Thunyarat (Bam) Amornpetchkul, NIDA Business School, Bangkok, Thailand, thunyarat.a@nida.ac.th
Thunyarat (Bam) Amornpetchkul, Boston College (Visiting), Chestnut Hill, MA, United States, thunyarat.a@nida.ac.th, Hyun-Soo Ahn, Ozge Sahin

Retailers who sell their products through multiple channels often hold inventory at separate locations, dedicated for demand arriving at each channel. When inventory level does not match with demand, transshipment across channels may be beneficial. We characterize and compare the effectiveness of the retailer's optimal pricing and transshipment policy. Furthermore, we investigate how the optimal pricing policy is affected by the transshipment policy, and vice versa.

3 - An Inventory System with Partial Backorders and Inventory Holdback

Arnab Bisi, Johns Hopkins Carey Business School, 100 International Drive, Baltimore, MD, 21202, United States, abisi1@jhu.edu, Yanyi Xu, Maqbool Dada

We consider a periodic-review base stock inventory system with partial backorders. In each period, an order of q is placed for delivery one period later and as much as possible of the realized demand is filled immediately from inventory on-hand. Of the excess demand above the inventory on-hand, up to q - k units are backordered to be filled from future orders. The on-order quantity k denotes the reservation quantity held back for use in subsequent periods. Our model yields the full lost sales and full backorder models as special cases. For both finite and infinite horizon problems, we determine structural properties of the optimal policy and discuss how to find the optimal base stock and hold back quantity.

1 - Index Policies and Performance Bounds for Dynamic Selection Problems

James E.Smith, Duke University, Fuqua School of Business, Box 90120, Durham, NC, 27708-0120, United States, jes9@duke.edu, David Brown

In this work, we study heuristics and performance bounds for dynamic selection problems. Examples of dynamic selection problems include assortment planning with demand learning, design of clinical trials, and screening a pool of applicants (e.g., for admission to colleges). We study a number of index-based policies, including one based on a Lagrangian relaxation of the problem. We characterize the performance of this Lagrangian index policy compared to an optimal policy. We also develop performance bounds that combine Lagrangian relaxations with information relaxations and show that these new performance bounds outperform standard Lagrangian relaxation bounds.

2 - Naloxone Procurement and Distribution in the Presence of High Drug Prices

Yijia Wang, University of Pittsburgh, Pittsburgh, PA, United States, YIW94@pitt.edu, Daniel Jiang

Naloxone, a drug for treating opioid overdose, is vital for public health agencies' efforts to combat the opioid epidemic. However, naloxone prices have recently surged so it is essential for public health agencies to effectively manage procurement and distribution of naloxone. The goal is to maximize naloxone distribution into affected communities under funding and storage constraints; this problem will be solved through a novel formulation of a hierarchical MDP along with an associated approximate dynamic programming technique. The main policy question we will answer is: under optimal operations, what is the effect of increasing prices on our ability to distribute Naloxone kits?

3 - An Origin-Destination Decomposition Method for Network Revenue Management

Rui Zhang, University of Colorado Boulder, 5377 Racegate Run, Boulder, CO, 21045, United States, rui.zhang@colorado.edu, Dan Zhang

In this paper, in contrast to resource-based decomposition method, we consider a decomposition method where the approximate linear programming of the network revenue management problem is decomposed into a collection of subproblems, each corresponding to an origin-destination pair, which we call the OD- based decomposition. We show that OD-based decomposition provides an upper bound to the total expected revenue and alternative heuristic control policies. We identify conditions under which the OD-based decomposition gives tighter upper bounds and better heuristic policies than the resource-based decomposition.

4 - An Approximate Dynamic Programming Approach to a Rolling-horizon Appointment Scheduling Problem

Fan You, University of Colorado-Boulder, 995 Regent Dr, Boulder, CO, 80302, United States, fayo4612@colorado.edu, Thomas Vossen, Dan Zhang

We consider a rolling-horizon appointment scheduling problem with multiple patient classes. The problem is formulated as an infinite horizon discounted cost Markov decision process. We consider affine and finite-horizon approximations and show that they admit compact representations and can be efficiently solved as small scale linear programs. A numerical study illustrates the performance of the heuristic control policies based on the approximations.

Power Generation Scheduling

Invited: Energy Systems Management

Invited Session

Chair: Kai Pan, University of Florida, Gainesville, FL, 32611, United States, kpan@ufl.edu

1 - A Novel Matching Formulation for Startup Costs in Unit Commitment

Bernard Knueven, University of Tennessee, 525K.Tickle Building, Knoxville, TN, 37996, United States, bknueven@vols.utk.edu, Jim Ostrowski, Jean-Paul Watson

We present a novel formulation for startup cost computation in unit commitment (UC). Both the proposed formulation and existing formulations in the literature are placed in dominance hierarchy based on their respective linear programming relaxations. The proposed formulation is tested empirically against existing formulations on large-scale unit commitment instances drawn from real-world data. Our proposed formulation is empirically demonstrated to be as tight as a perfect formulation for startup costs. This tightening reduces the computational burden in comparison to existing formulations, especially for UC instances with large variability in net-load due to renewables production.

2 - Data-driven Chance-constrained Stochastic Unit Commitment under Wind Power Uncertainty

Ali Bagheri, Oklahoma State University, 320 E McElroy Road, Apt 508, Stillwater, OK, 74075, United States, ali.bagheri@okstate.edu

Rapid integration of cheap, clean but highly intermittent wind energy into power systems brings challenges to ISOs to maintain the system reliability. Stochastic programs may result in biased and unreliable unit commitment (UC) and economic dispatch (ED) decisions by fixing the probability distribution of wind output. Robust optimization (RO) approaches sacrifice system's cost-effectiveness in exchange of reliable UC and ED schedules. We develop a data-driven chance-constrained stochastic UC model, where the data-driven chance constraint limits the worst-case chance of load imbalance to be no more than a specified tolerance, by taking advantage of historical data.

3 - Optimal Bidding Strategy for Market Participants Considering Both Renewable Generation and Price Uncertainties

Kai Pan, University of Florida, 411 Weil Hall, Gainesville, FL, 32611, United States, kpan@ufl.edu, Yongpei Guan

We present an optimal bidding strategy which is adaptive for the independent power producers to participate in both day-ahead and real-time markets by considering both renewable generation and price uncertainties. This proposed strategy is theoretically justified of its significant advantages over existing alternative ones. To improve the computational efficiency, polyhedral structures have been explored to strengthen the corresponding deterministic equivalent formulation.

4 - Economic Impacts Caused by the Diffusion of Hydrogen Energy

Tetsuya Tamaki, assistant professor, Kyushu University, 744 Motooka, Fukuoka City, 8190395, Japan, tamaki@doc.kyushu-u.ac.jp, Shunsuke Managi

This research focuses on the economic impacts of the diffusion of hydrogen energy, which is an environment-friendly source of energy. Hydrogen energy is expected to reduce CO2 emission from not only the transportation sector but also the energy sector. However, the related technology is still expensive, and the usage and effects of hydrogen energy will change by the difference of the cost. In this research, to estimate the economic impacts caused by the diffusion of hydrogen energy, we use a dynamic optimization model that analyzes the economics related to climate change and also prescribe a policy for the use of hydrogen energy in society.

