape. We apply the model to habitat restoration for woodland caribou in boreal forest in Cold Lake area, Alberta, Canada.

37 - Investigating the Effect of Prescription Sequence on Developing Adverse Drug Reactions

Behrooz Davazdahemami, Oklahoma State University, 4599 N. Washington St, Apt 40A, Stillwater, OK, 74075, United States, davazda@okstate.edu, Dursun Delen

Adverse Drug Reactions (ADR) is a pharmacovigillance term that refers to any injury caused by taking drugs in the way prescribed by physicians. In this study applying an emergent pattern mining approach to electronic health records of more than 370,000 diabetic patients, we examine the potential effect of drug prescription sequence on the development of ADRs. Specifically we focus on Acute Renal Failure as a condition that frequently occurs in diabetic patients. We first investigate whether common diabetic drugs play any confounding role in developing renal failure; afterwards, the effect of prescription sequence on this ADR is examined. The results verify that such role exists.

38- Analysis on the Coordinated Development Between Logistics Industry and the Other Industries in Sichuan Based on Grey Relativity Analysis

Si Chen, Dr., Southwest Jiaotong University, #111 North of Erhuan Road, ChengDu, 610031, China, chensi@swjtu.edu.cn, Xinyuan Li, Yinying Tang, Mi Gan

Logistics industry plays an important role in the development of Sichuan economy. We research into the relationship between the logistics industry and the agriculture,manufactory and business, which are the main economic development departments in Sichuan. And we analysis the gray correlation and the coupling degree of logistics industry and the other industries based on the logistics related data of Sichuan province from 2011 to 2016. Therefore, the development of logistic industry is a strong influence to the other industries, and it can provide adaptive supporting environment forthe other industries.

39 - Pricing and Service Strategies in E-retailing: the Effects of Safety Stock

Yi Ding, Southeast University, Sipailou 2, Nanjing, 210096, China, drdingyi@outlook.com

This study aims to examine service and price competition in an online retailing system comprised of two suppliers and one e-retailer. A Stackelberg game is formulated with the suppliers as the leaders who determine wholesale prices and service times and the e-retailer as the follower who sets the retail prices. Changes of service time affect safety stock which is characterized by the guaranteed service model. We find that the "service first" strategy should be pursued when suppliers face increasing safety stock cost, and the influence of one supplier's service can be spilled over to the competing product's wholesale and retail prices, depending on the difference between consumer transfer ratios.

40 - Forecasting Strategies for Predicting the Peak Load Demands of a University Campus: A Case Study on Rochester Institute of Technology

Harshit Saxena, Master of Science, Rochester Institute of Technology, 1 Lomb memorial drive, Rochester, NY, 14623, United States, hs3185@rit.edu, Katie McConky

Academic institutions spend thousands of dollars every month on their electric power consumption. A large percentage of these institutions follow a demand charges pricing structure; here the amount a customer pays to the utility not just depends upon the energy consumed during the month but also on the maximum load required by the customer over a moving window of time as decided by the utility. This research is a case study conducted on Rochester Institute of Technology which aims at developing a forecasting strategy to predict the occurrence of peak load periods and hence run a demand response plan to maximize the financial savings for the institution.

41 - Signal Effect of XBRL Filing: An Investor's Perspective

Soohyun Cho, Assistant Professor, Rutgers University, Newark, NJ, United States, scho@business.rutgers.edu

The SEC requires companies to provide financial data in the XBRL format as well as traditional financial statements. Despite XBRL disclosures containing information identical to the statements, and belying corporate sector doubt of the disclosures' benefits, most capital market investors tend to respond positively to the filing. For market reaction analysis, we develop a stylized model using two investor groups - market leaders and market followers, depending on their respective information sets. Applying this model, we find that the level of the XBRL filing's capital market impact is associated with the number of market followers.

42 - An Analysis of One Version of the Tracking Signal

Peruvemba Sundaram Ravi, Associate Professor, Wilfrid Laurier University, Operations & Decision Sciences, Waterloo, ON, N2L.3C5, Canada, pravi@wlu.ca

Tracking signals are used to determine whether a sequence of forecasts is unbiased. We analyse a version of the CUSUM tracking signal that is used in standard Operations Management texts. We show that this version of the tracking signal can indicate that the sequence is not unbiased even when it is unbiased. We suggest a simple modification that serves to eliminate this flaw.

43 - Data-driven Decision Making for Re-timing and Optimization of Signalized Intersections

Nabaruna Karmakar, PhD Candidate, North Carolina State University, 3609 Research Building IV, Raleigh, NC, 27695, United States, nkarmak@ncsu.edu, Thomas Chase, Billy M. Williams

This research is aimed at using a variety of data sets to enable intelligent decision-making regarding signal re-timing and maintenance. The final product of this research is building a data-driven optimization technique, using mathematical programming to identify corridors that need re-timing and suggesting different time of day signal timing plans for such corridors. With continuous data like high resolution controller data and Vehicle Probe Data, enhanced performance metrics can be calculated to strategically prioritize and select systems for re-timing that have a higher potential of improvement solely based on optimization benefits.

44 - Content Discovery and User Engagement in Digital Platforms: A Field Experiment in Music Platforms

Shadi Janansefat, PhD Candidate, University of Pittsburgh, 229 Mervis Hall, Pittsburgh, PA, 15260, United States, shj35@pitt.edu

Digital content provider platforms focus on improving success metrics such as engaged time and content discovery, which create continuous usage and engagement. We draw from information foraging theory and social foraging model to investigate how platforms can use social design to improve users' engagement and content discovery. We employ a randomized field experiment on a social music platform mobile application to study how availability of two information signals, popularity on platform and popularity among peers, can enhance user engagement and content discovery. We enumerate the experiment design to test our hypotheses.

45 - Challenges with Data Collection in Methods to Reduce Clinic Wait Times

Rachel Moeckel, Graduate Student, University of Michigan, 504 1/2 N.5th Avenue, Ann Arbor, MI, 48104-1110, United States, rachwold@umich.edu, Amy Cohn, Paula Anne Newman-Casey

A chief complaint received at an Ann Arbor clinic concerns long wait times during appointments. A team assembled with goals of reducing wait times and introducing patient education in irreducible periods, thereby enabling the clinic to see patients with better efficiency and effectiveness, increase adherence through education, and ultimately improve the patient experience. To do so, we implemented passive RFID technology, the data from which enables exact and automatic calculation of wait times. However, challenges arose with clinic staff, collaboration of engineering and medicine, and conversion of RFID signals to wait times. Here we explore such matters and provide insight into solutions.

46 - Method of Update Forecast Sales Data for DDMRP Respecting Product Similarity

Shuto Tsuchiya, Master, The University of Tokyo, 4-6-1, Komaba, Meguro-ku, Tokyo, 1530041, Japan, shuto555@iis.u-tokyo.ac.jp, Mondo Sygiyama, Motoki Tajima, Tsuyoshi Nobata, Miyuki Wakasugi, Yudai Honma, Masayuki Soneda

Demand Driven Material Requirements Planning (DDMRP) is one of production methods that can flexibly respond to a variety of factors such as supply, operation, and demand in supply chains. Although it has established a short-term strategy policy to decide inventory volume for actual demand in DDMRP, it has not been established on how to make a long-term strategy using demand forecast. Thus, it can be said to be a developing method. In this paper, we devise a method of updating demand forecast by an actual demand that can deal with cases of demand change, seasonal variation, new products, and discontinued products in adopting DDMRP. We also show examples of simulations utilizing actual sales performance data.

47 - Optimal Design of Multi-tiered Drug Formularies in Canada: Multiple Criteria Decision Making

Vusal Babashov, Doctoral Student, University of Ottawa, 55 Laurier Ave East, DMS.6115, Ottawa, ON, K1N.6N5, Canada, vusal.babashov@uottawa.ca, Sarah Ben Amor, Gilles Reinhardt

We focus on the downstream relationships between pharmacy benefit management and consumers. In this phase, we assume that the set of products and the formulary structure (number of tiers and copay schedule) are fixed. We develop drug-to-tier allocation model that uses multi-criteria decision methods to maximize the expected return of the plan, its coverage, and other objective criteria that take into account operational factors (demand, capacity, inventory, and service level), clinical factors (drug effectiveness, interactions, and indications), and economic factors (cost, utility, and preference).

48 - Night Team Scheduling for Pediatric Inpatient Residents

Bassel Salka, Center for Healthcare Engineering and Patient Safety, 1075 Beal Avenue, Ann Arbor, MI, 48109, United States, bsalka@umich.edu

We present our development of a decision-support tool that uses linear programming to automate the construction of team assignments for residents rotating on the inpatient ward night team each month in a pediatric hospital.

49 - MAP Estimation in Bayesian Variable Selection Models via MINLP

Michael Lindon, PhD Student, Duke University, Durham, NC, 27710, United States, michael.lindon@duke.edu

A Bayesian approach to variable selection in regression models formulates a prior over the coefficients as a mixture of a continuous distribution and a point mass at zero. Full Bayesian inference, even with moderate numbers of predictors, is computationally prohibitive due to the combinatorial explosion in the number of models. I demonstrate that MAP estimation in many models can be formulated as a mixed integer nonlinear programming problem for a variety of popular priors over the model space. I also provide strategies for developing heuristic algorithms that are able to quickly find good incumbent solutions, which, when used to warm start the MINLP solver, can enhance performance greatly.

50 - A Dynamic Approach to Improve Chemotherapy Pre-mix Policies

Hwon Tak, University of Michigan, 500 S.State St, Ann Arbor, MI, 48109, United States, hwontak@umich.edu

The key goal of our project is to reduce patient waiting time by mixing chemotherapy drugs before patients arrive in the system or at earlier stages in the process (i.e. pre-mix). In collaboration with the University of Michigan Comprehensive Cancer Center (UMCCC) pharmacy, we have developed an improved template model based on their current pre-mix policy efforts. We present a data driven pre-mix template generator to customize the pre-mix list that the UMCCC currently uses by day of week. We show that full utilization of our dynamic template reduces waste costs, pharmacy workload and patient waiting time.

51 - Dynamic Inventory and Price Controls Involving Unknown Demand

Tingting Zhou, Rutgers University, Newark, NJ, United States, tingzhou@rutgers.edu, Michael N.Katehakis, Jian Yang

We study adaptive policies that handle dynamic inventory and price controls when the random demand for discrete nonperishable items is unknown. Pure inventory control is achieved by targeting newsvendor ordering quantities that correspond to empirical demand distributions learned over time. On the basis of it, we conduct the more complex joint inventory-price control, where demand-affecting prices are chosen. We identify policies that strive to balance between exploration and exploitation and measure their performances by regrets.

52 - Lifted Polymatroid Inequalities for Mean-risk Optimization with Indicator Variables

Hyemin Jeon, University of California Berkeley, Sutardja Dai Hall, 450, Berkeley, CA, 94720, United States, hyemin.jeon@gmail.com, Alper Atamturk

We investigate a conic quadratic minimization problem with 0-1 indicator variables that arises in mean-risk optimization. Observing that the problem reduces to a submodular function minimization under the binary restriction on the continuous variables, we derive three classes of strong convex valid inequalities by lifting the polymatroid inequalities on the binary variables. We report the result of computational experiments on mean-risk problems with fixed charges and cardinality constraints, which demonstrate the effectiveness of the inequalities in strengthening the convex relaxations and improving the solution times.

53 - Optimal Decentralized Network Formation using a Continuous-time Actor-oriented Model

Abhinav Perla, University at Buffalo, Buffalo, NY, 14260, United States, aperla@buffalo.edu, Alexander Nikolaev, Eduardo Pasiliao

We address a network formation problem in a decentralized context. The network actors (nodes) are assumed to be independent decision-makers that pursue the same objective - to build a network whose global structure has desirable properties, based on connectivity and closeness. Each actor has partial information about the network structure: the structure of its connections with peers and an estimate of its centrality. We present a continuous-time actor-oriented model as a form of solution and analyze the steady state distribution over the networks formed under this model. Then, we present an approach to infer the model parameters to achieve network outcomes enabling robust global communication.

54 - Research on Logistics Efficiency of the E-commerce with the Influence of the Storage Information Visualization Online

Si Chen, Assistant Professor, Southwest Jiaotong University, #111 North of Erhuan Road, ChengDu, 610031, China, chensi@swjtu.edu.cn, Yu Cai, Gang Wu, Mi Gan

The effective operation of E-commerce logistics system is the key guarantee for the operation. The efficiency of logistics system can be influenced by many factors. Among all the influences, the improvement of logistics information can be significantly improved with low investment. To study the impact of E-commerce logistics system efficiency from the product storage information visualization. An empirical analysis with DEA model has been used to analyze the influence on the JingDong platform from 2009 to 2016. The results show that relatively low product warehousing information visualization investment can bring preferable logistics operational efficiency improvement.

55 - Analysis on the Coordinated Development Between Logistics Industry and the Other Industries in Sichuan Based on Grey Relativity Analysis

Xinyuan Li, Southwest Jiaotong university, ChengDu, China, lixinyuan331@qq.com, Si Chen, Yinying Tang, Mi Gan

Logistics industry plays an important role in the development of Sichuan economy. We research into the relationship between the logistics industry and the agriculture,manufactory and business, which are the main economic development departments in Sichuan. And we analysis the gray correlation and the coupling degree of logistics industry and the other industries based on the logistics related data of Sichuan province from 2011 to 2016. Therefore, the development of logistic industry is a strong influence to the other industries, and it can provide adaptive supporting environment forthe other industries.

56 - Does Firm Innovation Improve Organization's Resilience? A Literature Review

Sima Sabahi, PhD Student, North Carolina A&T State University, 119 D.Village Lane, Greensboro, NC, 27409, United States, sima.sabahi@gmail.com

This research investigates whether firms that are more innovative are also more resilient to supply chain disruptions, and if so, what capabilities of innovative firms support the firms' resilience. Our findings indicate that a firm with a more innovative environment would be more resilient to disruptions, because innovation helps them fortify capabilities that are also antecedents of resilience. More specifically, we found that the practices of collaboration, leadership, and information sharing, which are all considered as antecedents of both resilience and innovation, would aid innovative firms to be more resilient.

57 - Signal Control Strategy to Improve Person Mobility and Air Quality

Farnoush Khalighi, PhD Student, University of Massachusetts, Amherst, 99 wildflower dr, amherst, MA, 01002, United States, fkhalighi@engin.umass.edu, Eleni Christofa

This study develops an analytical model to estimate emissions produced by cars and buses at signalized intersections. Then, a real-time signal control system to minimize person delay and vehicular emissions is developed. The objective of the optimization problem presents different weighted combinations of person delay and vehicular emissions. A Pareto frontier of optimal solutions is generated to demonstrate the trade-off between person delay and emission levels and provide policy makers with a tool to choose between different signal control systems based on traffic conditions and air pollutant levels. This system provides priority to buses due to the higher weight given to them in the model.

58 - The Case for Nearliers

Jeffry N. Savitz, SavitzConsulting, LLC, 1500 Locust St. #2120, Philadelphia, PA, 19102, United States, jsavitz@savitzresearch.com

Nearliers are data points within a random sample whose values are closer to the sample mean than the average data point. In an empirical study, 719 respondents' average ratings were computed for 30 popular brands. The average ratings of the Nearliers was within an absolute percentage difference of only 2.5% with the variance of the Nearliers being 17.4% less than the random sample. Thus, accurate and reliable predictions of population means can be made using Nearliers with a sample size 17.4% less than a random sample at an annual cost savings to the U.S. survey research community of $1.7 billion dollars based on information from CASRO and ESOMAR.

Monday Poster Competition

Competition Poster Session

Chair: Jeffrey W. Herrmann, University of Maryland-College Park, Department of Mechanical Engineering, College Park, MD, 20742, United States, jwh2@umd.edu

Co-Chair: Sergiy Butenko, Texas A&M University, 4037 Emerging Technologies Building, Mail Stop 3131, College Station, TX, 77843-3131, United States, butenko@tamu.edu

1 - Maximizing the Probability of Reaching a Set of States While Avoiding a Forbidden Set

Daniel Felipe Ávila, Universidad de los Andes, Bogotá, Colombia, df.avila353@gmail.com, Mauricio Junca

Using average cost functions we present a solution to the problem of finding a control policy that maximize the probability of reaching a set A while avoiding a set B. We show discounted cost functions provide an approximation to the solution. Both approaches can be solved using a linear program, the discounted case happens to admit an easier linear program than the average. We present simulations for the control of a plane under stochastic wind.

2 - Airline and Passenger Incentive Optimization Models for Airport Congestion Mitigation

John Park, Assistant Professor, North Carolina A&T.State University, 800 revolution mill drive, apt 232, greensboro, NC, 27405, United States, hpark1@ncat.edu

Bilevel Optimization Extended to Anticipatory Stochastic to Accommodate the Uncertainty. Passenger accessing based on airport with check in and security scheduling multiple airports with incentives.

3 - Estimating an Inverse Mean Subspace

Jiaying Weng, University of Kentucky, 300 Alumni Drive, Apt 179, Lexington, KY, 40503, United States, jiaying.weng@uky.edu, Yin Xiangrong

Estimating an inverse regression space is specially important in sufficient dimension reduction, and it typically requires a tuning parameter such as a number of slices in slicing method or bandwidth selection in kernel estimation approach, which then increases difficulties for multivariate responses. In this paper, we use Fourier transform idea to avoid such difficulties while easily incorporates with multivariate responses. We further develop Fourier transform method to deal with a sparse issue, categorical predictor variables and large p, small n data. Asymptotic as well as the sparse eigen-decomposition method for dimensionality tests are obtained.

4 - A Semantic Text Mining Technique for Classification of Manufacturing Suppliers Based on Their Capabilities

Ramin Sabbagh, Graduate Research Assistant, Texas State University, 601 University Dr., San Marcos, TX, 78666, United States, r_s343@txstate.edu

This work proposes a novel framework for capability-based supplier classification that relies on the unstructured capability narratives available on the suppliers' websites. Naïve Bayes is used as the text classifier technique. One of the innovative aspects of this work is incorporating a thesaurus that contains the informal vocabulary used in the contract manufacturing industry for advertising manufacturing capabilities. An Entity Extractor tool is developed for the generation of the vector model associated with each capability narrative. The proposed framework is validated experimentally through forming two capability classes (heavy & complex machining) based on real capability data.

5 - Data Enabled Planning of Transcatheter Aortic Valve Replacement Procedure using Logistic Regression Model and 3d-printing

Geet Lahoti, Graduate Research Assistant, ISyE, Georgia Institute of Technology, 1038 Mcmillan St. NW, Atlanta, GA, 30318, United States, glahoti6@gatech.edu, Zih Huei Wang, Kan Wang, Zhen Qian, Mani Vannan, Chuck Zhang, Ben Wang

Paravalvular leak (PVL) is a defect around the valve replacement, through which blood can leak. Prior assessment of PVL is preferable as it helps in procedural planning of TAVR. Patient-specific features can help predict PVL. We develop a logistic regression model for predicting PVL using computed tomography heart valve data. Five significant features including annulus diameter, none calcium, patients' basic information (e.g. age and valve size) and the ratio of annulus diameter and valve size are used as predictors. Considering 178 patients, the accuracy of the developed model for training data is found to be 75.16% and that for testing data is 69.22% after performing 10-fold cross validation.

6 - Flexcct: A Methodological Framework and Software for Ratings Analysis and Wisdom of the Crowd Applications

Stephen L. France, Assistant Professor, Mississippi State University, 324 McCool Hall, 40 Old Main, Mississippi State, MS, 39762, United States, sfrance@business.msstate.edu, Mahyar Sharif Vaghefi, William H. Batchelder

FlexCCT provides an integrated framework and tool-set for analyzing and aggregating ratings. It utilizes a likelihood based statistical model to create aggregate ratings weighted for rater competencies and rater biases. It has features for the analysis of multiple rating cultures and for consensus adjusted reliability. Multiple optimization algorithms are implemented, along with a range of identifiability options to restrict certain subsets of the model parameters. Bootstrapping and jackknifing based methods are implemented to give confidence intervals for parameters. A holdout validation method is developed to allow for the testing of solution reliability and stability.

7 - Reducing Discarded Organs and Improving Physician-patient Decision-making via Decision-support Tools and Systems Optimization

Ethan Mark, Georgia Institute of Technology, Atlanta, GA, United States, emark3@gatech.edu, David Goldsman, Pinar Keskinocak, Hannah Smalley, Joel Sokol

Organ supply is not sufficient to meet demand for transplant. Organs with increased risk for Hepatitis B, Hepatitis C, HIV, and infectious Encephalitis could help fill the gap. We developed decision-support tools which estimate infection risks for donor organs and personalized post-transplant and waitlist survival curves for potential transplant recipients. In some cases, a potentially infected organ provides higher survival probability versus remaining on the waitlist. The decision support tools encourage shared and informed decision making between physicians and patients and may decrease the number of discarded organs by quantifying the tradeoffs of using a potentially infected organ.

8 - Improving the Resilience of Service System by a Network Flow Approach

Jing Gong, Jinan University, School of Public Administration, Guangzhou, China, tgongjing@jnu.edu.cn

Recent catastrophic events precipitate a wide range of impacts so that public awareness continues to grow of resilience as an important means of characterizing the ability to deal with them. The best service systems aren't just cost-effective. They also respond quickly, handle smoothly and recover promptly from disruptions. This paper proposes a linear piecewise recovery function and applies it to the decision-making processes of improving a service system's resilience to disasters. A numeric example is developed to demonstrate the proposed model enables tradeoff between a cost minimum system and a resilient system.

9 - Causal Analyses for the Impact of Homecare Services on Patient Discharge Disposition

Biplab Bhattacharya, University at Buffalo, 80 Sterling Ave, Upper, Buffalo, NY, 14216, United States, biplabsu@buffalo.edu, Sabrina Casucci, Yuan Zhou, Li Lin, Alexander Nikolaev

Improving health outcomes for low-income adult Medicaid beneficiaries is challenging due to high rates of chronic disease comorbidities, limited mobility, and inconsistent access to care. We demonstrate how causal inference modeling can derive actionable insights from a home healthcare claims dataset. This innovative understanding of the impact of chronic disease comorbidities and service utilization on patient health outcomes can inform healthcare policies that improve the effectivity of home health care services.

10 - Using Nash Equilibrium Mathematical Model to Explore the Impact of Slots Competition on Profitability of Airlines

Yuan Feng, National Tsing Hua University, Dept of Industrial Engineering and Management, Hsinchu, 30073, Taiwan, erinfeng830624@gmail.com, Yu-Ching Lee

Having the data of known number of airlines, passenger capacity, load factor, operating cost and average fare income, we use Nash equilibrium model to find an solution, which could be used to analyze the profitability of the airlines. We derive the Nash equilibrium formulation from the KKT condition of the profit maximizing problems for every airline. We assume that the airline will not withdraw from any market. The analysis under two conditions for satisfying the market demand and the total number of flights shows that the routes will concentrate on the higher lucrative routes. Furthermore, by reducing the total slots in a certain range will enhance the average passenger load factor and the profits.

11 - Developing a Location Model to the Planning of Sustainable Perinatal Care Network in Korea

Hoon Jang, Science and Technology Policy Institute, 370 Sicheng-daero, Sejong, 30147, Korea, Republic of, hoonjang@stepi.re.kr, Kyosang Hwang, Taeho Lee, Taesik Lee

The reformation of rural perinatal service systems is an important public health task in Korea. For this, the government set up a support program; locating hospitals is one of key strategies to cover populations. Motivated this, we proposed the location model addressing how to design a rollout plan to maximally serve the demand. The novelty of our model lies in the incorporation of the uncertainty of future demand and individuals' hospital choice behavior. To build this model, we combine a discrete choice model with a location model, and the model is formulated by using the robust optimization framework. With the case study using a real dataset, we provide insights on how to design a better rollout plan.

12 - Statistical Modeling and Analysis of Chronic Disease Progression using Electronic Health Record (EHR) Data

Rema Padman, Professor of Management Science & Healthcare IS, Carnegie Mellon University, 5000 Forbes Avenue, Pittsburgh, PA, 15213, United States, rpadman@cmu.edu, Vijaya Priya Rama Vijayasarathy

Improved risk stratification of chronic disease patients may enable early identification of disease progression and allow appropriate interventions to mitigate preventable adverse outcomes and improve care delivery. Leveraging 22-years of EHR data and two clinical markers of chronic kidney disease, we develop and compare data-driven, statistical models to identify and profile groups of patients following four distinct trajectories of disease progression and their statistically significant covariates, potentially enabling better management of the patients.

13 - Supporting the Definition and Analysis of Cervical Cancer Public Health Policies

Ivan Mura, Visiting Professor, Universidad de Los Andes, Carrera 1 Este #19A-40, Bogota, 111711, Colombia, i.mura@uniandes.edu.co, Karen Daniela Angulo, Maria F. Cortés, Daniel Felipe Otero, Raha Akhavan-Tabatabaei

Cervical cancer is a global health issue, and developing countries bear the highest death rates. Though, cervical cancer etiology is well understood and prevention is possible. Both vaccines and effective screening tests exist, which can significantly reduce incidence. While designing cost-effective public health policies is of paramount importance in countries with limited resource availability, it requires an ability to generate reliable long-term predictions about the dynamics of a population health state, a task that entails significant complexity. This poster presents a simulation-based computational tool that can assist decision-makers in shaping national public health policies.

Sponsored: Decision Analysis

Sponsored Session

Chair: Jun Zhuang, University at Buffalo, SUNY, Buffalo, NY, 14260, United States, jzhuang@buffalo.edu

1 - System Defensibility in Reality

Alexander Gutfraind, Uptake Technologies, 600 W. Chicago St, Suite 775, Chicago, IL, 60654, United States, agutfraind.research@gmail.com, Vicki Bier

A system is termed defensible if modest investment of resources can significantly improve the outcome to the defender. Defensibility in reality is made quite complex when e.g. the more valuable assets are also more costly to defend. We report on how these realities affect defensibility and optimal defense strategies.

2 - Individual Terrorism Risk Assessment: A Signal Detection Theory Framework

Richard S.John, University of Southern California, Dept of Psychology MC 1061, Los Angeles, CA, 90089-1061, United States, richardj@usc.edu

Increasingly analytics are utilized to assess individual terrorism threat. Such "risk-based" approaches are designed to bin individuals in order to apply differential levels of scrutiny based on individual characteristics related to terrorism threat. A Signal Detection Theory framework is proposed, and sensitivity analysis is conducted to determine conditions in which such threat assessments are useful. The viability of risk-based approaches depends heavily on priors, indicator diagnosticity, and the relative cost of false-positives and false negatives. Risk-based approaches are severely limited for highly adaptive adversaries who can effectively diminish indicator diagnosticity.

3 - An Overview of Uncertainty-tolerant Decision Support for Cybersecurity

Samrat Chatterjee, Pacific Northwest National Laboratory, Richland, WA, United States, samrat.chatterjee@pnnl.gov

Cyber system defenders face the challenging task of continually protecting critical assets and information from a variety of malicious attackers. Defenders typically function within resource constraints, while attackers operate at relatively low costs. Thus, design and development of resilient cyber systems that support mission goals under attack, while accounting for the dynamics between attackers and defenders, is an important research problem. This talk will highlight decision support challenges under uncertainty within non-cooperative cybersecurity settings.

4 - Robust Resource Allocation to Interdependent Networks under Multiple Disruption Scenarios

Hannah Lobban, University of Oklahoma, 202 W. Boyd St, Room 124, Norman, OK, 73069, United States, hannahrose@ou.edu

In recent years, the threat of intentional attacks on infrastructure networks, such as water, electrical, communication, and transportation, has grown. Due to interdependency in the networks, a disruption could have far-reaching effects on the networks' ability to meet demand. Common disruption scenarios include degree- and capacity-based attacks; however, attackers targeting a network may give additional weight to components with less quantitative (e.g., religious, governmental) significance. This work attempts to determine the allocation of defensive resources that accounts for all these factors while minimizing both costs and the unmet demand in the disrupted network.

5 - Estimating Effectiveness of Investment, Optimal Resource Allocation, and Predictive Risk Analytics for Fire Protection

Vineet Madasseri Payyappalli, University at Buffalo, SUNY, Buffalo, NY, United States, vineetma@buffalo.edu, Adam Behrendt, Jun Zhuang

Fire hazards are an everyday phenomenon, and the estimated total cost of fire was $329 billion in 2011. Using the large amount of data available from National Fire Protection Association (NFPA) and National Fire Incident Response System (NFIRS), we create empirical and theoretical models to estimate the effectiveness of investment and to formulate optimal resource allocation strategies. Our results show that fire losses have decreased exponentially in investment with high R2 values (~0.8) and also show potential under- and overspending in fire protection for certain years/regions. The research will be of use to policymakers and analysts in fire protection, and will help in mitigating fire losses.

Healthcare Decision Analysis I

Sponsored: Decision Analysis

Sponsored Session

Chair: L Robin Keller, University of California-Irvine, Irvine, CA, 92697-3125, United States, LRKeller@uci.edu

1 - A Preliminary Decision Model for Brest Cancer Screening

Cristina del Campo, PhD, Universidad Complutense de Madrid, Madrid, Spain, campocc@ccee.ucm.es, Manuel Luque, Cristina Antón Rodríguez, Manuela Parras, Francisco Javier Diez

Breast cancer is one of the leading causes of cancer-related deaths in women all over the world. It is therefore imperative to determine an optimal screening pattern for breast cancer that trades off between early cancer detection and avoiding unnecessary procedures for healthy women. We present a preliminary decision model, implemented as a Markov influence diagram, for evaluating the cost-effectiveness of the optimal breast screening policy for an individual patient. The model takes into account major risk factors such as a positive family history or age and uses clinical data to recommend the best screening policy.

2 - Markov Cost-effectiveness Analysis for Cancer Treatment

Jiaru Bai, Binghamton University, School of Management, Binghamton, NY, 13902, United States, jiarub@uci.edu, L. Robin Keller

We present a way to build a Markov decision tree to model cancer progression and cost-effectiveness analysis for two or more cancer treatments. We propose several problems researchers can encounter in this kind of research and provide possible solutions.

3 - The Effects of Assigning Buddies in Online Health Communities

Ali Esmaeeli, University of California, Irvine, 1914 Verano Place, Irvine, CA, 92617, United States, esmaeeli@uci.edu, Cornelia Pechmann

We look at the effects of assigning buddies on the relationships between them and its result on abstinence in online smoking cessation groups. We show that directed links to active buddies are stronger than directed links to active non-buddies. We also show that for inactive buddies, the directed relations to them is not looser than the directed relations to inactive non-buddies. Then we show that those participants who have stronger directed relations with their pairs have better performance in quitting smoking.

Optimization Methods for Supervised Machine Learning: From Linear Models to Deep Learning

Invited: Tutorial

Invited Session

Chair: Jiming Peng, University of Houston, Houston, TX, 77204, United States, jopeng@Central.uh.edu

Co-Chair: Rajan Batta, University at Buffalo (SUNY), 410 Bell Hall, Buffalo, NY, 14260, United States, batta@buffalo.edu

1 - Optimization Methods for Supervised Machine Learning: From Linear Models to Deep Learning

Katya Scheinberg, Lehigh University, Bethlehem, PA, United States, katyas@lehigh.edu, Frank E.Curtis

The goal of this tutorial is to introduce key models, algorithms, and open questions related to the use of optimization methods for solving problems arising in machine learning. It is written with an INFORMS audience in mind, specifically those readers who are familiar with the basics of optimization algorithms, but less familiar with machine learning. We begin by deriving a formulation of a supervised learning problem and show how it leads to various optimization problems, depending on the context and underlying assumptions. We then discuss some of the distinctive features of these optimization problems, focusing on the examples of logistic regression and the training of deep neural networks. The latter half of the tutorial focuses on optimization algorithms, first for convex logistic regression, for which we discuss the use of first-order methods, the stochastic gradient method, variance reducing stochastic methods, and second-order methods. Finally, we discuss how these approaches can be employed to the training of deep neural networks, emphasizing the difficulties that arise from the complex, nonconvex structure of these models.

Data-Driven Revenue Management

Sponsored: Applied Probability

Sponsored Session

Chair: Gah-Yi Ban, London Business School, London Business School, London, NW1 4SA, United Kingdom, gban@london.edu

1 - A Nonparametric Self-adjusting Control for Multi-product Pricing with Unknown Demand Function and Finite Resource Capacity

George Chen, University of Texas at Dallas, Richardson, TX, United States, georgeqc@umich.edu, Stefanus Jasin, Izak Duenyas

We study a multi-period network revenue management problem where the underlying demand function is unknown (in the nonparametric sense) to the seller who uses dynamic pricing to minimize expected revenue loss. It is known that the asymptotic revenue loss of any feasible pricing policy is O(k^{1/2}) (k indicates the size of the problem), but there is a considerable gap between this theoretical lower bound and the performance bound of all existing heuristics. We propose a Nonparametric Self-adjusting Control and show that it guarantees a revenue loss of O(k^{1/2+epsilon} log k) for any arbitrarily small epsilon>0, provided that the underlying demand function is sufficiently smooth.

2 - Assortment Optimization of Vertically Differentiated Products for Quality-conscious Customers

Arnoud Victor den Boer, University of Amsterdam, Postbus 94248, Room number F3.33, Amsterdam, 1090 GE, Netherlands, boer@uva.nl, N. Bora Keskin

A product is available in a continuum of different quality levels. Potential customers are differentiated according to their minimum required quality level, which is random and unknown to the seller. We discuss the full-information assortment optimization problem of determining which subset of products maximize the seller's expected revenue. This is an optimization problem over measurable subsets of the positive real line. In addition we discuss a version of the problem with incomplete information, where the distribution of required quality is learned from data.

3 - Personalized Dynamic Pricing with Machine Learning

N. Bora Keskin, Duke University, Fuqua School of Business, 100 Fuqua Drive, Durham, NC, 27708-0120, United States, bora.keskin@duke.edu, Gah-Yi Ban

Motivated by online retail applications, we consider a seller who offers personalized prices to individual customers. The seller initially does not know the impact of individual customer characteristics on demand, but can learn about this relationship via sales observations. We construct and analyze near-optimal policies that balance the learn-and-earn tradeoff in this setting.

4 - Statistics for Cross-sectional Surveys: Inferring Total Eventual Time in Current State using Only Elapsed Time-to-Date

Richard C.Larson, Massachusetts Institute of Technology, E40-233, Cambridge, MA, 02139, United States, rclarson@mit.edu, Louis Cammarata

A recent paper by the 2nd author focused on cross-sectional surveys in which a question asked is, "How long have you been in this temporary state?" The result is a derivation of distribution of total duration in the temporary state based only on answers to that question. The method utilizes properties of longevity bias. Here, using nonparametric estimation methods we investigate the statistical accuracy of the method as a function of survey sample size and properties of underlying distributions. We report Monte Carlo simulations using discrete and continuous distributions and provide confidence interval results.

Static and Dynamic Optimization in Revenue Management

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Huseyin Topaloglu, Cornell University, Ithaca, NY, 14853, United States, topaloglu@orie.cornell.edu

1 - Dynamic Resource Allocation with Reusable Resources and Customer Choice

Mika Sumida, Cornell University, Ithaca, NY, 14850, United States, ms3268@cornell.edu, Paat Rusmevichientong, Huseyin Topaloglu

We consider a resource allocation model with reusable resources. Customers arrive in an online fashion and are offered an assortment of products. When a customer selects a product, it becomes unavailable for a fixed service time. After the service time, the resource is returned to the system for reallocation. The goal is to pick assortments that maximize the total expected revenue. This problem has a number of applications in the hotel and rental car industries, cloud computing, and the sharing economy. We present a computationally efficient policy with provable performance guarantees.

2 - Single-leg Revenue Management with Fare-locking

Huseyin Topaloglu, Cornell University, 223 Rhodes Hall, Ithaca, NY, 14853, United States, topaloglu@orie.cornell.edu, Mika Sumida

We study a revenue management model over a single flight leg, where the customers are allowed to lock an available fare. Each customer arrives into the system to purchase a ticket for a particular fare class. If this fare class is available, the customer either immediately purchases the ticket by paying the fare or locks the fare by paying a fee. If the customer locks the fare, then the airline reserves the capacity for the customer for a certain duration of time. At the end of this duration of time, the customer makes her ultimate purchase decision. We give a 2-approximation algorithm.

3 - Dynamic Assortment Optimization with Inventory Cost

Venus Lo, Cornell University, 206 Rhodes Hall, Ithaca, NY, 14853, United States, vhl8@cornell.edu, Huseyin Topaloglu

We consider a dynamic assortment optimization problem of selecting an assortment of products and their inventory level to offer to a stream of customers. Unlike traditional revenue management problem where the seller controls the products available to each arriving customer, the seller only makes initial inventory decisions. There is a cost of stocking the inventory, with no salvage value. The assortment available to each customer depends on the initial stock and the purchases of preceding customers, who are willing to substitute. We present a dynamic program for deterministic customer arrivals with nested preferences and develop related heuristics for the case of stochastic customer arrivals.

4 - Pricing Discounts in an Electric Vehicle Share System

Bobby Nyotta, UCLA Anderson School of Management, Los Angeles, CA, United States, bobby.nyotta.1@anderson.ucla.edu, Fernanda Bravo, Jacob Feldman

We study the use of pricing discounts in an electric vehicle share-system with free-floating parking. Specifically, we examine the optimal policy for the operator to offer free rides to the charging stations. Free rides can help to keep vehicles charged and to rebalance the system, however a revenue loss is experienced. Based on the optimal policy structure, we decompose and approximate the problem with an algorithm that performs well on real problem instances.

Empirical Studies with a Behavioral Element

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Robert Batt, Wisconsin School of Business, UW-Madison, Wisconsin School of Business, UW-Madison, Madison, WI, 53706, United States, rbatt@bus.wisc.edu

1 - Managing Capacity in an Outbound Contact Center with Crowdsourced Servers

Marcelo Olivares, Universidad de Chile, Beaucheff 851, Santiago, Chile, molivares@u.uchile.cl, Andres I.Musalem

Customer contact centers are increasingly using crowd-sourcing strategies to hire agents that provide service remotely, providing more flexibility and lower the cost of operating at low utilization levels. Lower system utilization reduces customer waiting times but can also affect productivity and churn of the agents. In this work we conduct an empirical study to measure time-sensitivity of customers and agent's behavior in this type of service system, using data from an outbound call center. We show how the empirical results can be used to conduct a cost-benefit analysis to plan service capacity.