MAS Special Speaker: Mission-based Forecasting for Military Operations

Sponsored: Military Applications

Sponsored Session

Chair: Greg H Parlier, North Carolina State University, 255 Avian Lane, Madison, AL, 35758, United States, gparlier@knology.net

1 - Mission-based Forecasting for Military Operations

Greg H. Parlier, North Carolina State University, 255 Avian Lane, Madison, AL, 35758, United States, gparlier@knology.net

The US Department of Defense operates the world's most complex global supply chains. To address persisting problems the US Army established the project to Transform Army Supply Chains (TASC) in order to investigate the nature, causes, and consequences of demand uncertainty and supply variability. Mission-Based Forecasting is a new concept for demand planning which relates resource investment levels and distribution policies directly to mission performance outcomes, thereby enabling the "resources-to-readiness" linkage. MBF improves forecast accuracy and reduces backorders, excess inventory, and costly work-arounds while increasing equipment readiness in military organizations.

Mining Text and Graph Data from Online Platforms

Invited: Social Media Analytics

Invited Session

Chair: Theodoros Lappas, Stevens Institute of Technology, 310 10th St, Hoboken, NJ, 07030, United States, tlappas@stevens.edu

1 - Social Connections and Venture Investments

Chuanren Liu, Drexel University, Philadelphia, PA, United States, chuanren.liu@drexel.edu

We present a Social-Adjusted Probabilistic Matrix Factorization (PMF) model to exploit the social relationship information from VC firms and startups for startup investment recommendations. Unlike previous studies, we make use of the directed social connections and quantify the variety of social network groups. As a result, this brings in much more flexibility, and the modeling results inherently provide meaningful managerial implications for the operators of VC firms and start-up companies. We evaluate our model on both synthetic and real-world data. The results show that our approach outperforms the baseline algorithms with a significant margin.

2 - Measuring Reputation Inflation in Online Platforms

Apostolos Filippas, New York University, New York, NY, United States, afilippa@stern.nyu.edu

In many online marketplaces, the distribution of feedback scores seems implausibly rosy. Using data from a large online marketplace, we show that average feedback scores have risen sharply over time, leading to substantial top-censoring. However, the increase in reputation could be either due to more satisfied raters, or raters who are lowering their standards. We employ a text-analytic approach to disentangle the two reasons, and we show that 36 to 48 percent of this increase is due to a phenomenon akin to inflation. We discuss the implications for our results for online marketplace design.

3 - Text-based Industry Classification and Network

Feng Mai, Stevens Institute of Technology, Hoboken, NJ, United States, feng.mai@stevens.edu, Lei Zheng

Traditionally, firms are placed within predefined industry groups using SIC or NAICS codes. These classifications are time-invariant and are not robust to changing primary business activities. We propose and validate a new text-based method that can quantify how firms differ from their competitors and redefine industry boundaries.

4 - Arousal, Hedonism, and Utility in Online Reviews

Jie Ren, Fordham University, New York, NY, United States, jren11@fordham.edu, Jeffrey V. Nickerson

To explain sales, in addition to online review valence and volume, this paper bases its argument on one less-studied hedonic versus utilitarian dimension of product type and also on a less-studied online review dimension - arousal, a measure that is extracted from individual review texts. Using panel data analysis on 26,357 Amazon products and an online experiment involving 600 subjects, the findings consistently show that product type moderates the impact of the three dimensions of online reviews (valence, volume, and arousal) on sales. These findings explain why sometimes online review valence is more influential than volume with respect to sales and why sometimes it is the other way around.

Matching Theory

Invited: Auctions

Invited Session

Chair: Umut Dur, NCSU, Raleigh, NC, 27695, United States, umutdur@gmail.com

1 - Parallel versus Sequential School Admissions: A Tale of Two Countries

Onur Kesten, Associate Professor of Economics, Carnegie Mellon University, 5000 Forbes Avenue, POS.- Posner Hall - Room 249, Pittsburgh, PA, 15213, United States, okesten@andrew.cmu.edu

This paper studies the recent reforms in the student assignment systems in Turkey and Sweden. There are two types of high schools in both countries: public and private schools. Public school admissions are administered in a centralized manner, whereas private school admissions are done in a decentralized manner. In Turkey, starting from 2014, private school assignments are carried out in a first round along with a policy change in the terms re-entry into the second round. We study the performance of old and new sequential assignment systems in both countries and show that alternative solutions that outperform both systems are available.

2 - Matching with Limited Information: A Case for Neighborhood Schools

Peter Troyan, Assistant Professor, University of Virginia, Charlottesville, VA, 22904, United States, pgt8y@virginia.edu, Andrew Kloosterman

Deferred acceptance is a popular school choice mechanism because it is strategyproof and stable. However, this relies on the assumption that all agents know their own preferences. We relax this by allowing agents to be either informed or uninformed. Ex-post stable outcomes need not exist, as uninformed agents may form a blocking pair after learning their match and updating their beliefs. Further, we find that informed agents gain at the expense of uninformed agents, who are more likely to be left with underperforming schools. Positive results can be recovered by giving all students a "neighborhood school": the equilibrium outcome is ex-post stable, and uninformed students are made better off.

3 - Sequential School Choice Theory and Evidence from the Field and Lab

Umut Dur, NCSU, Raleigh, NC, United States, umutdur@gmail.com, Robert Hammond, Thayer Morrill, Onur Kesten

We analyze sequential preference submission in matching problems. Our motivation is school districts that use a website where students submit preferences sequentially. Comparing the Boston Mechanism (BM) to the Deferred Acceptance (DA), we show that sequential BM is more efficient than sequential DA. Any equilibrium outcome under BM Pareto dominates the student optimal stable matching. We present two sets of empirical tests. First, we study a field setting in which sequential BM was used. The field data provide evidence that is consistent with our theory. Second, we conduct an experiment to do comparison in a lab. BM improves upon DA when students submit sequentially but not simultaneously.

4 - On Finding Stable and Efficient Solutions for the Constrained Coalition Formation Problem

Hoda Atef Yekta, PhD Candidate, University of Connecticut, 2100 Hillside Rd,, Storrs, CT, 06869, United States, hoda.atefyekta@business.uconn.edu, David Bergman, Robert Day

This research explores the constrained coalition formation problem with constraints on the size of each coalition and the characteristics of the members of each coalition. We develop a branch-and-cut-and-price (BCP) algorithm to address both minimizing the maximum instability, and maximizing total utility, simultaneously. This problem arises in a variety of real-world settings, including project management, military platooning, and peer-to-peer ride-sharing

Sponsored Session

Chair: Meisam Razaviyayn, Ph.D., University of Southern California, 3715 McClintock Ave, Los Angeles, CA, 90089, United States, razaviya@usc.edu

1 - Stochastic Primal-Dual Methods and Sample Complexity of Markov Decision Processes

Yichen Chen, Graduate Student, Princeton University, 751 Hibben Magie Road, Apt 109, Princeton, NJ, United States, yichenc@princeton.edu

We study the online estimation of the optimal policy of a Markov decision process (MDP). We propose a class of Stochastic Primal-Dual (SPD) methods which exploit the inherent minimax duality of Bellman equations. The SPD methods update a few coordinates of the value and policy estimates as a new state transition is observed. We first consider a basic version of SPD that uses Euclidean projection for both the primal and dual updates. We then propose an accelerated version of SDP that uses relative entropy projection in the dual update. For MDPs that are "sufficiently" ergodic, the improved SPD has a near-optimal sample/running-time complexity.