2 - Manager Incentives, Outcomes, and Operational Decisions

Saravanan Kesavan, University of North Carolina-Chapel Hill, Kenan-Flagler Business School, Cb 3490 McColl Building, Chapel Hill, NC, 27599-3490, United States, skesavan@unc.edu

As customers increasingly shopping through their desktops, laptops and mobile devices, retailers across the industry are looking to ramp up their investments in omnichannel retailing to offer them a seamless shopping experience. These new workflows can create serious challenges to store management. So, retailers are figuring out ways to restructure the compensation plan for store managers to enhance cooperation. In this study, we explore data from a retailer that changed it compensation plan to emphasize greater coordination among store managers.

3 - Oversight and Efficiency in Public Projects: A Regression Discontinuity Analysis

Ruomeng Cui, Goizueta Business School, Emory University, Atlanta, GA, United States, ruomeng.cui@gmail.com, Eduard Calvo, Juan Serpa

During the execution of a public project, should regulators continually scrutinize the contractor's operations? In this paper we explore the causal impact of government oversight on a project's delay time and cost overrun. We glean a detailed procurement database of public projects spanning 173 U.S. federal agencies. We exploit a regulatory bylaw in federal procurement: if a project's budget exceeds a cutoff, the project's operations are surveilled. Using a regression discontinuity design, we find that decreasing the intensity of oversight significantly decreases a project's delay time and cost overrun. Further, the result depends on contract type and the contractor's experience.

4 - The Effects of Searching and Learning on Pick-worker Performance

Robert Batt, Wisconsin School of Business, UW-Madison, 5279 Grainger Hall, 975 University Ave., Madison, WI, 53706, United States, rbatt@bus.wisc.edu, Santiago Gallino

We study "chaotic storage" order-fulfillment systems in which dissimilar items are stored together in a single location. This necessitates a searching task as part of the item picking process. We show that pick times increase by as much as 16% as the searching task becomes more difficult. However, the deleterious effect of searching decreases with pick worker experience. Using simulation, we show that pick times can be improved by approximately 5% by incorporating distance, complexity, and picker experience into pick assignments and pick routing.

1 - Testing by Competitors in Enforcement of Product Standards

Erica Plambeck, Stanford University, Graduate School of Business, 518 Memorial Way, Stanford, CA, 94305-5015, United States, elp@stanford.edu

This paper explores a potentially efficient mechanism to encourage compliance with and identify violations of safety and environmental standards: Firms testing competitors' products.

2 - Cooperative Approaches to Managing Social Responsibility in Supply Chains

Xin Fang, Singapore Management University, 50 Stamford Road, #05-01, Singapore, 178899, Singapore, xfang2015@gmail.com, Soo-Haeng Cho

This paper investigates two cooperative approaches of firms' managing social responsibility violations of suppliers: auditing a common supplier jointly or sharing independent audit results with other firms. We develop a model based on a cooperative game in partition function form, and show that: (1) competing firms have incentives to cooperate when the negative externality of one firm's social responsibility violation on other firms is high; and (2) neither cooperative approach necessarily improves social responsibility, especially when one firm can benefit from others' social responsibility violations (i.e., the positive externality is high).

3 - Joint Carbon Abatement Efforts in Supply Chains
Tarkan Tan, Eindhoven University of Technology, School of Industrial Engineering, Den Dolech 2 Paviljoen F-07, Eindhoven, 5612AZ, Netherlands, t.tan@tue.nl, Mohsen Reisi, Behnam Fahimnia

We consider carbon emission abatement decisions taking manufacturer-supplier interactions into account. We present a set of models to identify the situations where cooperation can help invest in joint emissions abatement projects. Various approaches are used to allocate project costs based on the role and bargaining power of each project participant.

4 - Supplier Centrality and Auditing Priority in Socially-responsible Supply Chains
Jiayu Chen, The University of Texas at Dallas, 800 W. Campbell Road, Richardson, TX, 75080, United States, jxc144030@utdallas.edu, Anyan Qi, Milind Dawande

In a supply network with multiple buyers and multiple suppliers, we explore how the degree centralities of the suppliers (i.e., the number of buyers they supply to) affect the social-responsibility decisions of both the buyers and the suppliers, and offer several novel and useful insights. For instance, while prioritizing the compliance audit of suppliers with a high degree centrality is better for the aggregate profit of the firms, downstream competition between the firms conspires to make them audit only their respective independent suppliers. This inefficiency can be corrected if the firms cooperate to jointly audit the suppliers.

5 - Should Brands Tighten Certification Standards? the Effect of Supplier-certifier Collusion
Shiqing Yao, Chinese Univ of Hong Kong, Flat C.8th floor, Sunning Building, Shatin Ce, N.T., Hong Kong, yaoshiqing@gmail.com, Kaijie Zhu, Li Chen

While enjoying low costs in sourcing from emerging economies, buyers also face serious quality risks in the form of supplier noncompliance. Supplier certification has been used widely to tackle such challenge in practice. In this paper, we study how supplier-certifier collusion can affect the buyer's optimal contracting and certification strategy.

Applied Operations in Health Services: Research by Bonder Scholars

Sponsored: Health Applications

Sponsored Session

Chair: Pooyan Kazemian, Harvard Medical School, 50 Staniford St, 930B, Boston, MA, 02114, United States, pooyan.kazemian@mgh.harvard.edu

Co-Chair: Alba Rojas-Cordova, Virginia Tech, Blacksburg, VA, 24060, United States, albarc@vt.edu

1 - Modeling Joint Inpatient and Outpatient Decisions to Reduce Hospital Readmissions
Xiang Liu, University of Michigan, 322 Village Green Boulevard, Apt 204, Ann Arbor, MI, 48105, United States, liuxiang@umich.edu, Jonathan Helm, Mariel Sofia Lavieri, Ted Skolarus

Hospital readmissions affect hundreds of thousands of patients, placing a tremendous burden on the healthcare system. We develop a two-stage stochastic dynamic programming framework that spans the inpatient stay and the post-discharge outpatient monitoring to reduce readmissions. By reducing readmission risk in the 1st stage, and monitoring the patient's condition in the 2nd stage, our goal is to jointly guide discharge and post-discharge decisions. This could lead to reduced readmissions.

2 - Efficient and Fair Allocation Rules for Heart Transplantation
Amin Khademi, Clemson University, 1267 Madden Bridge Rd Apt B, Central, SC, 29630, United States, khademi@clemson.edu, Farhad Hasankhani

The optimal allocation of limited donated hearts to patients on the waiting list is one of the top priorities inheart transplantation management. In order to design an efficient and fair system for allocating donor heartsto patients waiting for transplantation, we model the problem as a constrained stochastic dynamic programto maximize total quality-adjusted life years (QALYs) of the population.

3 - Resource Allocation Decision-making in Sequential Adaptive Clinical Trials
Alba Rojas-Cordova, Assistant Professor, Southern Methodist University, Caruth Hall 339. Southern Methodist University., Dallas, TX, 75205, United States, alba@smu.edu, Ebru Korular Bish, Niyousha Hosseinichimeh

Adaptive clinical trials promise significant savings to the pharmaceutical industry and an expedited access to new drugs and therapies. Certain designs allow decision makers to alter the course of a trial based on interim results on a new drug's performance. We develop: 1) a simulation model to study and quantify the risk of false negatives, and the amplification thereof as a result of a behavioral phenomenon, and 2) a stochastic dynamic programming model to derive an optimal resource allocation strategy, based on Bayesian updates on the estimate of a drug's efficacy. We propose an augmented methodology for optimal stopping and optimal resource allocation in sequential adaptive clinical trials.

4 - Ambulance Emergency Response Optimization in Developing Urban Centres
Justin James Boutilier, University of Toronto, 532 Palmerston Boulevard, Apartment 6, Toronto, ON, M6G 2P5, Canada, j.boutilier@mail.utoronto.ca, Timothy Chan

Time sensitive medical emergencies are a major health concern comprising one third of all deaths in low and middle income countries (LMICs). Despite evidence that ambulance services can save lives, poor access and availability of emergency medical care in LMICs continues to be a widespread problem. In this paper, we develop a novel ambulance location-routing model, tailored to address the challenges faced by urban areas in LMICs. We use extensive field data from Dhaka, the capital of Bangladesh and one of the most densely populated cities on earth, to apply our modelling framework.

Hospital Operations Management I

Sponsored: Health Applications

Sponsored Session

Chair: Hui Zhang, University of Chicago, Chicago, IL, 60637, United States, corinnaz@uchicago.edu

Co-Chair: Thomas Best, tbest3@bsd.uchicago.edu

1 - Improving Hospital Operations using a Real-time Locating System
Hyojung Kang, University of Virginia, 1557 Montessori Terrace, Charlottesville, VA, 22911, United States, hkang@virginia.edu, Ethan Haswell

Long waiting times indicate costly inefficiencies for healthcare facilities and influence patient satisfaction and outcomes. Hospitals have adopted a Real-Time Locating System (RTLS) technology to identify bottlenecks in a system and improve its operations by tracking entities at all times throughout a facility. However, limited studies have shown how the RTLS data has been utilized to support operational decision-makings. This study demonstrates how the RTLS data combined with electronic health records and scheduling data can be used to provide hospitals insights into patient flow, patient-provider interactions, and scheduling.

2 - Predicting if New Patients in the Comprehensive Care Physician Program will Attend Most of their Appointments with their Comprehensive Care Physician
Thomas J. Best, University of Chicago, Chicago, IL, United States, tbest3@bsd.uchicago.edu, Arnab Bose, Devdeep Banerji, Reelina Sircar, David O.Meltzer

The Comprehensive Care Physician (CCP) program at the University of Chicago strives to provide more cost-effective healthcare for patients at high risk of hospitalization by enrolling them with a CCP who manages all their hospitalizations and outpatient care. Initial data suggests that the program can be especially cost-effective when enrollees attend most of their clinic appointments with their CCP. We describe our application of machine learning techniques to improve predictions of whether a new enrollee will attend most of their clinic appointments with their CCP in the first six months of enrollment. We also describe how we use the predictions to target efforts to improve attendance.

3 - Distance, Quality or Relationship? Interhospital Transfer of Heart Attack Patients
Susan F. Lu, Purdue University, Krannert 441, West Lafayette, IN, 47907, United States, lu428@purdue.edu, Lauren Xiaoyuan Lu

We empirically investigate the pattern of where heart attack patients are transferred between hospitals. Using 2011 Florida State Emergency Department and Inpatient Databases, we demonstrate the relative importance of three key factors in determining transfer destinations: (1) the distance between sending and receiving hospitals, (2) publicly-reported quality measures of receiving hospitals, and (3) the relationship between sending and receiving hospitals as indicated by whether they are affiliated with the same multihospital system.

4 - Hospitalist Service Mix and Patient Length of Stay
Masoud Kamalahmadi, Indiana University, 1309 E. 10th Street Room HH 4100, Bloomington, IN, 47405, United States, maskamal@iu.edu, Jonathan Helm, Alex Mills, Kurt M. Bretthauer

Hospitalists are physicians that specialize in caring for hospital inpatients, replacing a primary care physician who may only make rounds once per day and thereby reducing delays. Given a limited number of hospitalists in a hospital, we seek to determine their optimal service mix (workload and patient types).

Real-time Models for Epidemiological Risk Assessment

Sponsored: Health Applications

Sponsored Session

Chair: Lauren Gardner, University of New South Wales, l.gardner@unsw.edu.au

1 - Influenza Phylogeography for Public Health Surveillance
Matthew Scotch, Arizona State University, Tempe, AZ, United States, Matthew.Scotch@asu.edu

Next-generated sequencing has resulted in a tremendous growth in the amount of virus sequences such as influenza. Phylogeography, which estimates the evolutionary diffusion of viruses, is potentially a valuable technique for utilizing this influx of sequence data. Unfortunately, most health agencies lack the bioinformatics expertise to implement these techniques. Here, we will highlight ZooPhy, a bioinformatics resource for virus phylogeography, via case studies of seasonal and avian influenza. We will also address potential issues with providing a "black box" model for informing policy decisions at the agency level as part of critical analyses of the system.

2 - Modeling HIV Transmissions Across At-risk Populations
Lu Zhong, City University of Hong Kong, Kowloon, Hong Kong, luzhong2-c@my.cityu.edu.hk, Qingpeng Zhang

We proposed a 2-layer social network framework to model the HIV transmissions across two at-risk populations, and evaluated the effectiveness of a set of structural intervention strategies. Experiments demonstrated the important role played by bridge individuals across layers. Isolating such nodes could segregate at-risk populations for a better prevention outcome.

3 - A Generalized Inverse Infection Model for Inferring the Spread of the 2015-16 Zika Outbreak
Lauren Gardner, University of New South Wales, Sydney, Australia, l.gardner@unsw.edu.au, Andras Bota

Most network-based infection spreading and diffusion models require a real value or (transmission) probability on the edges of the network as an input, which is often unknown in real-life applications. This work presents a general framework to estimate the value of these probabilities on a network exposed to an infection process, where spatiotemporal information on the outbreak pattern is known. The model is applied to the 2015-16 Zika outbreak in the Americas. This general model works with a range of infection models, and is able to handle an arbitrary number of observations on such processes.

Stochastic Models in Healthcare

Sponsored: Health Applications

Sponsored Session

Chair: Oguzhan Alagoz, University of Wisconsin-Madison, Madison, WI, 53706, United States, alagoz@engr.wisc.edu

Co-Chair: Ali Hajjar, University of Wisconsin-Madison, Madison, WI, 53706, United States, hjaar@wisc.edu

1 - An Explicit Stochastic Model of ICU Length of Stay
Mehmet Yasin Ulukus, University of Pittsburgh, 3700 O'Hara Street, 1048 Benedum Hall, Pittsburgh, PA, 15261, United States, myu1@pitt.edu, Andrew J.Schaefer, Guodong Pang, Gilles Clermont

There have been numerous attempts to predict ICU LOS. Statistical models, are commonly used to make predictions of the LOS but almost none consider time progression of the health status of patients. In this study, we present an explicit stochastic ICU LOS model by (1) considering the health progression of the patients via a novel score process, (2) modeling the transfer decision via a threshold policy, and (3) considering the downstream bed availability and transfer delay dynamics. We characterize LOS for different stochastic score processes, and test the estimation power with empirical data.

2 - Stochastic Optimization Models for the Active Surveillance of the Prostate Cancer
Zheng Zhang, University of Michigan, 2361 Lancashire Drive, Apt 1B, Ann Arbor, MI, 48105, United States, zzhang0409@gmail.com, Brian T.Denton, Christine Barnett, Todd Morgan

Active surveillance (AS) has become a popular management option among favorable-risk prostate cancer patients to avoid unnecessary surgeries or radiations. We describe a stochastic programming model for optimization of AS strategies that allow for personalized patient feathers, unobservable health states, and stochastic cancer progression. The results show our model solutions outperformed the benchmark strategies in terms of maximizing the quality-adjust life years.

3 - Optimal Decision Making in Risk Reduction for Women at High Risk of Breast Cancer
Mehmet Ali Ergun, University of Wisconsin-Madison, Madison, WI, United States, mergun@wisc.edu, Murtuza Rampurwala, Oguzhan Alagoz

Breast cancer (BC) is the most common non-skin cancer and a leading cause of death among U.S. female population. Studies provide estimates on the individual risk of a woman as well as finding interventions to reduce it for the high-risk patients. On the other hand, the guidelines tying individual risk assessments to risk reduction interventions are not as rigorously studied and not as detailed. To fill this gap, we have developed finite-horizon Markov Decision Process (MDP) model that finds optimal preventative actions given the individual risk when the objective is to maximize quality-adjusted life years of the patients.

Multi-faceted Supply Chains

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Rodney P. Parker, Indiana University, Bloomington, IN, 47405, United States, rodp@indiana.edu

1 - Negative Shocks and Innovation Incentives: Evidence from Medical Device Recalls
George Ball, Indiana University, Kelley School of Business, 1309 E. 10th St, Bloomington, IN, 47405, United States, gpball@indiana.edu, Jeffrey Macher, Ariel Stern

Medical device firms seek to operate at the frontiers of innovation. When functioning properly, innovative medical devices can prolong and improve lives; when malfunctioning, the same devices may harm patients and lead to product recalls. Consequently, medical device firms' innovation efforts may be influenced by innovation failures. Using 13 years of FDA product recall and new product submission data, we explore the impact of recalls on subsequent innovation. We utilize a recurrent-event hazard model to examine how recalls of varying severity influence the hazard of different types of new product submissions by firms. The results identify a relationship between recalls and future innovation.

2 - Social Responsibility Auditing of Supply Chain Networks
Han Zhang, Indiana University, Bloomington, IN, 47404, United States, hz8@indiana.edu, Goker Aydin, Rodney P.Parker

We study a buyer's problem of auditing its supply network for social responsibility concerns, when the suppliers' identities and relations further upstream are initially invisible, and only discernible via costly auditing. The buyer may suffer economic damages if an upstream supplier, even if unknown to the buyer, is exposed as unethical. We characterize the equilibrium in the production stage, and study the buyer's auditing strategies before the production stage.

3 - Supply Chain Strategy: Beyond Fisher's Framework
Tava Olsen, University of Auckland, ISOM, Business School, University of Auckland, Auckland, 1142, New Zealand, t.olsen@auckland.ac.nz, Quan Spring Zhou

Devising an effective supply chain strategy is essential for exporters. Fisher's framework provides exporters some guidance on this and has also been extended in a number of ways. In this talk we first discuss what is known (mathematically, empirically, and qualitatively) about applying Fisher's framework in practice. Then we discuss our own empirical analysis based on New Zealand data, where we investigate the practice of using efficient, responsive, and, potentially, ambidextrous supply chain strategies and their associated impacts.

4 - The Role of the Regulator in Product Recalls

Rodney P. Parker, Indiana University, Kelley School of Business, 1309 E.10th Street, HH4129, Bloomington, IN, 47405, United States, rodp@indiana.edu, George Ball, Ruth Beer

A firm selling products faces the prospect of failures in the market. However, the firm is uncertain whether these product failures are the result of a systemic cause (for which they are responsible) or purely random (for which they are not). As failure reports arrive (while sales continue), the firm updates their belief whether the failures are "recall-worthy" or not. Similarly, the relevant regulator (NHTSA or FDA) will possibly intervene if they have sufficient evidence. We investigate how the firm's optimal recall-behavior changes under the gaze of the regulator.

Operations in Sharing Economies

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Yi Xu, University of Maryland, College Park, MD, 20742, United States, yxu@rhsmith.umd.edu

1 - Referral and Learning on Social Network: Implications for Newsvendor

Guangwen Kong, gkong@umn.edu, Guangwen Kong, Ankur Mani, Yuanchen Su

We consider a firm selling differentiated products to customers in a social network . We study how the network structure and learning influence the demand distributions and thus have an impact on the firm's inventory decision and the optimal design of referral programs.

2 - Strategically Giving Service: the Effect of Real-time Information on Service Efficiency

Nil Karacaoglu, Kellogg School of Management, 531 Grove Street, Evanston, IL, 60201, United States, n-karacaoglu@kellogg.northwestern.edu, Antonio Moreno-Garcia, Can Ozkan

Using data from a on-demand taxi service, we study the impact of information on driver behavior.

3 - Managing and Designing Online Platform Networks

Hongfan Chen, University of Chicago, International House, 1414 East 59th Street, 657, Chicago, IL, 60637, United States, hongfan.chen@chicagobooth.edu, John R.Birge, Ozan Candogan, Daniela Saban

In this paper we provided a model of a platform which matches buyers with suppliers. The transaction prices are determined endogenously, and the platform tries to improve its revenues through admission control and display control. We characterize the platform's optimal policies, and relate it to the underlying compatibility network structure.

4 - An Empirical Analysis of Price Formation, Utilization, and Value Generation in Ride Sharing Services

Weiming Zhu, IESE Business School, Avenida Pearson 21, Barcelona, 08034, Spain, zhuwm923@gmail.com, Liu Ming, Tunay Tunca, Yi Xu

Using data obtained from a leading company, we construct a structural model to estimate price formation in ride-sharing services based on operational characteristics such as the number of consumers and the utilization of drivers. Further, we conduct counterfactual analysis to examine efficiency and welfare implications.

The Employee Role in Retail Operations

Sponsored: Manufacturing & Service Oper Mgmt, Service Operations

Sponsored Session

Chair: Santiago Gallino, Dartmouth College, Hanover, NH, 03755, United States, santiago.gallino@tuck.dartmouth.edu

1 - Does Online Learning Work in Retail?

Santiago Gallino, Dartmouth College, 100 Tuck Hall, Hanover, NH, 03755, United States, santiago.gallino@tuck.dartmouth.edu, Marshall L.Fisher, Serguei Netessine

A knowledgeable retail sales associate (SA) can explain the features of the available product variants and give the customer sufficient confidence in her choice that she becomes willing to purchase. It is thus plausible that increasing SA knowledge will increase sales. Given that training is not costless, an important question is whether training increases SA productivity, and if so, whether the increase is enough to justify the cost of training. We found that as SAs engaged in training over time, their sales rate increased by 1.8 percent for every module taken.

2 - Structural Estimation of Traffic at Retail Store to Achieve Better Conversion

Anup Hanamant Walvekar, INSEAD, 1 Ayer Rajah Avenue, PhD Office, Singapore, 138676, Singapore, anup.walvekar@insead.edu, Nils Rudi, Serguei Netessine

Conversion rate is an important KPI used by retail chains to compare the performance of stores across different locations and times intervals. Using the traffic data coded using video footage obtained from multiple retail stores from Europe and UAE, we observe that a group of customers seldom have multiple transactions. Hence it is better to use #groups as a measure of traffic instead of #individuals to estimate conversion rate. We model the customer arrival process and structurally estimate the #groups from a stream of customers. We compare the performances of different methods using the real and simulated traffic data.

3 - Ration Gaming and the Bullwhip Effect

Robert Louis Bray, 830 Hinman Ave., 2s, Evanston, IL, 60202, United States, robertlbray@gmail.com

We model a single-supplier, 73-store supply chain as a dynamic discrete choice problem. We estimate the model with transaction-level data, spanning 3,251 products and 1,370 days. We find two phenomena: ration gaming (strategic inventory hoarding) and the bullwhip effect (the amplification of demand variability along the supply chain). We estimate that the bullwhip effect would be 12% smaller in the counterfactual scenario without ration gaming incentives, confirming the long-standing hypothesis that ration gaming causes the bullwhip effect.

4 - Field Evidence on Employee Training and Customer Performance

Ryan Buell, Harvard Business School, Morgan Hall 429, Boston, MA, 02163, United States, rbuell@hbs.edu, Tatiana Sandino

Using data from a randomized field experiment conducted in collaboration with a global consulting firm, we examine the effects of a training program that broadens the front line's perspective on the firm's service offerings. We examine whether the program affects job engagement, the types (and consistency) of services offered by the consultants, sales, profitability, and the trajectory of service relationships.

Service Networks: Empirics and Theory

Sponsored: Manufacturing & Service Oper Mgmt, Service Operations

Sponsored Session

Chair: Gad Allon, I, The Wharton School, gadallon@wharton.upenn.edu

Co-Chair: Qiuping Yu, Kelley School of Business, Indiana University, Bloomington, IN, 47405-1701, United States, qiupyu@indiana.edu

1 - A Quality Value Chain Network: Linking Supply Chain Quality to Customer Lifetime Value

Qiuping Yu, Kelley School of Business, Indiana University, 1309 E. Tenth Street, Bloomington, IN, 47405-1701, United States, qiupyu@indiana.edu, Shawn Mankad, Masha Shunko

We create a quality value chain network concept to analyze the impact of supply chain quality (SCQ) on the customer lifetime value (CLV). We apply our framework to a rich dataset from a major restaurant chain utilizing text analysis of the complaints to measure SCQ, a two-stage least squares (2SLS) model with instruments to assess the impact of SCQ on customer experience, and a structural model of consumer purchasing behavior to eventually link customer experience to CLV. We identify the profile of the most valuable customers and provide insights on which SCQ issues the supply chain should focus on, and which restaurants should be prioritized for supply chain improvements.

2 - The Impact of Delay Announcements on Hospital Network Coordination

Jing Dong, Northwestern University, 2145 Sheridan Road, Room C210, Evanston, IL, 60208, United States, jing.dong@northwestern.edu, Elad Yom-Tov, Galit Bracha Yom-Tov

We investigate the impact of delay announcements on the coordination within hospital networks using a combination of empirical observations and numerical experiments. We offer empirical evidence which suggests that patients take delay information into account when choosing emergency service providers and that such information can help increase coordination in the network, leading to improvements in performance of the network, as measured by Emergency Department waiting times.

3 - Growth and Customer Loyalty: Evidence from the App Economy

Ken Moon, The Wharton School, Philadelphia, PA, 19104, United States, kenmoon@wharton.upenn.edu, Haim Mendelson

We study a dataset encompassing apps' daily, weekly, and monthly usership time series and show how its nested-echelon structure allows researchers to reliably infer how and when an app's customers adopt, use, and leave its services. Thereby gaining novel visibility into these services' customer flows, we study how developers should prioritize the acquisition of customers and market share via viral effects against cultivating customer loyalty. In particular, evidence suggests that a potent experience curve rewards developers' experience with loyal customers.

4 - Managing Service Systems in Presence of Social Networks

Gad Allon, The Wharton School, Philadelphia, PA, United States, gadallon@wharton.upenn.edu, Dennis Zhang

We study a service system with the presence of a social network. In our model, firms can differentiate resource allocations among customers, and customers learn the service qualities from the social network. We study the interplay among network structure, customer characteristics, and information structure, and characterize the optimal policy. We further calibrate our model with data from Yelp.com and quantify the value of social network knowledge empirically.

Health Care, Processes

Contributed Session

Chair: Alaa Alazzam, Binghamton University, Binghamton, NY, United States, aalazza2@binghamton.edu

1 - Healthcare Analytics

Isabel Smith-Nino, London Business School, 26 Sussex Place, London, NW1 4SA, United Kingdom, ismithnino@london.edu, Nicos Savva, Sandra Sulz

We investigate two questions regarding hospital operations. First, we study the impact of staffing mix in the emergency department on patient outcomes by exploiting a natural experiment where junior doctors went on strike. Second, we investigate whether an additional physician dedicated to discharging patients during some weekends improves the discharge rate as compared to other weekends where no such physician was deployed. Our results show the importance of empirical work in the healthcare context, not only for patient safety and quality, but also for efficiency.

2 - Measurement Variability of Postoperative Nausea and Vomiting in the Postanesthesia Care Unit

Elnaz Torkamani, PhD Student, Wayne State University, 4815 Fourth Street, Detroit, MI, 48202, United States, fj6985@wayne.edu

Postoperative nausea and vomiting (PONV) is common and distressing to the patient. The incidence and severity of PONV has been found to depend on patient specific factors, the type of surgery performed, prophylaxis, the type of anesthetic and the treatment if symptoms occur. Post anesthesia care unit (PACU) nurses routinely document the presence of any PONV into the patients' medical record. In this study, we will study the variation attributable different PACU nurses in the assessment of PONV.

3 - Disease Phenotype Search Algorithm Application Improves Surgical Outcomes of Diabetic Patients

Danny Whipple, Health Systems Engineer, Mayo Clinic, 200 First Street SW, Rochester, MN, 55905, United States, whipple.daniel@mayo.edu

Poor management of diabetes mellitus in surgical patients is shown to increase their hospital length of stay (LOS) and 30 day readmission rate. The study determined proper management begins with accurate identification and communication of the diabetes condition to the surgical team and proposed the development of a disease phenotype search algorithm application that systematically identifies the presence of diabetes based on medical history, medications, and lab results and utilizes the indication for proper disease management. This resulted in a 1.5% increase in diabetes identification of surgical patients which led to a 7% decrease in LOS as well as a 4% decrease in the 30 day readmission rate.

4 - Efficient Transition to Post-acute Care

Alex Mills, Assistant Professor, Indiana University Bloomington, 1309 E. Tenth St, Bloomington, IN, 47405, United States, millsaf@indiana.edu, Xiaoyang Yu, Jonathan Helm

Many hospital patients are discharged to a skilled nursing facility (SNF) for post-acute care. A shortage of SNF beds can lead to expensive discharge delays. Using a queueing control model, we show that the system can be coordinated through a capacity reservation contract. When the hospital is a monopolist, both the hospital and SNF benefit from this arrangement. However, when two hospitals form a duopoly, coordination leads to a prisoners' dilemma, where each hospital has an incentive to coordinate with its preferred SNF but all parties are worse off when both hospitals coordinate. The results of our model lead to insights for urban and rural hospital systems.

5 - An Empirical Analysis on Stroke Care Process: Changes in EMS Field Triage Decisions and Their Effect on Stroke Patient Care Outcomes

Brandon Lee, Clemson University, 100 Sirrine Hall, Clemson, SC, 29634, United States, woohyel@clemson.edu, Bernardo F. Quiroga, Lawrence Fredendall, Aleda Roth

This study examines how some of the recent methodological and structural changes for the stroke patient care (e.g., formation of telestroke network, stroke center certification with endovascular neurological services, and the use of a stroke severity scale, etc.) have affected the field triage decision-making behavior of the EMS providers and the consequent clinical outcomes (i.e., disability, mortality, etc.).

6 - A Process Mining Based Approach to Study Patient Flow in Emergency Departments

Alaa Alazzam, PhD Student, Binghamton University, Binghamton, NY, 13902, United States, aalazza2@binghamton.edu

Due to the Affordable Care Act (ACA) guidelines and the rapidly rising healthcare costs, hospitals are in an urgent need to reform their processes to provide better quality at lower costs. To do so, clinical pathways need to be discovered and analyzed to help manage the variation among physicians. Therefore, this paper aims at applying a process mining-based approach to build process models for care flows in two different emergency departments (EDs) based on knowledge extracted from event logs. The generated models are analyzed in terms of cost reduction, capacity gains, and resource utilization, which can lead to a long-term success in process optimization in a wider variety of healthcare settings.

New Approaches to Value in Health Care

Sponsored: Manufacturing & Service Oper Mgmt, Healthcare Operations

Sponsored Session

Chair: Noah Gans, University of Pennsylvania, Philadelphia, PA, 19104-6340, United States, gans@wharton.upenn.edu

Co-Chair: Ozge Yapar, University of Pennsylvania, Philadelphia, PA, 19103, United States, yapar@wharton.upenn.edu

1 - Bayesian Bandits for Sequential Clinical Trials of Multiple Technologies

Ozge Yapar, University of Pennsylvania, Wharton School of Business, 3730 Walnut Street, Philadelphia, PA, 19103, United States, yapar@wharton.upenn.edu, Stephen E.Chick, Noah Gans

We focus on the design of multiarm multistage (MAMS) clinical trials. We build on two trends, on the one hand allowing for more than two arms in a trial and on the other using information accumulated during a trial to modify its experimental design as the trial progresses. We frame the problem as a stoppable bandit problem with multiple correlated arms, and we allow for arbitrarily many stages of sampling by using a diffusion approximation that allows for adaptive stopping rules. We develop new allocation and stopping rules that can be used in fully sequential sampling algorithms.

2 - Accelerated Approval: Gatekeeper or Roadblock?

Liang Xu, The Pennsylvania State University, 419A Business Building, Penn State University, State College, PA, 16801, United States, lzx103@psu.edu, Hui Zhao

In 1992, FDA enacted the accelerated approval pathway which allows fast approval of drugs but requires further post-market study to verify the true clinical benefit. Unfortunately, most of these post-market studies are delayed or never completed. Indeed, managing such post-market studies are very challenging due to moral hazard and asymmetric information. We propose mechanisms to assure compliance on post-market study and use realistic data to show the results.

3 - Outcomes-based Reimbursement Policies for Chronic Care Pathways

Sasa Zorc, INSEAD, Singapore, Singapore, sasa.zorc@insead.edu, Stephen E.Chick, Sameer Hasija

We develop an outcomes-based model of contracting in care of chronic patients, using data from United Kingdom's NHS. The government contracts with healthcare providers in effort to maximise population health minus the cost. We consider the decision of whether to contract with individual healthcare providers or groups of such providers, as well as which contract type to use. Individual contracts fail to provide the desired incentives if providers under such contracts cooperate (collusion), however so do group contracts if group members fail to coordinate (free-riding). We demonstrate that individual outcomes-adjusted capitation contracts are the most resistant to these adverse effects.

4 - An Instrumental Variable Tree Approach for Detecting Heterogeneous Treatment Effects in Observational Studies

Guihua Wang, Ross School of Business, University of Michigan, 1209 McIntyre Drive, Ann Arbor, MI, 48105, United States, guihuaw@umich.edu, Jun Li, Wallace J. Hopp

We develop a new Instrumental Variable (IV) tree approach for detecting heterogeneous treatment effects in observational studies. We show that the IV tree approach effectively corrects for endogeneity issues and partitions subjects into groups such that those in the same group have similar treatment effects and those in different groups have different treatment effects. We demonstrate the practical application of the IV tree approach by using colectomy as the clinical setting to compare teaching (treatment) and non-teaching (control) hospitals and find that the outcome differences between teaching and non-teaching hospitals are heterogeneous across patient types.

Sustainable Supply Chains

Sponsored: Manufacturing & Service Oper Mgmt, Supply Chain

Sponsored Session

Chair: Suresh Muthulingam, Pennsylvania State University, University Park, PA, 16803, United States, suresh@psu.edu

1 - Diversity vs. Efficiency: A Policy to Service and Survive

Mahyar Eftekhar, Arizona State University, BA 433, Main Campus, P.O. Box 874706, Tempe, AZ, 85287, United States, eftekhar@asu.edu, Iman Parsa, Charles J.Corbett

Nonprofit firms are resource-dependent entities whose existence relies on donations they collect. This research empirically examines which factors impact nonprofits' income, and discusses whether nonprofits can develop a sustainable policy to fulfill their mandates efficiently while maximizing their income. Our data contains information of 120 organizations over 15 years.

2 - Recycling as a Strategic Supply Source

Gilvan Souza, Indiana University, Kelley School of Business, 1309 E.10th St, Bloomington, IN, 47405, United States, gsouza@indiana.edu, Gal Raz

We investigate how recycling can be used as a strategic source of supply in the presence of competition and a powerful material supplier. We examine the economic and environmental impact of a manufacturer's decision to recycle its products and the implications for its customers, supplier, and society. We show that the result depends on the type of recycling the manufacturer does as well as on the market dynamics and price of recycling.

3 - The Impact of Spill and Pollution Controversies on Firm Environmental Activity

Rick Hardcopf, University of Minnesota, 321-19th Avenue S, Suite 3-150, Minneapolis, MN, 55455, United States, hardc001@umn.edu, Rachna Shah, Suvrat Dhanorkar

The adoption of environmental management practices (EMPs) intended to reduce a firm's environmental footprint has increased steadily over the years. EMPs are also positively related to superior environmental, financial, and operational performance. Yet, no empirical research has evaluated how a negative environmental event, such as an environmental spill or pollution controversy, impacts a firm's on-going pattern of EMP adoption. Does the controversy accelerate, decelerate or have no impact on adoption? We evaluate this relationship using a novel secondary dataset derived from 10k filings, sustainability reports, and other public sources.

4 - Predicting Outcomes of Carbon Abatement Opportunities using Textual Analysis

Christian Blanco, Ohio State University, Columbus, OH, United States, blanco.58@osu.edu

Managers need to predict the outcome of carbon abatement opportunities before they can decide to implement them. Are there features of a project that can predict the monetary savings and carbon emissions reduction outcome of these opportunities? We explore this question using textual analysis on 45,554 carbon abatement opportunities reported to CDP (formerly the Carbon Disclosure Project) from 2011-2016.

Inventory Management

Contributed Session

Chair: Yossiri Adulyasak, HEC Montreal, Montreal, QC, Canada, yossiri.adulyasak@hec.ca

1 - A Statistical Analysis Study to Optimize Working Capital from Product Inventories in a Steel Manufacturing Company

Mohammed Almethen, Alfaisal University, Riyadh, Saudi Arabia, methenma@gmail.com

The success of a product in today's global marketplace depends on capabilities of firms in the product's supply chain. Among these capabilities, effective working capital management is a capability necessary to lead in the global marketplace. The purpose of this research is to investigate the working capital reduction opportunities by analyzing the safety stock of product inventories in the Arabian Gulf Steel Industry. A history of high profit margins had created a culture where relatively little attention was paid to cash, benchmark shows that SMC (Steel Manufacturing Company) to be less efficient than its peers with a huge working capital value of around $1 billion against sales of $0.365 billion. That is nearly twice as much working capital investment for every $1 billion as the top Steel Industry performers. Experiential learning was applied in an MBA course to find opportunities in the Gulf environment for innovative working capital management approaches with particular focus on inventory management. A Bottom-up approach is taken to Identify opportunities of reducing inventories per SKU (Stock Keeping Unit) i.e. +1000 SKU by calculating the SS (safety stock) and CS (cycle stock) by using a mathematical model. Data to be analyzed includes historical sales/inventory/supply/consumption to calculate variabilities. The findings were inventory reduction opportunity by $22.1MM from FP, $107MM from LP and $103MM from row materials. A total of $232.1MM. The DIOH (Days Inventory on Hand) will be reduced by 25 Days. Working capital optimization techniques from product inventories vary between industries. This research can significantly ease the optimization using scientific methods with agreed bases. This analysis can reduce working capital in this SMC if top management endorsed these opportunities and execute it.

2 - Joint Pricing and Inventory Optimization under Min-max Regret

Chengzhang Li, Purdue University, 403 W. State Street, west lafayette, IN, 47906, United States, li1392@purdue.edu, Mengshi Lu

We study a robust pricing newsvendor problem under the min-max regret framework where the firm only knows the interval in which the random factor lies with high confidence in the demand model. We characterize the optimal decisions with a general demand model and further study the impact of inventory risk by comparing the optimal price and the risk-free price. We also study comparative statics of the optimal price with different unit cost and degree of demand ambiguity. Finally, our approach outperforms the traditional one in a data-driven setting with small sample sizes, high demand variability, or demand model misspecification.

3 - Ordering Policy with Demand Learning for a New Product

Yanzhi Li, City University of Hong Kong, Department of Management Sciences, Tat Chee Avenue Kowloon, Hong Kong, Hong Kong, yanzhili@gmail.com

Consider a retailer that needs to prepare inventory for a new product. Due to the inherent demand uncertainty, the firm needs to learn the demand over time in the meanwhile of achieving an economy of scale in ordering. This paper attempts to address the trade-off faced by the retailer between business efficiency and prediction accuracy.

4 - Inventory Policies in Dual Sourcing Systems with Uncertain Yield

Andrei Sleptchenko, Assistant Professor, Qatar University, Dep. of Mechanical & Industrial Engineering, P.O. Box 2713, Doha, Qatar, andrei.sleptchenko@qu.edu.qa, Adriana Gabor

We study an inventory system with uncertain demand and two supply sources, one using Traditional Manufacturing processes (TM) and the other Additive Manufacturing (AM), aka 3D printing. Traditional manufacturing has lower costs, guaranteed quality, but longer lead time. Additive manufacturing has shorter lead time, but higher costs and uncertain yield due to unstable production quality. For this problem, we propose close to optimal inventory policies and study the conditions at which Additive Manufacturing can help to reduce the total costs.

5 - Optimal Buffer Capacity of Steel Strips in Continuous Steel Pipe Manufacturing

Md Shahriar J.Hossain, Graduate Research Assistant, Louisiana State University, 4141 Burbank Dr. Apt. 3, Baton Rouge, LA, 70808, United States, msjhossain1@gmail.com, Bhaba R.Sarker

The steel strip joining process in a seam welded pipe manufacturing line, is followed by a coil accumulator that facilitates buffer inventory. Size of the buffer determines the allowable time for strip joining. High buffer inventory increases cost for the accumulator but reduces the occurrence of line stoppage due to additional joining time. The problem is to find an appropriate buffer capacity that minimizes the total cost. Considering the issues of line stoppage, buffer storage and strip joining parameters, a total cost function is formulated and solved optimally in this research.

6 - Multi-item Inventory Optimization Approach under Multiple Target Levels

Yossiri Adulyasak, Assistant Professor, HEC Montreal, 3000 Cote-Sainte-Catherine, GOL.department, Montreal, QC, H3T.2A7, Canada, yossiri.adulyasak@hec.ca, Eric Prescott Gagnon, Thierry Moisan

This research focuses on a development of a multi-item inventory optimization approach under group target levels which is represented as a coupled Markov decision process (MDP). This problem is solved in a decomposition framework where a master problem will select a policy for each item that minimize overall costs while satisfying a set of targets such as a minimum cycle service level. A set of subproblems, one for each item, generates new inventory policies using an MDP approach. We discuss the practical considerations and extensions of the framework.

Queueing Systems

Sponsored: Applied Probability

Sponsored Session

Chair: Yunan Liu, North Carolina State University, Raleigh, NC, 27695-7906, United States, yliu48@ncsu.edu

1 - Optimal Controls for Double-ended Queues with Time-varying Demand

Ling Zhang, North Carolina State University, Raleigh, NC, United States, lzhang42@ncsu.edu, Chihoon Lee, Xin Liu, Yunan Liu

Continuous manufacturing has received much of recent attention both in academia and industry. We consider production systems with a time-varying demand, perishable inventory, and abandonment of backorders. The system incurs inventory-related costs of holding and perishment, and demand-related costs of waiting and abandonment. We study the finite-time production planning to minimize the sum of the demand and production related costs. We use fluid models to derive time-dependent production rates that are asymptotically optimal as the system scale increases; specifically, we prove a limit theorem to verify the asymptotic effectiveness of the optimal solution.

2 - Delay-based Service Differentiation in a Time-varying Environment

Xu Sun, Columbia University, New York, NY, 10027, United States, xs2235@columbia.edu, Ward Whitt

We study service differentiation in the presence of diverse customer needs and time-varying arrivals. We propose a new control family that exploits the head-of-line delay information. We refer to this family as the head-of-line-delay-ratio (HLDR) rule and show that it achieves desired differentiated service in a multi-class multi-server queue with non-stationary arrivals.

3 - Data-driven Inpatient Bed Assignment: Balancing Boarding and Overflowing using the P-model

Shasha Han, NUS.Business School, Singapore, Singapore, shashahan@u.nus.edu, Shuangchi He, Hongchoon Oh

Balancing boarding and overflowing are a chanllenge to most public hospitals. To tackle with it, we provide a practical P-model approach, which is able to capture critical features of patient flow management, while keep the resulting optimization problem tractable. Based on a set of patient flow data from a hospital, our simulation study shows that the proposed approach can greatly reduce patients' transfer delays and mitigate the time-of-day effect on boarding. Through the study with real data, we demonstrate that the P-model could be a useful tool for the control of queueing systems with time-sensitive service requirements.

4 - Queueing Models in Interactive Random Environments

Guodong Pang, Penn State University, 310 Leonhard Bldg., Industrial and Manufacturing Engineering, University Park, PA, 16802, United States, gup3@psu.edu

We study queueing models in interactive random environments. The arrival and/or service parameters are driven by a Markov process whose generators depend on the state of the queueing system. The underlying Markov process can be a Markov chain with a finite/countable state space, or a (reflected) diffusion process. We study the ergodicity properties and characterize the joint stationary distributions of the queueing processes and underlying Markov processes under certain conditions.

1 - Optimal Placement of a Small Order under a Diffusive Limit Order Book Model

Jose E. Figueroa-Lopez, Washington University-St Louis, One Brookings Drive, St Louis, MO, 63130, United States, figueroa@math.wustl.edu, Hyoeun Lee, Raghu Pasupathy

We present a framework to study the optimal placement problem of a stock trader who wishes to clear his/her inventory by a predetermined time horizon by using a limit order or a market order. Building on diffusion approximations for LOB models, we consider the analogous problem in a diffusive market and characterize the optimal limit order placement under different market conditions. In particular, we propose a simple method to determine the optimal order placement and show its performance.

1 - Financing and Supply Chain Network Structure

John R.Birge, University of Chicago, Booth School of Business, 5807 South Woodlawn Avenue, Chicago, IL, 60637, United States, John.Birge@ChicagoBooth.edu

Firms have differing incentives to form specific supply chain relationships depending on their relative positions downstream or upstream in the chain. These incentives including reliability of physical fulfillment and flexibility in financing. This talk will discuss a model that captures these dual roles of supply chain relationships and its implications for observed supply chain network configurations.

2 - Production and Capacity Management with Internal Financing

Matthew J. Sobel, Case Western Reserve University - Retired, Department of Operations, 10900 Euclid Avenue, Cleveland, OH, 44106-7235, United States, matthew.sobel@case.edu, Jie Ning

We analyze a price-taking firm that manages production and capacity, uses only internal financing, and faces stochastic market environments. The firm has two operationally independent production facilities, each of which makes two products, and a cash reserve which finances all operations and dividend issuance. We completely characterize the optimal policy and the endogenous values of the capacities and cash reserve, and show that they invite a real-option interpretation. We find that internal financing creates a spillover between the endogenous values of the two operationally independent facilities and we specify how this leads to interdependence of their optimal policies.

3 - Managing Inventory for a Multi-divisional Firm with Cash Pooling

Kevin Shang, Duke University, Fuqua School of Business, Duke University, Durham, NC, 27708, United States, khshang@duke.edu, Jianan Wang, Yi Yang

We consider a firm with N divisions, each replenishing inventory from an external supplier to satisfy a random, nonstationary demand in a finite horizon. The headquarter consolidates cash in a master account for external investments and purchasing inventory. The objective is to optimize the expected working capital at the end of the horizon. We derive near-optimal heuristics for the joint inventory and cash retention policy. We also investigate the value of cash pooling and the impact of cash on the order variability with correlated demands.

Managing New Product Development Uncertainties

Sponsored: Technology, Innovation Management & Entrepreneurship

Sponsored Session

1 - To Better Manage Risks in Multi-Period New Product Development — Select Riskier Projects

Janne Kettunen, Assistant Professor, George Washington University, Department of Decision Sciences, 2201 G. Street NW, Washington, DC, 20052, United States, jkettune@gwu.edu, Shivraj Kanungo

We consider multi-period new product development (NPD) where the decision maker chooses, periodically, which development projects to fund from the pool of available projects. We show that the availability of new development projects in future periods, which the initiated projects can be switched for, has major implications for what projects are optimal to select and thereby for the portfolio value and risk. Furthermore, we show that a risk-averse NPD portfolio selection approach implies higher risk than a risk-neutral selection approach. We name this phenomenon the risk aversion paradox and develop an approach to overcome it.

2 - A Theoretical Analysis of the Lean Start-up's Agile Product Development Process

Onesun Yoo, University College London, London, United Kingdom, o.yoo@ucl.ac.uk, Tingliang Huang, Kenan Arifoglu

Lean startup paradigm is emerging as a best practice for early product development for entrepreneurs and is widely adopted by entrepreneurship curricula in business schools. Despite its influence, there is no theoretical underpinning, leading to lack of clarity in its generalizability and explanation of implementation challenges in practice. We present a stylized model of the lean startup implementation problem. We show how the (vertical) quality of minimum viable product impacts learning about consumer's (horizontal) taste, and also how product-market characteristics impact its effectiveness.

3 - Learning Strategies to Deal with Market Disruptions and Turbulences in a Finite Time Horizon

Leonardo Santiago, Copenhagen Business School, Copenhagen Business School, Solbjerg Plads 3, Blok B.5. sal, Frederiksberg, 2000, Denmark, leonardo.p.santiago@gmail.com, Julia Couto, Nitin Joglekar

The ability to continuously innovate is a key asset to maintain a competitive advantage. However, very often, market turbulences or disruptions force firms to shift gears in their new product development strategies. This work considers the question of how firms should react to such disruptions when pursuing a finite time initiative. In particular, we focus on the role of pivoting strategies and cognitive maps to manage efforts to explore and exploit.

4 - Firm Clockspeeds: Toward a Theory of Relativity

Sina Moghadas Khorasani, Doctoral Student, David Eccles School of Business, Salt Lake City, UT, 84112, United States, sina.moghadas@eccles.utah.edu, Glen M.Schmidt

Fast clockspeeds imply short product lifespans. However, we find that two firms running at the same internal clockspeed may, to an outside observer, have quite different external clockspeeds, depending on product "type," market competitiveness, and whether product innovation or process innovation prevails.

5 - When is Necessity the Mother of Invention?

Sezer Ulku, McDonough School of Business, Georgetown University, DC, United States, Sezer.Ulku@georgetown.edu

We conduct several experiments to investigate how time, resource and performance constraints influence the search behavior and the performance achieved in problem solving tasks. We find that solution quality attained under a moderate constraint is superior to that attained when no such constraint is present. This is explained by differences in search effectiveness. We also find that in the presence of a challenging performance goal, participants exert more effort on average, they are more attentive to the tasks and as a result they achieve better results. As expected, when the resource constraint becomes very tight, performance suffers.

Data-driven Studies in Revenue Management

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Ken Moon, The Wharton School, Philadelphia, PA, 19104, United States, kenmoon@wharton.upenn.edu

Co-Chair: Kostas Bimpikis, Stanford University, 655 Knight Way, Stanford, CA, 94305, United States, kostasb@stanford.edu

1 - Leveraging Comparables for New Product Sales Forecasting

Georgia Perakis, Massachusetts Institute of Technology, Sloan School of Management, MIT, 100 Main Street Rm E62-565, Cambridge, MA, 02142-1347, United States, georgiap@mit.edu, Lennart Baardman, Divya Singhvi

We introduce a simple and intuitive approach for forecasting demand for new products. We identify comparable products that allow us to make accurate predictions. The approach we propose is both simple and intuitive and mimics the current operational practice of retailers. We show that our approach is fast and scalable. In collaboration with two big industry partners, we provide prediction improvements of the order of 40%-50% (WMAPE) that are robust across various product categories.

2 - Predicting with Proxies: Pitfalls and Solutions

Hamsa Sridhar Bastani, IBM Thomas J. Watson Research Center, Yorktown Heights, NY, United States, hamsab@wharton.upenn.edu

An increasingly common problem with machine learning is that true outcomes of interest are costly to measure. Instead, practitioners use proxy outcomes for prediction and subsequent decision-making. For example, a content recommender may make critical decisions based on predicted click-through rates (easily available) rather than user experience (costly to measure). However, the proxy outcome may be biased and result in poor decisions. We introduce a novel estimator that leverages many proxy outcomes and a few true outcomes to provably detect and reduce bias. Simulations on real datasets demonstrate significant improvements in prediction accuracy.

3 - Welfare Implications of Congestion Pricing: Evidence from SF Park

Hsin-Tien Tsai, UC Berkeley, 1822 Francisco St., Apt 4, Berkeley, CA, 94703, United States, hsintien@berkeley.edu, Pnina Feldman, Jun Li

Using data from San Francisco both before and after the implementation of a congestion pricing policy, we estimate the welfare implications of the policy. We find that congestion pricing increases consumer welfare in popular areas, but when implemented in less-congested areas, it may actually hurt consumers. In less congested areas, a simpler pricing policy may actually achieve higher welfare than a complex one.

4 - Optimal Retail Location: Empirical Methodology and Application to Practice

Chloe Kim Glaeser, University of Pennsylvania, 3730 Walnut St. Suite 500, Philadelphia, PA, 19104, United States, chloekim@wharton.upenn.edu, Marshall L.Fisher, Xuanming Su

We empirically study the spatio-temporal location problem motivated by an online grocery retailer. Customer demand is influenced by the convenience of pick-up locations and days. We combine demographic and economic data, business location data, and the retailer's historical sales and operations data to predict demand at potential locations. We introduce a novel procedure that combines machine learning and econometric techniques. Based on the predicted demand, we solve the spatio-temporal integer program using quadratic program relaxation to find the optimal pick-up location configuration and schedule.

Recent Development on Revenue Management and Pricing

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Ruxian Wang, The Johns Hopkins Carey Business School, Baltimore, MD, 21202, United States, ruxian.wang@jhu.edu

1 - New Bounds for Assortment Optimization under the Nested Logit Model

Sumit Kunnumkal, Queen's University, Kingston, ON, 500032, Canada, sk162@queensu.ca, Huseyin Topaloglu

We consider the assortment optimization problem under the nested logit choice model. We establish new bounds on the quality of revenue ordered assortments.

2 - Is Ignorance Bliss? Demand Learning in Dynamic Pricing with Limited Inventory

Chengyu Wu, Duke University, 877 Louise Circle, Durham, NC, 27705, United States, chengyu.wu@duke.edu, Li Chen

We examine the value of Bayesian demand learning in the context of a dynamic pricing problem with inventory scarcity. An interesting and counter-intuitive numerical result is discovered where a no-learning system may outperform the corresponding Bayesian learning system. We perform analytical analysis to shed light on this observation.

3 - Omni Channel Assortment Pricing

Shivaram Subramanian, IBM.Research, Yorktown Heights, NY, United States, subshiva@us.ibm.com, Pavithra Harsha, Markus Ettl

We analyze certain large-scale constrained optimization problems that arise in the retail industry in the context of pricing product assortments sold across multiple sales channels and locations. The problem becomes challenging when we consider cross-product and cross-channel demand interactions. We derive an effective global optimization approach and present computational results.

4 - Pricing Ancillary Service Subscriptions

Ruxian Wang, The Johns Hopkins Carey Business School, 100 International Dr, Baltimore, MD, 21202, United States, ruxian.wang@jhu.edu, Maqbool Dada, Ozge Sahin

We investigate customer choice behavior in the presence of main products, ancillary services with options of pay-per-use and subscription, as well as the outside option with heterogeneous customers.

Spatial Decision Analysis

Sponsored: Decision Analysis

Sponsored Session

Chair: Valentina Ferretti, London School of Economics and Political Science, London, United Kingdom, v.ferretti@lse.ac.uk

1 - Preferences in Spatial Decision Making

Jay Simon, American University, 4400 Massachusetts Avenue, NW, Washington, DC, 20016, United States, jaysimon@american.edu, L. Robin Keller

Decision maker preferences for spatial decisions can be challenging both to model and to assess. When outcomes occur over a geographic space, the decision maker must consider not only uncertainty, risk, relative preferences for different levels of an attribute, and tradeoffs between attributes, but also the geographic areas in which each attribute level is realized. We provide several representation theorems ensuring the existence of value and utility functions for spatial decisions, explore a range of viable elicitation techniques, and demonstrate the concepts with simple examples.

2 - Sustainability of Potential Areas for Deep Geothermal Energy Systems: A Preliminary Application to Switzerland

Matteo Spada, Paul Scherrer Institut, OHSA/D19, Villigen PSI, 5232, Switzerland, matteo.spada@psi.ch, Marco Cinelli, Peter Burgherr

Deep geothermal energy (DGE) is a renewable technology with a secure base-load, which is gaining interest among stakeholders due to its theoretically large resource potential. However, as for other geoenergy systems, the feasibility of DGE is strongly dependent on local conditions such as, for example, geological/geophysical ones. This study presents a methodology to assess the sustainability of potential areas of interest for DGE. The proposed method is based on outranking approaches combining explicit (e.g., heat flux) and calculated (e.g., risk indicators) criteria for specific a priori defined capacity plants. The results will be presented for a case study of Switzerland.

3 - Multi Criteria Decision Analysis for Contingency Base Siting

Jeffrey Cegan, USACE, 676 Virgiia Road, Concord, MA, 01742, United States, jeffrey.c.cegan@usace.army.edu, Matthew Bates

The US Army is in need of the ability to rapidly plan and site base camps in order to maximize the combat effectiveness of deployed forces. By defining mission specific requirements prior to the deployment of base camps, commanders are able to optimize base camp site selection. Currently, existing doctrine and guidance for contingency basing (CB) are not developed to support deployment in dense urban environments. Preliminary research reveals the inadequacy of current doctrine for conducting operations in such environments (Chief of Staff of the Army, 2013). The CB-SITE project seeks to address these problems by utilizing multi-criteria decision analysis for base camp site suitability assessment.

4 - Any Cognitive Bias in Spatial Decision Analysis Processes?

Valentina Ferretti, London School of Economics and Political Science, Houghton Streetl London l WC2A 2AE, London, United Kingdom, V.Ferretti@lse.ac.uk

The need and interest to consider cognitive and motivational biases has been recognized in different disciplines (e.g. economics, decision theory, finance, risk analysis, to name the most relevant ones) and has recently reached environmental decision making. Within this domain, the intrinsic presence of a spatial dimension of both alternatives and criteria calls for the use of maps throughout decision analysis processes. This talk presents insights from a literature review on cognitive biases in spatial decisions, as well as some preliminary results from a behavioural experiment on the spatial dimension of biases.

Control and Optimization Techniques for Power Systems II

Invited: Energy Systems Management

Invited Session

Chair: Javad Lavaei, University of California-Berkeley, United States, lavaei@berkeley.edu

1 - Promises of Conic Relaxations in Optimal Transmission Switching of Power Systems

Salar Fattahi, University of California-Berkeley, Berkeley, CA, United States, fattahi@berkeley.edu, Javad Lavaei, Alper Atamturk

In this talk, we consider the problem of optimal transmission switching (OTS) in power systems. The goal is to identify a topology of the power grid that minimizes the cost of the system operation while satisfying the operational constraints. In the first part of the talk, we study the difficulty of finding a strong MILP formulation of the OTS problem. Then, we propose a convex conic relaxation of the problem based on a semidefinite program (SDP). Strong valid inequalities are proposed to strengthen the SDP relaxation by multiplying different linear constraints and then convexifying them in a lifted space. We extensively evaluate the performance of the proposed method on IEEE benchmarks systems.

2 - Opportunity for Strategic Behavior in Electricity Distribution Network Marginal Cost Based Markets

Fatma Selin Yanikara, Boston University, 15 St. Mary's Street, Room 140, Boston, MA, 02215, United States, yanikara@bu.edu, Michael C. Caramanis

Transmission & Distribution (T&D) network day-ahead market co-clearing of energy and reserves must rely on Distributed Algorithms that discover Nash Equilibria of participating Distributed Energy Resources (DERs).Given the required individual DER self-scheduling - with or without the involvement of aggregators — strategic behavior may be possible under certain network information availability conditions available to DER market participants and the Network Operator. We examine the theoretical possibility for strategic behavior and quantify possible deviations from social welfare on a small T&D network.

3 - Error Bounds on Power Flow Linearizations: A Convex Relaxation Approach

Daniel K. Molzahn, Argonne National Laboratory, 1111 S. Wabash Ave., Apt 1507, Chicago, IL, 60605, United States, dan.molzahn@gmail.com, Krishnamurthy Dvijotham

The power flow equations relate the voltages and power injections in an electric power system. The nonlinearity of these equations results in algorithmic and theoretical challenges, including non-convex feasible spaces. Accordingly, many practical approaches for solving power system optimization and control problems employ linearizations of the power flow equations. By leveraging developments in convex relaxation techniques, this presentation describes a method for bounding the worst-case errors resulting from power flow linearizations over a specified range of operational conditions.

4 - Robustness Analysis of Power Grid under False Data Attacks Against AC State Estimation

Ming Jin, jinming@berkeley.edu, Javad Lavaei

The integration of sensing and information technology renders the power grid vulnerable to cyber-attacks. To understand how robust state estimators are, we study their behavior under worst attacks possible. Three types of data injection attacks are formulated in an optimization with "unobservability" and "sparse attack" constraints. A novel treatment of the continuous nonconvexity and discrete nonlinearity of the problem is proposed based on semidefinite programming (SDP) relaxation with a sparsity penalty, where a rank-1 and sparse solution exists under mild conditions. In light of the analysis, measures to improve the robustness of power grid are discussed.

Innovative Methods in Productivity and Efficiency Measurement

Invited: Data Envelopment Analysis

Invited Session

Chair: Abolfazl Keshvari, Aalto University School of Business, Helsinki, 00100, Finland, abolfazl.keshvari@aalto.fi

1 - A Comparative Study of Alternative Approaches to Estimate Productivity

Joseph Atwood, Montana State University, Bozeman, MT, United States, jatwood@montana.edu, Saleem Shaik

The main objective of the paper is to estimate & compare productivity measures between & within three approaches for single output-input technology. The following models are considered - index (Tornqvist and Fisher), programming (Malmquist Input, Output & Graph; Malmquist total factor productivity) and parametric (Input & Output; total factor productivity). Results support differences in productivity growth rate across approaches due to the composition of the frontier and the underlying assumptions. However, within nonparametric (parametric) approach, differences are due to the use of distance functions (residuals) or ratio of conditional distance functions (conditional residuals).

2 - Estimating Parameter Uncertainty in the Stoned Model

Endre Bjørndal, Norwegian School of Economics, Bergen, Norway, Endre.Bjorndal@nhh.no, Ørjan Mydland, Jonas Andersson

We investigate the performance of estimators for parameter uncertainty in the StoNED model (Kuosmanen and Kortelainen, 2012). More specifically, we study the performance of the bootstrap for making inference on the estimation of model coefficients. The estimators, based on different versions of the bootstrap, are investigated by means of a Monte Carlo study. We apply the method to a dataset for Finnish electricity distribution companies, and we discuss the relevance and importance of measuring the uncertainty in cost function coefficient estimates in a regulatory context.

3 - A Data Mining Approach to Hedonic Pricing Model via Nonparametric Piecewise Linear Regression

Abolfazl Keshvari, Abolfazl, Helsinki, Finland, abolfazl.keshvari@aalto.fi

This paper first reviews the main developments in nonparametric piecewise linear regressions. The statistical properties and applications of a family of such models are discussed. Numerical techniques to solve the related problems are also explained. Next, nonparametric concave regression is used to build a hedonic pricing model, which determines similar pricing strategies and categorizes observations accordingly. Advantages of this model are demonstrated and it is compared with similar approaches.

Marketing Insights from Social Media

Invited: Social Media Analytics

Invited Session

Chair: Ali Hojjat, University of New Hampshire, 10 Garrison Ave., Durham, NH, 03824, United States, ali.hojjat@unh.edu

1 - The Impact of Product Placement on Brand-related Social Media Conversations and Website Traffic

Beth Fossen, Indiana University, 3013 E.Daniel St, Bloomington, IN, 47401, United States, bfossen@indiana.edu, David Schweidel

Despite the popularity of product placement, there is limited research that empirically explores the impact of placement activities in television programs. We examine the effect of television product placements on the volume of social media activity and web traffic for the placed brand. Using data on 2,800 product placements, we find that placements contribute to both more online conversations and web traffic for the brand, with audiovisual placements yielding the largest increases. We also find that television advertising can enhance the impact of product placement on social media activity.

2 - Exit, Voice, and Response in Digital Platforms: An Empirical Investigation of Online Management Response Strategies

Naveen Kumar, University of Memphis, Memhis, TN, United States, nkumar7@memphis.edu, Liangfei Qiu, Subodha Kumar

In the past decade, we have witnessed the growing importance of management responses to online reviews in digital platforms. In this study, we examine the impact of such responses on business performance. We also uncover the spillover effect of such responses on the nearby businesses and identify conditions under which business owners are more likely to respond to consumer comments. Our findings have direct implications for both the business owners and digital platforms that can help businesses develop the right engagement strategies by taking the online response strategies into account.

3 - Influence of Flavors on the Propagation of Electronic Cigarettes Related Information

Jiaqi Zhou, City University of Hong Kong, 83 Tat Chee Avenue, 6/F, Academic 1, Kowloon, 12180, Hong Kong, jiaqi.zhou@my.cityu.edu.hk, Qingpeng Zhang, Daniel Dajun Zeng, Kwok-Leung Tsui

Depicting the influence of e-cigarette flavors on information propagation is critical for understanding the use of e-cigarettes and the reception of flavors. Modeling such influence could provide quantitative policy decision support concerning smoking initiation and contagion, and e-cigarettes regulations. This study aims to characterize the influence of flavors on the propagation of e-cigarette related information on social media. The occurrence of three flavors (coffee, fruits, and herbs&spices) did not enhance the popularity of information, indicating users' lack of interests in flavors.

Matching and Assignment

Invited: Auctions

Invited Session

Chair: Thayer Morrill, North Carolina State University, Raleigh, NC, 27695, United States, thayermorrill@gmail.com

1 - The Simple Structure of Top Trading Cycles in School Choice

Irene Yuan Lo, Columbia University, New York, NY, 10025, United States, iyl2104@columbia.edu, Jacob Leshno

Top Trading Cycles (TTC) is attractive for school choice, as it is strategy-proof, Pareto efficient, and allows school boards to guide the allocation via priorities. However, the combinatorial description of TTC makes it non-transparent to parents and designers. We give a simple characterization of TTC for school choice: the TTC assignment is given by n2 admission thresholds, where n is the number of schools, and these thresholds can be easily observed after running the mechanism. To calculate these thresholds, we define TTC through trade balance equations, which correspond in a continuum model to a differential equation. The model allows us to compute comparative statics and evaluate welfare.

2 - Communication Requirements and Informative Signaling in Matching Markets

Peng Shi, Assistant Professor, USC Marshall School of Business, 3670 Trousdale Pkwy, Los Angeles, CA, 90089, United States, pengshi46@gmail.com, Itai Ashlagi, Mark Braverman, Yash Kanoria

We study how much communication is needed to find a stable matching. Previous results show that any protocol must incur a high communication cost per agent, which scales linearly in the number of agents. On the other hand, we show that when the distribution of preferences satisfy natural restrictions, the amount of communication needed is much less. We give efficient protocols based on giving agents an estimate of whom they have realistic chances of matching, and recommending that agents reach out to easier-to-match partners while waiting for harder-to-match partners to reach out to them. Our protocols have good incentive properties and give insights on how to reduce congestion in matching markets.

3 - Competitive Equilibria in School Assignment

Thayer Morrill, North Carolina State University, Campus Box 8110, Raleigh, NC, 27695, United States, thayermorrill@gmail.com, Umut Dur

Top Trading Cycles was originally developed as an elegant method for finding a competitive equilibrium of Shapley and Scarf's housing market. We extend the definition of a competitive equilibrium to the school assignment problem and show that there remains a profound relationship between Top Trading Cycles and a competitive equilibrium. Specifically, in every competitive equilibrium with weakly decreasing prices, the equilibrium assignment is unique and exactly corresponds to the Top Trading Cycles assignment. This provides a new way of interpreting the worth of a student's priority at a given school. It also provides a new way of explaining Top Trading Cycles to a school board.

4 - The Effects of Thickness and Competition in Ride-sharing Markets

Afshin Nikzad, Stanford University, 741A Homer Ave, Stanford, CA, 94301, United States, afshin.nikzad@gmail.com

We study the effects of thickness and competition in ride-sharing markets. We vary thickness by varying the size of labor supply while holding the customer side fixed. When the market is sufficiently thick, wage and workers' average welfare decrease with labor supply. Otherwise, wage and workers' average welfare increase with labor supply, countering the prediction by the law of demand. Intuitively, workers are "complements" in a thin market -for example, their hourly wage and average employment time goes up with the labor supply- whereas they become "substitutes" and compete with each other in a thick market.

Robust Optimization and Machine Learning

Sponsored: Artificial Intelligence

Sponsored Session

Chair: Marek Petrik, University of New Hampshire, 33 Academic Way, Kingsbury W233, Durham, NH, 03861, United States, mpetrik@cs.unh.edu

1 - Efficient Algorithms for Robust Markov Decision Processes with State Rectangularity

Clint Chin Pang Ho, Imperial College Business School, London, United Kingdom, c.ho12@imperial.ac.uk, Marek Petrik, Wolfram Wiesemann

Robust Markov decision processes (MDPs) seek for optimal policies in view of the worst transition kernel from within an ambiguity set that specifies the knowledge about the unknown true Markov process. Although robust MDPs have emerged as powerful modeling tools, robust MDPs have typically been considered to be intractable, except for special cases where the ambiguity sets are rectangular in both the states and the actions. In this talk, we develop tractable solution techniques for robust MDPs whose ambiguity sets are only required to be rectangular in the states.

2 - Information Collection Optimization in Designing Marketing Campaigns for Market Entry

Somayeh Moazeni, Assistant Professor, Stevens Institute of Technology, Babbio Center, 1 Castle Point Terrace on Hudson, Hoboken, NJ, 07030, United States, smoazeni@stevens.edu

Developing marketing strategies for market entry is challenging due to the scarcity of relevant data. A sequential information collection optimization assists in creating new data points, given a finite learning budget to identify effective features maximizing the final outcome. We model the marketing campaign performance by a multiplicative advertising exposure model with Poisson jumps whose intensity depends on the marketing features. We develop an optimal learning policy and propose a computationally efficient algorithm to handle the large number of features. The performance of the optimal learning policy is compared to commonly used benchmark policies.

3 - Robust Reinforcement Learning with a Baseline

Yinlam Chow, IBM.Research, 1101 Kitchawan Rd, Yorktown, NY, 10598, United States, na, Marek Petrik, Marek Petrik, Marek Ghavamzadeh

A fundamental problem in sequential decision-making under uncertainty is to compute a safe policy, i.e., a policy that is guaranteed to have a better performance than a baseline strategy, given a batch of data. In this talk, We describe a model-based approach to this problem, in which the goal is to compute a safe policy, given an inaccurate model of the system with known accuracy guarantees. The inaccurate model and error bound may be constructed using the batch of data and prior knowledge about the system.

Supporting Personal Decisions with Social Media Analytics

Invited: Social Media Analytics

Invited Session

Chair: Xue Tan, University of Washington, University of Washington, Seattle, WA, 98105, United States, xuetan@uw.edu

1 - Assessing the Impact of Disclosure Policy on Investment Pattern: Evidence from a Natural Experiment in Supply Chain Finance Market

Zhijin.Zhou, University of Washington, Foster School of Business, Seattle, WA, 98195, United States, zjzhou@uw.edu

We examine the effect of exogenous information disclosure policy change on projects' fundraising performances in an online supply chain finance market. Regression Discontinuity analysis was conducted to verify a discontinuous jump in fundraising performances around the shock. Panel model was then used to assess the inside mechanism of the jumps. Results show that the policy change has a positive effect on projects' fundraising speed and investment rate, while has a negative influence on projects' average investment amount. Moreover, the influence will be attenuated by the fundraising target and debtors' ex experience, and strengthen by creditors' ex experience.

2 - Value of Information in Online Dating: An Empirical Study

Kyungmin Park, University of Washington, Seattle, WA, United States, parkk30@uw.edu

Online dating service has become a popular source to meet new people. A typical challenge to a firm in this market is matching people who are likely to be attractive to each other. In this regard, improving matching efficiency is important to enhance a firm's competence in the market. An user wants to find a person not only whom he like, but also who would like him. In this setting, a firm should also consider dyad-level characteristics of each pair of users in addition to individual-level characteristic of each user. This research explore this point by analyzing a rich data from a Korean major online dating application.

3 - Uber Introduction and Spillover Effects on Transportation System: Empirical Study

Kyungsun Rhee, University of Washington, 4725 24th Avenue NE, # 405, Seattle, WA, 98105, United States, ksr22@uw.edu, Jinyang Zheng, Yong Tan, Youwei Wang

This study aims to investigate whether the entry of Uber influences on the demand patterns in overall transportation system. Using a national panel data set constructed from four sources, we examine the longitudinal relationship between Uber entry and Taxi efficiency, along with its horizontal and vertical spillover effects. To identify the entry effects on shift of transportation demands to other transportation, we rely on a natural experiment setup inherent in city Shanghai in China, as the policy is applied at same time everyday. Our empirical analyses reveal that the demand on taxi is reduced whereas demand for other alternative transportation increased.

4 - Competition in Mobile Operating Systems: the Strategy of Facebook

Tongxin Zhou, University of Washington, 3927 Adams Lane NE, Seattle, WA, 98105, United States, txzhou5@uw.edu, Xue Tan

React Native is a JavaScript-based cross-platform mobile development language that has attracted a lot of attention among mobile development teams. Much of the code used to develop an iOS app in React Native will work on Android and vice versa. It reduces the dependency on this very limited pool of iOS and Android platform developers and repurposes the large community of web JavaScript developers to mobile development.

Simplicity Versus Complexity in Forecasting and Prediction

Invited: Forecasting and Prediction

Invited Session

Chair: Nathaniel Phillips, University of Basel, Basel, 4001, Switzerland, nathaniel.phillips@unibas.ch

1 - FFTrees: How to Easily Create and Visualise Fast-and-frugal Decision Trees to Make Accurate Decisions Based on Minimal Information
Nathaniel Phillips, Basel, 4053, Switzerland, Nathaniel.D. Phillips.is@gmail.com, Hansjoerg Neth, Wolfgang Gaissmaier, Jan Woike

Fast and frugal decision trees (FFTs) are simple decision algorithms that allow people to make efficient and effective decisions based on limited information. We introduce an R package called FFTrees that allows anyone to create, visualize, and use FFTs from data with minimal programming. We explain how FFTs work and provide a 5 step tutorial for using the FFTrees package to create them. We then present a simulation across a 10 datasets that show how FFTs created by FFTrees can predict data as well as complex machine learning algorithms while remaining simple enough for anyone to understand and use.

2 - Recency: Predicting with Smart Data
Florian Artinger, Max Planck Institute for Human Development, Berlin, Germany, artinger@mpib-berlin.mpg.de

Since the early 1910s, managers have been using a simple recency-based decision strategy, the hiatus heuristic, to identify valuable customers. This study analyzes the role of recency using a library of 60 data sets from business and other areas including weather, sports, and medicine. We find that the hiatus heuristic can perform on par with complex algorithms such as from machine learning and taking into account further variables apart from recency does not improve performance. We show that the results are not so much driven by limited sample size than by the dominant role that recency plays in most of these environments.

3 - Simple Rules for Complex Decisions
Daniel G.Goldstein, Microsoft Research, New York, NY, United States, dan@dangoldstein.com, Jongbin Jung, Connor Concannon, Ravi Shroff, Sharad Goel

We present a new method, select-regress-and-round, for constructing simple rules that perform well for complex decisions. These rules take the form of a weighted checklist and can be applied mentally. Importantly, our method for creating these rules is itself simple, and can be carried out by practitioners with basic statistics knowledge. Across 22 domain, including a key example of bail decision making, we find that these simple rules are nearly as good as state of the art models trained on all available features.

4 - Social Learning Strategies for Matters of Taste
Pantelis Pipergias-Analytis, Cornell University, Ithaca, NY, United States, pantelispa@gmail.com, Daniel Barkoczi, Stefan Herzog

Most choices people make are about "matters of taste", where no universal, objective truth about the options' quality exists. Still, people can learn from the experiences of individuals who have already evaluated available options. We mapped recommender system algorithms to social learning strategies for "matters of taste". Using computer simulations, we studied how people can leverage the opinions of (similar) others to make better decisions. We show that experienced individuals can benefit from relying more on the opinions of seemingly similar people, whereas inexperienced individuals are better off picking the mainstream option despite inter-individual differences in taste.

1 - Probabilistic Decision Making and Airline Operations: Why it Pays to Play Games of Chance
Tim Niznik, Director, Operations Systems and Decision Support, American Airlines

Decisions made in the absence of probability-based analytics will not just usually be wrong, they will consistently be wrong, especially when those decisions involve weather and ATC. One of the objectives of the Decision Support Vision for the Operations Control Center at American Airlines is to improve how we respond to weather events, specifically in terms of the determining the timing, level of risk, and specific actions to take. We need to move away from deterministic decision making that is primarily ad-hoc and experience-based to a more data-driven process that is built on predictive analytics and accounts for uncertainty. This talk looks at some examples where probabilistic decision making could be applied, some examples in the industry of where these techniques are already being applied, and finally, our current efforts to develop this capability internally.

Applications of Cyber Defense

Sponsored: Military Applications

Sponsored Session

Chair: Natalie M Scala, Towson University, Towson, MD, 21252, United States, natalie.scala@gmail.com

1 - Reinforcement Learning for Autonomous Cyber Defense
Ahmad Ridley, Department of Defense, Washington, DC, United States, adridle@tycho.ncsc.mil

Our research goal is to build an autonomous cyber defense system that will make an enterprise network, and its associated missions/services, more resilient to cyber-attack. Such a cyber defense system should make decisions and implement appropriate responses to anticipate, withstand, recover from and/or evolve in the presence of cyber-attacks. Since attack methods are constantly evolving, this defense system must be adaptive, and also operate in real-time and at network scale. Therefore, in our research, we apply reinforcement learning to train the system to perform sequential decision making under uncertainty to defend the network.

2 - Performance Benchmarking of Cyber Streaming Analytics
Caleb Baechtold, Janine Bainger, BAH, Baltimore, MD, baechtold_caleb@bah.com

This research effort explores streaming platform behaviors to build models predicting performance metrics of concern as they relate to combinations of system environments and analytic configurations. The research focuses on WaterSlide, an open-source streaming analytic technology commonly used to perform Cyber operations by processing metadata using its event-at-a-time architecture.

3 - Risk Implications in Cybersecurity Applications

Natalie M.Scala, Towson University, Dept. of e-Business and Technology Management, 8000 York Road, Towson, MD, 21252, United States, nscala@towson.edu, Michel Cukier, Allison C. Reilly, Paul L.Goethals

This research addresses risk in cyber defense and identifies opportunities to incorporate risk modeling and decision analysis into current initiatives. Specifically, the Science of Security Five Hard Problems approach frames cybersecurity from a computer science perspective. We identify the problems/attributes that are collectively exhaustive from a risk perspective as well as the overlap with the hard problems framework. Finally, we discuss approaches to take to address risk, including predictive analytics, value modeling, and developing metrics to score performance and measure risk.