2 - Nonnegative Polynomials, Nonconvex Polynomial Optimization, and Applications to Learning

Georgina Hall, Princeton University, Charlton Street, Sherrerd Hall, Princeton, NJ, 08544, United States, gh4@princeton.edu

We give a brief overview of the developments in the field of sum of squares optimization and show how it can be applied to two problems at the interface of machine learning and polynomial optimization. In part (i), we study the problem of learning a monotone polynomial from data. This is motivated by regression problems where the underlying function to be learned is monotone (consider the price of a car as a function of its fuel efficiency). In part (ii), we study the problem of optimally decomposing a multivariate polynomials as the difference of two convex polynomials. This is motivated by certain majorization-minimization algorithms used in nonconvex optimization that require such a decomposition.

3 - Learning to Optimize: Training Deep Neural Networks for Wireless Resource Management

Mingyi Hong, University of Virginia, 3019 Black Engineering Building, IMSE Department, Ames, IA, 50011, United States, mingyi@iastate.edu

We propose a new learning-based approach for wireless resource management. The idea is to treat the input and output of a resource allocation algorithm as an unknown non-linear mapping and use a deep neural network (DNN) to approximate it. If the non-linear mapping can be learned accurately and effectively by a DNN of moderate size, then such DNN can be used for resource allocation in almost real time, since passing the input through a DNN to get the output only requires a small number of simple operations. We first characterize a class of 'learnable algorithms' then design DNNs to approximate some algorithms of interest in wireless communications. We use extensive numerical simulations to demonstrate the superior ability of DNNs for approximating two considerably complex algorithms that are designed for power allocation in wireless transmit signal design.

4 - From Predictive Methods to Missing Data Imputation: An Optimization Approach

Colin F. Pawlowski, Massachusetts Institute of Technology, Cambridge, MA, 02143, United States, cpawlows@mit.edu, Dimitris Bertsimas, Ying Zhuo

We propose a framework based on optimization to impute missing data which can readily incorporate predictive models including K-NN, SVM, and decision tree based methods. We derive a family of fast first-order methods opt.impute that obtains high quality solutions in seconds for data sets with 100,000s of missing values. In large-scale synthetic and real data experiments, opt.impute produces the best overall imputation in almost 80% of all data sets benchmarked against state-of-the-art methods. We also discuss extensions to explicitly account for multi-class categorical variables.

1 - How to Make a Persuasive Pitch: An Extended Text-mining Model for Crowdfunding Analysis

Sukhwa Hong, Virginia Tech, Pamplin College of Business, 880 West Campus Drive, Blacksburg, VA, 24061, United States, sukhwa@vt.edu, David Michael Goldberg, Onur Seref, Christopher Zobel

Crowdfunding is a new funding source and growing in popularity, providing a vital service to individuals especially in developing countries, who could not otherwise get the financial resources they need. Understanding factors that determine the funders' decisions is important in writing persuasive crowdfunding pitches for successful projects. In this paper, we present an integrated text-mining model that combines the Bag-of-Words model and related variables for predicting the success of crowdfunding projects in Kiva. Furthermore, association rule mining is used to identify factors that influence the funders' decisions for writing persuasive crowdfunding pitches for successful projects.

3 - Temporal Effects, Opinion Extremity, and Information Quality in Online Word of Mouth

David Michael Goldberg, Virginia Tech, Blacksburg, VA, 24061, United States, goldberg@vt.edu

Online text frequently describes increasingly extreme opinions over time as additional contributors seek to differentiate their opinions from the crowd. We examine how information quality is affected by this phenomenon, as these extreme viewpoints may not reflect the general consensus.

4 - Impact of Health Social Media on the Health State of Patients with Chronic Illness

Zachary Davis, Virginia Tech, 1007 Pamplin Hall, Blacksburg, VA, 24061, United States, zached1@vt.edu, Qianzhou Du, Alan Gang Wang, Christopher Zobel, Lara Z Khansa

Online health communities are utilized by a vast number of people with limited objective evidence regarding the impact on their actual health state. We examine an online health community consisting of members managing a chronic illness and empirically analyze objective and fully observable data regarding their health state to determine if participation and the giving and receiving of social support has an impact on the overall health state. Our novel contribution is the identification of the observable measure of the health state and our preliminary findings indicate that the use of health social media has a positive impact on the health state.

1 - Online vs. Offline: A Structural Estimation of Consumer Purchase Behavior

Luna Zhang, PhD, Lehigh University, College of Business and Economics, xiz313@lehigh.edu, Daisy Dai, Oliver Yao

Using large-scale POS datasets, we develop a structural model and estimate the demand for consumer packaged goods in both online and offline channels. Based on our structural model estimates, we conduct counterfactual analyses and examine consumer purchase behavior between the focal product and substitute products when the price changes and stockout occurs. We find that: 1) online own-price elasticity is 1.41 times higher than offline own-price elasticity 2) offline cross brand cross-price elasticity is 2.49 times higher than that online; 3) offline consumers are 3.96 times more likely to purchase substitute brands when the focal brand is out-of-stock as compared with online consumers.

2 - Enterprise Information Systems and Value Creation in Mergers and Acquisitions

Chengxin Cao, PhD, Iowa State University, caoxx161@umn.edu

This paper examines the impact of enterprise systems (ES) on the premium and the capital market reaction of mergers and acquisitions (M&A). Our results that the extensiveness and standardization of ES are significantly associated with both market value enhancement of the acquirer and target highlights the important role information systems play in the creation as well as the deployment of firm resources and capabilities that deliver competitive advantages to firms. Also, the ES capability enables the acquirers to accurately assess the unique synergy that can be realized in the acquisition, thus preventing the acquirer from overpaying for the acquisition.

3 - Tempting Fate: Social Media Posts by Firms, Customer Purchases, and the Loss ofFollowers

Shuting (Ada) Wang, Temple University, Philadelphia, PA, United States, tuf49919@temple.edu, Brad Greenwood, Paul A. Pavlou

In this study, we examine how a firm's social media posts influence the propensity of its followers to purchase products and unfollow the firm, both in the short and the long term. Using a unique dataset from a fashion retailer, we find that while social media posts do increase the retailer's sales by 5% in the short-term, they also amplify the followers' propensity to unfollow the firm by 300%. Strikingly, results also indicate that posts cannibalize long-term cumulative sales. The negative effects of posts on unfollowing and sales are exacerbated in more crowded cities and during peak traffic hours. The study contributes to the emerging IS literature on social media and informs managerial practice on how to leverage social media posts for enhancing sales and preventing the loss of followers.

4 - Empirical Analysis on Online Job Reviews, Social Media Usage and Firm Performance

Fujie Jin, Kelley School of Business, Indiana University, 1309 E.Tenth Street, H H.4100, Bloomington, IN, 47401, United States, jinf@indiana.edu

In this study, we look at how employee-contributed job reviews and firm-managed social media posts jointly build up "employer brand" as an intangible asset and influence market valuation. Using a unique dataset combining job reviews, social media posts and firm performance data, we find that positive job reviews increase firm market value, particularly in labor-intensive industries, and for positions with higher employee mobility. In addition, firms can complement this effect by including more employee-related content on their social media pages. This is likely because different sources of information could jointly influence employees' job movement decisions, and firms with stronger employer brands are likely to retain key employees for longer periods of time and save costs in recruiting. Overall, our results indicate that firms should have coordinated strategies across platforms, presenting a consistent employer brand, to maximize their market valuation.