Supply Chain Management

Contributed Session

Chair: Xingxing Chen, Washington University-St. Louis, Saint Louis, MO, United States, xingxing.chen@wustl.edu

1 - Customer Order Value Evaluation Model for Customer Classification in Multi-class Production Systems

Hyun-jung Kim, Professor, Seoul School of Integrated Sciences & Technologies, Seoul, Korea, Republic of, charitas@empal.com, Eungab Kim

We consider a manufacturer that produces make-to-order products in retail industry. While inventory rationing has extensively been covered in the literature, how to classify customer orders practically has not been studied yet. We develop a sophisticated modeling scheme that quantifies the value of customer orders. This model is based on statistical and machine learning algorithms. Using data collected from financial statements of retail companies in Korea, we show that our model can be very effective in customer classification for multi-class production systems in practice.

2 - Developing a Continuous Location Routing Model and Solving it by using Benders Decomposition

Ali Sarabi, Arizona State University,Tempe, AZ 85287, United States, asarabi1@asu.edu

One of the most important measures, in order to reduce the costs of logistic and distribution, is to integrate the location of distribution centers and the routing paths of the goods. In this study, we try to develop a model for the decision-making in a continuous situation. The proposed model is actually a model to determine the locations of the facilities and routing in order to deliver products to the customers in a bi-level distributed system. Although the proposed approach and locating in the continues space may be associated with complications, the time and money spent to collect the information about the potential locations for solving the problem will be reduced.

3 - Cooperative Supply Chain Coordination using Sustainability-focused Joint Economic Lot-sizing

Kurt A.Masten, Assistant Professor of Supply Chain Management, Fairleigh Dickinson University, 285 Madison Ave., Unit E, Madison, NJ, 07940, United States, masten@fdu.edu

Considerable efforts have been spent on how to best define and explain "sustainability" from multiple perspectives. Most research in the area concludes that significant savings should be possible with proper application of sustainability principles. However, little attention has been given to the practical logistics and methods required to help shift the discussion from "what" to "how". An updated cooperative solution based on an established joint economic lot-sizing model is proposed to offer a quantitative aid to practitioners and researchers.

4 - Project-based Supply Chain: Role of Operational Hedging

Xingxing Chen, Washington University-St. Louis, Campus Box 1156, One Brookings Drive, Saint Louis, MO, 63130, United States, xingxing.chen@wustl.edu, Panos Kouvelis, Yu Xia

We analyze a two stage supply chain where a Manufacturer sources a key component from suppliers in order to complete a project. The consumption level of the component can't be perfectly predicted due to various reason. Therefore, planning for the component inventory can be critical. We formulates a newsvendor model which includes a linear penalty when delay materializes. We find that 1) optimal operational hedges is contingent on time buffer in an integrated supply chain 2) under a decentralized supply chain, optimal operational hedges occur at different level of the supply chain and may vary with time buffers; 3) supply chain coordination can be achieved.

5 - Consignment Contract with Revenue Sharing in Online Retailing under Strategic Information Sharing

Tatyana Chernonog, Bar-Ilan University, Ramat Gan, Israel. Tatyana.Chernonog@biu.ac.il

This work suggests a general model of a two-echelon supply chain where a dominant retailer and a manufacturer interact via a consignment contract with revenue sharing. The manufacturer's cost function is known only to him, whereas the retailer has to evaluate this function. We formulate the problem as a Retailer-Stackelberg game in which the less-informed party moves first. We investigate a strategic information-sharing policy of the manufacturer when the revenue and cost functions are general as well as the set of his decisions.

1 - Examining the Impact of Employees with Disabilities on Productivity

Sriram Narayanan, Michigan State University, 632 Bogue Street, Room N357 North Business College Complex, East Lansing, MI, 48824, United States, narayanan@broad.msu.edu, Tharo Soun, Kalyanmoy Deb

In this study, we examine the role of team diversity on employee productivity using real-life time study data. In particular, we examine how diversity of different forms of disability in a garment manufacturing unit.

2 - Diversities in Supply Chain Network an Empirical Study on Supply Chain Governance Strategies in Reducing Carbon Emissions

Baiyang 'Herbie' Huang, Kenan-Flagler Business School, 123B S. Roberson St, None, chapel hill, NC, 27516, United States, herbie_huang@kenan-flagler.unc.edu, Jayashankar M.Swaminathan, Sriram Narayanan

Suppliers are an important aspect of firms in reducing greenhouse gas emissions. Firms use multiple strategies to facilitate this reduction. We empirically examine this question using a novel secondary dataset of 1400 global companies' supply chain carbon emissions mitigation strategies with their supply base. We theorize and empirically test the impact of supplier base diversity in both industry and geographic locations, supply chain's network properties and regulatory environment on the strategies they pursued.

3 - Collaboration Among Supply Chain Partners: Better Outcomes or More Conflict?

Muge Yayla Kullu, University of Central Florida, 4000 Central Florida Blvd., Orlando, FL, 32816, United States, muge@ucf.edu

In this paper, we are interested to find out how acceptable or fragile collaborative sourcing partnership models would be under various supply chain configurations. We account for the heterogeneity of the customer base and differentiation of the products in the market which has not been done before in this context. Our findings indicate that if the end products have independent demand structures, all parties benefit from the end results. However, when there is a quality differentiated product structure with heterogeneous customer base, collaborative sourcing would be lethal for the national brand manufacturer.

Applications in Supply Chain Management

Sponsored: Service Science

Sponsored Session

Chair: Sara Saberi, Worcester Polytechnic Institute (WPI), Worcester, MA, 01609, United States, ssaberi@wpi.edu

1 - Regulation Compliance in the Multilevel Supply Chain

KiHyung Kim, Purdue University, School of Industrial Engineering, 315 N.Grant Street, West Lafayette, IN, 47907-2023, United States, kim1151@purdue.edu

As the supply chain is more globalized, imposing regulation along the supply chain is an issue. In our model, there are three participants in the supply chain, the brand owner, the manufacturer, and the supplier. The supplier is located overseas, and it is a critical issue for the brand owner to let participants comply the domestic regulation. We study three cases: the stick only case, the carrot only case, and the stick and carrot case. Equilibrium is investigated, and our analysis indicates that the stick and carrot strategy can prevent collusion and let participants comply the regulation.

2 - Coordinating a Dual-channel Supply Chain with a Risk-averse Retailer under Deferred Payment

Bo Li, College of Management and Economics at Tianjin University, No.92 Weijin Road, Nankai District, Tianjin, 300072, China, libo0410@tju.edu.cn

The study considers a dual-channel supply chain with a risk-averse retailer under a deferred payment contract. We design a benchmark without deferred payment to compare the equilibrium solutions. We find that if the retailer is moderately risk-averse and the unit production cost is large, the profits of the manufacturer and the entire supply chain will decrease as she tends to be risk-neutral, and vice versa. In addition, whether the two agents benefit from the deferred payment depends on two key parameters (unit production cost and risk-averse attitude). Finally, a mixed contract that combines revenue sharing and deferred payment is introduced to coordinate the dual-channel supply chain.

3 - A Responsive Pricing Retailer Sourcing from Competing Suppliers Facing Disruption

Tao Li, Santa Clara University, 2730 Park Ave Apt 3, Santa Clara, CA, 95050, United States, tli1@scu.edu, Suresh P.Sethi, Xi Shan

We study a problem of a retailer who orders from two competing strategic suppliers subject to independent or correlated disruptions and responds by setting the retail price upon delivery. We model it as a Stackelberg-Nash game with the suppliers as the leaders and the retailer as the follower. We identify a scenario in which an increase in the reliability of a supplier may, counter to our intuition, hurt him. In the literature without responsive-pricing, the retailer's profit increases and a supplier's profit decreases in the disruption correlation, whereas with responsive-pricing, the retailer's profit increases and a supplier's profit may not decrease in the disruption correlation.

4 - Pricing of New Product Technologies in Supply Chains and Technology Markets

Ayhan Aydin, George Mason University, 4400 University Drive, Enterprise Hall, Fairfax, VA, 22030, United States, aaydin2@gmu.edu

Upstream firms can market their technology to downstream tiers either by licensing the use of the technology or through a product carrying the advanced technology. We compare the levels of technology transfer under three different price tariffs - only fixed tariff, only variable tariff, and two-part tariff - and under two methods of marketing on the level of technology transferred.

1 - A Two-Phase Algorithmfor the Multi-Parametric Linear Complementarity Problem with Sufficient Matrices and Parameters in General Locations

Nathan Adelgren, Edinboro University of PA, 159 Ross Hall, Edinboro, PA, 16444, United States, nadelgren@edinboro.edu

In this talk we present a new two-phase procedure for solving the multiparametric Linear Complementarity Problem (mpLCP) with sufficient matrices. As the variant of mpLCP considered in this talk was previously unsolved, we first consider the theoretical properties of this problem which allow it to be solved. We then present the solution procedure and explore its use on an example. Finally, we present the results of some preliminary computational experiments.

2 - Multiobjective Quadratic Programming: State of the Art and Application to Portfolio Optimization

Pubudu Jayasekara Merenchige, Clemson University, Clemson, SC, 29634, United States, pwijesi@clemson.edu, Margaret M. Wiecek, Nathan Adelgren

We review algorithms for computing efficient solutions to multiobjective quadratic programs (MOQPs) and analyze their applicability to the portfolio selection problem. We compare the algorithms with respect to the type of MOQPs they can handle. The type is determined by the number of quadratic criteria and the properties of the feasible set.

3 - On the Robustness Gap in Uncertain Multiobjective Optimization

Margaret M.Wiecek, Clemson University, Mathematical Sciences Dept, Clemson, SC, 29634-1907, United States, wmalgor@clemson.edu, Corinna Krüger, Anita Schöbel

We propose a definition of robustness gap in uncertain multiobjective optimization. Under convexity assumptions and using of the weighted-sum scalarization, we derive upper and lower bounds for the gap that are easier to calculate than the gap itself. We also specify conditions under which the gap is zero.

4 - A Cost to Coverage Ratio Based Heuristic Algorithm for the Multiobjective Set Covering Problem

Lakmali Weerasena, University of Tennessee Chattanooga, 9629 Shooting Star Circle, Chattanooga, TN, 37379, United States, lakmali-weerasena@utc.edu

The multiobjective set covering problem (MOSCP), a NP-hard combinatorial optimization problem, has received limited attention in the literature from the perspective of approximating its Pareto set. We present a two-phase heuristic algorithm to approximate the Pareto set of the MOSCP. Computational experiments on instances with two, three and four-objective set covering problems are conducted to analyze the performance of the algorithm.

Smart Services and Service Systems

Sponsored: Service Science

Sponsored Session

Chair: Robin Qiu, Pennsylvania State University, Malvern, PA, 19355, United States, robinqiu@psu.edu

1 - Research on the Quality Promotion System of Logistics Service

Zuqing Huang, PhD, China Jiliang University, Hangzhou, 310018, China, hzq1210@163.com

With the rapid development of e-commerce, the logistics industry has been got the rapid development. But the quality of logistics service is unsatisfied. From the perspective of the quality of logistics service, this paper constructed the index system of logistics service and provided a method to evaluate the quality of logistics service.

2 - A Patient-centric Approach to Mitigating Alzheimer's Disease Progression

Robin Qiu, Pennsylvania State University, 30 E. Swedesford Road, Malvern, PA, 19355, United States, robinqiu@psu.edu

In 2016, about 5.4 million Americans were diagnosed with Alzheimer's disease (AD). The project was to develop a predictive model to classify a patient into normal, mild, and moderate, and severe AD stages. Based on the patient's cognition evaluation, we aim to develop a cheap, convenient, and accurate self-diagnostic tool. More importantly, actionable factors that could slow down the disease's progression are determined. Hence, this study would be able to facilitate developing a platform to guide an individual in making the necessary lifestyle choices, ultimately resulting in retaining or rejuvenating the brain's cognitive ability of the individual.

3 - Identification of Critical Quality Dimensions for Continuance Intention in mHealth Services: A Case Study of Onecare Service

Ki-Hun Kim, Pohang University of Science and Technology, 77 Cheongam-Ro Nam-Gu, Engineering Building 4-316, Pohang, Gyeongbuk, 790-784, Korea, Republic of, kh_kim@postech.ac.kr, Kwang-Jae Kim, Dae-Ho Lee, Min-Geun Kim

Mobile health (mHealth) services provide health-related support through mobile devices. Onecare is an mHealth service to support health behavior monitoring of college students by utilizing daily behavior data collected through activity trackers and smartphones. This study aims to identify the quality dimensions that are crucial for users' intention to continue the use of Onecare based on the survey responses of 191 Onecare users. This study would serve as a basis for planning mHealth service improvement to enhance users' continuance intention.

4 - Directed Disease Networks in Support of Multiple-disease Risk Prediction Modeling

Tingyan Wang, Ph.D candidate, Tsinghua University, Beijing, 100084, China, wangty14@mails.tsinghua.edu.cn, Robin Qiu, Ming Yu

In this study, we propose a novel framework that combines directed disease network and collaborative filtering techniques for multiple disease risk prediction modeling. Firstly, a directed disease network considering temporal information was built on grouped diseases. Then based on this network, we explore different disease risk score computing approaches. We validate the proposed methods with real-world datasets. The results demonstrate the potential value of the proposed modeling framework, e.g. a reference for medical experts to provide patients healthcare guidance, or a tool helps individuals design a better healthcare plan over time.

1 - Crew Decision Assist: Optimizing Crew Deployment for Freight Trains

Dasaradh Mallampati, BNSF, Ft. Worth, TX, United States, dasaradh.mallampati@bnsf.com, Brian Roth, Anant Balakrishnan, Pooja Dewan, April Kuo, Juan Morales

Crew costs account for a significant portion of train operating expenses, and so effective crew deployment is an important priority for railroad companies. Motivated by BNSF Railway's desire to replace the current manual crew planning process with a systematic and efficient approach, we developed an optimization model and solution methodology, and implemented a system called Crew Decision Assist (CDA) to support crew scheduling for single-ended districts at BNSF. Our approach is novel because it incorporates many practical details in train crew scheduling and accounts for uncertainty in train schedules. CDA interfaces with existing systems to quickly generate effective crew deployment plans, and is expected to yield cost savings of several million dollars per year.

2 - Optimized Scoring Systems: Towards Trust in Machine Learning for Healthcare and Criminal Justice

Cynthia Rudin, Duke University, 737 E. Franklin St, Chapel Hill, NC, 27514, United States, cynthia@cs.duke.edu, Berk Ustun

Questions of trust in machine learning models are becoming increasingly important, as these models are starting to be used widely for high-stakes decisions in medicine and criminal justice. Transparency of models is a key issue affecting trust. The topic of transparency in modeling is being heavily debated in the media, and there are conflicting laws on the use of black box models between the European Union and the United States. This paper reveals that: (1) There is new technology to build transparent machine learning models that are often as accurate as black-box machine learning models. (2) These methods have had impact already in medicine and criminal justice. This work calls into question the overall need for black box models in these applications.

Health Care, Modeling and Optimization

Contributed Session

Chair: Anders Gullhav, Norwegian University of Science & Technology, Trondheim, Norway, anders.gullhav@iot.ntnu.no

1 - Impact of Budget Uncertainty in a Coordinated Vaccine Market

Nicholas Morris, Rochester Institute of Technology, Rochester, NY, 14623, United States, njm2868@rit.edu, Jose Batista, Ruben Proano

This study evaluates the impact on total welfare in a coordinated vaccine market when countries' procuring budgets are uncertain. This uncertainty is represented through two approaches. A simulation is used to evaluate each procurement approach on randomly generated scenarios. Each experimental instance is solved via a mixed integer nonlinear program model that generates a procurement schedule. An example is discussed on how uncertainty in the US Federal budget for vaccine procurement could impact the global vaccine market.

2 - An Approximate Dynamic Programming Approach for Patient and Process Prioritization in a Hospital Environment

Lida A. Apergi, University of Maryland, 8223 Paint Branch Drive, 2243 AV. Williams, ISR, College Park, MD, 20742, United States, lapergi@rhsmith.umd.edu, John Baras, Bruce L. Golden, Kenneth Wood

This research tackles the problem of patient and process prioritization in a healthcare environment with limited resources. Considering the medical cardiology department of a large medical center, a holistic model is designed and developed towards optimizing the decisions of allocating the available resources to the patients in order to minimize patients' waiting costs. Approximate Dynamic Programming techniques are applied to optimize the aforementioned decisions over time, as well as capture the heterogeneity of the patients.

3 - Optimizing the Appointment Scheduling at MRI Labs

Anders N. Gullhav, Norwegian University of Science & Technology, Department of Industrial Ec & Tech Man, Trondheim, 7491, Norway, anders.gullhav@iot.ntnu.no, Marielle Christiansen, Anders R. Eilertsen, Bjorn Nygreen, Hanna M. Selvaag

We study the appointment scheduling problem, where randomly arriving examination requests are to be allocated to an MRI machine at a specific time and day in the future. Due to the different urgency levels of the requests, ranging from hours to weeks and months, the MRI planners must ensure that there is enough available time at any given day to schedule urgent patients, while maintaining a high utilization. We develop an optimization model that schedules non-urgent patients and facilitates the scheduling of urgent patients. The model is run in a rolling horizon framework, and is tested on real data from a Norwegian hospital. We show how the model can be used as decision support in the scheduling process.

1 - Optimization Modeling Tools from LINDO Systems

Mark A.Wiley, LINDO.Systems Inc, 1415 No. Dayton Street, Chicago, IL, 60622, United States, mwiley@lindo.com

Exceptional ease of use, widest range of capabilities, and flexibility have made LINDO software the tool of choice for thousands of Operations Research professionals across nearly every industry for over 30 years. LINDO offers a full range of solvers to cover all your optimization needs. The Linear Programming solvers handle million variable/constraint problems fast and reliably. The Quadratic/SOCP/Barrier solver efficiently handles quadratically constrained problems. The Integer solver works fast and reliably with LP, QP and NLP models. The Global NLP solver finds the guaranteed global optimum of nonconvex models. The Stochastic Programming solver has a full range of capabilities for planning under uncertainty. Get all the tools you need to get up and running quickly. LINDO provides a set of versatile intuitive interfaces to suit your modeling preference. What's Best is an add-in to Excel that you can use to quickly build spreadsheet models that managers can use and understand. LINDO has a full featured modeling language for expressing complex models clearly and concisely, and it has links to Excel and databases that make data handling easy.LINDO API is a callable library that allows you to seamlessly embed the solvers into your own applications. You can pick the best tool for the job based upon who will build the application, who will use it, and where the data reside. Technical support at LINDO is responsive and thorough - whether you have questions about the software or need some guidance on handling a particular application. Get started today. Visit our booth or www.lindo.com to get more information and pick up full capacity evaluation licenses to try them out on your toughest models.

2 - Discover Artelys Knitro, the Leading Solver for Nonlinear Optimization

Richard Waltz, Artelys, 150 N.Michigan Avenue, Suite 800, Chicago, IL, 60601, United States, Richard.waltz@artelys.com

Artelys Knitro is the premier solver for nonlinear optimization problems. This software demonstration will highlight the latest Knitro 10.3 developments, including a new preconditioner option, advancements in solving large nonlinear least-squares models and enhancements to the R interface. In addition, we will summarize some of new features coming in Knitro 11.0. The demo will also provide an overview of how to effectively use Knitro in a variety of environments.

Humanitarian and Disaster Relief Logistics

Sponsored: Public Sector OR

Sponsored Session

Chair: Christopher Zobel, Virginia Tech, Blacksburg, VA, 24061-0235, United States, czobel@vt.edu

Co-Chair: Andrew N. Arnette, University of Wyoming, Laramie, WY, 82071-2000, United States, aarnette@uwyo.edu

1 - An Optimization Model for Disaster Relief Asset Pre-positioning

Andrew Arnette, University of Wyoming, aarnette@uwyo.edu, Christopher Zobel

This research extends previous work on improving the pre-positioning of assets used for disaster relief. It is founded on an evidence-based analytical model that utilizes multiple factors for analytically characterizing risk. This, in turn, is used to determine the potential need for the sheltering of impacted populations in the face of multiple possible natural disasters. By explicitly considering risk, the model is able to consider overall effectiveness at the same time that it ensures equity in the resource allocations.

2 - Resiliency: How Perception Informs Action
Michelle Seref, Virginia Instiitute of Technology, Blacksburg, VA, United States, mmhseref@vt.edu

This research uses text mining to analyze how the perception of a community's resilience stance, as reflected in newspaper accounts of disaster events, affects subsequent actions taken by the community, both businesses and public policy. Preliminary results show a correlation between resilience stance and type of action, as well as resilience stance and type of disaster.

3 - Optimal Allocation of Reserved Inventories in a Supply Network with Demand Surge
Liu Fang, Nanyang Technological University, Singapore, Singapore, Liu_Fang@ntu.edu.sg, Pengfei Guo, Yulan Wang

We study the optimal pre-positioning of reserved emergency inventories in a supply network that faces random demand surge, with the aim of minimizing the expected total unmet demand. The demand surge follows a time-dependent stochastic process, and the post-surge transshipments of the reserved inventories are scenario-driven uncertain. We characterize the matching processbetween the post-surge delivery of the reserved inventories and the corresponding demand surge process and derive the expected total unmet demand.

4 - Routing for Post-disaster Needs Assessment to Improve Information Accuracy
Duygu Pamukcu, Middle East Technical University, Ankara, 06400, Turkey, duygupamukcu@gmail.com, Melih Celik, Burcu Balcik

In the aftermath of the disaster, the accuracy of the estimates on disaster effects depends on how much time is spent for statistical sampling to collect information. In this study, we consider the problem of routing needs assessment teams, where there exists an inherent trade-off between information collection and travel time. Mathematical models and solutions approaches are presented to analyze this trade-off and support sample size and site selection decisions.

Marketing

Contributed Session

Chair: Omid Javidbakht, Lehigh University, Bethlehem, PA, United States, omj212@lehigh.edu

1 - When Does Price Matching Mitigate Showrooming
Yilong Luo, Illinois Institute of Technology, 565 West Adams Street, Chicago, IL, 60661, United States, yluo4@hawk.iit.edu, Jiong Sun

Consumers' "showrooming" behavior poses a threat to brick-and-mortar stores. In our paper, we study when the price matching policy is effective in mitigating this behavior and enhancing stores' profits. First, we show that price matching may hurt stores when the mis-match risk is relatively high and only a few consumers are aware of this policy. Second, we show that under some cost conditions, the manufacturer can benefit from price matching and, therefore, has incentives to support this policy without intensifying the downstream market competition.

2 - Tie-in with Downstream Competition
Sreya Kolay, Assistant Professor, University of California, Irvine, 8 Vega Court, Irvine, CA, 92617, United States, skolay@uci.edu

Sellers often use tie-in contracts, offering a product only as a part of a bundle of two or more products and not by itself. Such contracts have been accused of being used for exclusionary purposes, i.e., a dominant firm in a primary product market can use such contracts to force buyers to purchase a secondary product from it to exclude a more efficient rival in the latter market. This paper examines a dominant firm's incentives to offer exclusionary tie-in contracts when it sells its products through downstream competing retailers. The profitability of exclusionary tying is shown to be related to two key factors: the ability to commit to prices by the upstream firms, and the nature of downstream competition.

3 - Strategic Choice of Quality for Entrants in the Presence of Anchoring Effect
Keita Nire, Keio University, Yokohama, Japan, k.nire1030@gmail.com, Nobuo Matsubayashi

In this study, using a two-stage duopoly model of vertical product differentiation, we investigate how the anchoring effect, where consumers' perceived quality is affected by a predetermined quality position, influences an entrant's quality choice when it competes with an incumbent firm. We show the optimal quality choice for the entrant, along with its resulting profitability, with varying degrees of anchoring effect.

4 - The Implications of Market Characteristics for Vertical Strategic Interactions in Supply Chains
Shahryar Gheibi, Siena College, The School of Business, Siena College, 515 Loudon Rd, Loudonville, NY, 13204, United States, sgheibi@siena.edu, Eunkyu Lee

Our analysis on the relationship between market characteristics and the type of vertical strategic interactions in supply chains fully identifies the linkage, and demonstrates that a single aggregate-level demand property, demand's decay rate, holds the key. We show the generality of our results and their practicality for managers. Our results indicate that an empirical distribution of consumers' willingness to pay provides insights into the type of strategic interactions in a decentralized distribution channel. Our findings also lead us to propose some interesting strategic implications of the product type (broadly targeted vs. niche) for price leadership in supply chains.

5 - Information Provision in a Vertical Channel
Chenchen Di, UIUC, Champaign, IL, 61820, United States, cdi2@illinois.edu, Yunchuan Liu, Jiong Sun

This paper investigates how manufacturers and retailers play different roles in revealing product quality information and facilitating consumers' learning their appreciation for quality, respectively, when consumers face uncertainties for both. We find that firms' incentives of information provision may or may not be aligned, and it depends on the flexibility of information provision. Both the retailer and the manufacturer can benefit from flexible information provision.

6 - Coupon Targeting Competition in Privacy Sensitive Market
Omid Javidbakht, Lehigh University, 19 Memorial Dr, Room 304, Bethlehem, PA, 18015, United States, omj212@lehigh.edu, Alberto J.Lamadrid, Parv Venkitasubramaniam

The problem of coupon targeting competition between two retailers which sell the same product with the same price and marginal cost is studied. The competition is modeled by a set of non-zero sum stochastic games over consumers located on a specific segment of Hoteling line. Equilibrium and optimal stationary policies of retailers on each segment is derived. Moreover, It is demonstrated that a retailer will have lower defensive strategy on the consumers with weak preference on him whilst the rival retailer will have higher offensive strategy on the same consumers as discounting factor increases.

Scheduling and Logistics

Invited: Project Management and Scheduling

Invited Session

Chair: Xiangtong Qi, Hong Kong University of Science & Technology (HKUST), Kowloon, Hong Kong, ieemqi@ust.hk

1 - Approximation Algorithms for Capacitated Vehicle Routing Problems with a Fixed Number of Depots

Liang Xu, Associate Professor, Southwestern University of Finance & Economics, 555 Liutai Avenue, Tongbo Tower A.202, Chengdu, China, arecxuliang1112@gmail.com, Zhou Xu

We study problems of routing capacitated vehicles to serve customers with an objective to minimize the total travel distance. In this talk, we present several novel constant ratio approximation algorithms, which run in polynomial time when vehicles are located at a constant number of depots.

2 - Scheduling Service Package with Acclimation and Non-homogeneous Memory Decay

Yifu Li, Hong Kong University of Science and Technology, Clear Water Bay, Kowloon, 999077, Hong Kong, ylick@connect.ust.hk, Tinglong Dai, Xiangtong Qi

Sequence decision of an experiential service is intensively studied by researchers from various disciplines. While empirical research shows that the ideal schedule is usually with the peak activity early in the interior, behavior study suggests that a sequence with the peak activity by the side is optimal. To address this inconsistency, we introduce a modification of the acclimation and memory decay model. We examine the condition of the interior peak optimal schedule, and we find the optimal position of the peak activity may change non-monotonically as its memory decay rate increases. Furthermore, we explore the shape property and propose an optimal algorithm for the service scheduling problem.

3 - Due Date Assignment and Scheduling on a Single Machine with Limited Information of Job Processing Times

Guohua Wan, Shanghai Jiao Tong University, 535 Fahua Zhen Road, Antai College of Economics and Management, Shanghai, 200052, China, ghwan@sjtu.edu.cn, Qing Yue, Shenghai Zhao

We study a single machine scheduling problem with due date assignment and stochastic job processing times, where only the mean and support of job processing times are known but not the distribution. The objective is to minimize the total costs of earliness, tardiness and due date assignment. We develop an approximation for the problem and propose both branch and bound and heuristic algorithms to find the optimal solution. We also conduct computational experiments to evaluate the efficiency of approximation and the performance of proposed heuristic algorithms.

4 - Stabilizing Unbalanced Cooperative Scheduling Games

Xiangtong Qi, Hong Kong Univ. of Science & Technology (HKUST), Dept of IELM, HKUST, Kowloon, Hong Kong, ieemqi@ust.hk

We consider cooperative parallel machine scheduling games. In many cases such games are unbalanced, i.e., having an empty core. Hence the grand coalition of the game is not stable. We study how an outsider can take some action to stabilize the game so that the grand coalition can be sustained. We will discuss different schemes and show how each of them works.

Chair: Yonghua Ji, University of Alberta, Edmonton, AB, T6G 2R6, Canada, yji@ualberta.ca

1 - Does Online Real Estate Information Affect Property Price? Evidence from Zillow

Zhengrui Jiang, Iowa State University, Iowa CIty, IA, United States, zjiang@iastate.edu, Yuheng Hu, Arun Rai, Hua Sun

Using data collected from Zillow.com, this study examines how online property information affects offline property price. Our results reveal that property information has a larger influence on the sale price of uncommon properties, i.e., those valued significantly lower or higher than neighborhood averages, than on the price of common properties, i.e., those valued close to neighborhood averages. Furthermore, we find that Zestimate, property value assessed by Zillow, influences the price of all properties. Finally, sellers tend to provide more property information when a property is more expensive, less comparable to surrounding ones, or priced higher than its estimated property value.

2 - Optimal Pricing and Workforce Composition for Service Delivery using a Hybrid Workforce

Monica Johar, University of North Carolina, 9201 University City Blvd, Friday 352 C, Charlotte, NC, 28223, United States, msjohar@uncc.edu

Organizations are increasingly able to use an on-demand workforce to complement in-house workers to perform sophisticated workflows in a Hybrid Service environment. Such sophisticated workflows include simple as well as more complex integration tasks. We present an optimization model that integrates pricing, workforce composition and task allocation decisions for such a hybrid service environment.

3 - How Much to Open, How Fast to Fix and Develop? Impacts of Openness on Software Development and Maintenance

Rakesh Mallipeddi, TX, United States, mallipeddi@tamu.edu, Emre Muzaffer Demirezen, Subodha Kumar, Ram Gopal

Proprietary software vendors have recently begun to emulate the open source software community in opening up part of their software. We analyze the impact of software openness in the context of resource allocation between bug fixing and new version development, an important operations issue that many software vendors face in light of prevalence of software defects. We first empirically analyze the impact of openness on time it takes to fix a defect. Using the findings from the empirical study, we formulate optimal control models to examine the effects of making the software code open (fully or partially) on the overall quality of the software and the development efforts of its next version.

4 - Dynamic Optimization of Software Maintenance Requests with Duplications

Yonghua Ji, University of Alberta, Business School, Edmonton, AB, T6G 2R6, Canada, yji@ualberta.ca, Said Samiedaluie

We study the problem of software request maintenance by using a dynamic optimization approach. We consider both duplication of and prioritization of requests. Duplicated requests can arrive independently and are grouped before being worked on. Also requests are classified into different priority classes. Our work explores various characteristics of an optimal policy.

1 - Humans are not Machines: Queueing with Human Servers

Amy R.Ward, University of Southern California, Marshall School of Business, Bridge Hall BR.I.401H, Los Angeles, CA, 90089-0809, United States, amyward@marshall.usc.edu

There is a long history of using queueing models for system design purposes. This is because there is a well-developed framework that provides insightful analytic expressions for many performance measures of interest, such as expected customer wait time. The issue is that traditional queueing models assume processing rates are fixed. However, in many systems that arise both in manufacturing and service applications, people rather than machines are doing the processing, and people may change their processing rates. In this talk, we discuss how to incorporate behavioral elements in queueing models. We highlight some surprising results, and propose some open questions.

2 - Beyond the Lab: Next Frontiers in Behavioural Research

Serguei Netessine, University of Pennsylvania, Philadelphia, PA, United States, netessin@wharton.upenn.edu

While vast majority of behavioural research in our field uses lab experiments, there are important complementary approaches that we need to utilise going forward to make stronger practical impact. I will discuss these approaches using recent papers as examples.

Influence of Human Behaviour on Project Success: Theories, Models and Practices

Invited: InvitedBehavioral Aspects of OR

Invited Session

Chair: Sijun Bai, Management School, Northwestern Polytechnical University, Xi'an, China, baisj@nwpu.edu.cn

Co-Chair: Lin Wang, Management School, Northwestern Polytechnical University, Xi'an, China, linwang.nwpu@gmail.com

1 - Research on Emergency Decision Management of Chemical Accidents Based on Game Theory

He Zhai, Northwestern Polytechnical University, Xi'an, China, zhaihe0218@163.com, Mengna Guo, Yuntao Guo

With the arrival of China's economic and social transition period,the complexity and dynamics of various projects are gradually increasing, which makes the project management more difficult. In recent years, the safety accidents and unexpected events in Shaanxi province emerge in endlessly,and the "conspiracy of optimism" is the main factor leading to the failure of decision-making. Based on the game theory, this paper analyzes the reasons of the "conspiracy of optimism" phenomenon in the process of emergency decision making and a model will be constructed based on this problem, which may provide a reference for the improvement of the emergency decision-making management.

2 - Project Portfolio Implementation under Uncertainty: A Behavioral Perspective

Lin Wang, Northwestern Polytechnical University, Xi'an, China, linwang.nwpu@gmail.com

Lin Wang, Institutes of science and development, Chinese Academy of Sciences, Beijing, China, linwang.nwpu@gmail.com, Sijun Bai

As a social system highly influenced by decision makers' behaviors, the management of project portfolios should highlight behavioral factors instead of adhering to rational and normative plans. This paper investigates the uncertainties generated by behavioral biases (e.g. planning fallacy, strategic misrepresentation and optimism bias), how should decision makers respond to these uncertainties, and the impact of individual and interactive biases (e.g. lies and delays) on the monitoring and control process. System dynamics is applied to model the complex system and provide the foresight of each decision, and an example is illustrated to validate the model.

Privacy in Urban Transportation

Sponsored: TSL, Urban Transportation

Sponsored Session

Chair: Christian Claudel, University of Texas-Austin, Austin, TX, United States, christian.claudel@utexas.edu

1 - Privacy Aware Traffic Monitoring in Work Zones

Daniel Work, University of Illinois, Urbana, IL, United States, dbwork@illinois.edu, Yanning Li

Despite the increasing popularity of Lagrangian sensors, fixed location traffic sensors are still irreplaceable in certain safety-critical applications, such as monitoring traffic in work zones. However, the high cost and privacy concerns of conventional fixed video-based monitoring systems create economic and policy challenges for dense sensor deployments. This talk advocates the use of a low-resolution passive infrared camera to reduce both energy demands and privacy challenges. To extract vehicle counts and speeds from the sensor, an unsupervised machine learning algorithm is proposed. Results from recent field experiments will be discussed.

2 - Differentially Private Road Traffic Estimation

Jerome Le Ny, Polytechnique Montreal, Montreal, QC, H3T1J4, Canada, jerome.le-ny@polymtl.ca

Urban transportation systems rely on an increasing number and variety of sensors capturing our activities in order to optimize their operations, which raises important privacy concerns. Naive data sanitization techniques such as removing names from location traces are known to provide insufficient protection. This talk gives an introduction to differential privacy, a state-of-the-art formal tool for privacy preserving data analysis, and illustrates its application to real-time traffic estimation with static sensors and floating car data.

3 - A Dual Machine Learning-model Based Framework for Privacy Analysis of Traffic

Christian Claudel, University of Texas-Austin, TX, 78750, United States, christian.claudel@utexas.edu

In this talk, we consider the problem of tracking vehicles generating anonymous GPS tracks. Using an Hamilton Jacobi formulation of traffic flow, we pose the problem of reidentifying anonymous tracks as a Mixed Integer Linear program (MILP). This MILP results is used as an input to an Artificial Neural Network (ANN) classifier that reidentifies vehicles from anonymous tracks. This framework is validated using experimental location data, and shows that 94% reidentification is possible, considerably above random reidentification (50%) or naive reidentification based on the kinematics of vehicles (88%).

4 - An Algorithm for Preserving the Privacy of Sharing Transport Service Route Data

Yueshuai He, New York University, New York, NY, United States, yh1995@nyu.edu, Joseph Y j Chow

Despite the increasing relevance of private transport operators as Mobility-as-a-Service in the success of smart cities, desire for privacy in data sharing limits collaborations with public agencies. We propose an original model and algorithm that circumvents this limitation, by designing a diffusion of the data—in this case, service tour data—such that passenger travel times remain reliable to the recipient agency. The Tour Sharing Privacy Design Problem is formulated as a nonlinear programming problem that maximizes entropy. An algorithm based on formulation of an equivalent kth best traveling salesman problem is evaluated using several network instances.

Field Experiment in Online Marketplace and Social Network

Sponsored: Information Systems

Sponsored Session

Chair: Tianshu Sun, University of Southern California, Los Angeles, CA, 90089, United States, tianshus@marshall.usc.edu

1 - Learning from Inventory Information: Field Evidence from Amazon

Ruomeng Cui, Goizueta Business School, Emory University, 1300 Clifton Rd, Atlanta, GA, 30322, United States, ruomeng.cui@gmail.com, Dennis Zhang, Achal Bassamboo

Many online retailers provide real-time inventory availability information. Customers can learn from the inventory level and update their beliefs about product quality. Based on a unique setting from Amazon lightning deals, which displays the percentage of inventory consumed in real time, we explore whether and how consumers learn from inventory availability information. We run randomized field experiments on Amazon and run a panel data analysis. We find evidence of consumer learning from inventory information: a decrease in product availability causally attracts more sales in the future; in particular, a 10% increase in past sales leads to a 2.08% increase in cart add-ins in the next hour.

2 - Dynamic Personalized Targeting with Hidden Use Engagement Stages: Mobile Tapstream Data and Field Experiment

Yingjie Zhang, Carnegie Mellon University, Pittsburgh, PA, United States, yingjie2@andrew.cmu.edu, Beibei Li, Xueming Luo, Xiaoyi Wang

Low engagement rate and high attrition rate have been major challenges for the success of mobile apps. To date, little is known towards how companies can improve user engagement and business revenues through designing effective in-app pricing strategies. We propose a structural model by accounting for time-varying nature of engagement and consumer forward-looking behavior. We analyze mobile tapstream data from a popular mobile reading app. Our results enable us to tailor optimal pricing strategy to each consumer based on their engagement status. Interestingly, we found such engagement-specific pricing strategy leads to lower average price for consumers and higher overall business revenues.

3 - Social Influence Across Products: A Large-Scale Randomized Experiment in Social Advertising

Shan Huang, Massachusetts Institute of Technology, 100 Main Street, # 427, Cambridge, MA, 02142, United States, shanh@mit.edu, Sinan Aral, Jeffrey (Yu) Hu, Erik Brynjolfsson

Spending on social advertising is increasingly dramatically. Unfortunately, large-scale experimental evidence of the lift from social ads almost always focuses on a single product at a time. As a result, we know little about how social influence and the effectiveness of social advertising vary across product categories. We, therefore conducted a randomized field experiment measuring social influence and social ad effectiveness across 71 products in 25 product categories among a random sample of more than 37 million users of WeChat Moments Ads.