1 - Optimal Ordering Policy for Defective Items under Temporary Price Discount with Inspection Errors and Investment to Increase the Screening Rate

Guiyang Zhu, Xi'an Jiaotong University, 28 Xianning West Road, Xi'an, China, zhuguiyang@stu.xjtu.edu.cn, Tao Jia

When a supplier offers temporary price discount for defective items, the demand would be stimulated, implying that the items screened as good may not satisfy the increased demand. Besides, the retailer's inspection errors are often considered in the quality checking process. A straightforward solution is to increase the screening rate through investments. Thus, this paper studies an inventory model for defective items under temporary price discount with inspection errors. The three profit functions are derived to find optimal solutions. Via sensitivity analyses, a high defective probability would spur the system to invest more intensively into improving the quality checking process.

2 - Coordination of the Supply Chain with Quality Improvement and Customer Returns

Xinghao Yan, Assistant Professor, University of Toledo, 105 Howald Farm Ct., Toledo, OH, 43551, United States, yanxinghao@gmail.com

This paper studies the supply chain with both quality improvement and customer returns. We analyze the retailer's incentives for refund price and the supplier's incentive for quality improvement. We also design coordinating contracts for the supply chain, which is influenced by several factors, profit negotiation, first-mover right, and information asymmetry.

3 - Information Sharing in Supply Chain of Durable Goods

Neda Khanjari, Rutgers University, 227 Penn St, BSB 260, Camden, NJ, 08102, United States, neda.khanjari@rutgers.edu, Hyoduk Shin, Seyed Iravani

We study a supply chain of a durable good product in which the retailer has advance demand information. We study how the policy of the retailer to share his information with the manufacturer depends on durability of the product. We show the retailer should share his information with the manufacturer when (i) the production cost is large and product is not very durable, or (ii) when the production cost is small and the product is very durable, or (iii) the production cost is intermediate and the durability of the product is intermediate.

4 - The Role of Market Evolution in Channel Contracting

Long Gao, University of California-Riverside, 900 University Avenue, 221 Anderson Hall, AGSM, Riverside, CA, 92521, United States, long.gao@ucr.edu

We study the contracting problem in a bilateral channel where the retailer has private information about evolving market conditions. We show market inertia offers a new coordination mechanism that dictates how the channel should adapt. Further, market inertia highlights the reach and limitation of existing models. We reveal that the dynamics by themselves do not preclude simple contracts; it is the nature of the dynamics—-market inertia—-that determines the contract complexity. Hence, simple contracts can arise as firms' best response to evolving market conditions. This work advances our understanding on when and how to use dynamic private information in channel contracting.

5 - Comparing Uniform and Differential Pricing Strategies in Multichannel Retailing

Jinpeng Xu, Xidian University, Xi'an, 710126, China, jinpxu@foxmail.com, Yufei Huang

We consider a retailer sells a product in both online and offline channels and his rival only operates in only online channel, and investigate his pricing strategy. We suppose consumers can be divided into three types by their channel performance, i.e., offline consumers, online consumers and channel-agnostic consumers. We derive the equilibrium prices for the two retailers when the retailer adopts uniform and differential pricing strategy across channels respectively. We compare the profits and find that differential pricing strategy does not always outperform uniform pricing strategy for the retailer. We also evaluate the consumer surplus and social welfare to derive managerial insights.

1 - Performance Based Contingency Fuel Planning

Luis Mesen, United Airlines, Chicago, IL, United States, luis.mesen@gmail.com

With the FAA's revision to OpSpec B343, performance-based contingency fuel planning is now available to US operators. This revision is meant to harmonize with ICAO Annex 6, Part 1 and take advantage of air carriers' considerable investment in fuel-planning technology. Unplanned contingency fuel can now be calculated using statistical estimation rather than using a prescriptive amount. This presentation will walk through some of the statistical, modeling, automation and validation techniques UAL used to become the first U.S. airline to fly under PBCF flight rules.

2 - Hackathons as a Vehicle for High Velocity Collaboration Between Engineers and Data Scientists

Ehsan Nobakht, Boeing Vancouver, Advanced Analytics Group, 1146 Homer Street, Vancouver, BC, V6B 2X6, Canada, ehsan.nobakht@boeing.com, Dawen Nozdryn-Plotnicki

Because of the vast amount of information captured by the CMC, specialized data science tools and techniques are required to work efficiently with the data. Additionally, the complex nature of modern aircraft like the C-17 requires specialized systems knowledge in order to interpret and find meaningful insights in the data. As these two skillsets are rarely possessed by the same person, it becomes imperative to create a forum that allows data scientists and systems engineers to work together when tackling big data problems.This presentation will focus on best practices for hosting concentrated working sessions, referred to as hackathons, as a means of bringing data scientists and systems engineers together.

3 - An Unpaired Pickup and Delivery Problem with Time-Dependent Assignment Costs

Farshid Azadian, Embry-Riddle University, 600 S Clyde Morris Blvd., College of Business, Daytona Beach, FL, 32114, United States, azadianf@erau.edu, Alper E. Murat, Ratna Babu Chinnam

This study considers a freight forwarder's operational implementation of alternative access airport policy in a multi-airport region for cargo transportation. Given a set of heterogeneous air cargo customers, the forwarder's problem is to simultaneously select air cargo flight itineraries and schedule the pickup and delivery of customer loads to the airport(s). This problem is formulated as a novel pickup and delivery problem, where the delivery cost is both destination and time dependent. A mixed-integer linear model in presented and an efficient solution method based on decomposition is developed. The performance of the solution algorithm is evaluated by computational experimental study.

4 - A Comprehensive Approach to Understanding the Future of Air France KLM's CDG Hub

Richard Solene, Air France/KLM, Paris, France, na/nasorichard2@airfrance.fr

Scheduling and Operations have always been fighting over the hub. Should the hub be peaked in banks of activity to improve the intrinsic connectivity of the network and its attractiveness, at the risk of driving up the costs of operations? Or should we flatten the hub activity to lower the costs of operations, while reducing connectivity opportunities for passengers in the meantime? With state-of-the-art machine learning and operations research techniques, we were able to develop a comprehensive two-sided tool, one side for computing the potential revenue of flight schedules, and one side for estimating their total cost of operations. Best practices and recommendations emerging from this tool helps Air France KLM in the building of the perfect schedule.

1 - A Decision Model to Examine the Impact of Flexibility and Agility on Mitigating Supply Chain Disruptions

Mansoor Shekarian, Graduate Student, North Carolina A&T.State University, 3100 N Elm St., Apt #22L, Greensboro, NC, 27408, United States, mshekarian@aggies.ncat.edu, Mahour Parast, Seyed Vahid Reza Nooraie

This paper examines the effect of flexibility and agility on improving supply chain responsiveness. We examine a multi-site, multi-period, multi-transportation channel, and multi-product planning in a supply chain under supply risk and demand risk. We determine the relationship between three objective functions related to responsiveness, risk, and cost, and discuss the impact of agility and flexibility on mitigating supply chain disruptions.

2 - Disruption Risk Management for Two-echelon Supply Chains: Early Commitment to Finished Goods

Florian Lücker, Kellogg School of Management, Evanston, IL, United States, florian.lucker@kellogg.northwestern.edu
Florian Lücker, Swiss Federal Institute of Technology EPFL, Lausanne, Switzerland, florian.lucker@kellogg.northwestern.edu, Sunil Chopra, Ralf W. Seifert

We consider the two-echelon inventory problem for different supply chain topologies (serial, assembly and distribution) in the presence of disruption risk and stochastic demand. For the assembly supply chain we show that in the presence of disruption risk downstream inventory is larger in the assembly supply chain compared to a serial supply chain. We call this effect early commitment as the finding is different from optimal safety inventory policies in assembly supply chains where often a delayed differentiation is optimal. In addition, we elaborate on when early commitment occurs in distribution supply chains.

3 - Differences in the Way Inventory and Reserve Capacity are Used to Deal with Supply Disruption Risk in Two-echelon Supply Chains

Florian Lücker, Kellogg School of Management, Evanston, IL, United States, florian.lucker@kellogg.northwestern.edu
Florian Lücker, Swiss Federal Institute of Technology EPFL, Lausanne, Switzerland, florian.lucker@kellogg.northwestern.edu

This research focuses on managing supply chain disruption risks using inventory and reserve capacity in a two-echelon supply chain under stochastic demand. We show that in assembly supply chains optimal reserve capacities are higher upstream whereas optimal inventory levels are lower downstream relative to a comparable serial supply chain. We further illustrate differences in the use of reserve capacity versus inventory held to deal with supply disruption risk.

4 - Integrated Supply Chain Design and Planning: A Risk Management Perspective

Nasim Nezamoddini, State University of New York-Binghamton, 222 Main Street, Apt 1, Binghamton, NY, 13905, United States, nasim.nezam@gmail.com

This research proposes an optimization framework to manage internal and external risks during strategic, tactical, and operational level decisions. The proposed model addresses uncertainties associated with demands, disruptions, delays, and failures. The structural design and communications plans between different centers are determined based on the risk perspective of the decision maker. A modified genetic algorithm is designed to solve the model. The experimental results show that increasing the backup paths and capacities makes the supply chain more robust against the potential risks.

5 - Cash to Cash and the Zone of Concern

Joyaditya Laik, University of Pittsburgh, 241 Mervis Hall, Katz Business School, University of Pittsburgh, Pittsburgh, PA, 15260, United States, joyaditya.laik@pitt.edu, Prakash Mirchandani

A firm which refers Cash Conversion Cycle (C2C) as a test of operational efficiency, might embark upon improvement projects which require costly investments. We contend that such steps may be uncalled for, since what is 'inferior' to a benchmark value, may really be an unfavorable fiscal cycle or seasonality in comparison to the benchmark firm. The effect of such idiosyncrasies limit the vision of firms to a 'zone of concern' which is a subset of the period of financial reconciliation, thereby rendering the firm's actions myopic. We propose that use of C2C without 'relevant' business context may be precarious which managers must be observant of.

5 - Development of a Logistics Risk Assessment Tool

Ryan Sanders, University of Arkansas, 2550 Sunset Ridge, Cave City, AR, 72521, United States, rpsander@uark.edu

This research aims to better understand what risks are present along each point in the supply chain and to develop a way to assess those risks. By organizing findings from literature and implementing an online risk assessment tool, we hope to allow organizations to identify and quantify risks along their supply chains. This user-friendly, web-based risk assessment tool is two-fold; a gap analysis will indicate which specific area of the supply chain a company should focus on improving, and a multi-objective decision analysis will quantify the benefit of different practices a company could use.

Best Service Science Cluster Award Paper Competition #II of II

Sponsored: Service Science

Sponsored Session

Chair: Robin Qiu, Pennsylvania State University, Malvern, PA, 19355, United States, robinqiu@psu.edu

1 - An Instrumental Variable Tree Approach for Detecting Heterogeneous Treatment Effects in Observational Studies

Guihua Wang, University of Michigan, 1169 McIntyre Drive, Ann Arbor, MI, 48105, United States, guihuaw@umich.edu, Jun Li, Wallace Hopp

We develop a new Instrumental Variable (IV) tree approach for detecting heterogeneous treatment effects in observational studies. We show that the IV tree approach effectively corrects for endogeneity issues and partitions subjects into groups such that those in the same group have similar treatment effects and those in different groups have different treatment effects. We demonstrate the practical application of the IV tree approach by using colectomy as the clinical setting to compare teaching (treatment) and non-teaching (control) hospitals and find that the outcome differences between teaching and non-teaching hospitals are heterogeneous across patient types.

2 - A Data-Driven Approach to Personalized Bundle Pricing and Recommendation

Anna M. Papush, Massachusetts Institute of Technology-ORC, Somerville, MA, 02143, United States, apapush@mit.edu, Georgia Perakis, Pavithra Harsha

The growing trend in online shopping has sparked the development of increasingly more sophisticated product recommendation systems. We construct a model that recommends a personalized discounted product bundle to a shopper that considers the trade-off between profit maximization and inventory management, while selecting relevant products to the consumer's preferences. We develop two classes of approximation algorithms to produce output in real-time. We provide analytical performance guarantees and implement our algorithms on data from a large U.S. e-tailer and a premier global airline. Our results show significant lifts in expected revenue over current practices on the order of 2-7%.

3 - Coopetition and Profit Sharing for Ride-sharing Platforms

Renyu Zhang, New York University Shanghai, Shanghai, China, renyu.zhang@nyu.edu, Maxine Cohen

The recent introduction of on-demand ride-hailing and ride-sharing platforms totally changed the way people commute. We consider a setting in which two competing platforms engage in a profit sharing contract by introducing a new hybrid service. We model the price competition between the platforms by using the Multinomial Logit model, and show that a unique equilibrium exists. Then, we analyze the impact of introducing the new joint service to the market. Interestingly, we show that a well-designed profit sharing contract benefits every single party (riders, drivers and both platforms).

Border Security, Risk Management and Resilience for Global Supply Chains

Sponsored: Service Science

Sponsored Session

Chair: Eleftherios T. Lakovou, Texas A&M Engineering Experiment Station, Texas A&M Engineering Experiment Station, College Station, TX, 77840, United States, eiakovou@tamu.edu

1 - Evaluating a Wicked Problem: A Conceptual Framework on Seaport Resiliency

Amir Gharehgozli, Texas A.& M.University, P.O. Box 1675, Galveston, TX, 77553, United States, gharehga@tamug.edu

Seaport infrastructure by virtue of its location can be severely impacted from disruptive adverse weather events. Disruptive adverse events range from long-term changes such as sea level rise caused by climate change to short-term impacts such as hurricanes. This paper proposes a new conceptual framework for evaluating how ports currently strategize against the risks associated with these potential events and how they plan to ensure port resiliency.