4 - Social Media Integration and E-commerce Platform Performance: A Randomized Field Experiment

Ni Huang, Arizona State University, Tempe, AZ, United States, ni.huang@asu.edu, Tianshu Sun, Pei-yu Chen, Joseph Golden

E-commerce platforms can integrate with social media to let users directly comment on product pages. Such integration can convey credible information but may also hinder product sales due to less control over user comments. Thus, it is not clear whether an ecommerce platform should embrace such integration. We conduct a randomized experiment with a large ecommerce platform to examine the impact of social media integration on users' shopping behaviors. We find customers in the treatment, who see product pages with Facebook comment integration, are significantly more likely to place an order. We further explore heterogeneous treatment effects and find them aligned with social learning mechanism.

Energy

Contributed Session

Chair: Zhi Zhou, Argonne National Laboratory, 9700 South Cass Avenue, Bldg 221, Argonne, IL, 60439, United States, zzhou@anl.gov

1 - Efficient Pricing Methodologies for Integration of Distributed Technology.

J.M.Omar Khaiam, PhD Candidate, University of Auckland, Auckland, New Zealand, jkha088@aucklanduni.ac.nz, Anthony Downward

With the rapid development of solar PV and holdhouse and grid-scale battery technology, the distribution network facing a number of challenges. In this presentation we discuss a model that determines how batteries should be installed in the distribution network (either by households, or by the distribution network owner), and how changes to the distribution tariff structure may induce efficient investment choices. We examine whether the economic 'death-spiral' for distribution assets can be avoids using efficient market signals.

2 - A Mixed Complementarity Problem Extension to Find Near Equilibrium Electricity Prices for Non-convex Unit Commitment Models

Mehrdad Pirnia, University of Waterloo, 200 University Ave, West, Waterloo, ON, N2L3G1, Canada, mpirnia@uwaterloo.ca, Hassan Shavandi, John David Fuller

We propose a realistic unit commitment model, based on an extension of the mixed complementarity problem method, to approximate the minimization of the opportunity cost of electricity market players, including generators, consumers and transmission line operators. The opportunity costs arise due to the nonconvexities of binary variables for the on/off status of generators. The solution of the proposed model reduces the opportunity cost of generators, compared to the standard maximum social welfare calculation for unit commitment, and it provides near equilibrium electricity market prices and generation dispatch quantities.

3 - Investments in Power Generation and Transmission: The Effect of Capacity Procurement

Kazuya Ito, Tokyo University of Science, 2641 Yamazaki, Noda-shi, Chiba, 278-8510, Japan, 7416605@ed.tus.ac.jp, Ryuta Takashima, Makoto Tanaka

The penetration of renewable energy has induced a decrease in capacity factors and a decommissioning for existing generations, and a reduction in new investments. This problem implies a fear for the shortage of capacity in the electricity market. Thus, in order to meet the capacity in the market, policymakers implement various policies for capacity procurements. In this work, we analyze investments in power generation and transmission by means of real options theory. The ISO decides the investment timing by maximizing social welfare whereas a generation firm invests by maximizing the own profit. Especially, we examine the effect of capacity procurement for the ISO on the investment decisions.

4 - Energy-water Nexus Modeling and Analysis: From Cooling Water Efficiency and Electric Grid Operation Perspectives

Zhi Zhou, Argonne National Laboratory, 9700 South Cass Avenue, Bldg 362, Argonne, IL, 60439, United States, zzhou@anl.gov, Ying Wang, Getnet Betrie, Eugene Yan

Most electricity generation needs large amounts of cooling water, which is extensively demanding in hot and arid areas. We propose a model to estimate the water usage (including water withdraw and consumption) in the power plants operation based on practical operation data. The water usage model reflects the impacts of environment temperature, electricity generation and cooling technologies, et. al. The cooling efficiency and water availability constraints are integrated into the power system operation model. Results show that water availability and temperature have significant impact on power grid economics.

Opportunities and Issues of Shared Mobility Services

Sponsored: TSL, Intelligent Transportation Systems (ITS)

Sponsored Session

Chair: Mohammad Abdollahi, Wayne State University, 4815 Fourth Street, Room 1067, Detroit, MI, 48202, United States, abdollahi@wayne.edu

1 - Dynamic Ride Pooling. Benefiting from Last Mile Opportunity

Mohammad Abdollahi, PhD Student, Wayne State University, 4815 Fourth Street, Room 1067, Detroit, MI, 48202, United States, abdollahi@wayne.edu, Kai Yang

This paper is addressing the design of DRT system where real-world practical constraints are considered in providing customized vehicle routing and scheduling. Designing this system allows for dispatch operators to quickly explore tradeoffs between level-of-service and operating costs. We have developed a constraint programming based benders decomposition algorithms for this system. Using the methodology developed in this paper we expect not to have just cost benefits, but also improved quality of service and the reduction in total vehicle-kilometers traveled which leads to environmental benefits.

2 - The Effect of New Shared Mobility Services on the Transportation Network

Mona Asudegi, Lead Technologist, Booz Allen Hamilton, 20 M St. SE, #1000, DC, 20003, United States, asudegi_mona@bah.com, Sara Sarkhili

Mobility market is rapidly changing due to changes in technology, information availability, and social trends. More people are using these new forms of mobility services for their day-to-day transportation. It is of interest to see how these new forms of services are affecting the transportation networks; are they taking more customers away from transit or are they reducing the single occupant vehicles on the road? This study models, simulates, and investigates difference scenarios of shared used mobility services, for a specific region, to determine their effects on traffic network performance measures.

3 - A Date-driven Analysis of the Impact Exerted on Government Regulations in Taxi Industry by E-hailing Service

Ziyang Guo, Sparkzone Research Group, Room6, Yard 7, Fenzi Hutong, Xidan North, Street, Xicheng District, Beijing, China, Beijing, China, 1872371084@qq.com, Yide Zhao, Yinghao Jia

Government has mainly regulated the traditional taxi market from four perspectives: taxi number, price and quality of service, as well as standard working time of drivers. However, the emergence of E-hailing service has posed a great challenge for the traditional industry. This study, emphasizing on the four aspects above, aims to capture the impact of E-hailing service on traditional market based on data-driven approaches. Primarily focusing on the flexibility and elasticity of the E-hailing service, we propose a model that takes into account the influence exerted on the equilibrium position of the taxi market, thereby optimizing regulation policies for administration.

Syngenta Crop Challenge in Analytics

Invited: Agricultural Analytics

Invited Session

Chair: Robin Lougee, IBM Research, Yorktown Heights, NY, 10598, United States, rlougee@us.ibm.com

1 - A Hierarchical-ensemble of Machineries to Optimize the Choice of Soybean Varieties

Durai Sundaramoorthi, Washington University in Saint Louis, 10352 Conway Road, Saint Louis, MO, 63131, United States, dsundaramoorthi@gmail.com, Lingxiu Dong, Iva Petrova Rashkova, Piruthiviraj Sivaraj

Selecting soybean varieties for planting is an important decision that has significant implications for the yield of a farm. With many soybean varieties available along with data on yield performance collected over several years at various farm locations, the seed-mix selection is a highly intriguing decision to modern day farmers and seed retailers. To aid soybean-mix selection, this work describes and evaluates a hierarchical-ensemble of machine learning and optimization methods which chooses soybean varieties to obtain optimal yield.

2 - A Decision Making Approach for Crop Seed Variety Selection via Hedging Against Weather Risk

Leyuan Shi, Peking University, Room 512 Founder Building, 298 Chengfu Road, Beijing, 10080, China, leyuan.shi@wisc.edu
Leyuan Shi, University of Wisconsin, Madison, WI, United States, leyuan.shi@wisc.edu, Zhongshun Shi, Yu Zhao, Xi Zhang

This paper develops an efficient decision making approach for the seed retailer to determine the seed varieties selection in appropriate proportions for the next season. The proposed approach integrates the customized portfolio selection theory and effective machine learning technique. We formulate this decision making problem as the mean-covariance model to balancing the weather risk and crop yield. A hybrid coefficients evaluation method is designed to produce the expected yield of each seed variety under different weather type. We develop a MIQP-based decomposition algorithm to solve the decision making problem efficiently and effectively.

3 - A Machine Learning Approach to the Syngenta Crop Challenge 2017

Wenjun Zhou, University of Tennessee, Knoxville, TN, 37996, United States, wzhou4@utk.edu, Yunhe Feng

Seed companies need to plan for the variety and quantity of seeds to stock at least a year in advance. There are a large number of seed varieties, each can perform best under different growing conditions. Since next year's weather is unpredictable, it is hard to foresee which seed varieties work the best in each field. We propose using multi-task learning for estimating the yield and risk of each variety as if they were planted at each location. The best mix of seeds for each location was then determined by seeking a trade-off between yield and risk.

Topics in Finance: Systemic Risk Management

Sponsored: Financial Services

Sponsored Session

Chair: Xuedong He, xdhe@se.cuhk.edu.hk

Co-Chair: Nan Chen, nchen@se.cuhk.edu.hk

1 - Submodular Risk Allocation

Paul Glasserman, Columbia University, 403 Uris Hall, Columbia Business School, New York, NY, 10027, United States, pg20@columbia.edu, Samim Ghamami

Changes in the over-the-counter derivatives markets leave dealers some flexibility in whether to trade bilaterally or through central counterparties (CCP) and which CCP to choose. We analyze the problem of optimal allocation of trades to portfolios to minimize risk-based margin and capital requirements. With submodular margin requirements, the problem becomes a submodular intersection problem; the dual provides per-trade margin attributions. We derive conditions under which standard deviation and other risk measures are submodular functions of sets of trades. We compare systemwide optimality with individually optimal allocations.

2 - On Default Probabilities in Financial Networks

Dohyun Ahn, PhD Candidate, KAIST, #2111, E2-2, KAIST, 291 Daehak-ro, Yuseong-gu, Daejeon, Korea, Republic of, dohyun.ahn@kaist.ac.kr, Nan Chen, Kyoung-Kuk Kim

We consider the Eisenberg-Noe network model for systemic risk, focusing on random shocks to financial institutions. Using duality, we characterize shock amplification caused by the network structure and find when a specific bank fails. These results enable us to improve our understanding of default probabilities in financial networks. Specifically, we establish general upper and lower bounds of firm-specific default probabilities. We also discuss the impact of network structure on default probabilities. In addition, as default events become rare, asymptotic behaviors of corresponding probabilities can be derived.

3 - Financial Contagion in a Multilayer Network

Zachary Feinstein, Washington University-St. Louis, St. Louis, MO, United States, zfeinstein@wustl.edu

This talk provides a general framework for modeling financial contagion in a system with obligations in multiple illiquid assets. In so doing, we develop a multi-layered financial network that extends the single network of Eisenberg and Noe (2001). In particular, we develop a financial contagion model with fire sales that allows institutions to both buy and sell assets to cover their liabilities and act as utility maximizers. We prove that, under standard assumptions, equilibrium portfolio holdings and market prices exist which clear the multi-layered financial system. We demonstrate the value of our model through illustrative numerical case studies.

4 - Leverage Constraint, Market Illiquidity, and Financial Fragility

Nan Chen, Chinese University of Hong Kong, William M.W. Mong Engineering Bldg, Rm 609, Shatin N.T, Hong Kong, nchen@se.cuhk.edu.hk, Jing Chen, Xuedong He

We establish a full equilibrium model to show how systemic fragility is built up in the presence of leverage constraints and market illiquidity. The model can generate two distinct regimes: normal and crisis. Due to highly nonlinear amplification effects caused by both illiquidity, the economy is prone to instability and occasionally enters into the volatile crisis regime. The equilibrium risky asset price demonstrates heteroscedasticity in different regimes. Our model shows that margin requirement, a common practice in risk management at the micro level, may yield an undesirable pro-cyclic effect in a systemic context.

Joint Session SOLA/PSOR: Public Sector Location Analysis

Sponsored: Location Analysis

Sponsored Session

Chair: Kayse Lee Maass, Mayo Clinic, Rochester, MN, 7, United States, maass.kayse@mayo.edu

1 - A Robust Model for Pre-positioning Relief Items for a Typhoon

Joline Uichanco, University of Michigan, Ross School of Business, 701 Tappan St, Room 4418, Ann Arbor, MI, 48109-1234, United States, jolineu@umich.edu

We consider the problem faced by a humanitarian agency in pre-positioning relief items to prepare for an oncoming typhoon whose future outcome (trajectory and wind speed) is uncertain. We develop probabilistic models of municipality-level demand and of damage to pre-positioned supply that are dependent on the typhoon outcome. The dependence of demand on the typhoon outcome is determined by a hierarchical linear model estimated from a dataset that includes typhoon effects from five West Pacific typhoons affecting the Philippines. We propose to solve the pre-positioning problem using a bi-objective two-stage stochastic optimization model.

2 - Anticipation Effects in Post-disaster Supply Chain Modeling

Diana Gineth Ramirez-Rios, Rensselaer Polytechnic Institute, 134 25th Street, Troy, NY, 12180, United States, ramird2@rpi.edu, Jose Holguin-Veras, Luk N. Van Wassenhove, Victor Cantillo, Shaligram Pokharel, Johanna Amaya-Leal, Trilce Encarnacion

This research focuses on disaster relief modeling, particularly in the period of time starting at the moment a disaster strikes and when the initial response takes place. This research introduces the anticipation function, which assesses both the deprivation and psychological cost or anxiety of the deprived individual. The results of an exploratory analysis of this anticipation function is empirically derived through SP surveys. Some management implications and its possible incorporation to the supply chain model formulation were also considered.

3 - Bike Sharing using Toggle Locations and Portable Stations

Rahul Swamy, University of Illinois at Urbana-Champaign, 205 E. Clark St, Apt 303, Champaign, IL, 61820, United States, rahulswamy91@gmail.com, Jose Luis Walteros

We explore an alternative approach to fixed station locations in a bike sharing system by turning on/off (toggle) certain locations for certain periods of time. A Mixed Integer Program is presented that decides which of the candidate locations to choose to serve as bike stations at what time, with the objective of minimizing the bike redistribution load. The MIP has a rich structure that is exploited using Bender's Decomposition. The second part of the talk focuses on how portable stations can be used to serve in the toggle station locations. This routing problem is solved using implicit enumeration followed by a variant of set covering problem. Computational results are presented with a Case Study in NYC.

4 - Selecting Locations of Rehabilitative Shelters for Human Trafficking Survivors among States in the U.S.: A Decision Analytic Approach

Kayse Lee Maass, Mayo Clinic, Rochester, MN, United States, maass.kayse@mayo.edu, Renata Alexandra Konrad, Andrew C. Trapp

Rehabilitative shelters are an important component of anti-human trafficking efforts and entail a large investment. While survivors of human trafficking exist in every U.S. state, roughly only 2/3 of states provide dedicated shelters. Even in states with shelters, demand exceeds the current capacity. Furthermore significant disparity exists between states with regard to the legislative environment and provision of auxiliary services for survivors. This project develops a decision analytic approach to evaluate the impact of a dedicated shelter at the state level. Using concepts from health and social welfare economics, we develop a budget allocation problem that maximizes societal value.

1 - Minimizing Patient Waiting Time at a Pure Walk-in Clinic

Eduardo Perez, Texas State University, Roy F. Mitte Complex, 749 N. Comanche St., San Marcos, TX, 78666, United States, eduardopr@txstate.edu, Vivekanand Anandhan

Walk-in clinics have grown in popularity in the United States as a substitute for traditional medical care delivered in primary care clinics and emergency rooms. The open access nature and lack of patient scheduling can lead to long wait times for patients or long periods of idle time for providers. In this talk, we derive a discrete event simulation model to study pure walk-in clinics where patients are served without appointments. A case study is discussed that consider a walk-in clinic located in central Texas. The computational study provides useful insights that are applicable to any walk-in health care facility.

2 - A JaamSim Model of Medical Evacuation and Treatment in Combat

Lawrence Fulton, Texas Tech University, 911 Stoney Ridge Road, Bulverde, TX, 78163, United States, lfulton159@gmail.com, Nathaniel D. Bastian

A JaamSim discrete event simulation (DES) of medical treatment and hospitalization requirements for a simulated, large-scale combat operation is presented. Simulation excursions illustrate the inherent trade-offs among the number of ground / air evacuation assets, the location of treatment / evacuation assets, and the type of treatment provided by location. The DES model is compared to a simpler Monte Carlo simulation of the same scenario. Results of these models are being used to support military force structure decisions.

3 - Multivariate Spatial Models for Substance Abuse Related Incidences

Rasim M.Musal, Texas State University, School of Business, 601 University Drive, San Marcos, TX, 78666, United States, mmusal@gmail.com

We investigate the relationship between correlated substance abuse incidences and socio-economic covariates within the counties of New York State.

4 - Medical Fraud and Abuse Assessment using Prescriber-level Medicare Data

Babak Zafari, Babson College, Babson Hall 218C, Babson Park, MA, 02457, United States, bzafari@babson.edu, Tahir Ekin

The existence and magnitude of fraud in health insurance programs, requires the utilization of fraud prevention and detection procedures. Data Mining methods are used to uncover odd billing patterns in large databases of health care claims history. In this work, we propose data-driven methods to find the anomalies in the medical claims data using publicly available CMS Part D Prescriber dataset. In so doing, we introduce a set of new indicators that can better separate providers with unusual billing patterns.

Route Optimization for Vehicle Fleet

Sponsored: Transportation Science & Logistics

Sponsored Session

Chair: Sebastien Martin, Massachusetts Institute of Technology, 70 Pacific Street, Apt 462A, Cambridge, MA, 02139, United States, semartin@mit.edu

1 - Clustering Algorithms for Vehicle Routing Problems

Castaing Jeremy, Applied Research Scientist, LLamasoft, Ann Arbor, MI, United States, jeremy.castaing@llamasoft.com

As the typical size of vehicle routing problems (VRP) solved in the industry keeps increasing, we need to develop ways to partition the data into smaller sub-problems. We describe several variants of clustering algorithms adapted to VRP that are used in the Transportation Optimization engine of Supply Chain Guru, developed by LLamasoft. These clustering methods allow to reduce the size of the problem with minimal loss of solution quality. We consider several VRP features such as different asset types, time windows or continuous pick-ups and deliveries.

2 - Dispatching Strategy for Autonomous Taxi Fleets

Barry R. Cobb, Associate Professor, Missouri State University, Department of Marketing, 216 Glass Hall, Springfield, MO, 65897, United States, barrycobb@missouristate.edu, Linda Li

We build a real time dispactching model for taxi fleets, assuming total backlogging if the customers not immediately served. We show if the assignment and repositioning costs are equivalent and proportional to the distance, then the optimal policy is non-repositioning and quasi-myopic. The strategies suggested are aimed at a centralized taxi dispatching system. For instance, an autonomous taxi system.

3 - Package Delivery with Trucks and UAVS

Siyuan Song, University of Southern California, 11657 Kerwwod Pl, El Monte, CA, 91732, United States, siyuanso@usc.edu

We determine the efficiency of a delivery system in which an unmanned aerial vehicle (UAV), or a fleet of UAVs, provides service to customers while making return trips to a truck that is itself moving. Although the hardware for such systems already exists, it is not yet understood to what extent such an approach can actually provide a significantly improved quality of service. In this paper, a mathematical formulation of this problem is given and followed by an asymptotic result based on probabilistic analysis. We then put forward a heuristic algorithm and give some numerical experiments based on it. In addition to that, some variants of this problem that may happen in practice are also discussed.

4 - Rich Trailer Routing Optimization for Chemicals and Liquid Bulk

Ashesh Kumar Sinha, Assistant Professor, Kansas State University, Manhatan, KS, 66502, United States, ashesh.sinha24@gmail.com

We consider a rich trailer routing problem with stochastic transit times for chemicals and liquid bulk shipments. A route of a trailer comprises of pickup and delivery of restricted sequence of shipments while undergoing specialized tank wash operations. Using stochastic models and efficient parallel computing, we determine optimal trailer, shipments, and washes combinations while meeting the expected service level and cost.

5 - Joint Electric Vehicle Sharing and Vehicle2grid Service System Operations

Dongfang Zhao, Doctor, University of South Florida, 4202 E. Fowler Avenue ENG 216, TAMPA, FL, 33617, United States, dongfangzhao@mail.usf.edu, Xiaopeng Li

This study proposes a new model for designing a new (electric vehicle) EV sharing and V2G service system. This model considers the operations of a fleet of EVs that may opt to serve a transportation system when transportation demand is high or return electricity to the grid when the power price shoots high. An integer programming model is proposed to determine the optimal allocation of the fleet's time over these two markets. This model is solved with an efficient dynamic programming algorithm. Real-world data about the configurations of these two markets are used to build numerical examples. Sensitivity studies are constructed to draw insights into the feasibility of this joint service system.

6 - Online Vehicle Routing the Edge of Optimization at Scale

Sebastien Martin, Massachusetts Institute of Technology, 77 Massachusetts Ave, Cambridge, MA, 02139, United States, semartin@mit.edu, Dimitris Bertsimas, Patrick Jaillet

Developing vehicle routing optimization algorithms that are capable of solving very large real-time problems involving tens of thousands of customers per hour is becoming more and more important and impactful. We introduce generalizable algorithms to scale mixed integer optimization to these practical problem sizes. A novel backbone algorithm allows us to dispatch in real time thousands of taxis serving more than 25,000 customers per hour in New York City. Historical simulations shows that our algorithms improve upon the performance of existing heuristics in real-world settings.

A Spectrum of Business Analytics Curricula

Sponsored: INFORMEd

Sponsored Session

Chair: Susan Wright Palocsay, James Madison University, Harrisonburg, VA, 22807, United States, palocssw@jmu.edu

1 - Implementing an Interdisciplinary Business Analytics and Data Science Program at an Urban University
J.D Jayaraman, Associate Professor, New Jersey City University, Jersey City, NJ, United States, jjayaraman@njcu.edu, EunSu Lee

One of the challenges in today's data driven world is educating students in being adept at working with large amounts of data and extracting meaning out of it. This study describes an attempt at meeting this educational challenge with the creation of an interdisciplinary business analytics and data science program at an urban university in New Jersey. Curricular challenges and needs for such a program are detailed. Tools, teaching techniques, industry involvement, marketing and administrative support required for successful implementation are outlined. Challenges and hurdles encountered are also presented.

2 - The Story of Operational Analytics Program at the University of South Dakota
Ali Dag, Assistant Professor, University of South Dakota, 414 E. Clark Street, Beacom Hall, Office : 217, Vermillion, SD, 57069, United States, ali.dag@usd.edu, Thomas Tiahrt

University of South Dakota's Beacom School of Business was established in 1927 and has been accredited by AACSB since 1949. The leading business school in the region, Beacom has recently started its new Operational Analytics major at the undergraduate level and Business Analytics focus at the MBA level. In this talk, we will present the structure of the curriculum of these newly created programs and the story behind it.

3 - Experiences with Business Analytics Curriculum Implementation
Susan Wright Palocsay, Professor, James Madison University, Msc 0202, Computer Info Sys & Bus Analytics Dept, Harrisonburg, VA, 22807, United States, palocssw@jmu.edu, Ina Samanta Markham, Scott Stevens

Advanced analytics is a key technology trend providing a plethora of new opportunities to create business value. Consequently, it has given business schools an opening to introduce extended coverage of statistical analysis, data mining, and OR/MS modeling skills in business education. We will describe our experiences in creating an undergraduate minor in business analytics, including how we have addressed challenges with student capabilities, faculty expertise, recruiters, and limited resources.

4 - Connecting OR/MS to General Studies
Michael J.Racer, University of Memphis, 302 Fogelman College of Business, Memphis, TN, 38152, United States, mracer@memphis.edu, Orrin Cooper

There's a huge part of what's going on in the "real" world that students aren't grasping or connecting to OR. Interdisciplinary content in OR classrooms is crucial to helping students value OR. Core courses like psychology, political science, and English, suffer from similar stereotypes but can be integrated into OR. One solution is requiring students to bring articles to class.

Joint Session MIF/PSOR: Nonprofit Operations and Humanitarian Logistics

Sponsored: Minority Issues

Sponsored Session

Chair: Irem Sengul Orgut, Lenovo, Raleigh, NC, 27612, United States, isengul@ncsu.edu

1 - Supply Chain Management in Limited Data Environments: Application to Community Health Workers
Kezban Yagci Sokat, Northwestern University, IEMS, 2145 Sheridan Rd, Evanston, IL, 60208, United States, kezban.yagcisokat@u.northwestern.edu, Karen Smilowitz, Irina Dolinskaya

Limited historical data and limited on hand inventory bring up additional difficulty to supply chain management. In collaboration with Last Mile Health, we develop an inventory optimization model for different levels of the supply chain where we link health outcomes to inventory optimization under limited data.

2 - Dynamic Allocation of NGO Funds among Program, Fundraising, and Administration
Telesilla Olympia Kotsi, 3400 S Sare Rd, Apt 917, Bloomington, IN, 47401, United States, tkotsi@indiana.edu, Goker Aydin, Alfonso J. Pedraza-Martinez

US NGOs report three types of spending: program spending to deliver services directly to beneficiaries; fundraising spending; and administrative spending. Watchdog organizations give higher ratings to NGOs that allocate more of their budget to the program. However, fundraising and administrative spending are also beneficial. Fundraising helps increase the NGO's future budget, while administrative spending helps make future program spending more impactful. We model this trade-off in a dynamic program. We use financial data from human services NGOs to conduct a case study. Our results show that prioritization of fundraising and administration spending is necessary under certain conditions.

3 - Assessment Routing with Uncertain Travel Times
Burcu Balcik, Ozyegin University, Industrial Engineering Department, Nisantepe Mah Orman Sok No 34-36, Cekmekoy, 34794, Turkey, burcu.balcik@ozyegin.edu.tr, Ihsan Yanikoglu

This study focuses on rapid needs assessment operations conducted immediately after a disaster occurs. We consider a stochastic selective assessment routing problem, which determines the sites to be visited within a limited amount of time to ensure coverage of different community groups affected by the disaster. We use ambiguous chance constraints to model random travel times and apply a safe approximation technique using robust optimization to obtain a tractable formulation. We present an efficient tabu search algorithm, which obtains high quality solutions for the problem.

4 - Modeling for the Equitable and Effective Distribution of Food Donations under Stochastic Capacities
Irem Sengul Orgut, Lenovo, 4944 Summit Arbor Dr, Apt 205, Raleigh, NC, 27612, United States, isengul@ncsu.edu

Motivated by our partnership with a local food bank, we present a robust optimization model to support the equitable and effective food distribution over the food bank's service area. Our model addresses uncertainty in the counties' capacities which depend on factors such as budget and workforce. Assuming the capacity of each county varies within a range, the model seeks to maximize total food distribution while enforcing a user-specified level of robustness. We derive structural properties of the model and develop an efficient exact solution algorithm. We illustrate our model using historical data, summarize the policy implications of our results and examine the impact of uncertainty on outcomes.

Smart Manufacturing

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Ran Jin, Virginia Tech, Blacksburg, VA, 24061, United States, jran5@vt.edu

1 - 3D Freeze Assembling Printing of Graphene Aerogel

Dong Lin, Assistant Professor, Kansas State University, 2080 Rathbone Hall, 1701 D Platt St., Manhattan, KS, 66506, United States, dongl@ksu.edu

The surging field of graphene aerogels (GA) provides a promising methodology for transferring inherent properties of graphene into macroscopic applications for composite materials, energy storage, stress sensor, thermal insulator, and shock damping. However, fabrication of GA with tailored macrostructures by scalable and controllable methods remains a significant challenge. The vision of tailoring macroarchitecture of GA for specific applications, including separation, all-solid-state batteries, micro pressure sensors, flexible electrodes, and electrochemical catalyst templates, has stimulated the research on 3D printing of GA. Here, we propose a printing methodology that contines multinozzle drop-on-demand inkjet printing of pure graphene oxide (GO) suspension with freeze casting for rapid printing of 3D GA architectures to achieve several key qualities, namely, pure, continuous, boundary free, controlled microstructure, and truly 3D architectures (e.g., 3D truss with overhang structures). To date, we have successfully printed world's lightest material via 3D printing through the proposed technique.

2 - Manufacturing Quality Modeling with Smooth Variable Selection Based on Spatial Predictors

Yifu Li, Virginia Tech, Blacksburg, VA, 24060, United States, liyifu@vt.edu

Spatial data are widely collected in manufacturing to reflect the product quality information. It is challenging to transform these spatial data into useful information for product quality improvements due to the increasing spatial resolution and defect complexity. Motivated by an aerosol jet® printing process, we propose a smooth variable selection estimator using spatial predictors from high-resolution microscopic images to model printed electronics' resistances as responses. We demonstrated the effectiveness of the proposed method for prediction and variable selection with simulation studies and a case study.

3 - Data Challenges from Modern Manufacturing System

Shan Ba, The Procter & Gamble Company, Cincinnati, OH, United States, ba.s@pg.com

Modern manufacturing systems are often equipped with numerous sensors and high-speed cameras, which constantly measure hundreds or thousands of quality and process variables throughout the production process. The high volume and velocity of the incoming sensor/image data streams pose major challenges in data storage, data transfer, and data analysis. Bigger data should bring bigger insights. In this talk, we will discuss several challenges in handling and analyzing manufacturing big data in order to boost quality, minimize waste and gain process insight in a timely manner.

4 - A Statistical Model for Computer Experiments in Smart Additive Manufacturing

Xinwei Deng, Department of Statistics, Virginia Tech, 406 Hutcheson Hall, Blacksburg, VA, 24061, United States, xdeng@vt.edu, Jingran Li, Ran Jin

For computer experiments in the additive manufacturing, the scanning path in the process often contains valuable information that links the time and space domains. A novel Gaussian process (GP) model is proposed to quantify the surface characteristics, which integrates the distinct effects of the time evolution and spatial distance at the printing process. This proposed GP model is examined on several geometrical designs to evaluate the performance of model prediction and model interpretation.

5 - Smart Manufacturing

Ran Jin, Virginia Tech, 1145 Perry Street, Durham Hall, Room 250 (0118), Blacksburg, VA, 24061, United States, jran5@vt.edu

Modern manufacturing needs to optimize the entire product lifecycle to satisfy the highly diverse customer needs. With the deployment of Internet of Things, data-driven decision making is expected to enable smart manufacturing to achieve high level of adaptability and flexibility. This talk discusses the recent advancement of methodologies, and the corresponding sensing, analysis and decision making to enable smart manufacturing.

Biophysical and Economic Modeling – Assumptions, Metrics, and Decisions

Invited: Energy and Climate

Invited Session

Chair: Carey King, The University of Texas at Austin, careyking@energy.utexas.edu

1 - A Long-term Macroscale Model Linking Biophysical and Economic States

Carey King, Energy Institute at The University of Texas at Austin, 2304 Whitis Ave., C2400, Austin, TX, 78712, United States, careyking@mail.utexas.edu

New macroeconomic frameworks are needed to properly interpret the post-2008 macroeconomic situation of high debt, low interest rates, and aging populations (primarily in advanced economies). Monetary models of finance and debt often assume that natural resources (energy, food, materials) and technology are not constraints on the economy. Energy scenario models often assume that economic growth, finance and debt will not be constraints on investment in resources. This presentation discusses a new modeling framework that eliminates aforementioned assumptions by integrating states of resources, economy (employment, debt, wages, capital), and population at a fundamental level.

2 - Changing Resource Productivity under Resource Constraints

Eric Kemp-Benedict, Senior Scientist, Stockholm Environment Institute, 11 Curtis Avenue, Somerville, MA, 02144, United States, eric.kemp-benedict@sei-international.org

Resource constraints are of growing economic importance. Nonrenewable resources have historically been so abundant that productive capacity has mattered more than the total stock, but now that the most accessible resources have been exhausted, extraction is increasingly resource-intensive. Renewable resources, if treated well, can produce indefinitely into the future, but productive potential, once it has been reached, can only expand slowly. Future economic prospects thus increasingly depend on the pace of resource productivity growth. This presentation shows how productivity and output might evolve under resource constraints in a model of cost share-driven technological change.

3 - Beyond GDP: National Accounting in the Age of Resource Depletion

Michael Carbajales-Dale, Clemson University, madale@clemson.edu

Energy-economy-environment systems analysis (E3SA) is becoming increasingly important in the drive for sustainable development and to better understand the imminent future energy transition. E3SA necessarily spans a multitude of scales and disciplines. This talk will give an overview of the work being done by the E3SA group at Clemson University at three different scales: life cycle assessment of electricity generation technologies, network analysis of the infrastructure and industries, and a physical input-output framework for national or global economies.

4 - How Should we Learn from Models of Complex, Open Systems?

Michael Gerst, University of Maryland, 1337 Meridian Place NW, Washington, DC, 20010, United States, mgerst@umd.edu

Biophysical and economic models represent complex, open systems. Such systems are difficult to understand; consequently models built to learn about them are necessarily incomplete. We introduce a novel framework to gauge model incompleteness using expert elicitation that links learning about model behavior to expert judgment on target system behavior.

Big Data II

Sponsored: Data Mining

Sponsored Session

Chair: Subhashish Samaddar, Georgia State University, s-samaddar@gsu.edu

Co-Chair: Milton Soto-Ferrari, miltonrene.sotoferrari@wmich.edu

1 - Methodology for Systematic Monitoring of Radiotherapy Administration to Breast Cancer Patients

Milton Soto-Ferrari, Indiana State University, 30 N.7th St, Terre Haute, IN, 47809, United States, miltonrene.sotoferrari@wmich.edu

The proposed methodology presents a Bayesian based quality control framework for the monitoring of patients to predict radiation receipt based on the associations among clinical and non-clinical variables. The framework was developed using information from a cancer center with a sample of 1922 patients from years 2009-2014. As result of the implementation, a total of 48 patients were flagged. The quality control framework flagged patients with a metastatic disease as condition for an aggressive treatment in the center. Physicians from the review panel denoted that radiation treatment is offered as a palliative treatment for patients in a metastatic phase to mitigate side effects and pain.

2 - Assessing the Accuracy of Influenza Incidence Characterization During an Emergency

Diana Prieto, Western Michigan University, Industrial and Manufacturing Engineering, 4601 Campus Dr. (Office E-213), Kalamazoo, MI, 49008-5336, United States, diana.prieto@wmich.edu, Yuwen Gu

In the United States, emergent influenza outbreaks pose challenges in public health operation. One of such challenges is in the process of collection and testing of specimens to characterize the incidence trend. It is currently unknown whether this process is capable of retrieving accurate and timely incidence trends for response planning. In this talk, we will discuss the results from a simulation based evaluation of the operational features that allow the specimen collection and testing in the state of Michigan.

3 - Forecasting for Hotel Revenue Management by using AI and Other Methods

Subhashish Samaddar, Georgia State University, Managerial Science, P.O. Box 4014, Atlanta, GA, 30302-4014, United States, s-samaddar@gsu.edu, Somnath Mukhopadhyay, Satish Nargundkar

Forecast accuracy is the most important factor for achieving additional revenue from hotel revenue management (HRM) models. HRM analyst can forecast product demands for all revenue buckets of the room inventory products to maximize the overall revenue. However, the literature on HRM is sparse on details of RM forecasts. This article uses archived hotel data from a major hotel chain to compare room bookings forecast accuracies of traditional forecasting methods, Bayesian Networks (BN) methods, random forest methods and AI methods such as neural networks (NN).

4 - Analysis of HealthcareService Quality from Hospital Data at the National Level

Satish V. Nargundkar, Georgia State University, 2802 Fairlane Dr., Atlanta, GA, 30340, United States, snargundkar@gsu.edu, Subhashish Samaddar

The secondary data from patient surveys from all hospitals in the US is obtained from Medicare and different attributes of healthcare service is analyzed at the city, state and national levels.

5 - Analyzing Disease Data for Detection: A Comparison of Methods

Subhashish Samaddar, Georgia State University, Atlanta, GA, United States, subhashish.samaddar@gmail.com, Somnath Mukhopadhyay

Clinical data is used for disease detection and the error rates obtained by using Neural Network, Linear Programming, and Decision Trees are compared and reported.

Maritime Transportation

Sponsored: TSL, Freight Transportation & Logistics

Sponsored Session

Chair: Harilaos Psaraftis, hnpsar@dtu.dk

Co-Chair: Thalis Zis, Technical University of Denmark, Lyngby, 2800, Denmark, tzis@dtu.dk

1 - A Hub-and-spoke Approach to the Liner Shipping Network Design

Rommert Dekker, Professor of Quantitative Logistics, Erasmus University-Rotterdam, Burg. Oudlaan 50, P.O. Box 1738, Rotterdam, 3000 DR, Netherlands, rdekker@ese.eur.nl, Judith Mulder

We present an hub-and-spoke approach to the Liner Shipping Network Design problem with transhipment costs. We apply it to the cases from Brouer et al (2016) and show that for large instances costs can be reduced considerably. Finally we show an application to the Asia-Europe lane.

2 - Optimal Investment for a Resilient Global Port Network

Ali Asadabadi, University of Maryland, 7700 Adelphi Road, Apt 34, Hyattsville, MD, 20783, United States, ali.asadabadi@gmail.com, Elise Miller-Hooks

Ports are critical components of the global supply chain, supplying key connections between land- and maritime-based transport modes. They operate in cooperative, but competitive environments wherein individual port throughput is linked through an underlying transshipment network. This presentation models and analyzes protective investment strategies aimed at enhancing resilience to disruption and protecting a port's market share.

3 - Berth Scheduling to Reduce In-port Emissions with Cold Ironing Provision

Thalis Zis, Technical University of Denmark, Lyngby, 2800, Denmark, tzis@dtu.dk, Harilaos ZisPsaraftis3, Michail ZisGkolias

Cold Ironing is a technology that allows vessels at berth to receive shorepower for their energy requirements at the port. This paper studies the (discrete space & dynamic arrival) berth scheduling problem with berth cold ironing capabilities. The problem is formulated as a multi-objective problem where the terminal operator seeks to simultaneously maximize the utilization of its cold ironing berths (i.e., minimize emissions) and customer satisfaction. Problem instances are solved for various penetration rates of cold ironing capabilities by vessels calling at the port, and a sensitivity analysis on the number of cold ironing-ready berths is conducted.

4 - Vessel Scheduling Problem in a Liner Shipping Route with Perishable Products

Maxim A. Dulebenets, Florida A&M.University-Florida State University, 2300 Bluff Oak Way, Apt. 8408, Tallahassee, FL, 32311, United States, mdlbnets@gmail.com, Eren Erman Ozguven, Ren Moses, Thobias Sando

Some of the products, transported in a containerized form by vessels, are perishable in nature. Perishable products deteriorate due to certain operational and environmental factors. This study proposes a novel non-linear mixed integer mathematical model for the vessel scheduling problem with perishable products, which explicitly captures decay of perishable products on board the vessels. Numerical experiments demonstrate that the developed mathematical model can serve as an effective planning tool for liner shipping companies and tackle important operational aspects.