2 - Information Dashboards for Enabling Business Continuity and Risk Management

Jim Wall, Texas A&M.University, TEES.Headquarters, 3470 TAMU, College Station, TX, 77843-3577, United States, jim-wall@tamu.edu, Keith Biggers

Decision makers routinely need quick access to dependable and relevant data to adequately assess risk to inform necessary decision making processes. We provide an overview of ongoing research and development of a technology platform for enhancing situational awareness and decision support including the implications for training. This platform allows for visual integration of disparate real-world data streams into a common user-defined operational picture. Data sources can include databases, sensors, and results from simulations. We will illustrate how this platform can support business continuity, logistics, and risk and consequence management across a range of real-world applications.

3 - A Game Theory-based Strategic Framework for Border Security Control and Risk Management for Protecting Globalized Supply Chains Against Illicit Use

Yanling Chang, Texas A&M.University, 1550 Crescent Pointe Pkwy, APT.1206, College Station, TX, 77845, United States, yanling.chang@tamu.edu, Eleftherios Iakovou, Jim Wall, Keith Biggers

Adversaries often utilize global supply chains as targeted delivery platforms by transporting illegal or unauthorized goods into the U.S. Such breaches may result in negative economic ramifications for all supply chain stakeholders or for launching a terrorist attack. This research aims to develop a novel, dynamic, quantitative strategic framework based on game theory to capture and understand the supply chain risk imposed by such adversaries for ensuring border security along with business continuity and supply chain resilience, while further securing the four flows of supply chains - products, process/work, information, and cash across the border.

Analytic Network Process (ANP) Best Practices

Sponsored: Multiple Criteria Decision Making

Sponsored Session

Chair: Orrin Cooper, University of Memphis, Memphis, TN, 38152, United States, olcooper@memphis.edu

1 - Implications of Coherency: A Literature Review

Orrin Cooper, University of Memphis, 332 Ba, Memphis, TN, 38152, United States, olcooper@memphis.edu, Enrique Mu, Michael Peasley

Coherency is an important test to run when creating ANP models. This claim is further motivated by reviewing all ANP publications from 2015 in the SSCI Index. Summary data of the publications' coherency levels and impacts on the final results when attempts were made to improve coherency are presented. These results provide additional motivation for Coherency testing. Simulations results are presented to generalize the effect incoherency can have on the results of an ANP model.

2 - After 25 Years ANP Best Practices

Enrique Mu, Carlow University, 3333 Fifth Avenue, Pittsburgh, PA, 15213, United States, emu@carlow.edu

The rule of thumb for scientific reports has been to provide enough information so the study can be understood, assessed its methodological validity and -given access to the proper dataset- to allow its replication. We have reviewed SSCI-indexed ANP studies published during 2015 and found that most of them are inconsistent in terms of what they report. While there are currently no specific rules about how to report ANP studies, we propose here some guidelines -to our knowledge, for the first time- to properly report them.

3 - Does a Shared-decision Making Model for Colorectal Cancer Screening Lead to Better Medical Outcome?

M. Gabriela Sava, College of Business, Clemson University, Clemson, SC, United States, msava@clemson.edu, Luis G. Vargas, Jerrold H. May, James G. Dolan

Choosing the most appropriate colorectal cancer screening option should be a joint decision, made by both the patient and the healthcare provider. We propose a multi-criteria decision making model that combines the patient's preferences regarding the currently available cancer screening options with the healthcare provider's expertise. The most preferred option is further analyzed, to assess its sensitivity and stability as additional medical information might be brought into the discussion.

Contributed Session

Chair: Xueping Li, University of Tennessee, 1350 Pershing Hill Lane, Knoxville, TN, 37919-0700, United States, xueping.li@gmail.com

1 - Understanding Treatment Strategies of Sepsis using a Decision Framework

Zhenzhen Shi, Post Doctoral Fellow, Kansas State University, P200 Mosier Hall, Manhattan, KS, 66506, United States, szztracy@ksu.edu, David Ben-Arieh, John C.Wu, Majid Jaberi-Douraki

Strategies for sepsis treatment have been discussed extensively in recent years, but no general agreement exists regarding efficacy of these strategies. This lack of consensus is due to the complex nature of what causes sepsis to progress, including heterogeneous groups of patients with infections caused by various microorganisms. Based on our computational-based decision framework, we found out the efficacy of treatment strategies is dependent on various parameters including the type of treatment, the time of treatment administration, the amount of treatment implementation, and the various groups of individuals.

2 - Doctors Performance in Emergency Room

Amir Mousavi, George Washington University, 475 K.St NW, Apt 419, Washington, DC, 20001, United States, ahmn00@gmail.com, Hernand Abeledo, Imad Khojah

Emergency Rooms are known as a fast paced and extremely vital ward in a hospital. Improving the efficiency in the ER has been a challenging question for researchers. Throughout the academic literature, people have defined different efficiency indexes and different decision variables in order to tackle this problem. This research aims to apply DEA techniques in order to identify the performance (i.e. productivity) variation among doctors and use this result as a component of the optimization model in order to improve the efficiency of the system.

3 - Predictive Modeling for Toxicities in Head and Neck Cancer Patients

Wei Jiang, Research Assistant, Department of Civil Engineering, Johns Hopkins University, Latrobe Hall, 3400 N. Charles Street, Baltimore, MD, 21218, United States, wjiang16@jhu.edu, Pranav Lakshminarayanan, Zhi Cheng, Xuan Hui, Sauleh Ahmad Siddiqui, Ilya Shpitser, Russell H. Taylor, Todd McNutt

Head and neck cancer patients experience acute and long-term toxicities such as weight loss, dysphagia, and xerostomia due to radiotherapy. Oncospace is a learning health system developed at Johns Hopkins University that is accumulating a large volume of patients' treatment data (imaging and radiation dose distributions) and clinical data (toxicities and demographic data). We build a machine learning model to predict head and neck cancer patients' toxicities and investigate the influence of the radiation dose distribution in specific organs. The goal is to better understand where we can improve our delivery of radiation to reduce toxicity while maintaining adequate treatment of cancer.

4 - Studying Length of Stay and Early Readmissions in General Surgery Service Line: A Data Analysis Approach

Wareef Al Najjar, Binghamton University, Binghamton, NY, United States, walnajj1@binghamton.edu, Khalid Aram

Patient Length of Stay (LOS) and hospital readmissions should be given attention by healthcare organizations. LOS and readmission rates have been used to measure efficiency and effectiveness of care respectively. In this study, we focus on LOS in general surgery service line and its association to readmissions and other factors in a hospital in middle Georgia. First, we identified Diagnosis-Related Groups that have major contribution to average LOS based on some factors. Then we applied data analysis techniques and built a predictive model which will predict readmission cases earlier in their stay, to help in providing early interventions to avoid readmissions, while shortening their stay.

5 - A Least Squares Monte Carlo Approach to Appointment Scheduling under Patient Cancellation and No-show Behavior

Jason Xiaotian Dou, PhD Student, University of Colorado Boulder, 995 Regent Dr, Boulder, CO, 80302, United States, xido4892@colorado.edu, Manuel Laguna, Dan Zhang

Patient cancellation and no-show behavior is a major challenge in appointment scheduling. A stochastic dynamic programming model for appointment scheduling is introduced. We develop a least squares Monte Carlo approach to tackle the problem and show promising performance via extensive numerical experiments.

1 - Outcome-Driven Personalized Treatment Design for Managing Diabetes

Eva Lee, Georgia Tech, Industrial & Systems Engineering, Ctr for Operations Research in Medicine, Atlanta, GA, 30332-0205, United States, evakylee@isye.gatech.edu

This work is joint with Grady Health Systems and Morehouse School of Medicine. We present a drug-effect-based personalized approach to improve treatment outcome for diabetic patients. First, a pharmacokinetic and pharmacodynamics (PK/PD) model is established to uncover drug effect based on analysis of anti-diabetic drug dosage and the blood glucose level recorded in the titration period of each patient. This personalized evidence is then utilized within a treatment plan model that optimizes the glycemic control and drug dosage. The optimized plans provide better glycemic control while using less drug.

2 - Dispatch Optimization in Bulk Tanker Transport Operations

Ted L.Gifford, Schneider National Incorporated, PO Box 2545, Green Bay, WI, 54306-2545, United States, giffordt@schneider.com, Tracy Opicka, Ashesh Sinha, Daniel Vanden Brink, Andy Gifford, Robert Randall

All modes of freight transportation are subject to flow imbalances that impact the efficiency of asset utilization. The use of Mathematical Programming optimization models has a rich history of application to this problem. We address a particularly difficult variant of this problem that occurs in bulk chemicals transport. This difficulty is created by a large volume of activity, requiring 1,000 tractors and 1,600 tankers, coupled with complex product-sequencing constraints, tanker wash and preparation processes, and driver work rule constraints. To address this problem the engineering group at Schneider has designed and implemented a multi-phase, multi-dimensional matching algorithm and associated software system that enables business planners to leverage optimized solution recommendations.

1 - Modeling Kidney Transplantation Decisions: Optimal Regulatory Oversight

Zahra Gharibi, SMU, Bobby B. Lyle School of Engineering, Dallas, TX, 75205, United States, zgharibi@smu.edu, Michael Hahsler, Mehmet Ayvaci

Regulatory oversight with report card programs are designed to evaluate transplant centers' performance, but it is controversial whether behavioral responses to such programs improve patient outcomes. I propose a stochastic model that determines the socially optimal kidney transplant decision and calculates social loss under no oversight. I introduce a game theoretical solution to derive optimal regulatory oversight implemented as a citation policy which minimizes social loss.

2 - The Interaction of Outbreaks and the Healthcare System: Closing the Feedback Loops for Disease Modeling

Craig Bakker, Pacific Northwest National Laboratory, 902 Battelle Blvd, Richland, WA, 99352, United States, craig.bakker@pnnl.gov, Matthew Robert Oster, Brent Daniel, Romarie Morales Rosado, Tim McPherson

Healthcare services affect and are affected by disease outbreaks. We have developed a disease model that incorporates the public health system and explicitly considers the two-way interaction between that system and the disease. Here, we model the baseline spread of an outbreak along with the potential impact of the outbreak on the public health workforce. We then explore the potential impacts of various treatment options, resource constraints, and interruptions on the outbreak's evolution. Finally, we discuss healthcare supply chain issues and how to incorporate them into our model.

3 - A Machine Learning Approach to Personalization from Observational Data

Nishanth Mundru, Massachusetts Institute of Technology, Operations Research Center, E40, Cambridge, MA, 02139, United States, nmundru@mit.edu, Dimitris Bertsimas

We consider the problem of assigning the best treatment option out of a finite number of choices to a patient/user depending on his/her observed features. Given historical observational data of patients which consists of their features, assigned treatments and their corresponding outcomes, we learn the optimal treatment policy for each patient in an offline setting. Using an optimization and machine learning approach, we demonstrate that our method outperforms the commonly used regress-and-compare methods on real data sets.

Additive Manufacturing - Data Analytics and OR II

Invited: Advanced Manufacturing

Invited Session

Chair: Alaa Elwany, Texas A&M University, Engineering, College Station, TX, 77843, United States, elwany@tamu.edu

1 - Locating AM Hubs in the United States via Hybrid Manufacturing

Guha Manogharan, Pennsylvania State University, University Park, PA, United States, gum53@engr.psu.edu, Michael G.Kay

The ever-growing applications of Additive Manufacturing (AM) in the production of low volume- high value metal parts can be attributed to improved AM processing capabilities and complex design freedom. However, secondary post-processing using traditional processes such as machining, grinding, heat treatment and hot isostatic pressing, i.e. Hybrid Manufacturing is required to achieve Geometric Dimensioning and Tolerancing (GD&T), surface finish and desired mechanical properties. It is often challenging for most traditional manufacturers to participate in the rapidly evolving supply chain of direct digital manufacturing (DDM) through in-house investments in cost prohibitive metal AM. This research investigates a system of strategically-located AM hubs which can integrate hybrid-AM with the capabilities and excess capacity in multiple traditional manufacturing facilities. Using North American Industry Classification System (NAICS) data for machine shops in the US, an uncapacitated facility location model is used to determine the optimal locations for AM hub centers based on: (1) geographical data, (2) demand, and (3) cost of hybrid-AM processing. Results from this study have identified: (a) candidate US counties to build AM hubs, (b) total cost (fixed, operational and transportation) and (c) capacity utilization. It was found that uncapacitated facility location models identified demand centroid as the optimal location and was affected only by AM utilization rate. The constrained p-Median model has identified 22 AM hub locations as initial sites for

AM hubs which grows to 44 AM hubs as demand increases. It was also found that transportation cost was not a significant factor in the hybrid-AM supply chain. Findings from this study will help both AM companies and traditional manufacturers to determine establishing and growing metal hybrid-AM supply chain.

2 - Random Planar Graphs to Quantify the Evolution of Surface Topography During Polishing Operations

Ashif S.Iquebal, Texas A&M.University, 3120 Texas A&M.University, Apt 1002, College Station, TX, 77843, United States, ashif_22@tamu.edu

We present a random planar graph representation to model the topography of the surface where the nodes represent the individual asperities, and the edges represent the propensity of the neighboring asperities to form a bridge. We provide theoretical bounds on spectral quantifiers of the graphs by invoking the packing density of hard spheres, that connote the various stages, including the end, of polishing.

3 - Process Control for Quality in Custom Additive Manufacturing

Neil Diaz, Texas A&M.University, College Station, TX, United States, nodiaz@tamu.edu, Jin Xu, Harshit Chawla, Satish Bukkapatnam, Natarajan Gautam

While additive manufacturing is a promising approach for customized products, because of variability each product could have different parameters. Thus to avoid defects which further increase the already long production times, we explore adaptive control strategies to set parameters on the fly using sensor-based measurements. To that end, we develop stochastic control methods with the objective of minimizing the expected cycle times.

4 - Multivariate Calibration of Computer Simulation Models for Additive Manufacturing

Alaa Elwany, Texas A&M.University, College Station, TX, United States, elwany@tamu.edu, Mohamad Mahmoudi, Gustavo Tapia, Brian Franco, Ji Ma, Ibrahim Karaman, Raymundo Arroyave

Computer simulation models are widely used to predict various additive manufacturing (AM) processes. Simulating the melt pool particularly for metal AM processes is the key step for understanding the microstructure and properties of the parts. We present a two-stage Bayesian approach to conduct multivariate calibration of simulation model parameters such that the predictions agree with experimental measurements. First, multivariate Gaussian processes are used to construct a surrogate of the original simulation model. Next, experimental measurements are obtained using a commercial AM machine and titanium alloy powder to compute the posterior distributions of the calibration parameters.