Electric Vehicle Charging

Sponsored: Transportation Science & Logistics

Sponsored Session

Chair: Eleftheria Kontou, National Renewable Energy Laboratory, Golden, CO, United States, ria.kontou@nrel.gov

1 - Data-driven Planning of PHEV Taxi Charging Stations in Urban Environments- A Case in Central Area of Beijing

Ziyang Guo, Sparkzone Research Group, Room6, yard 7, Fenzi Hutong, Xidan North, Street, Xicheng District, Beijing, China, Beijing, China, 1872371084@qq.com, Yinghao Jia, Yinghao Jia, Yide Zhao

Plug-in hybrid electric taxis (PHETs) contribute to energy and environmental challenges. In this study, we provide a spatial and temporal PHET charging demand forecasting method based on one-month Global Positioning System(GPS)-based taxi travel data in Beijing. Then, a mixed integer linear programming (MILP) model is formulated to plan PHET charging stations which minimizes investment and operation costs of all the PHET charging stations and takes into account the service radius of charging stations, charging demand satisfaction and rational occupation rates of chargers. At last, the plan is carried out numerically through simulation and the analysis is complemented according to the results

3 - Risk-averse Joint Capacity Evaluation of PV Generation and Electric Vehicle Charging Stations in Distribution Networks

Yu Xin, Sparkzone Research Group, Beijing, 100084, China, lewis_xy@hotmail.com, Yide Zhao, Yinghao Jia, Yinghao Jia

Increasing penetration of distribution generation(DG) and electric vehicles (EVs) calls for an effective way to estimate the achievable capacity connected to the distribution systems, but uncertainties of DG outputs and EV charging loads make it challengeable. This study provides a joint capacity evaluation method for photovoltaic (PV) generation and EV charging stations. The method is formulated as adistributionally robust joint chance constrained programming model. And the worst-case conditional value at risk approximation and an iterative algorithm based on semi definite program (SDP) are used. Finally, the test is carried out numerically on IEEE 33-bus radial distribution system.

4 - Integrated Two-level Inventory Problems: Applications to Electric Vehicle and Drone Battery Management

Amin Asadi, University of Arkansas, Fayetteville, AR, United States, asadi@email.uark.edu, Sarah G.Nurre

We examine a new class of integrated two-level inventory problems (ITLIP) with applications in drone and electric vehicle battery management. In this class of problems, the first level inventory corresponds to battery capacity and the second-level the battery charge. The two-levels of inventory are integrated in which the first-level is depleted (capacity) as a direct result of the replenishment and satisfaction of demand for the second-level (battery charge, discharge, and use). We formulate a Markov Decision Process model for an ITLIP problem to determine optimal policies for inventory management and equipment replacement for an electric vehicle battery swap station application.

6 - Incentive Schemes for Maximizing the Benefits from Battery Electric Vehicle Adoption

Eleftheria Kontou, Postdoctoral Researcher, National Renewable Energy Laboratory, 15013 Denver West Parkway, Golden, CO, 80401, United States, ria.kontou@nrel.gov, Yafeng Yin

Battery electric vehicles (BEVs) promise elimination of tank-to-wheel emissions and, thus, are widely recognized as a means towards reaching greenhouse gas abatement goals from the passenger transportation sector. Such vehicles are promoted by local and national governments by allocating financial incentives to directly subsidize their sales, or through funding charging stations. This work aims to answer the following research question: what is the optimal magnitude and timeframe of BEV subsidies and chargers investment allocation that the government should plan for to maximize the monetized social benefits from the household vehicle electrification?

1 - Modelling Regression Quantile Processes using Monotone B-splines

Yuan Yuan, Research Scientist, IBM.Research Singapore, Singapore, Singapore, idayuan@sg.ibm.com, Nan Chen, Shiyu Zhou

Quantile regression studies the covariate effects on the entire response distribution by fitting quantile regression models at multiple different quantiles or even fitting the entire regression quantile process. However, estimating the regression quantile process is inherently difficult because the induced conditional quantile function needs to be monotone at all covariate values. We proposed a regression quantile process estimation method based on monotone B-splines, which can easily ensure the validity of the regression quantile process, and offers a concise framework for variable selection and adaptive complexity control. We demonstrated its use and effectiveness in real problems.

2 - Pairwise Estimation of Multivariate Gaussian Process Models with Replicated Observations: Application to Multivariate Profile Monitoring

Qiang Zhou, University of Arizona, Tucson, AZ, United States, q.zhou@arizona.edu, Yongxiang Li, Li Zeng

Existing profile monitoring methods almost exclusively deal with univariate profiles, but multivariate profiles are increasingly encountered. In this paper, we advocate the use of multivariate Gaussian process model for such data, which offers a natural way to accommodate both within-profile and between-profile correlations. To mitigate the high computation, a pairwise estimation strategy is adopted and its asymptotic properties are investigated.

3 - Additive Gaussian Process for Computer Models with Qualitative and Quantitative Factors

Xinwei Deng, Department of Statistics, Virginia Tech, 406 Hutcheson Hall, Blacksburg, VA, 24061, United States, xdeng@vt.edu, Devon Lin, K-W. Liu, R. K. Rowe

Computer experiments with qualitative and quantitative factors occur frequently in various applications. In this work, we propose an additive Gaussian process model for computer experiments with qualitative and quantitative factors. The proposed method considers an additive correlation structure for qualitative factors, and assumes that the correlation function for each qualitative factor and the correlation function of quantitative factors are multiplicative. The merits of the proposed method are illustrated by several numerical examples and a real data application.

1 - Physics-based Attacks Detection in Machining Cyber-physical Systems using In-situ Sensors as Side Channels

Mohammed Shafae, Virginia Tech, 1145 Perry Street, Virginia Te, Durham Hall, Room 250, Blacksburg, VA, 24061, United States, shafae1@vt.edu

Physics-Based Attacks Detection in Machining Cyber-Physical Systems Using In-Situ Sensors as Side Channels

2 - Knowledge Based Data Monitoring in Advanced and Additive Manufacturing

Bianca Maria Colosimo, Politecnico di Milano, Via La Masa, 1, Milan, I-20156, Italy, biancamaria.colosimo@polimi.it

The contribution describes different applications where knowledge of the manufacturing signature can aid quality optimization, monitoring and control. Examples in foam production and additive manufacturing are presented.

3 - Self-segmented Classification via Adaptive Network Lasso with Application in Purchase Prediction
Shuyu Chu, IBM T.J. Watson Research Center, Yorktown Heights, Yorktown Heights, NY, 10598, United States, cshuyu@vt.edu, Huijing Jiang, Xinwei Deng, Zhengliang Xue, Naoki Abe

Predicting the purchase likelihood of potential clients is essential in finding the optimal pricing strategy in business. However, the heterogeneity within clients and products lead to different purchase behaviors. Thus, building one global model on all data is no longer appropriate. In this work, we created a self-segmented classification method to perform segmentation and model fitting simultaneously. This method ensures that the estimated models under different segments are distinctive and data points with a common model structure are grouped into the same segment. The performance of the method and its merits are illustrated by numerical examples and a case study with the IBM pricing data.

4 - A Spatial Statistical Method for Designing 3D Laser Scan Paths
Romina Dastoorian, Western Michigan University, Kalamazoo, MI, United States, romina.dastoorian@wmich.edu, Lee Wells

The emergence of 3D laser scanning technologies has significantly enhanced inspection system capabilities by providing high-density point cloud data. However, these new capabilities also bring new challenges regarding both the effective and efficient use of point cloud data. To improve the analytical power these datasets provide, it is essential to reduce or eliminate measurement noise. This presentation will introduce a methodology for modeling scan-path induced measurement. This methodology is based upon a spatial statistics model that assumes a point cloud's spatial correlation is the combined effect of both surface induced and scan-path induced is variation.

Chair: Hadi Karimi, Clemson University, hkarimi@g.clemson.edu

1 - Grow your Own Feedstock to Mitigate the Impact of Biomass Supply Uncertainty: A Case of Cellulosic Biofuel Investment
Yihua Li, Graduate Student, Iowa State University, 230 Raphael Ave, Unit 12, Ames, IA, 50014, United States, yihuali@iastate.edu, Guiping Hu

A decision-maker wants to enter the cellulosic biofuel market, where his primary option is to invest in a biofuel facility. Corn stover can serve as a main feedstock, while its yield fluctuates due to change in weather conditions. To hedge against supply uncertainty, he has a secondary option of investing in a land to grow his own feedstock (e.g., switchgrass) to achieve dual sourcing in biomass supply. The optimal investment timing for both investments are investigated via a real options approach. The effect of facility and land lead times, as well as risk aversion, are also discussed

2 - Meeting Corporate Renewable Power Targets
Danial Mohseni-Taheri, TA Coordinator, University of Illinois, Chicago, IL, 60607, United States, smohse3@uic.edu, Selvaprabu Nadarajah

We study the procurement problem faced by a firm trying to purchase a target percentage of its power demand from renewable sources by a future date and sustain this target going forward. We provide analytical insights into the structure of the procurement portfolio when employing recent variants of power purchase agreements. In addition, we discuss the challenges of setting up such a portfolio over a long time horizon and provide computational solutions.

3 - The Optimal Operation Policy of a Grid-connected Microgrid
Jong-hyun Ryu, Hongik University, 2639 Sejong-ro, Jochiwon-eup,, Sejong, 30016, Korea, Republic of, jongh.ryu@gmail.com, Dong Gu Choi, Daiki Min

This work considers the optimal operation of a gird-connected microgrid which comprises renewable energy resources, energy storage devices, controllable loads, and controllable generators. To satisfy the increasing electricity demand in a sustainable way, the efficient use of renewable energy is needed and the microgrid concept is one of the approaches. In this work, the optimal operating policy to minimize the generation cost in the microgrid is identified considering the uncertainty in renewable energy generation and load demand.

4 - A Stochastic Multiobjective Optimization Model to Analyze the Economic and Environmental Impacts of Biopower Supply Chains
Hadi Karimi, Clemson University, 1108 Tiger Blvd., Apt. 117, Clemson, SC, 29631, United States, hkarimi@clemson.edu, Sandra D. Eksioglu, Michael Carbajales-Dale

In this study we propose a stochastic multiobjective optimization model to analyze the economic and environmental impacts of biomass power supply chains. While generating electricity from biomass is known to provide an economically attractive option for coal-fired power plants to comply with emission regulations, the total footprint of the associated supply chain still needs to be carefully investigated. The multiobjective model aims at maximizing the potential profits and minimizing the life cycle emissions in the biomass supply chain. We consider the uncertainty in biomass feedstock quality and use sampling-based chance constraints to capture the uncertainties in the optimization model.

1 - Graph Regularization Based Framework for Product Filtering in E-commerce
Mukul Gupta, Indian Institute of Management Indore, Indore, 453331, India, mukulg@iimidr.ac.in, Rajhans Mishra

The multitude of choices for users of e-commerce has created a challenging problem for them to select the product of their choice in a reasonable time. Product filtering for helping a user to narrow down to a product of their choice is getting the tremendous attention of researchers. In this work, we propose a preference diffusion approach using graph regularized framework for product filtering. The user-product network with the attribute information of products is formed to diffuse the preference of a user to generate recommendation after filtering of less relevant products for that user.

2 - A Cognitive Framework for Optimal Service Composition
Ahmed Nazeem, Research Staff Member, IBM.Research, IBM.Almaden Research Center, San Jose, CA, 95123, United States, nazeem.35@gmail.com

With the evolution of the cloud based services and the Internet of things, there is an increasing need to develop an end-to-end framework that automates the solution design.

3 - Recommendation System Incorporating User Profile and Sequential Information
Rajhans Mishra, Indian Institute of Management-Indore, Faculty Block B, First Floor, Rau, Indore, 453331, India, rajhans111@gmail.com, Mukul Gupta

Recommendation system generates suggestions to the users as per their preferences with respect to various products and services. The proposed work focuses on generation of recommendations using user profile, content and sequential information with respect to user activities. User profiling may be done on various user specific parameters while sequential and content information can be captured through user activities as web navigation, product /service selection etc. Considering user profile, content, and sequential information collectively may help to capture the preferences of the users.

4 - A Text Based Decision Support System to Detect Fraudulent Bank Activity
Matthew A. Lanham, Clinical Assistant Professor, Purdue University, West Lafayette, IN, United States, lanhamm@purdue.edu, Jeffery Mei, Alan Abrahams, Rich Gruss

We develop a text analytics decision support system to detect fraudulent bank account activity. This research is motivated by the 2016 Wells Fargo scandal which entailed a $190 million settlement with federal regulators and prosecutors for opening more than two million deposit and credit card accounts without customer authorization. We show that our DSS can be used by regulators and financial institutions for internal control.

Sponsored Session

Chair: Daniel Bienstock, Columbia University, New York, NY, 10027, United States, dano@columbia.edu

1 - Extension Complexity Lower Bounds for Mixed-integer Extended Formulations

Robert Hildebrand, IBM T.J. Watson Research Center, Yorktown Heights, NY, United States, robDhildebrand@gmail.com

We prove that any mixed-integer linear extended formulation for the matching polytope of the complete graph on n vertices, with a polynomial number of constraints, requires $\Omega(\sqrt{\sfrac{n}{\log n}})$ many integer variables. By known reductions, this result extends to the traveling salesman polytope. This lower bound has various implications regarding the existence of small mixed-integer mathematical formulations of common problems in operations research. This provides a first non-trivial lower bound on the number of integer variables needed in such settings.This is joint work with Robert Weismantel and Rico Zenklusen.

2 - Cutting Planes from Reverse Polars of Disjunctive Sets

Egon Balas, Professor, Carnegie Mellon University, Posner Hall Rm 232B, 5000 Forbes Avenue, Pittsburgh, PA, 15213-3890, United States, eb17@andrew.cmu.edu, Aleksandr Kazachkov

Lift-and-project cuts from a union of polyhedra can also be obtained without lifting, from the intersection of the reverse polars of those polyhedra, involving their V-polyhedral representation.. In particular, strong cuts can be obtained from the intersection of the reverse polars of polyhedra representing the active leaves of a branch-and-bound tree. We explore and test this approach.

3 - Aggregation-based Cutting-planes

Santanu Subhas Dey, Georgia Institute of Technology, School of Industrial and Systems Engineering, 765 Ferst Drive Nw,, Atlanta, GA, 30332, United States, santanu.dey@isye.gatech.edu, Merve Bodur, Alberto Del Pia, Marco Molinaro, Sebastian Pokutta

We study the strength of aggregation cuts for packing and covering integer programs (IPs). Aggregation cuts are obtained as follows: Given an IP formulation, first generate a single implied inequality using aggregation of the original constraints, then obtain the integer hull of the set defined by this single inequality with variable bounds, and finally use the inequalities describing the integer hull as cutting-planes. We show that for packing and covering IPs, the aggregation closures can be 2-approximated by simply generating cuts from original formulation constraints. On the other hand, aggregation cuts can be arbitrarily stronger than cuts from individual constraints for general IPs.

4 - On Exploiting Submodularity in Conic Quadratic Mixed-0-1 Optimization

Andres Gomez, University of California, 2020 Delaware Street, Apt 3, Berkeley, CA, 94709, United States, a.gomez@berkeley.edu, Alper Atamturk

We describe convex valid inequalities for conic quadratic mixed-0-1 optimization. The inequalities are based on decomposing the quadratic term into two components, one of which is submodular. We prove that the proposed inequalities completely describe the convex hull of a single conic constraint over binary variables and unbounded continuous variables, and are also sufficient to describe the convex hull of rotated cone constraints with a diagonal quadratic term. Computational experiments with value-at-risk minimization and assortment optimization problems indicate that the inequalities strengthen the convex relaxations substantially and lead to significant performance improvements.

1 - A Two Echelon Humanitarian Supply Chain Model

Chrysafis Vogiatzis, North Dakota State University, 1057 35th Street North, Apt 105, Fargo, ND, 58102, United States, chrysafis.vogiatzis@ndsu.edu

In this talk, we discuss two-echelon VRPs for logistics operations during a humanitarian crisis. It differs from typical multi-echelon supply chain management systems as there exist no intermediate facilities to organize goods for delivery; instead all decisions are made en-route. This paradigm offers advantages for logistics during extreme events, as it can parallelize the last mile of delivery. It also enables city logistics, where smaller, more flexible, and maneuverable vehicles are in charge of final delivery. Last, with the increasing availability of unmanned vehicles, it helps automate the supply process, while also serving areas that are difficult to reach or are rendered inaccessible.

2 - Toward the Development of Resilience Indices for Multi-echelon Assembly Supply Chain Networks

Huy Q. Nguyen, Rensselaer Polytechnic Institute, 110 8th Street, 5119 Center for Industrial Innovation, Troy, NY, 12180, United States, nguyeh7@rpi.edu, Thomas Sharkey, William A. Wallace, John E.Mitchell

We develop scheduling rules to optimize the recovery performance of multi-echelon assembly supply chain networks (MEASC) from large-scale disruptive events. Each supplier within the MEASC network assembles a component from a series of sub-components received from other suppliers. Utilizing these decision rules, we develop resilience indices to help supply chain managers evaluate the vulnerability of their networks to different types of disruptive events. Our decision rules and indices are applied on a data set modeling an industry partner's supply chain.

3 - An Optimization Model for Multiagent Path Selection and Scheduling with Geographic Conflict

Navid Matin Moghaddam, nmatinmo@asu.edu, Jorge A. Sefair

We study the problem of finding the minimum arrival time of multiple agents traveling between known origins and destinations in a network. Paths must not be conflicting, meaning that there must be a minimum distance between agents at any time. We discuss the problem complexity and present an optimization model to find the path and schedule for each agent to traverse the network. Typical examples of this problem include the transportation of hazardous materials and transportation operations under geographic failures. We present a cutting-plane exact solution approach to solve this problem.

4 - Restoration of Interdependent Infrastructures using Integrated Network Design and Scheduling Problems with Machine Movement Interdependence

Aniela Garay Sianca, University of Arkansas, Fayetteville, AR, 72701, United States, agaraysi@email.uark.edu, Sarah G. Nurre

Researchers have examined how to restore interdependent infrastructure systems by deciding what components are repaired, when the repairs are scheduled, and who performs each repair using integrated network design and scheduling problems. A main limitation of this work is the assumption that a machine can feasibly move using the transportation network when assigned two consecutive tasks. Flooding and other obstructions on the transportation network often prohibit such assignments. We present a new optimization model by explicitly including the machine movement interdependence. We present the results of computational experiments for the interdependent infrastructure networks of Panama.

Statistical Learning and Optimization

Invited: Operations Research and the Future of Computing

Invited Session

Chair: Emma Frejinger, Universite de Montreal, Universite de Montreal, Montreal, QC, H3C 3J7, Canada, emma.frejinger@cirrelt.ca

1 - On the Role of (Machine) Learning in (Mathematical) Optimization

Andrea Lodi, École Polytechnique Montréal, Montréal, QC, Canada, andrea.lodi@polymtl.ca

In this talk, I try to explain my point of view as a Mathematical Optimizer — especially concerned with discrete (integer) decisions — on Big Data. I advocate a tight integration of Machine Learning and Mathematical Optimization (among others) to deal with the challenges of decision-making in Data Science and I discuss in details two areas in which machine learning techniques have been (successfully) applied to mixed-integer programming.

2 - Discrete-continuous Maximum Likelihood Estimation

Anna Fernandez-Antolin, École Polytechnique Fédérale de Lausanne, Lausanne, Switzerland, anna.fernandezantolin@epfl.ch, Virginie Lurkin, Matthieu de Lapparent, Michael Bierlaire

In statistics, maximum likelihood estimation involves solving a nonlinear optimization problem, that is often non-convex. It generates statistical estimates of the unknown parameters of a model. In the context of discrete choice modeling, the structure of the model is also unknown. For instance, a nested logit model assumes a partition of the choice set. Obtaining the partition from the data assumes involving discrete variables into the maximum likelihood estimation problem. In this paper, we aim at formulating the problem as a mixed integer linear problem (MILP).

3 - Approximating an Integer Linear Program by Structured Prediction Models

Emma Frejinger, Université de Montréal, FAS, Pavillon Andre-Aisenstadt, Montreal, QC, H3C 3J7, Canada, emma.frejinger@cirrelt.ca, Eric Larsen, Yoshua Bengio, Simon Lacoste-Julien, Andrea Lodi

We consider an operational planning problem for which we have an ILP that can be solved in reasonable time using a commercial solver. We propose to learn a structured prediction model that allows to compute approximate solutions to the ILP in very short computational time. We generate data by simulating problem instances and computing the corresponding solutions to the ILP. We can hence control the characteristics of the data and its size can be as large as the computational budget allows. The input to the structured model defines the problem instance and the output its solution. The structured prediction model is part of the solution methodology to a tactical service network design problem.

4 - LP-based Misclassification Minimization

John W. Chinneck, Carleton University, Systems and Computer Engineering, 1125 Colonel By Drive, Ottawa, ON, K1S.5B6, Canada, chinneck@sce.carleton.ca

Placing a separating surface that misclassifies the minimum number of points can be cast as an instance of maxFS, the problem of finding the maximum subset of constraints that can be simultaneously satisfied in an infeasible linear program. Fast and effective heuristics for maxFS can thus be used to construct classifiers. These algorithms also allow for selecting features while placing the separator, and can guide the placement for purposes such as equalizing the prediction accuracies, protecting minority types, etc.

Mixed-integer Two-stage Optimization Methodology and Applications

Sponsored: Computing

Sponsored Session

Chair: Leonardo Lozano, Clemson University, Clemson, SC, 29631, United States, llozano@g.clemson.edu

1 - Optimal Clustering on a Graph

Gokce Kahvecioglu, Northwestern University, Evanston, IL, United States, GokceKahvecioglu2014@u.northwestern.edu, David Morton

We study a clustering problem defined on an undirected graph with nonnegative weights on the edges. We remove a subset of edges to break the graph into smaller pieces, i.e., clusters. We incur a cost based on the weight of edges that are removed, and we obtain a gain in terms of the number of clusters we form. We consider the model from a bi-criteria perspective, and we aim to construct a family of solutions minimizing cost while maximizing gain.

2 - Vector-valued Multivariate Conditional Value-at-risk

Simge Kucukyavuz, University of Washington, Box 352650, Industrial & Systems Engineering, Seattle, WA, 98195, United States, simge@uw.edu, Merve Merakli

In this study, we propose a new definition of multivariate conditional value-at-risk (MCVaR) as a set of vectors for discrete probability spaces. We explore the properties of the vector-valued MCVaR (VMCVaR) and show the advantages of VMCVaR over the existing definitions given for continuous random variables when adapted to the discrete case. Finally, we discuss optimization of problems involving multivariate CVaR.

3 - Generalized Benders' Algorithm for Mixed Integer Bilevel Linear Optimization

Suresh Bolusani, Lehigh University, Bethlehem, PA, United States, sub214@lehigh.edu, Ted Ralphs

Mixed integer bilevel linear optimization provides a framework for modeling optimization problems involving multiple, independent decision makers with multiple, possibly conflicting objectives. In this talk, we present a generalized Benders' algorithm for solving these problems. As with any Benders' algorithm, the strategy is to project out the second-stage variables to obtain a reformulation involving only first-stage variables. This reformulation involves the value function of the bilevel optimization problem resulting from fixing the first-stage variables, which is then iteratively approximated. We present preliminary computational results with an open-source implementation.

4 - Robust Optimization with Evacuation Transportation under Boudedly Rationality User Equilibrium

Guanxiang Yun, University of Central Florida, Orlando, FL, 32816, United States, ygx8822@knights.ucf.edu, Qipeng Zheng

We proposed several models for the transportation path problems. We supposed that all the users in the system will obey the bounded rational user equilibrium principle. In real world instances, people will feel just fine even if they do not reach the best utility they can get but only attain a certain level. We proposed totally four conditions for our models with two of them having the pricing strategy, which will have a robust optimization model. We solved it by using the column and constraint generation. And Because of the huge number of variables and constraints we have in our system, we still used the column generation for the variables and also check the most violation constraint to check the convergency.

Interactions of Optimization and Statistical Learning II

Sponsored: Optimization, Nonlinear Programming

Sponsored Session

Chair: Ethan Xingyuan Fang, Pennsylvania State University, University Park, PA, 16802, United States, xxf13@psu.edu

Co-Chair: Zhaoran Wang, Princeton University, Princeton, NJ, 08540, United States, zhaoran@princeton.edu

1 - Variance Reduction for Restricted Strong Convexity

Huan Xu, Georgia Institute of Technology, Industrial and Systems Engineering, Atlanta, GA, 30332, United States, huan.xu@isye.gatech.edu, Chao Qu

Computational challenges of statistical estimators and machine learnng algorithms are an active area of study. Stochastic first order methods based on variance reduction have attracted significant attention because of light computation load for each iteration, and fast convergence speed for strongly convex problems. Yet, many powerful statistical and machine learning models are not strongly convex, and sometimes even non-convex. In this talk, I will argue that a nice statisitical property of those problems - restricted strong convexity - ensures that linear convergence of variance reduced stochastic first order methods for those statistical models.

2 - Taming Nonconvexity with Data

Zhaoran Wang, Princeton University, Apt 302, 13 Lawrence Drive, Princeton, NJ, 08540, United States, zhaoran@princeton.edu

In this talk, I will illustrate how statistical thinking enables us to harness the power of nonconvex optimization. In specific, I will present an algorithmic framework for exploiting the latent geometry induced by the randomness of data. By integrating three new global exploration meta-algorithms — namely, homotopy continuation, tightening after relaxation, and noise regularization — with local search heuristics — such as the variants of gradient descent — this unified framework leads to new nonconvex optimization algorithms for a broad variety of challenging learning problems.

3 - Gradient Descent Converges to Local Minimizers

Jason Lee, University of Southern California, San Marino, CA, United States, jasondlee88@gmail.com

We show that saddlepoints are easy to avoid for even Gradient Descent — arguably the simplest optimization procedure. We prove that with probability 1, randomly initialized Gradient Descent converges to a local minimizer. Next we show that gradient descent takes exponential time to converge to a local minimizer with Gaussian initialization, yet stochastic gradient or trust-region method take only polynomial time. This is joint work with Max Simchowitz, Ben Recht, Michael Jordan, Simon Du, Chi Jin, Barnabos Poczos, and Aarti Singh.

4 - Non-stationary Streaming PCA

Apurv Shukla, Columbia University, New York City, NY, United States, as5197@columbia.edu, Daniel Bienstock, Seyoung Yun

Motivated by rapidly changing dynamics of energy systems and poor performance of machine learning algorithms in non-stationary noisy environments, we present a novel memory-limited streaming algorithm to track time-varying subspaces for detecting anomalies. Our main theoretical contribution includes a novel proof-technique for analyzing convergence of the algorithm. Our algorithm uses low storage memory and shows promising results as compared to other existing algorithms.

Dynamic Programming Based Methods for Discrete Optimization

Sponsored: Optimization, Integer and Discrete Optimization

Sponsored Session

Chair: Selvaprabu Nadarajah, College of Business, University of Illinois at Chicago, Chicago, IL, 60607, United States, selvan@uic.edu

Co-Chair: Andre Augusto Cire, University of Toronto-Scarborough, Toronto, ON, M1C-1A4, Canada, acire@utsc.utoronto.ca

1 - An Exact Algorithm for a Dynamic Knapsack Problem

Alejandro Toriello, Georgia Institute of Technology, Atlanta, GA, United States, atoriello@isye.gatech.edu, Daniel Blado

We examine a stochastic knapsack problem with random item sizes that are realized upon an attempted insertion. The goal is to maximize expected profit and the process ends after a failed insertion. We propose an exact algorithm based on a reformulation of the value function linear program that dynamically prices variables to refine a value function approximation and generates cutting planes to maintain a dual bound. We discuss the algorithm's theoretical properties and its empirical performance.

2 - Approximate Linear Programming for Discrete Optimization

Selvaprabu Nadarajah, College of Business, University of Illinois at Chicago, 601 South Morgan Street,, U. H.2406, Chicago, IL, 60607, United States, selvan@uic.edu, Andre Augusto Cire

We consider a hierarchy of approximate linear programming based approximations to a general class of discrete optimization problems. We present theory regarding the relative quality of these approximations and test them on challenging discrete optimization problems arising in practice.

3 - Toward Breaking the Curse of Dimensionality: An FPTAS for Stochastic Dynamic Programs with Multidimensional Action and Scalar State

Giacomo Nannicini, IBM T.J. Watson, 1101 Kitchawan Road, Yorktown Heights, NY, United States, nannicini@us.ibm.com, Nir Halman

We propose an FPTAS for stochastic dynamic programs with multidimensional action, scalar state, convex piecewise linear costs and linear state transition function. The action spaces are polyhedral and described by parametric linear programs. The FPTAS relies on the solution of polynomial-sized linear programs to recursively compute an approximation of the value function at each stage. Our paper enlarges the class of dynamic programs that admit an FPTAS by showing how to deal with multidimensional action spaces and with vectors of continuous random variables under suitable conditions, therefore getting one step closer to overcoming the curses of dimensionality of dynamic programming.

Algorithms for Semidefinite Programming and Conic Optimization

Sponsored: Optimization, Linear and Conic Optimization

Sponsored Session

Chair: Sercan Yildiz, University of North Carolina at Chapel Hill, Statistical and Applied Mathematical Sciences Institute, 19 TW Alexander Drive, Research Triangle Park, NC, 27703, United States, syildiz@email.unc.edu

Co-Chair: David Papp, North Carolina State University, Raleigh, NC, 27606, United States, dpapp@ncsu.edu

1 - Solving Conic Systems via Projection and Rescaling

Negar Soheili Azad, University of Illinois-Chicago, 601 S. Morgan Street, University Hall 2416, Chicago, IL, 60607, United States, nazad@uic.edu, Javier F.Pena

We propose a projection and rescaling algorithm to solve conic feasibility problems. Our algorithm is inspired by previous work on rescaled versions of the perceptron algorithm and by Chubanov's projection-based method for linear feasibility problems. As in these predecessors, each main iteration of our algorithm contains two steps: a basic procedure and a rescaling step. We compare the performance of different basic procedures and study the rescaling algorithm's performance on linear feasibility problems.

2 - Convex Optimization via Domain Driven Barriers and Primal Dual Algorithms

Mehdi Karimi, University of Waterloo, 200 University Ave W, Waterloo, ON, N2L.3G1, Canada, m7karimi@uwaterloo.ca, Levent Tuncel

During the last two decades, primal-dual algorithms enjoyed significant advances in solving convex optimization problems in conic form over symmetric cones. However, many other highly demanded optimization problems lack such advances. To make the gap closer, we develop a theory of infeasible-start primal-dual algorithms for problems in the "Domain-Driven" setup, which covers many interesting problems including those with a "natural" conic formulation. After presenting our techniques, and our convergence theorems, we introduce our developing Matlab-based code, DDS, that solves a large class of problems including LP, SOCP, SDP, QCQP, geometric programming, and entropy programming.

3 - Polynomial Optimization with Sum-of-Squares Interpolants

Sercan Yildiz, University of North Carolina at Chapel Hill, SAMSI, 19 TW. Alexander Drive, Research Triangle Park, NC, 27703, United States, syildiz@email.unc.edu, David Papp

Sums-of-squares relaxations define a hierarchy of lower bounds for polynomial optimization problems. Although these relaxations can be represented as semidefinite programs, solving these semidefinite programs poses practical challenges at higher levels of the hierarchy. First, their size depends quadratically on the size of the sums-of-squares relaxation. Second, numerical problems are often encountered in their solution. In this talk, we show that non-symmetric conic programming and polynomial interpolation techniques can be used to optimize efficiently over the sums-of-squares cone.

Electric Energy Storage Planning: Methods and Results

Sponsored: Energy, Natural Res & the Environment Electricity

Sponsored Session

Chair: Elaine Hale, National Renewable Energy Laboratory, elaine.hale@nrel.gov

1 - Investing in Grid-scale Energy Storage: Placement in Transmission vs. Distribution Systems?

Yury Dvorkin, New York University, 185 Stevens Way NE, Paul Allen Center, Room AE104R, New York, NY, 11201, United States, dvorkin@nyu.edu

If current trends continue, electrochemical energy storage will soon be widely deployed to perform various grid services in both transmission and distribution systems. It is expected that a significant portion of these devices will be owned by merchant, i.e. profit-seeking, entities. Since compensation and regulatory requirements in the distribution and transmission systems vary, merchant investors need to carefully optimize investments in energy storage to achieve maximum gains. This presentation will describe a modeling framework that makes it possible for merchant investors to trade-off investments in energy storage between the transmission and distribution systems.

2 - Optimized Dispatch for Concentrating Solar Power Subject to Forecast Uncertainty

Michael J. Wagner, National Renewable Energy Laboratory, 15013 Denver West Pkwy, MS-RSF033, Golden, CO, 80401, United States, Michael.Wagner@nrel.gov

Concentrating Solar Power (CSP) systems are capable of efficient storage of thermal energy that can then be dispatched to generate electricity at night or during cloudy periods. The optimal energy dispatch schedule depends on weather and pricing forecasts which are inherently uncertain. Furthermore, these forecasts and their uncertainty may be correlated depending on local market structure and prominence of renewable generators on the grid. We present methods and results for optimal dispatch of CSP systems subject to weather and pricing forecast uncertainty. The model is implemented in the publicly available System Advisor Model software, and design sizing sensitivity results are discussed.

3 - Planning for Concentrating Solar Power in the Western United States

Elaine Thompson Hale, National Renewable Energy Laboratory, 15013 Denver West Parkway, MS RSF300, Golden, CO, 80401, United States, elaine.hale@nrel.gov, Brady Stoll, Jennie Jorgenson

Concentrating solar power with thermal energy storage (CSP-TES) is a flexible renewable energy technology that could be an attractive complement to solar photovoltaics (PV) and wind in the Southwestern United States (U.S.). When and where such investments may be attractive depends on future policies, fuel prices, and cost trajectories of alternative technologies such as PV and battery storage. We apply the Resource Planning Model (RPM), which is a capacity expansion model designed for regional power systems and high levels of renewable generation and complementary flexible technologies, to this question for a region centered on current U.S. CSP deployment and looking out to 2035.

4 - Friend or Foe? the Impact of Energy Storage on Solar and Wind Investments

John Erik Bistline, Electric Power Research Institute, 3300 Sawtelle Blvd, Apt. 310, Los Angeles, CA, 90066, United States, john.bistline@gmail.com

Energy storage is often linked with improving the economic proposition of variable renewables like wind and solar, though few existing studies examine how low-cost storage simultaneously impacts electric sector operations and investments. This talk investigates the economics of grid-connected energy storage and its effect on system investments, emissions, and costs using the US-REGEN capacity planning and dispatch optimization model. Model experiments illustrate how the effects of storage depend on the supply responsiveness of different generators and vary across different market conditions, which may favorably or adversely influence solar and wind deployment.

5 - A Future Outlook on Wind, Solar, and Energy Storage Deployment

Cara Marcy, Renewable Electricity Analyst, U.S. Energy Information Administration, Washington, DC, 20585, United States, cara.marcy@eia.gov

EIA's National Energy Modelling System (NEMS) provides a future multi-decadal assessment of U.S. energy sectors, including electricity. Recently, variable technologies, such as wind and solar, have increased in market share. In NEMS, challenges arise in accounting for this variability in a manner that preserves computational time. In addition energy storage is one option that can take advantage of value streams presented from this variability, such as curtailments, as well as other market value streams. This presentation will review the model structure for energy storage and curtailments in NEMS, as well as highlight scenarios that study the relationship between renewables and energy storage.

1 - Exact and Heuristic Approaches for Bidirectional Leaf Trajectory Optimization in Intensity-modulated Radiotherapy

Seyedali Mirzapour, Wichita State University, 203A-Engineering Building, 1845 Fairmount St,, Wichita, KS, 67260, United States, mirzapour.ie@gmail.com, Ehsan Salari

Traditionally, unidirectional leaf-sweeping schemes have been used to dynamically modulate radiation beams in radiotherapy. However, the unidirectional leaf-motion restriction may lead to poor beam modulation when the available beam-on time is limited. This research investigates the potential gain in beam-modulation quality and delivery efficiency obtained from relaxing this restriction and allowing for bidirectional leaf trajectories. A mixed-integer programming formulation with exact and heuristic solution methods are developed to optimize for bidirectional piecewise-linear leaf trajectories.

2 - Optimal Child Delivery Strategies for Hypertensive Disorders of Pregnancy

Aysegul Demirtas, PhD Candidate, Arizona State University, Tempe, AZ, United States, Aysegul.Demirtas@asu.edu, Esma S. Gel, Soroush Saghafian, Dean V. Coonrod

Hypertensive disorders of pregnancy (HDP) constitute one of the leading causes of maternal and neonatal mortality and morbidity. We study the decision problem of timing of child delivery for women with HDP. We formulate a Markov decision process (MDP) model that minimizes the risks of maternal and neonatal adverse outcomes, and assess its results with a probabilistic sensitivity analysis (PSA). In PSA, we construct instances by generating model parameters in restricted orders to incorporate physicians' intuition in part of the estimations with low sample size. We also build a robust MDP model that considers the sensitivity of transition probabilities while avoiding over-conservative policies.

3 - Analytic Advancements in the Project Data Sphere Open Access Data Sharing Platform

Steven B.Cohen, Vice President, RT.I.International, 701 13th Street NW, Washington, DC, 20005-3967, United States, scohen@rti.org

Project Data Sphere (PDS) is a research platform providing broad access to both de-identified patient-level data from oncology clinical trials and related analytic tools. Data providers are required to de-identify patient-level data by removing key demographic data. To address these analytic constraints, the patient-level cancer phase III clinical data has been augmented by linking the social, economic and health related characteristics of like cancer survivors from nationally representative health and healthcare-related survey data. This presentation will provide an overview of the methodologies used and an analysis of the association between these factors and patient outcomes.

4 - A Recommendation System for Managing Physical Fatigue in the Workplace

Lin Lu, Auburn University, 371 W. Glenn Ave, Apt 13, Auburn, AL, 36830, United States, lzl0032@auburn.edu, Fadel Mounir Megahed, Lora Cavuoto

In this talk, we propose a system for managing fatigue in the workplace based on combining principles from artificial intelligence, safety science and management. Our system consists of the following modules: (a) a knowledge base, (b) an inference engine, and (c) a user interface. The system recommends appropriate interventions based on the type of fatigue and the different constraints at the workplace.

5 - Using Decision Analytics to Provide Patient-centered Care in Battling Childhood Epilepsy

Shreya Gupta, PhD Student, The University of Texas-Austin, 3452 Lake Austin Blvd, Apt E, Austin, TX, 78703, United States, shreya.gupta@utexas.edu, John Hasenbein

We propose using decision analytics methods from operations research and statistics to improve quality of life and provide patient centered care in childhood epilepsy. Epilepsy researchers estimate that at least 90,000 children per year are not receiving the epilepsy treatment they need, leading to years of poor quality of life and increased mortality for these children. We propose building a Markov decision process (MDP) model of the decision process for childhood epilepsy, utilizing data analytics and personal utility analysis to provide decision support systems for both providers and patients. The primary advantage of such models is that they can be tuned for each patient and/or provider.

Uncertainty-aware Expansion Planning in Complex Infrastructures

Sponsored: Energy, Natural Res & the Environment Electricity

Sponsored Session

Chair: Yuri Dvorkin, New York University, New York, NY, 11201, United States, dvorkin@nyu.edu

1 - The Value of Demand Response Controllability

Kenneth Bruninx, KU. Leuven, Celestijnenlaan 300, Post Box 2421, Leuven, B3001, Belgium, Kenneth Bruninx, EnergyVille, Genk, Belgium, Kenneth Bruninx, VITO, Mol, Belgium, kenneth.bruninx@mech.kuleuven.be

Demand response (DR) resources, such as thermostatically controlled loads, are not fully controlled by the system operator and their availability is limited by user-defined comfort constraints. We present an operational model that optimizes power plant scheduling in the presence of stochastic RES-based generation and DR resources (here: residential electric heating systems) that are partially controllable and governed by user-defined comfort constraints. This model is used to evaluate the operating cost savings that can be attained via DR on a model of the Belgian power system.

2 - Data-driven Stochastic Transmission Expansion Planning

Jianhui Wang, Southern Methodist University, Dallas, TX, United States, jianhui@smu.edu
Jianhui Wang, Argonne National Laboratory, Argonne, IL, United States, jianhui@smu.edu

We present a data-driven two-stage stochastic transmission expansion planning method with uncertainties. We first use a confidence set for the unknown distribution of the uncertain parameters. Then, a two-stage data-driven transmission expansion framework is developed considering the worst-case distribution within the constructed confidence set. A decomposition framework embedded with Benders' and Column-and-Constraint generation methods is used to solve the problem.

3 - Optimization of Integrated Gas-electric Systems under Uncertainty

Line Roald, Los Alamos National Laboratory, Los Alamos, NM, United States, lineroald@gmail.com, Sidhant Misra

The electric grid depends on gas-fired generation to balance the intermittent renewable energy production, resulting in time-varying and unpredictable gas flows. To ensure secure and economic operation of the integrated system, we solve an optimization problem that minimizes cost of operation, subject to constraints from both the electric and gas systems. The electric grid is modelled using chance constraints, which provide probabilistic bounds on the gas withdrawals. The gas constraints are modelled using partial differential equations, and are formulated as robust constraints based on monotonicity properties of the gas flows. We demonstrate the benefits of the method through a case study.

4 - Long-term Coordination of Transmission and Storage to Integrate Wind Power

Antonio J. Conejo, The Ohio State University, Department of Integrated Systems Engineering, 210 Baker Systems Building, Columbus, OH, 43210, United States, conejonavarro.1@osu.edu, Ning Zhang, Chongqing Kang, Yaohua Cheng

A power system with a high wind power integration requires extra transmission capacity to accommodate the intermittency inherent to wind power production. Storage can smooth out this intermittency and reduce transmission requirements. This presentation describes a stochastic optimization model to coordinate the long-term planning of both transmission and storage facilities to efficiently integrate wind power. Both long-term and short-term uncertainties are considered in this model. Long-term uncertainty is described via scenarios, while short-term uncertainty is described via operating conditions.

Optimizing Distributed Energy Generation

Sponsored: Energy, Natural Res & the Environment, Energy

Sponsored Session

Chair: Alexandra M Newman, Colorado School of Mines, Golden, CO, 80401, United States, anewman@mines.edu

1 - Parameterization for Optimized Dispatch of Concentrating Solar Power Production

Will Hamilton, Colorado School of Mines, Golden, CO, United States, whamilton@mymail.mines.edu

Concentrated solar power technologies can store solar energy, decoupling electricity generation from time periods with solar resource. The decision to produce electricity or to store thermal energy for later use is complex and involves multiple inputs. We have developed a profit-maximizing mixed-integer linear program that determines start-up and shutdown times for the power cycle and solar receiver. Here, we present the results of sensitivity studies on these key plant performance parameters, which provide insight into the importance of the accuracy of each parameter to ensure the viability of operational decisions using optimal thermal energy storage dispatch.

2 - Power Curve Prediction through a Nonparametric Additive Multivariate Kernel Approach

David Perez, Texas A&M.University, College Station, TX, United States, dmp4@tamu.edu

This presentation intends to demonstrate how to estimate a wind turbine's power curve based on environmental conditions through an additive multivariate kernel (AMK) approach. The power curve represents the sigmoidal relationship between power output of a wind turbine and velocity. However, other environmental variables like wind direction and air density also impact power production. The AMK method uses these other variables to formulate an estimator of power production, taking advantage of the multiplicative, nonlinear relationship between the response and multiple explanatory variables. Finally, the AMK method is compared to other popular approaches for prediction accuracy.

3 - A Polyhedral Study of Min-up/-down and Ramping Polytope

Kai Pan, University of Florida, 411 Weil Hall, Gainesville, FL, 32611, United States, kpan@ufl.edu, Yongpei Guan

We present a comprehensive polyhedral study on the integrated minimum-up/-down time and ramping polytope, which has broad applications in power generation scheduling (on both transmission/distribution levels), manufacturing scheduling, chemical engineering, etc. Both theoretical and numerical results are provided to demonstrate the strength and applications of the proposed cutting planes.

1 - Demand Forecasting for New Products in a Cosmetic Company

Shanshan Huang, shanshanhuang@u.nus.edu

We build a Bayesian structure model to study demand estimation for new products. Based on historical product covariates and sales, we are able to learn the sales pattern and forecast the future demand.

2 - Smart "Predict, then Optimize"

Adam Elmachtoub, Columbia University, 500 W. 120th St., New York, NY, 10027, United States, adam@ieor.columbia.edu, Paul Grigas

We consider a class of optimization problems where the objective function is not explicitly provided, but contextual information can be used to predict the objective based on historical data. A traditional approach would be to simply predict the objective based on minimizing prediction error, and then solve the corresponding optimization problem. Instead, we propose a prediction framework that leverages the structure of the optimization problem that will be solved given the prediction. We provide theoretical, algorithmic, and computational results to show the validity and practicality of our framework.

3 - Failing to Learn via Exploration Boosts

Michael Jong Kim, University of British Columbia, Vancouver, BC, Canada, mike.kim@sauder.ubc.ca, Ya-Tang Chuang

We investigate a class of sequential Bayesian maintenance optimization problems where parameters of the lifetime distribution are learned using right-censored failure data. We show that the optimal preventive maintenance (PM) time can be expressed as the sum of a myopic-optimal PM time plus an "exploration boost" that is proportional to the posterior variance. We conduct asymptotic structural and performance analysis of the optimal PM policy.

4 - A DC Optimization Approach to Sparse Spline Regression

Jun-ya Gotoh, Professor, Chuo University, 1-13-27 Kasuga, Bunkyo-ku, Tokyo, 112-8551, Japan, jgoto@indsys.chuo-u.ac.jp, Yuichi Misawa

In this paper we consider the estimation of a spline regression with a constraint on the number of splines to be employed. Reformulating the cardinality constraint into a DC (difference of two convex functions)-constraint, we further reformulate the problem to an unconstrained one, where the DC constraint is moved to the objective after multiplying a positive constant. Then a proximal DC algorithm (Gotoh, Takeda, Tono, 2015) is applied, so that a stationary point can be efficiently attained. Numerical results will be presented in comparison with an existing l1-regularized formulation.

Sponsored Session

Chair: Kartikey Sharma, Northwestern University, Evanston, IL, 60208, United States, kartikeysharma2014@u.northwestern.edu

1 - Optimization under Connected Uncertainty

Kartikey Sharma, Northwestern University, Room C223, 2145 Sheridan Road, Evanston, IL, 60208, United States, kartikeysharma2014@u.northwestern.edu, Omid Nohadani

Distributionally robust and standard robust optimization methods provide a tractable way to address uncertainties. In many applications, past observations influence future uncertainties. In this presentation, we leverage this dependence via connected uncertaintysets, where the set parameters at each period depend on previous realizations. To find optimal here- and-now solutions, we reformulate distributionally robust and standard robust constraints for connected uncertainty sets. We illustrate the advantages of this framework with an application in portfolio optimization.

2 - Multistage Robust Optimization with Dynamic Uncertainty Sets for Power System Operations

Alvaro Lorca, Pontificia Universidad Catolica de Chile, Santiago, Chile, alvarolorca@uc.cl, Andy Sun

Motivated by the deep integration of volatile renewable energy sources such as wind and solar power, we will present robust optimization models for real-time and day-ahead power system operations, considering uncertainty in the power output of there sources. An essential component of the developments presented is the proposal of dynamic uncertainty sets to capture temporal and spatial correlations of wind and solar power. We will also discuss the solution methods designed for these challenging problems and the insight obtained from computational experiments.

3 - The Stochastic Container Relocation Problem: Sampling in Multi-stage Stochastic Optimization with Bounded Cost

Virgile Galle, Massachusetts Institute of Technology, 77 Massachusetts Avenue, Building E40-130, Cambridge, MA, 02139, United States, vgalle@mit.edu, Setareh Borjian Boroujeni, Vahideh Manshadi, Cynthia Barnhart, Patrick Jaillet

The Container Relocation Problem (CRP) is concerned with finding a sequence of moves of containers that minimizes the number of relocations needed to retrieve all containers, while respecting a given order of retrieval. This paper studies the stochastic CRP, which relaxes the assumption of knowing the full retrieval order of containers (particularly unrealistic in real operations). We introduce a new multi-stage stochastic model, and propose an optimal algorithm based on pruning as well as a near-optimal algorithm with bounded average error. Algorithms are tested on existing instances.

Stochastic Optimization and Variational Inequality Problems

Sponsored: Optimization, Optimization Under Uncertainty

Sponsored Session

Chair: Konstantin Pavlikov, University of Florida, 1350 N. Poquito Road, Shalimar, FL, 32579-1163, United States, kpavlikov@ufl.edu

1 - SI-ADMM: A Stochastic Inexact ADMM Framework for Resolving Structured Stochastic Convex Programs

Yue Xie, Pennsylvania State University, 445 Waupelani Dr, Pennsylvania, PA, 16801, United States, yux111@psu.edu, Uday Shanbhag

We consider the resolution of the structured stochastic convex program: min $E[f(x,)] + E[g(y,)]$ such that $Ax + By = b$. To exploit problem structure and allow for developing distributed schemes, we propose a stochastic inexact ADMM (SI-ADMM) in which the subproblems are solved inexactly via stochastic approximation schemes. Based on this framework, we prove that (i) when the inexactness sequence satisfies suitable summability properties, SI-ADMM produces a sequence that converges to the unique solution a.s.; (ii) if the inexactness drops at a geometric rate, the sequence converges to the unique solution in a mean-squared sense at geometric rate, and the total sample complexity can be canonical.

2 - On the Variants of Projection and Extragradient Schemes for Stochastic Variational Inequality Problems

Shisheng Cui, Pennsylvania State University, University Park, PA, 16801, United States, cuishisheng05@gmail.com, Shanbhag Uday

The stochastic generalizations of the extragradient methods are complicated by a key challenge: the scheme requires two projections on a convex set and two evaluations of the map for every major iteration. It becomes a concern if the sets are complicated. Thus, we consider two related avenues where every iteration requires a single projection: (i) A projected reflected gradient method; and (ii) A subgradient extragradient method. We prove the almost sure convergence of the iterates to a random point in the solution set and show that the gap function associated with the averaged sequence diminishes to zero at the optimal rate.

3 - Multi-period Probabilistic Set Covering Problem

Konstantin Pavlikov, University of Florida, 1350 N. Poquito Road, Shalimar, FL, 32579-1163, United States, kpavlikov@ufl.edu

This study extends the classical probabilistic set coverage problem to a multi-period setting. The problem focuses on finding a least cost facility locations to cover random demand over one period of time with a specified probability. If facility engagement lasts more than one period of time, then little is known about how well the remaining operational facilities can satisfy demand in period two. Hence, the two-period model maximizes the probability of satisfying demand in period two by facilities not engaged in satisfying demand from period one. We demonstrate how solving multi-period version of the problem can be reduced to solution of a sequence of one-period probabilistic set coverage problems.

Keynote- INFORMing Process Improvement and Patient Safety in Healthcare

Invited Session

1 - INFORMing Process Improvement and Patient Safety in Healthcare

Victoria Jordan, Emory

Because of my previous position as Executive Director, Performance Improvement at the University of Texas (UT) M. D. Anderson Cancer Center, the conference committee asked me to share information about and the history behind the Texas Medical Center and MD Anderson. I will also discuss my role at UT as Chancellor's Fellow for Systems Engineering and how our team was able to establish partnerships between university faculty (in Business and Engineering) and healthcare professionals to spread the use of operations research and management science in healthcare. I will share some exciting accomplishments from those efforts as well as more general applications across the healthcare industry. I hope you will leave this session with a new understanding of the challenges in healthcare and an interest in using Operations Research and Management Science to address some of these challenges.

Keynote: Systems Approach to Managing Risk in Human Spaceflight Missions

Invited Session

1 - Systems Approach to Managing Risk in Human Spaceflight Missions

Nancy Currie-Gregg, Texas A&M.(formerly NASA)

Human spaceflight is an inherently risky endeavor. From the first human space exploration missions to recent problems on the International Space Station, NASA has faced many challenges and has relied on creative and innovative engineering solutions to complete the mission and safely return the crew. However, over the past 50 years, NASA has also experienced three fatal accidents resulting in the loss of seventeen crewmembers. Addressing the complex interdependencies and systemic causes associated with these tragedies, including those associated with organizational culture and management, provides insight to the advantages of a systems approach to managing risk in high reliability organizations.

1 - Biased Random-Key Genetic Algorithms: Components, Evolutionary Dynamics and Applications

Celso Ribeiro, Universidade Federal Fluminense

A biased random-key genetic algorithm (BRKGA) is a general search procedure for finding optimal or near-optimal solutions to hard combinatorial optimization problems. It is derived from the random-key genetic algorithm of Bean (1994), differing in the way solutions are combined to produce offspring. BRKGAs have three key features that specialize genetic algorithms. First, a fixed chromosome encoding using a vector of N random keys over the real interval [0, 1), where the value of N depends on the instance of the optimization problem. Second, a well-defined evolutionary process adopting a parameterized uniform crossover to generate offspring and thus evolve the population. Third, the introduction of new chromosomes called mutants in place of the mutation operator usually found in evolutionary algorithms. Such features simplify and standardize the procedure with a set of self-contained tasks from which only one is problem-dependent: that of decoding a chromosome, i.e. using the keys to construct a solution to the underlying optimization problem, from which the objective function value or fitness can be computed. In this talk, we review the basic components of a BRKGA and introduce a framework for quick implementations of BRKGA heuristics. We then illustrate the application of this framework to a few case studies in a network routing, load scheduling and data mining problems. We conclude with a brief review of other domains where BRKGAs have been applied.

Decision Analysis Awards

Sponsored: Decision Analysis

Sponsored Session

Chair: Jason Merrick, Virginia Commonwealth University, jrmerric@vcu.edu

1 - DAS Student Paper Award

Emanuele Borgonovo, Bocconi University, Bocconi University, Via Sarfatti 25, Milano, 20136, Italy, emanuele Borgonovo@unibocconi.it, John Hahn

The Student Paper Award is given annually to the best decision analysis paper by a student author, as judged by a panel of the Decision Analysis Society of INFORMS. Students who did not complete their PhD prior to May 1, 2016 are eligible for this year's competition.

2 - DAS Publication Award

Vicki Bier, University of Wisconsin, Dept of Ind. Eng. Mechanical Eng Bldg., 1513 University Avenue, Madison, WI, 53706, United States, bier@engr.wisc.edu

This award is given annually to the best decision analysis article or book published in the second preceding calendar year (i.e. calendar year 2015for consideration in 2017). The intent of the award is to recognize the best publication in "decision analysis, broadly defined." This includes, but is not limited to, theoretical work on decision analysis methodology (including behavioral decision making and non-expected utility theory), descriptions of applications, and experimental studies.

3 - DAS Practice Award

Gregory L. Hamm, Stratelytics, LLC, 933 Taylor Avenue, Alameda, CA, 94501, United States, ghamm@strts.com

The Decision Analysis Practice Award is awarded to the best example of decision analysis practice as judged by the Decision Analysis Practice Award Committee. The purpose of the award is to publicize and encourage outstanding applications of decision analysis practice. We will present the finalists and this year's winner.

4 - DAS Ramsey Medal

J. Eric Bickel, The University of Texas at Austin, Graduate Program in ORIE, 1 University Station, C2200, Austin, TX, 78712-0292, United States, ebickel@mail.utexas.edu

The Ramsey Medal of the Decision Analysis Society is awarded for distinguished contributions in decision analysis. Distinguished contributions can be internal, such as theoretical and procedural advances in decision analysis, or external, such as developing or spreading decision analysis in new fields. We will introduce the 2017 Ramsey Medal winner, followed by a presentation by the winner.

Managing Surgical and Inpatient Capacity

Sponsored: Health Applications

Sponsored Session

Chair: Joonyup Eun, PhD, Vanderbilt University Medical Center, 1211 21st Avenue South, Medical Arts Building, Nashville, TN, 37212, United States, joonyup.eun@vanderbilt.edu

Co-Chair: Vikram Tiwari, Vanderbilt University Medical Center, Nashville, TN, 37221, United States, vikram.tiwari@vanderbilt.edu

1 - A Randomized Controlled Trial of a Predictive Modelling-based Scheduling System

Panagiotis Kougias, MD, Baylor College of Medicine, Houston, TX, United States, pkougias@bcm.edu

We randomly scheduled cases in a single operating room by predicting their length using either their historical mean (HM) duration or a regression modeling (RM) system that took into account operative and patient characteristics. Mean imprecision in predicting the end of operative day was higher with the HM approach (30.8 vs. 7.2 minutes, p=0.024). RM was associated with higher throughput (379 vs. 356 cases scheduled over the course of the study, p=0.04) and lower overutilization rate (34 vs. 51% of days with overutilization, p = 0.004). Mean length of overutilization (58 vs. 93 minutes, p=0.002) and undertulization (42 vs. 65 minutes, p=0.013) were superior in the RM arm.

2 - Real-time Bed Assignment Improves Patient Flow at Massachusetts General Hospital

Andrew Martin Vanden Berg, Massachusetts Institute of Technology, Cambridge, MA, United States, avdberg@mit.edu, Aleida Braaksma, Bethany Daily, Peter Dunn, Retsef Levi, Ben Orcutt, Ana Cecilia Zenteno

Assigning newly admitted patients to beds involves multiple constraints. Suboptimal patient-to-bed assignment may cause excessive patient wait times, crowding in upstream areas, and prolonged length-of-stays. We develop algorithms for real-time assignment of patients to beds, aiming at shortening patient wait times and decreasing upstream congestion. Through data-driven simulation, we quantify the benefits of the developed algorithms. Implementation of our results at Massachusetts General Hospital has resulted in significant decreases in patient wait times for beds, in addition to multiple other benefits.

3 - Risk-sensitive Stochastic Surgery Scheduling using CVAR

Amirhossein Najjarbashi, University of Houston, 6377 Chevy Chase Dr, Apt 210, Houston, TX, 77057, United States, amirhossein.najjarbashi@gmail.com, Gino J.Lim

This paper considers a daily surgery scheduling problem where surgical time requirements are stochastic with known probability distributions. A scenario-based mixed-integer linear programming formulation is proposed to minimize the conditional value-at-risk (CVaR) of overtime costs. Besides having desirable mathematical properties, applying CVaR enables hospital managers to adjust their approach toward the uncertainty using different probability levels. A set of benchmark instances is solved to evaluate the effectiveness of the proposed approach in providing low-cost and risk-averse schedules.

4 - Is More Information Always Better in Predicting Daily Surgical Case Volume?

Joonyup Eun, Vanderbilt University Medical Center, 1211 21th Avenue South, Medical Arts Building, Nashville, TN, 37212, United States, joonyup.eun@vanderbilt.edu, Vikram Tiwari, Warren S. Sandberg

We evaluate the tradeoff among two different dimensions of information - quality and quantity of information, by testing the accuracy of a series of data models to predict the daily surgical case volume. We retrieve detailed data of surgeons' working patterns from several information sources. We find that greater amount of information may not improve prediction accuracy if the additional information is prone to errors; however, deploying analytical data treatment strategies to ameliorate those errors improves information quality and results in better surgical case volume predictions.

4:30- 5:15 Gurobi / 5:15 - 6:00 Princeton Consultants Inc.

Invited: Vendor Tutorial

Invited Session

1 - Optimization with R

Renan Garcia, Gurobi Optimization, Houston, TX, United States, garcia@gurobi.com

Are you interested in leveraging mathematical programming technology from within R? This tutorial will survey some of the more popular optimization-related packages in the vast R ecosystem. This includes an overview of the Gurobi R package, along with detailed examples of how to build the optimization models you are looking to solve.

2 - Analytics Model Review and Validation

Irvin J.Lustig, Princeton Consultants, 25 Sylvan Way, 2 Research Way, Short Hills, NJ, 07078, United States, irv@princeton.com

Acting as an independent third party, Princeton Consultants reviews analytics models and how they are deployed in a business. Through our Advanced Analytics Model Review and Validation service, we ask questions such as: What is a correct model? What data is being integrated and how? How are solutions published and used in the business? How sensitive are the answers to the inputs? Did the implemented model reflect the intentions of the practitioner? In this tutorial, Irv Lustig will illustrate the importance of addressing these questions in the context of deploying advanced analytics models in practice.

Markov Decision Processes, Alpha Go, and Monte Carlo Tree Search: Back to the Future

Invited: Tutorial

Invited Session

Chair: Jiming Peng, University of Houston, Houston, TX, 77204, United States, jopeng@Central.uh.edu

Co-Chair: Rajan Batta, University at Buffalo (SUNY), 410 Bell Hall, Buffalo, NY, 14260, United States, batta@buffalo.edu

1 - Markov Decision Processes, AlphaGo, and Monte Carlo Tree Search: Back tothe Future

Michael Fu, University of Maryland-College Park, Robert H.Smith School of Business, Van Munching Hall, College Park, MD, 20742, United States, mfu@rhsmith.umd.edu

In 2016, a computer Go-playing program called AlphaGo stunned the (human) world by winning a match (4 games to 1) against the reigning human world champion, a feat more impressive than previous victories by computer programs in chess (Deep Blue) and the TV game show Jeopardy (Watson). The main engine behind AlphaGo combines machine learning approaches in the form of deep neural networks with a technique called Monte Carlo tree search, whose roots can be traced back to an adaptive multistage sampling simulation-based algorithm for Markov decision processes (MDPs) published in Operations Research back in 2005 (and introduced even earlier in 2002). This tutorial describes AlphaGo and the simulation-based MDP algorithm, as well as providing contextual and historical background material for both, and uses simple examples to illustrate the main ideas behind Monte Carlo tree search.

1 - Designing Incentives to Scale Marketplaces

Ashish Kabra, INSEAD, Boulevard de Constance, Fontainebleau, 77305, France, ashish.kabra@insead.edu, Elena Belavina, Karan Girotra

Marketplace operators run aggressive incentive schemes to achieve scale, that is key to the efficacy, survival and eventual domination of a marketplace. This study quantifies and compares the effect of incentives given to the "buyer" side and "seller" side using data from a leading ride-hailing market. We build a structural model to accurately capture the driver and passenger response to incentives, and the nature of incentives. Driver effort on the platform is unobserved, for which we devise a novel local matching model based imputation method. We find that in short-term (current week) passenger incentives are more effective while the opposite is true in the long-term (next 3 months).

2 - We are on the Way - Analysis of On-demand Ride-hailing System

Zizhuo Wang, University of Minnesota, 1009 5th Street SE, Minneapolis, MN, 55414, United States, zwang@umn.edu, Guiyun Feng, Guangwen Kong

In this paper, we build a stylized model to analyze the efficiency (average waiting time of passengers) of on-demand ride-hailing systems and compare it to the traditional street-hailing systems. We find that the on-demand matching mechanism could result in higher or lower efficiency than the traditional street-hailing mechanism, depending on the parameters of the system. We further propose adding response caps to the on-demand hailing mechanism and develop a heuristic method to calculate a near-optimal cap.

3 - The Costs and Benefits of Sharing: Sequential Individual Rationality and Fairness

Ragavendran Gopalakrishnan, Research Scientist, Conduent Labs India, Etamin Block, 4th Floor, Wing - A, Prestige Technology Park.- II, Bangalore, 560103, India, ragavendran.gopalakrishnan@conduent.com, Koyel Mukherjee, Theja Tulabandhula

We introduce the notion of sequential individual rationality in dynamic shared service systems, that requires that the disutility of existing customers is nonincreasing as the system state changes due to new customer arrivals. Given SIR, cost sharing can also be viewed as benefit sharing, under which we introduce a natural definition of sequential fairness—-the total incremental benefit from a new customer is shared among existing customers in proportion to the incremental inconvenience suffered. We demonstrate the effectiveness of these notions by applying them to a ridesharing system, where unexpected detours taken to pick up subsequent passengers inconvenience the existing passengers.

4 - A Tale of Timescales: Transient Network Dynamics, Demand Hot Spots, and Surge Pricing

Zhe Liu, Columbia University, New York, NY, United States, zliu18@gsb.columbia.edu, Philipp Afeche, Costis Maglaras

We consider an online platform that operates a ride-hailing network with price and delay sensitive passengers and strategic drivers that supply processing capacity. We study the interplay between demand shocks and surge pricing that is meant to a) moderate demand, and b) incentivize supply to reposition to demand hot spots, exploring the impact of travel delays on drivers' responsiveness to the surge signals.

Empirical Studies on Pricing

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Antonio Moreno-Garcia, Kellogg School of Management, Evanston, IL, 60201, United States, a-morenogarcia@kellogg.northwestern.edu

1 - The Hidden Costs of Dynamic Pricing Empirical Evidence from Online Retailing in Emerging Markets

Richard Zhiji Xu, PhD Student, Kellogg School of Management, Evanston, IL, United States, zhiji-xu@kellogg.northwestern.edu, Antonio Moreno-Garcia, Chaithanya Bandi

We investigate how dynamic pricing can lead to higher operational costs through more product returns in the online retail industry. Using detailed sales data of more than 2 million transactions with return information from the Indian online retail market, we document two types of strategic customer behavior, opportunistic returns and strategic choice of payment method, which have not been considered by previous research.

2 - Managing Market Thickness in Online B2b Markets

Wenchang Zhang, Robert H. Smith School of Business, 7621 Mowatt Lane, PHD Carrel, College Park, MD, 20740, United States, wzhang@rhsmith.umd.edu, Kostas Bimpikis, Wedad Jasmine Elmaghraby, Kenneth Moon

Excess inventory amounts to $424 billion a year, and much of this inventory is sold through online auctions. Based on a natural experiment on a major B2B auction platform, we find that increasing the market thickness by concentrating the auction ending times to certain days of the week has a significant positive effect on the platform's revenues. This finding illustrates the role of listing policies in matching supply to demand and provides evidence of trading frictions. We develop a structural model, which characterizes the bidders' equilibrium strategies. The counterfactual analysis provides a systematic way for the platform to design its listing policy and other market design levers.

3 - Customer Perceptions of Dynamic Pricing in on Demand Services

Nil Karacaoglu, Kellogg School of Management, 531 Grove Street, Evanston, IL, 60201, United States, n-karacaoglu@kellogg.northwestern.edu, Antonio Moreno-Garcia

On-demand services adopt dynamic pricing practices to match supply and demand. We investigate how customers perceive the trade-offs between increased prices, waiting time, and unavailability. We examine ways of reducing negative effects of dynamic pricing on customers' fairness perceptions and satisfaction by controlling price and the supply representation.

4 - Dynamic Pricing of the Ride Sharing Market in a Spatial Search Model

Weiming Zhu, IESE Business School, Barcelona, Spain, zhuwm923@gmail.com, Jingting Fan, Wenlan Luo, Liu Ming

Ride-sharing platforms employ flexible pricing during peak hours to match supply with demand. We build a spatial search model to study the geographic dynamics among drivers. Utilizing data from a leading ride-sharing platform, we assess the impact of different pricing schemes on drivers' capacity distribution, platform profit and consumer surplus.

Sustainability and Social Responsibility in Operations

Sponsored: Manufacturing & Service Oper Mgmt, Sustainable Operations

Sponsored Session

Chair: Sang Kim, Yale University, New Haven, CT, 06520, United States, sang.kim@yale.edu

1 - Ensuring Corporate Social and Environmental Responsibility through Vertical Integration and Horizontal Sourcing

Adem Orsdemir, University of California Riverside, Anderson Hall, Riverside, CA, 92507, United States, orsdemirademe@gmail.com, Bin Hu, Vinayak V. Deshpande

We investigate vertical integration as an alternative strategy for ensuring corporate social and environmental responsibility (CSER) at a supplier in a competitive setting. We show that when horizontal sourcing from a competitor is not feasible, NGOs' tighter scrutiny may discourage a firm from vertically integrating with its supplier and becoming responsible. However, we also find that possibility of supplying a competitor and existence of demand externalities due to violation exposures may fundamentally change firms' behaviors and CSER outcome.

2 - Can Brands Claim Ignorance? Unauthorized Subcontracting in Apparel Supply Chains

Anna Saez de Tejada Cuenca, UCLA, Anderson School of Management, Los Angeles, CA, United States, anna.sdtc.1@anderson.ucla.edu, Felipe Caro, Leonard Lane

The collapse of the Rana Plaza building in Bangladesh brought into focus the poor safety conditions faced by many workers in the apparel industry. A common way in which safety and environmental standards are violated is through unauthorized subcontracting. We analyze empirically some factors that can lead suppliers to outsource their production to third parties without their retailers' knowledge. We use data provided by a supply chain manager that consists of over 30,000 orders, including 36% of subcontracted ones. Our results provide managerial insights to retailers on what factory and order characteristics increase the probability of unauthorized subcontracting, and how it can be prevented.

3 - Design of Public Warning Systems

Saed Alizamir, Yale University, 339 Willow St., New Haven, CT, 06511, United States, saed.alizamir@yale.edu, Francis E. De Vericourt, Shouqiang Wang

We study the design of public warning systems in a multi-period model. In each period, the sender (she) receives an imperfect signal about the true state of the world (dangerous or safe), and has to decide whether to warn the receiver to act. Depending on the true realization of the random event, the receiver updates his belief about sender's credibility. The sender, therefore, has to dynamically manage her reputation over time, while also incentivizing the receiver to act on her warnings. We characterize the optimal warning policy, and gain insights into why it may sometimes be optimal for the sender to distort her signal.

Applications of Stochastic Models in Medical Decision Making Problems

Sponsored: Health Applications

Sponsored Session

Chair: Saeideh Mirghorbani, University of Alabama, Tuscaloosa, AL, 35401, United States, smirghorbani@crimson.ua.edu

1 - The Effect of Adherence on the Anti-Hypertensive Therapy Plans in Patients with Type 2 Diabetes

Saeideh Mirghorbani, University of Alabama, 1214, 12th St, Apt 17, Tuscaloosa, AL, 35401, United States, smirghorbani@crimson.ua.edu, Sharif Melouk, John Mittenthal

The importance of adherence to the anti-hypertensive medications in patients with diabetes has been emphasized. Adherence is the extent to which the patient follows medical instructions and has been identified as the primary reason for suboptimal clinical benefits. In this research, we address the optimal antihypertensive therapy plans while considering patient adherence, the medication side-effects, and the cardiovascular complications. We develop a finite horizon, discounted Markov decision process in which patients transition through health states. The objective is to maximize the expected quality-adjusted life years.

2 - Challenges in Modelling Time-dependent Transitions in Markov Cost-effectiveness Analysis

Jiaru Bai, Binghamton University, School of Management, Binghamton, NY, 13902, United States, jiarub@uci.edu, L. Robin Keller

We propose challenges in estimating Markov model parameters with limited clinical data. With limited data from registration trials, we developed a way to estimate time-dependent transition probabilities in a Markov model for cancer progression. The method is applied to cervical cancer data in a clinical study.

3 - Yardstick Competition for Service Systems

Ozlem Yildiz, Assistant Professor, University of Virginia, Darden School of Business, Charlottesville, VA, United States, YildizO@Darden.virginia.edu, Nicos Savva, Tolga Tezcan

We study whether an alternate pay-for-performance method can alleviate Emergency Department (ED) overcrowding through incentivizing socially-desired ED capacity levels, although the healthcare regulator does not know the capacity cost structure. Using yardstick competition, we propose a regulatory scheme that achieves this using the waiting time and arrival rate information of each ED.

4 - Optimal Treatment Model for Choosing Art Initiation Time

Huaiyang Zhong, Stanford University, 119 Quillen Ct, Apt 217A, Stanford, CA, 94305, United States, hzhong34@stanford.edu, Xiaocheng Li, Margaret L. Brandeau

HIV is now a chronic disease with the more and more availability of antiretroviral therapy (ART). WHO is advising that an infected individual should start ART as soon as the CD4 level drops to 500. However, because of diverse characteristics and different risk attitude of each patient, a personalized starting time of ART for each patient becomes very important. In this presentation, we present a new algorithm of Markov Decision Process (MDP) which will take into account of risk attitude and it will help solve the problem presented above.

Hospital Operations Management II

Sponsored: Health Applications

Sponsored Session

Chair: Hui Zhang, University of Chicago, Chicago, IL, 60637, United States, corinnaz@uchicago.edu

Chair: Thomas Best, tbest3@bsd.uchicago.edu

1 - A Queueing Framework for Evaluating Adoption of New Diagnostic Tests into Clinical Workflow with Application to Pulmonary Embolism in EDS

Zhongjie Ma, Purdue University, West Lafayette, IN, 47906, United States, zhongjiema@purdue.edu, Pengyi Shi, H. Sebastian Heese, Jonathan Helm, Alice Marina Mitchell

In medical research, new diagnostic tests are developed and evaluated solely on their efficacy in detecting a disease. However, ignoring the workload impact of introducing new tests into existing workflow can create barriers to adoption, particularly in busy units e.g. Emergency Department (ED). In collaboration with an ED physician, we develop a queueing framework for evaluating the workload impact of adopting new tests to bridge the gap between medical research and clinical workflow. We apply the framework to a new test, D-dimer, for detecting Pulmonary Embolism in EDs to understand what characteristics make adopting this test feasible and how to best integrate it into the ED workflow.

2 - Simulation-based Optimization to Improve Hospital Inpatient Placement under Capacity Strain

Hui Zhang, University of Chicago, Chicago, IL, 60637, United States, corinnaz@uchicago.edu, Thomas Best, Anton Chivu, David O.Meltzer

Many hospitals are confronted with capacity strain at their inpatient units resulting in delayed patient admissions, rejected admissions, and physician burnout. We develop a simulation-based optimization framework to improve hospital resource utilization using inpatient placement and overflow strategies. We use Discrete-Event Simulation approach and formulate an optimization model that maximizes hospital and physician revenue while accounting for various impact of patient overflow. We apply the model to a case study of hospitalist inpatient sector in University of Chicago Medical Center. Our findings inform hospital decision makers of how to address the capacity strain challenge.

3 - Diagnosing Variations of Length of Stay through Integrating Control Charts and Lean Management Practices within the Crisp DM Framework

Fadel Mounir Megahed, Miami University, Oxford, OH, fmegahed@miamioh.edu, Nasibeh Azadeh-Fard, Fatma Pakdil

In-patient length of stay (LOS) at hospitals is considered a critical metric because it is widely used to measure the overall efficiency of healthcare services. Given the fact that abnormal LOS results in increasing cost both for hospitals and patients, this study proposes a new methodology, based on CRISP-DM framework including control charts and lean management understanding, for monitoring and improving LOS. The utility of the proposed method is demonstrated through a case study involving 11,722 internal medicine patients at a large hospital in Southwest Virginia.

4 - Simulation of Interdependent Operations in Outpatient Clinics: A Case Study

Vahab Vahdat, PhD Candidate, Northeastern University, 334 Snell Engineering, 360 Huntington Avenue, Boston, MA, 02215, United States, vahdatzad.v@husky.neu.edu, Jacqueline Griffin

Many patients require multiple services provided by different clinics during one visit to a health center. In this research an example of interdependencies among three outpatient clinics in Massachusetts, USA are explored. While orthopedic and rheumatology outpatient clinics both work independently, their operations are interdependent with the radiology clinic that provides imaging services for both clinics. In order to improve patient length of stay, a discrete-event simulation model is constructed to model day-to-day operations of each clinics and evaluate the impact of integrated decisions in patient scheduling and resource allocation.

Models and Algorithms for Scheduling Healthcare Providers

Sponsored: Health Applications

Sponsored Session

Chair: Amy Cohn, University of Michigan, Ann Arbor, MI, 48109, United States, amycohn@umich.edu

1 - Algorithms to Generate Annual Rotation Schedules for Medical Residents

William Pozehl, University of Michigan, Ann Arbor, MI, United States, pozewil@umich.edu, Amy Cohn

An ever-growing list of educational requirements and service coverage needs make generating high-quality annual rotation schedules for medical residents increasingly difficult. On top of these rules, program leadership wishes to satisfy as many of the residents' requests as possible to reduce the risk of burnout and prepare the residents for their desired career paths. We explore algorithms to generate schedules that not only meet the needs of the residents and services under these complex conditions, but also do so rapidly.

2 - Optimal Bed Assignment in Multi-occupancy Facilities

Ruben Proano, Associate Professor, Rochester Institute of Technology, Gleason College of Engineering, 81 Lomb Memorial Drive, Rochester, NY, 14623, United States, rpmeie@rit.edu, Brenden M. Hoff

In many parts of the globe, hospitalizations take place in multi-occupancy rooms. The need to admit as many patients as possible, and mitigate the risk of exposing inpatients to infections carried by other patients results in a constant shuffle of patients across different rooms. This study proposes a multi-stage optimization model that minimizes the impact of patient shuffles, and maximizes unit occupation. Experimentally, the model is also used to illustrate the effect of relying on batch bed-assignments to mitigate the need of shuffles.

1 - Using Genetic Information to Guide Cholesterol Treatment Planning

Wesley Marrero, University of Michigan, Ann Arbor, MI, United States, wmarrero@umich.edu, Suzanne Butler, Jeremy Sussman, Mariel Sofia Lavieri

We derive optimal cholesterol treatment plans for patients at risk of cardiovascular events due to clinical and genetic factors using a Markov decision process. We also introduce a simulation-based framework to estimate the risk of a coronary heart disease event due to genetic factors.

2 - Optimal Inventory Control for Adaptive Trial Supply

Wei-An Chen, Purdue University, 610 Purdue Mall, West Lafayette, IN, United States, chen1702@purdue.edu, Nan Kong

As adaptive clinical trials receive growing attention in the past decade, a clinical supply management tool is required to address the adaptiveness. Our research aims at bringing more flexibility to drug supply and coordinate it with adaptive trial design. Our stochastic optimization model is founded on drug inventory control and used to address several important aspects of drug supply, e.g., drug wastage, resupply policy, trial span, and overall cost, under the uncertainty of participant enrollment. With the focus of trial size and length re-estimation, we also consider jointly optimize the trial design parameters and supply decisions while incorporating the patient response uncertainty.

3 - Optimal Risk-based Group Testing

Hrayer Y Aprahamian, Virginia Tech, 1145 Perry Street, Blacksburg, VA, 24060, United States, ahrayer@vt.edu

Group testing, i.e., testing multiple subjects simultaneously within a group, is an essential tool for classifying subjects as positive or negative for a binary characteristic; and is utilized in a variety of settings. We study optimal group testing schemes that incorporate subject-specific risk characteristics into the testing design. We consider various objectives, and characterize key structural properties of optimal testing designs. These properties allow us to develop efficient algorithms and derive important insights on the trade-offs being incurred. Our case study considers Chlamydia screening, and demonstrates the value of risk-based testing within a public health framework.

4 - Optimal Timing of ALS Interventions to Improve the Disease Course

Kalyan Pasupathy, Mayo Clinic, Rochester, MN, 4Mayo Clinic, Rochester, MN, Contact: pasupathy.kalyan@mayo.edu, Ozden Onur Dalgic, Fatih S. Erenay, Osman Yalin Ozaltin, Mustafa Y. Sir, Brian A. Crum

ALS is a neurodegenerative disease causing continuous decay of motor neurons and muscle atrophy. Patients suffer from losing their abilities to speak, eat, move and breath. Due to having no permanent treatment, ALS eventually affects all abilities but disease progression shows a great variability. Using medical records of over 400 patients from Mayo Clinic, we analyze the ALS progression pathways, and estimate risks of losing abilities and needing medical interventions (e.g., feeding tube, ventilator). We then develop a stochastic natural history model to optimize the timing of ALS interventions for improving patients' well-being in their disease course.

Robust Optimization and its Application

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Daniel Long, zylong@se.cuhk.edu.hk

1 - Matching Supply with Demand for Online Retailing

Yun Fong Lim, Associate Professor, Singapore Management University, 50 Stamford Road, 04-001, Singapore, 178899, Singapore, yflim@smu.edu.sg, Song Jiu, Marcus Teck Meng Ang

We consider an online retailer selling multiple products over a multi-period setting. At the start of each period, the retailer replenishes her products from multiple suppliers. After receiving the products, the retailer allocates the inventory to different fulfillment centers. At the end of each period when the demands for the products from different zones are realized, the retailer fulfills them from different fulfillment centers. We formulate a robust optimization model to determine the replenishment and allocation decisions at the start of each period and the fulfillment decisions at the end of the period. Our approach can handle large-scale problem instances with good quality solutions.

2 - A Study of Distributionally Robust Multistage Stochastic Optimization

Yongpei Guan, University of Florida, 303 Weil Hall, P.O. Box 116595, Gainesville, FL, 32611, United States, guan@ise.ufl.edu, Kezhou Zhou, Jianqiu Huang

In this talk, we focus on a data-driven risk-averse multistage stochastic programming (RMSP) model considering distributional robustness. We optimize the RMSP over the worst-case distribution within an ambiguity set of probability distributions constructed directly from historical data samples. The proposed RMSP is intractable due to the multistage nested minimax structure in its objective function, so we reformulate it into a deterministic equivalent that contains a series of convex combination of expectation and conditional value at risk (CVaR), which can be solved by a customized stochastic dual dynamic programming (SDDP) algorithm. As the size of collected data samples increases to infinity, we show the consistency of the RMSP with distributional robustness to the traditional multistage stochastic programming.

3 - Risk Minimization in Robust Inventory Routing Problem
Zheng Cui, Chinese University of Hong Kong, Hong Kong, zcui@se.cuhk.edu.hk, Daniel Zhuoyu Long, Jin Qi, Lianmin Zhang

We study a finite horizon stochastic inventory routing problem. In this problem, the supplier acts as a central planner who determines the replenishment quantities as well as the times and routes to all customers. We allow ambiguity in the probability distribution of uncertain demand at each customer. To quantify the risk in fulling the demand, we propose a decision criterion called Collective Requirement Violation (CRV) Index, which takes into account both the frequency and magnitudes of violation. The whole problem can be formulated as a mixed integer programming problem and the exact optimal solution can be found effectively. We compare the performance of our solutions with several benchmarks.

4 - A Convex Optimization Approach for Computing Correlated Choice Probabilities with Many Alternatives
Xiaobo Li, University of Minnesota, Minneapolis, MN, 55414, United States, lixx3195@umn.edu, Karthik Natarajan, Selin Damla Ahipasaoglu

The Cross Moment model (CMM) has been proposed as an alternative to MNP when the covariance information is available. Computing the choice probabilities with many alternatives is challenging in CMM. We develop a simpler formulation as a representative agent model by maximizing over the choice probabilities in the unit simplex. We develop a simple first order gradient method with inexact line search to compute choice probabilities and establish local linear convergence of this algorithm. Numerical experiments show that this method can compute choice probabilities for a large number of alternatives within a reasonable amount of time while explicitly capturing the correlation information.

Social Responsibility in Sourcing

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Goker Aydin, Johns Hopkins University, Baltimore, MD, 21202, United States, goker.aydin@jhu.edu

1 - Supply Risk Mitigation via Supplier Diversification and Improvement: An Experimental Evaluation
Basak Kalkanci, Georgia Institute of Technology, 3151 Stillhouse Creek Dr SE, Apt 25517, Atlanta, GA, 30339, United States, basak.kalkanci@scheller.gatech.edu

We use lab experiments to evaluate two sourcing strategies developed for mitigating supply risks of a buyer firm with heterogeneous suppliers: dual sourcing and single sourcing with supplier improvement. We also develop behavioral theories to elucidate the decision-making process of the buyer more effectively. With dual sourcing, human buyers allocate orders between suppliers more evenly than theory and exhibit quantity hedging behavior. We propose and empirically validate a theory of order allocation error minimization to explain this phenomenon. Human buyers use supplier improvement relatively successfully, despite being subject to supplier selection errors due to bounded rationality.

2 - Coordinating Supply Chains via Advance-order Discounts, Minimum Order Quantities, and Delegations
Prashant Chintapalli, University of California Los Angeles, Los Angeles, CA, United States, prashant.chintapalli.1@anderson.ucla.edu, Stephen M. Disney, Christopher S. Tang

Buyers often place rush orders with suppliers only after they receive firm orders from their customers. Rush orders are coslty for both the parties because the supplier incurs higher production costs. We show that though an advance-order discount (AOD) contract alone cannot coordinate the supply chain, the contract when combined with pre-specified minimum-order-quantity as a qualifier for the buyer to avail the discount, can coordinate the supply chain. We analyze another contract in which the buyer delegates the inventory decisions to the supplier in return for a discount on all units procured. We find both the combined contracts coordinate the supply chain in a Pareto improving manner.

3 - Curbing the Usage of Conflict Minerals: A Supply Network Perspective
Han Zhang, Student, Indiana University-Bloomington, Bloomington, IN, 47405, United States, hz8@indiana.edu, Goker Aydin, H. Sebastian Heese

Legislation and NGOs pressure manufacturers to disclose their sources of "conflict minerals" — natural resources whose trade might finance conflicts. We study the effect of such interventions, using a model of a supply network consisting of mines, smelters, and manufacturers. We show that imposing penalties on manufacturers alone is not sufficient to eliminate conflict minerals from supply chains, and that an industrial alliance to pool auditing costs among compliant manufacturers is effective in reducing the equilibrium quantity traded of non-certified metals.

Empirical Studies of Operational Quality

Sponsored: Manufacturing & Service Oper Mgmt, Service Operations

Sponsored Session

Chair: Robert L. Bray, Northwestern University, IL, United States, robertlbray@gmail.com

1 - Show or Tell: A Tanzanian Mobile Money Field Experiment on the Impacts of SMS Messages on Agent Performance
Christopher Parker, Penn State, State College, PA, United States, chris.parker@psu.edu, Jason Acimovic, David F. Drake, Karthik Balasubramanian

Mobile money allows consumers without physical bank accounts to conduct financial transactions through a wireless provider's network. Deposits and withdrawals are performed by agents who decide how much physical and electronic cash to stock each day in order to fulfill customer demands for deposits and withdrawals. We implement an experiment in Tanzania to test whether sending explicit recommendations for cash levels or informative estimates of transaction volume are better for reducing agents' stockout rates. Treated agents had a lower proportion of days-stocked-out by 80 basis points as compared to the control group. We also investigate treatment heterogeneity using agent characteristics.

2 - Menu Costs and the Bullwhip Effect: Empirical Evidence
Ioannis (Yannis) Stamatopoulos, The University of Texas at Austin, McCombs School of Business, Austin, TX, United States, Yannis.Stamos@mccombs.utexas.edu, Soheil Ghili

We empirically study the question of whether lower menu costs (operational costs of pricing) at a brick and mortar retail store imply higher or lower sales variability, and hence higher or lower bullwhip. We develop a theory for this question and test it using a structural estimation approach on data from a natural experiment.

3 - Supply Chain Proximity on Product Quality
Juan Serpa, McGill University, juan.serpa@mcgill.ca

We xplore the effect of supply chain proximity on product quality. To study this relationship, we merge five independent data sources from the automotive industry, collecting (i) auto component failure rates, (ii) upstream component factory locations, (iii) downstream assembly plant locations, and (iv) product-level links connecting the upstream and downstream factories. Combining these datasets yields one of the most detailed supply chain samples ever created, detailing the flow of 27,807 products through 529 supplier factories and 175 assembly plants. We find that, on average, the defect rate of a component increases by 0.21 percent when the distance increases by 100 kilometers.

4 - How Does Servers' Workload Impact Customer Lifetime Value? An Empirical Study
Qiuping Yu, Kelley School of Business, Indiana University, 1309 E. Tenth Street, Bloomington, IN, 47405-1701, United States, qiupyu@indiana.edu, Masoud Kamalahmadi, Yong-Pin Zhou

Using a rich data set from a casual dining restaurant chain, we explore how servers' workload impact customer repurchasing behavior thus their lifetime value. Through counterfactual studies, we demonstrate its implication in firm's staffing decisions.

Social Networks and Service Operations

Sponsored: Manufacturing & Service Oper Mgmt, Service Operations

Sponsored Session

Chair: Gad Allon, PA, United States, gadallon@wharton.upenn.edu

Co-Chair: Eren Basar Cil, University of Oregon, Lindquist College of Business, Eugene, OR, 97403-1208, United States, erencil@uoregon.edu

1 - Managing Workplace Flexibility: the Case of Agents with Task Preferences

Vasiliki Kostami, London Business School, London, United Kingdom, vkostami@london.edu, Rouba Ibrahim

Flexibility in operations is beneficial in matching supply and demand in both the manufacturing and service industries but it does not come for free. In many workplaces, employees are expected to excel in different skills as part of their job but they are also heterogeneous in their preferences to perform certain tasks associated with their employment. We study and compare two innovative flexibility arrangements in the workplace that are related to the task assignment against the traditional one where the task routing is a decision made by the firm with the ultimate objective of improving both the employees' welfare and the employer's revenue.

2 - Multiple Equilibria When Servers Value Idleness and Compensation

Dongyuan Zhan, University College London, UCL.School of Management, Gower Street, London, WC1E 6BT, United Kingdom, d.zhan@ucl.ac.uk, Amy R.Ward

Most common queueing systems used for service system design assume the servers work at fixed rates. However, real-life service system are staffed by people, who may change their service speed in response to their compensation incentives and idleness utility. We study the equilibrium service rate under this setting. We find that depending on the servers' idleness utility function, two equilibria, which allow different service rates and amount of idleness, may exist. The system manager may induce one of the equilibria by imposing more restrictions on servers' behavior.

3 - Hidden-City Travel and its Impact on Airfare

Woonghee Tim Huh, University of British Columbia, Sauder School of Business, Operations and Logistics Division, Vancouver, BC, V6T.1Z2, Canada, tim.huh@sauder.ubc.ca, Jaelynn Oh

We study the cause of hidden city fare and the effect of hidden city travelers on airfare when airlines price compete on hub-and-spoke flight networks.

4 - Does Marginal Wage Reveal your Cost of Waiting?

Simin Li, Kellogg School of Management, Northwestern University, 2211 Campus Drive, Evanston, IL, 60208, United States, simin.li@kellogg.northwestern.edu, Achal Bassamboo, Martin Lariviere

We investigate how an agent's cost of waiting depends on income structure and non-market activities. We find the conventional metric, marginal wage, is only a fair estimation to marginal cost of waiting if earnings are smooth. The equality breaks down once any friction is introduced. The marginal wage can over or under estimate agents' true cost of waiting.

5 - Skill Management in Large-scale Service Marketplaces

Eren Basar Cil, University of Oregon, 1208 University Of Oregon, Lindquist College of Business, Eugene, OR, 97403-1208, United States, erencil@uoregon.edu, Gad Allon, Achal Bassamboo

We consider a large-scale service marketplace where the moderating firm can run two skills tests on agents to assess if their skills are above certain thresholds. Our main objective is to evaluate the effectiveness of skill screening as a revenue maximization tool. We find that skill screening leads to negligible revenue improvements in marketplaces where agent skills are highly compatible. As the compatibility of agent skills weakens, we show that the firm starts to experience as much as 25% improvement in revenue from skill screening. Apparently, the firm can reap the most of these substantial benefits when it runs only one test.

Game Theory

Contributed Session

Chair: Alok Raj, IIM Lucknow, Lucknow, India, fpm15002@iiml.ac.in

1 - Consolidation in Urban Goods Distribution - Cost Allocation Based on Approximate Solutions

Joen Dahlberg, Linköping University, Norrköping, Sweden, joen.dahlberg@liu.se, Stefan Engevall, Maud Göthe-Lundgren, Jenny Karlsson

We consider the cost allocation problem that arises when a number of stakeholders, responsible for the distribution of goods in an urban area, collaborate by goods consolidation. This problem is formulated as a cooperative game, where the characteristic function value is defined as the cost of a Vehicle Routing Problem (VRP). For large sized problems, it is impractical to solve the VRP to optimality. We investigate the effects of allocating costs based on approximate VRP solutions. The viability, quality and validity of the method are verified by applying the method on instances of real life data.

2 - Bileratal Competition in Crowd Logistics with Game Theory and Emotion Theory

Yi Song, Huazhong University of Science and Technology, Wuhan, China, songyi@hust.edu.cn, Bin Hu

With the increasingly use of sensor-embedded smartphones, many crowdsourcers and a large population of service providers form a bilateral competition market, where crowdsourcers compete for the limited logistics service and service providers compete for the limited budget. In this paper, we present emotion theory embedded with a game theory of such market. We formulate the dynamics behavior of service providers as an evolutionary game, take their feelings of crowdsourcers and then present a simulation model for the implementation of the evolution process. For crowdsourcers, we use a non-cooperative game. Through this paper, we can understand the dynamic evolution of the crowd logistics market.

4 - An Ascending Auction for Freight Forwarders Collaboration in Capacity Sharing

Minghui Lai, Assistant Professor, Southeast University, China, Room A-411, Economics and Management Building, Southeast University (Jiulonghu Campus), Nanjing, China, laimh@seu.edu.cn

We propose an ascending auction mechanism for the capacity sharing problem, where each forwarder submits a set of bundles of capacity for their shipping requests. To achieve strategy-proofness, all the winning bundles for an accepted request must have the same payment and the payment is ascending during the iterations. To improve social welfare, the mechanism iteratively expands the set of bundles and approximates the loss of private revenues to search optimal allocations, using the dual solution derived from minimizing primal-dual slackness. We prove that the mechanism is strategy-proof, individually rational, weakly budget balanced, and finitely convergent.

5 - Sustainable Supply Chain Channel Coordination using Game Theoretic Approach

Alok Raj, IIM.Lucknow, Lucknow, India, fpm15002@iiml.ac.in

The importance of triple bottom line has been widely recognized by both industry and supply chain (SC) literature. However, in the context of SC coordination, simultaneous treatment of greening effort, social responsibility, and profit have received scant attention in the extant literature. This paper focuses on this gap and we propose a generalized analytical model for a dyadic supply chain with triple bottom line approach. We formulate a supplier-buyer stackelberg game and design linear two-part tariff contract for coordination. Our generalized analytical model is able to capture the dynamics of pure profit maximizing SC, green SC, and socially responsible SC as special cases.

Mathematical Models and Empirical Methods for Improving Healthcare Operations

Sponsored: Manufacturing & Service Oper Mgmt, Healthcare Operations

Sponsored Session

Chair: Goh Joel, jgoh@hbs.edu

1 - Maximizing Intervention Effectiveness

Brian Rongqing Han, Marshall School of Business, USC, Los Angeles, CA, United States, rongqing.han.2019@marshall.usc.edu, Vishal Gupta, Song-Hee Kim

In the emerging paradigm of evidence-based decision making in healthcare and social science, policymakers often face challenges when deciding whom to receive an intervention that has previously been proven effective. With heterogeneous intervention effects and no access to raw experimental data, who should be selected for intervention? We propose a novel robust optimization framework that uses only summary statistics from a published paper to select a subset of the candidate population to maximize intervention effectiveness. We assess the practical significance of our method using data from a large teaching hospital who wants to reduce frequent Emergency Department visits.

2 - Issuing Policies for Hospital Blood Inventory

Alireza Sabouri, Haskayne School of Business, University of Calgary, 2500 University Dr. NW, SH132, Calgary, AB, T2N.1N4, Canada, alireza.sabouri@haskayne.ucalgary.ca, Tim Huh, Steven Shechter

We propose a model for allocating red blood cells for transfusion to patients, which is motivated by recent evidence suggesting that transfusing older blood is associated with increased mortality rate. We study the properties of blood issuance policies that balance the trade-off between "quality" measured in average age of blood transfused and "efficiency" measured in the amount of shortage. Based on our analysis, we design efficient issuance policies and evaluate their performance.

3 - An Empirical Study of Adding Physician Assistants to Critical Care Rapid Response Teams

Carri Chan, Columbia Business School, 3022 Broadway, Uris Hall, New York, NY, 10027, United States, cwchan@columbia.edu, Mor Armony, Yunchao Xu

Physician assistants (PAs) can sometimes be cost-effective alternatives to physicians in healthcare systems, but their impact on critical care delivery remains unclear. Over the course of 18 months, PAs were incrementally added to the Critical Care Rapid Response team at a major urban hospital system. We empirically measure the impact of part-time versus full-time PA coverage. We find that adding PAs can reduce the average time-to-transfer for all ICU patients and reduce mortality risk for low-severity patients. Interestingly, we do not find evidence that the benefits of having PAs further improves patient outcomes when adding PAs on non-weekdays.

4 - Gate Keeping under Uncertainty: An Empirical Study of Referral Errors in the Emergency Department

Michael Freeman, INSEAD, 1 Ayer Rajah Avenue, 138676, Singapore, mef35@cam.ac.uk, Susan Robinson, Stefan Scholtes

We study admission decisions made by physicians in a congested emergency department (ED) using data from 600,000 visits over 7-years. As the ED becomes congested, we find that ED physicians respond by admitting to hospital more patients for short observational stays while also making fewer discharge errors. This causes a bullwhip-type effect: demand surges in the ED lead to relatively greater demand pressures in the hospital. We then show that replacing the direct one-stage (ED physician to hospital) referral system with a two-stage process in which ED physicians can stream patients with high diagnostic uncertainty to an intermediate "semi-specialist" referral unit can improve routing decisions.

Business Model Innovation

Sponsored: Manufacturing & Service Oper Mgmt, Supply Chain

Sponsored Session

Chair: Simone Marinesi, Wharton, Philadelphia, PA, 75003, United States, marinesi@wharton.upenn.edu

1 - Dynamic Contests in the Lab

Mohamed Mostagir, University of Michigan, 701 Tappan Ave, Ann Arbor, MI, 48109, United States, mmostagir@yahoo.com, Yan Chen, Iman Yeckehzaare

We develop Knapsack Contests. An experimental framework where agents compete in a contest whose feasibility is uncertain. They learn about feasibility from their actions as well as from the progress of their competitors. A contest designer is interested in maximizing the efforts that agents exert, and utilizes the contest's information disclosure mechanism as a lever to that end. We examine several information disclosure designs that a contest designer can utilize and we compare their properties in terms of the designer's objective and the contestants' welfare.

2 - Referral Priority Program: Leveraging Social Ties via Operational Incentives

Luyi Yang, Johns Hopkins University, Baltimore, MD, 21202, United States, luyi.yang@jhu.edu, Laurens G. Debo

The referral priority program, an emerging business practice adopted by a growing number of technology companies that manage a waitlist of customers, enables existing customers on the waitlist to gain priority access if they successfully refer new customers to the waitlist. We study the effectiveness of such a scheme as a marketing tool for customer acquisition and an operational approach for waitlist management.

3 - Competitive Equilibria in two Sided Matching Markets with Non-quasilinear Utility Functions

Azarakhsh Malekian, Rotman School of Management, 105 Saint George, malekian, Toronto, ON, 02143, Canada, azarakhshm@gmail.com

We consider two sided matching markets consisting of agents with non-transferable utilities; agents from the opposite sides form matching pairs (e.g., buyers-sellers) and negotiate the terms of their math which may include a monetary transfer. Competitive equilibria are the elements of the core of this game. We present the first combinatorial characterization of competitive equilibria that relates the utility of each agent at equilibrium to the equilibrium utilities of other agents in a strictly smaller market excluding that agent; thus automatically providing a constructive proof of existence of competitive equilibria in such markets.

4 - Choosing the Right Campaign Mode in Crowdfunding

Simone Marinesi, Wharton, 201 S.25th Street, Apt 621, Philadelphia, PA, 75003, United States, marinesi@wharton.upenn.edu, Karan Girotra

We compare the two most popular campaign modes employed by reward-based crowdfunding platforms: All-or-Nothing, in which the entrepreneur (creator) collects the money pledged by consumers (backers) only if the project is fully funded, and Flexible Funding, in which the entrepreneur collects the money even when the project is partially funded. A comparison between the two campaign modes reveals that an entrepreneur should choose a Flexible Funding campaign for projects with a low budget, high market prospects, or if capital markets are particularly accessible.

Inventory Management

Contributed Session

Chair: Yang Zhou, Huazhong University of Science and Technology, Wuhan, China, m201673799@hust.edu.cn

1 - An Analysis of Production Process Considering Yield Distribution

Sungyong Choi, Assistant Professor, Yonsei University, College of Government and Business, 1 Yoneseidae-gil, Wonju, 26493, Korea, Republic of, sungyongchoi@gmail.com, Sumin Jeon, Jinmin Kim, Kwangtae Park

We study a binomial yield production process using a newsvendor approach by incorporating underage and overage costs. We provide a reformulation of the original model to convert the discrete and exact model to the continuous and approximate model via normal approximation. We conduct comparative static analysis for model parameters in the approximate model and derive the monotone properties of the optimal solution. All of the analytical results are consistent with our insights and supported by economic explanations. Our numerical study with sample-based optimization indicates that the approximate model is close to the exact model in most of the real world examples including some limiting cases.

2 - Single Period Inventory Problem under Differentiated Service Levels using a Responsive Allocation Policy

Pablo Escalona, Universidad Técnica Federico Santa María, Av Espana 1680, Valparaiso, 2390123, Chile, pablo.escalona@usm.cl

We study the rationing of a single order quantity among multiple customer classes under stochastic demands and differentiated service levels using a responsive allocation policy when demand is made during the lead time. The problem is formulated as a nonlinear problem with chance constraints, for which we exploit the geometrical properties of the model, to propose a decomposition technique to solve it. Although the heuristic does not guarantee an optimal solution, our computational experiments have shown that it provides good-quality solutions that, under a mild assumption, are epsilon-optimal.

3 - Optimality of Price-setting Newsvendor Problems Subject to Mean-variance Risk Measures: An Elasticity Approach
Javier Rubio-Herrero, Assistant Professor, St. Mary's University, One Camino Santa Maria, San Antonio, TX, 78228, United States, jrubioherrero@stmarytx.edu, Melike Baykal-Gursoy

We introduce a set of sufficient conditions for the optimality of certain price-setting newsvendor problems in terms of three different elasticities, namely, the lost sales rate elasticity, the optimal price elasticity, and the elasticity of the excess of safety stock. Our idea is to give a more managerial approach to the assessment of optimality in price and inventory decisions for this type of inventory problems.

4 - Inventory Model for a Fixed Life Perishable Product with Price and Inventory Level Dependent Demand
Nilesh Asnani, Doctoral Candidate, Indian Institute of Management Indore, Rau-Pithampur Road, Indore, 453331, India, f14nilesha@iimidr.ac.in, Hasmukh Gajjar, Bhavin J. Shah

In this study, we consider a deterministic demand that depends upon deterioration rate, price discount, and displayed inventory level. We propose inventory model to optimize retailer's profit by optimally determining order quantity, shelf space, and price discount.

5 - Inventory Strategy in O2O Supply Chain Based on Drop Shipping by the Retailer
Yang Zhou, Huazhong University of Science and Technology, Wuhan, China, m201673799@hust.edu.cn, Shihua Ma

In order to solve the order delivering dilemma of manufactures' electronic channel, O2O model based on drop shipping by the retailer was proposed. Taking newsvendor model to analyze the optimal stocking decisions in three different models of manufacturers and retailers. Furthermore, through numerical experiments, we analyze the impact of demand uncertainty and drop shipping fee on the optimal inventory levels and the optimal choices of manufacturers and retailers.

Storage and Flexibility in Energy Systems

Sponsored: Energy, Natural Res & the Environment Environment & Sustainability

Sponsored Session

Chair: Rodrigo Moreno, University of Chile, Tupper 2007, Santiago, 2007, Chile, rmorenovieyra@ing.uchile.cl

1 - Application of Stochastic Dual Dynamic Programming to the Real-Time Dispatch of Storage under Renewable Supply Uncertainty
Anthony Papavasiliou, CORE, UCL, Voie du Roman Pays 34, L1.03.01, Office b.114, Louvain la Neuve, 1348, Belgium, tpapva@hotmail.com

This talk presents a multi-stage stochastic programming formulation of transmission constrained economic dispatch subject to multi-area renewable production uncertainty, with a focus on optimizing the dispatch of storage in real-time operations. This problem is resolved using stochastic dual dynamic programming. The applicability of the proposed approach is demonstrated on a realistic case study of the German power system calibrated against the solar and wind power integration levels of 2013-2014, with a 24-hour horizon and 15-minute time step. The value of the stochastic solution relative to the cost of a deterministic policy amounts to 1.1%, while the value of perfect foresight relative to the cost of the stochastic programming policy amounts to 0.8%. The relative performance of various alternative real-time dispatch policies is analyzed, and the sensitivity of the results is explored.

2- Power System Planning Considering Flexibility Requirements: Impact of Energy Storage
Angela Flores, University of Chile, Av Tupper 2007, Santiago, Chile, angelafq@gmail.com, Kai Strunz

The capacity planning problem with high penetration of variable renewable generation is addressed by a multi-stage stochastic model including unit commitment constraints such as: minimum operating times, ramp rates, operating reserves and start-up costs. Different energy storage technologies are modeled and included as investment options. The resulting large-scale MILP is solved by the column generation algorithm. The impact of different energy storage systems in the optimal power mix and their role in the integration of renewables are analyzed.

3 - Co-optimizing Network and Storage Investments in Electricity Systems: A Stochastic Optimization Approach
Rodrigo Moreno, University of Chile / Imperial College, Tupper 2007, Santiago, 2007, Chile, rmorenovieyra@ing.uchile.cl, Hector Otarola, Angela Flores

We present a stochastic optimization model to determine optimal investment decisions in planning under uncertainty in the long term. The model optimizes new network investments along with energy storage investments to minimize both investment and system operational costs. Uncertainty is associated with long-term scenarios of investment costs, operational costs, demand growth and policy incentives. We solve the optimization model through a column generation algorithm which is compared against the performance of progressive hedging. We conclude on computational performance and quality of the solutions to appropriately allocate investments in new transmission lines and storage plants.

Operations Decisions in the Presence of Tax

Sponsored: Manufacturing & Service Oper Mgmt, iFORM

Sponsored Session

Chair: Vernon Hsu, Shatin, Hong Kong, vhsu@cuhk.edu.hk

1 - Ex-post Transfer Pricing in a Multinational Firm
Zhu Kaijie, Chinese University of Hong Kong, Shatin, Hong Kong, kzhu@baf.msmail.cuhk.edu.hk, Vernon Hsu, Xiaopeng Zhang

We study a decentralized transfer-pricing model in which regional divisions of a multinational firm decide retail prices to maximize their respective profits before its headquarter determines the transfer price to maximize the firm-wide after-tax profit. Our analysis indicates such ex-post transfer pricing may render gaming behaviors by the regional divisions and thus a distortion in their decision making. The gaming behaviors can cause severe consequences, e.g., the firm's profit being decreased in the presence of tax rate reduction. We present approaches to mitigating the gaming behaviors.

2 - The Impact of Arm's Length Principle (ALP) on a Supply Chain and Consumers when a Rival is Also a Customer
Kun Soo Park, Associate Professor, KAIST, 85 Hoegiro, Dongdaemum-Gu, Seoul, 130-722, Korea, Republic of, kunsoo@kaist.ac.kr, Woonghee Tim Huh, Se Youn Jung

We consider a supply chain with a vertically integrated producer (VIP) and a rival retailer who is also a wholesale customer of the VIP. We study the wholesale pricing decision of the VIP and the quantity decisions of both retailers whose retail expertise in the market are not necessarily the same. In particular, we investigate the impact of the regulation on the transfer pricing of the VIP, which is commonly referred to as the arms length regulation, on the operational decisions of each entity in this supply chain and consumers.

3 - The Internal Decentralization Effects in Off-sourcing Procurement
Gangshu Cai, Santa Clara University, Department of OMIS, 216n Lucas Hall, Santa Clara, CA, 95053, United States, gcai@scu.edu, Zhiqiao Wu, Jiafu Tang

We study the internal decentralization effects in different types of offshore procurements and show that a firm can benefit from more internal decentralization.

TIMES Distinguished Speaker

Sponsored: Technology, Innovation Management & Entrepreneurship

Sponsored Session

Chair: Juliana Hsuan, Copenhagen Business School, Department of Operations Management, Solbjerg Plads 3 B 5.27, Frederiksberg, DK-2000, Denmark, jh.om@cbs.dk

1 - What's Industry Got to do with it?

John Paul MacDuffie, University of Pennsylvania, Wharton School, Philadelphia, PA, United States, macduffie@wharton.upenn.edu

Studies of technological change and the management challenges it can create for incumbents commonly strive (like most social science) for theoretical insights and empirical findings that can be generalized to all settings. My research experiences have, through a mix of good luck, choice, and inertia, given me the opportunity for deep and prolonged study of a single context, the global automotive industry. This "industry of industries" (to quote Peter Drucker) has, over more than a century, seen an evolution in production system paradigms from craft to mass to lean production and is now facing a time of tremendous ferment as new technologies combine with new business models in a broader ecosystem of mobility services. Many analysts observing this time of ferment are applying the lens of theories of industry change developed during the rise of ICT/digital tech companies, with expectations of rapid transformation. I will argue that the application of these lenses can often be misguided, creating distorted assessments and misleading predictions, and revealing the need for better theorizing about contingencies and mechanisms as well as different research designs and methods. I will extract from my immersion in "industry studies" (both my research and my participation as a founding board member of the Industry Studies Association) some lessons for TIMES scholars about the advantages of bringing deep contextual knowledge about industries to the study of technological change and ecosystem evolution.

Decision Analysis and Natural Hazards

Invited: InvitedNatural Hazard Planning

Invited Session

Chair: Sara Shashaani, University of Michigan, sshashaa@umich.edu

1 - Modeling Uncertainty: the Cost of Wrong Assumptions in Infrastructure Disaster Risk Modeling

Benjamin Rachunok, Purdue University, West Lafayette, IN, United States, brachuno@purdue.edu, Roshanak Nateghi

Risk modeling is a stochastic endeavor which commonly requires selecting a probability distribution to represent uncertainty in model inputs. No empirical data truly follows a theoretical distribution, as such distributions impose additional assumptions whenever they are used. In this talk, we aim to assess the cost of making incorrect assumptions in infrastructure disaster risk analyses. We present examples using publicly available tropical cyclone data (from NHC) and severe-weather related power outages (from the DoE) to illustrate the consequences of making incorrect assumptions in modeling risk, that can lead to over/under investments in infrastructure resilience.

2 - Preemptive Decision-making to Support Power System Resilience

Andrea Staid, Sandia National Labs, 412 Morningside Dr NE, Albuquerque, NM, 87108, United States, astaid@sandia.gov, Jean-Paul Watson, Michael Bynum, Bryan Arguello

The electric power system is vulnerable to natural hazards; consequences can have huge financial, social, and health impacts. To improve power system resilience, we must first understand the critical threats, potential damage, and how consequences can propagate through the system. Here we focus on improving resilience to by identifying optimal actions to take in advance of adverse weather. We use data from a large electric utility company to develop realistic scenarios of transmission system outages for use in a stochastic programming formulation using a DC optimal power flow model. We evaluate several mitigation strategies and characterize the impact on system resilience.

3 - Hurricane Power Outage Prediction with Out of Bag Feature Selection Approaches

Sara Shashaani, University of Michigan, 1777 Plymouth Rd Apt 2C, Ann Arbor, MI, 48105, United States, sshashaa@umich.edu, Seth Guikema

Predicting hurricane power outages facilitates natural hazards response decisions. However the spatial data is largely zero-inflated with a sizable number of explanatory variables, and finding statistical models that can provide reliable predictions remains to be a challenge. We study a feature selection approach by using out of bag performance of the predictors for such datasets. A combinatorial optimization model is developed to seek contributing variables to the accuracy of the prediction model. We found promising results experimenting on actual central gulf coast outage data.

1 - Optimal Maximum GAP Estimation in Multi-armed Bandit

Yuan Zhou, Indiana Unviersity at Bloomington, Bloomington, IN, 47401, United States, yzhoucs@indiana.edu, Chao Tao, Xi Chen

In this paper, we study the problem of maximum gap estimation in multi-armed bandit. We propose a new PAC-learning algorithm named MaxGapEst, which provides an $\eps$-close estimate of the maximum gap with probability $1-\delta$. The algorithm achieves the optimal sample complexity $\Theta(\frac{n}{\eps^2} \ln \\delta^{-1})$ for sufficiently small $\eps$. As a subroutine of the MaxGapEst, we propose a new algorithm for cost-sensitive best-arm identification problem, which assumes that sampling different arms incurs different costs. This result generalizes the classical results on the problem of best-arm identification with uniform sampling cost, which is of independent interest.

2 - Deep Exploration in Reinforcement Learning via Randomized Value Functions

Daniel Russo, 3170 N. Sheridan Road, Apt. 1216, Chicago, IL, 60657, United States, Dan.Joseph.Russo@gmail.com

Reinforcement learning algorithms learn to optimize performance in complicated MDPs by using observed state transitions. A major challenge is the ability to collect the right training data, and even important breakthroughs have relied on highly naive exploration, or the imitation of humans who have mastered the control task. We study the use of randomized value functions to guide sophisticated deep exploration in RL. This offers an elegant means for synthesizing statistically and computationally efficient exploration with common approaches to value function learning. We develop RL algorithms that leverage randomized value functions, and present computational studies and regret bounds.

3 - Non-stationary Stochastic Optimization with Local Spatial and Temporal Changes

Yining Wang, Carnegie Mellon University, 5000 Forbes Avenue, 8203 Gates-Hillman Center, Pittsburgh, PA, 15213, United States, ynwang.yining@gmail.com

We study the non-stationary stochastic optimization problem with local temporal and spatial changes by imposing an L_{p,q} norm constraints on the changes of functions between consecutive time epochs. We derive matching upper and lower bounds for our considered model, which have a few notable differences from the classical non-stationary stochastic optimization model where no locality of changes is imposed. In particular, we show a curse of dimensionality under our setting, which means the optimization problem gets harder when the problem dimension increases.

4 - Thompson Sampling Approach for Dynamic Assortment Selection

Vashist Avadhanula, Columbia University, Industrial Eng. and OR, 423 SW Mudd Building, New York, NY, 10027, United States, vavadhanula18@gsb.columbia.edu, Shipra Agrawal, Vineet Goyal, Assaf Zeevi

We consider a sequential subset selection problem under parameter uncertainty, where at each time step, the decision maker selects a subset of cardinality K from N possible items (arms), and observes a (bandit) feedback in the form of the index of one of the items in said subset, or none. Each item in the index set is ascribed a certain value (reward), and the feedback is governed by a Multinomial Logit (MNL) choice model whose parameters are a priori unknown. The objective of the decision maker is to maximize the expected cumulative rewards over a finite horizon T, or alternatively, minimize the regret relative to an oracle that knows the MNL parameters. We refer to this as the MNL-Bandit problem. This problem is representative of a larger family of exploration-exploitation problems that involve a combinatorial objective and arise in several important application domains. We present an approach to adapt Thompson Sampling to this problem and show that it achieves near-optimal regret as well as attractive numerical performance.

Sponsored Session

Chair: Arnab Bisi, Johns Hopkins Carey Business School, 100 International Drive, Baltimore, MD, 21202, United States, abisi1@jhu.edu

1 - Healthcare Payment Models under Competition

Zheng Han, University of Kansas, Lawrence, KS, United States, hanzheng@ku.edu, Mazhar Arikan, Suman Mallik

We consider two hospitals competing as profit-maximizers by choosing their own quality levels under different payment schemes (i.e., bundled payment (BP) vs. fee-for-service (FFS)). A game-theoretic model is built to analyze equilibrium outcomes. We show that: BP (FFS) is not always associated with high (low) equilibrium quality, and identify threshold payments for both FFS and BP that can lead the corresponding hospital to choose the highest or lowest level of quality; a higher reimbursement for hospital readmissions under FFS may result in quality improvement, rather than deterioration; a higher reimbursement from either FFS or BP does not necessarily result in a higher beneficiary welfare.

2 - Dynamic Pricing or Dynamic Logistics?