Chair: Sung Hoon Chung, Binghamton University, Binghamton, NY, 13902, United States, schung@binghamton.edu

1 - An Algorithm for Efficient Evacuation Planning in Congested Multi-class Time-expanded Networks

Changhyup Oh, POSTECH, Pohang, 37673, Korea, Republic of, changhyup.oh@postech.ac.kr, Min Hee Kim, Byung-In Kim, Jang Won Choi, Young Myung Ko

In this study, we present an efficient heuristic algorithm that generates an evacuation plan close to the optimal one in time-expanded multi-class networks. The proposed algorithm significantly reduces computational time compared with other approaches based on mixed integer programming (MIP) models. We construct several networks from real world data including a multiplex cinema and a subway station as well as a generated network for intuition. Numerical results show that the proposed algorithm produces high quality evacuation plans with short computational time and is scalable in terms of population and network size.

2 - Drone Assisted Last Mile Delivery for Disaster Relief Operations

Jinkun Lee, Binghamton University, Binghamton, NY, United States, jinlee@binghamton.edu, Sung Hoon Chung, Duaa Serhan, Sang Won Yoon

We consider the use of unmanned aerial vehicles, also known as drones, as an assistant to conventional vehicle routing for disaster relief operations. The advantage can be summarized in two folds: 1) faster delivery of critical supplies and 2) expanded delivery areas. A mixed integer programming problem is formulated and multiple objectives, such as minimizing population-weighted arrival times, minimizing total traveling times, and minimizing the latest arrival time, are considered. As the model gets much more complicated, a hybrid heuristic method, utilizing adaptive neighborhood search, insertion algorithm, and tabu search, is proposed. We present case study examples.

3 - Mobile Pharmacies for Reducing Supply Chain Inequities in Low Resource Settings

Biplab Bhattacharya, University at Buffalo, 82 Springville Ave, Amherst, NY, 14226, United States, biplabsu@buffalo.edu, Rajan Batta, Li Lin

Needs of medical drug supplies are not sufficiently addressed by an equal distribution approach. Equity, different from equality, provides a realistic perspective to identify medical drug demand. A measure is developed that incorporates factors affecting inequity. A mobile-pharmacy location-tour model uses that inequity measure as a criterion to choose communities to serve. The model formulation consists of two parts; the first part involves location selection and frequency determination; the second part is a tour based integer programming formulation. Lastly, a modified Gini coefficient that takes into account demand is used to observe changes in inequity.

4 - Values-based Performance Measures in Humanitarian Relief

Michael Veatch, Gordon College, Wenham, MA, 01984, United States, mike.veatch@gordon.edu

Models and assessments of humanitarian relief efforts need to incorporate additional factors, beyond quantity or cost of relief delivered, in performance measures. These factors include humanitarian principles, specific values of faith-based organizations, donor priorities, and fundraising considerations. We review some performance measures that have been proposed and report on our efforts to construct empirically-based performance measures for disaster response that incorporate values of the organization.

Chair: Yifei Luo, University of Science and Technology of China, Hefei,Anhui, China, ustclyf@foxmail.com

1 - Buyer-induced and Seller-induced Learning when Product Quality is Uncertain

Lu Zhang, School of Management, University of Science and Technology of China, Hefei, China, zlu@mail.ustc.edu.cn, Chuanyong Xu, Yong Zha

As product uncertainty can be reduced by consumer learning in different ways, we investigate the impact of learning mechanisms on seller's pricing decisions. We build a two-period pricing model to explore buyer-induced learning and seller-induced learning. We find that under buyer-induced learning the learning rate target increases with consumer learning efficiency, leading to lower prices. Moreover, under seller-induced learning, the learning rate target is not continuous in seller's education efficiency, implying a shift in pricing strategy.

2 - Coordination through Cooperative Advertising in a Two Period Consumer Electronics Supply Chain

Xiaohang Yue, University of Wisconsin-Milwaukee, Milwaukee, WI, United States, xyue@uwm.edu, Qingyun Xu, Yi He

Firms in the consumer electronics industry frequently launch new styles of their products, which leads to a "two-period" phenomenon of their product sales. Only a few published articles have considered two-period models in cooperative advertising. This paper investigates co-op advertising strategies in a two-period supply chain consisting of single manufacturer and single retailer. Utilizing the game theory, we consider two different scenarios: decentralized scenario with a cooperative advertising program and integrated scenario. Aside from these scenarios, we propose a supply chain contract to coordinate this supply chain system.

3 - The Addition of Social Attributes and Product Differentiation

Qingyuan Zhu, University of Science and Technology of China, 1952 S.Orchard Street, Apt A, Urbana, IL, 61801-6196, United States, zqyustc@mail.ustc.edu.cn, Jiong Sun, Yunchuan Liu

This paper studies the addition of a social attribute onto a product line and its effects on product differentiation decisions. We show that the firm benefits more from adding a social attribute onto a high-quality product than onto a low-quality product, and adding a social attribute results in a non-monotonic impact of quality differentiation on profits and, hence, it alters the firm's product differentiation decision.

4 - The Effect of Aggregated Purchasing on Promotion of Quantity Discount in Social Network

Yifei Luo, PhD candidate, University of Science and Technology of China, School of Management, USTC, 96 Jinchai Road, Hefei,Anhui, 230026, China, ustclyf@foxmail.com, Yugang Yu, Jie Liu

Quantity discount, a traditional marketing tool as promotion, is commonly used by single consumers to buy more goods with cheaper price. But now in web-based network era, quantity discount is frequently used by a group consumers to aggregate purchase to share the benefit of quantity discount. Communication and purchase behavior in social network is a key factor determining the optimal profit . We consider how the firm set a discount to make it the optimal profit. We solve the optimal profit function in two categories of consumers. We show that the promotion with aggregated purchasing not necessarily inferior to traditional quantity discount even if the level of communication is sufficiently high.

1 - Analyzing the Effect of Demand Cannibalization in Multi-channel Retailing

Yasamin Salmani, PhD Candidate, Drexel University, 3220 Market St., Philadelphia, PA, 19104, United States, ss3858@drexel.edu

Having multiple channels to sell the products has been regarded as a principal method to attract more customers. From the other side, a major concern in any multi-channel retailing is that adding a marketing channel may grab demand of other established channels to some extent. This paper investigates some fundamental reasons of this phenomenon, the so-called cannibalization, as well as propose some solutions to alleviate its effects on demand.

2 - Context-effect Models for Online Recommendations

Uzma Mushtaque, Rensselaer Polytechnic Institute, 110 8th Street, Troy, NY, 12180, United States, uzmamu@rpi.edu

Post filtering models are developed for online personalized assortments under a random utility framework. Four variants of MNLCE explicitly incorporate the impact of information overload by redefining item level representative utility. The models are novel as they capture the context of information overload and the notion of novelty and diversity in addition to the common goal of recommending high preference items.

3 - Should Retailers Open Outlet Malls?

Xiuli He, Associate Professor, UNC-Charlotte, 9201 University City Blvd, Charlotte, NC, 28223, United States, xhe8@uncc.edu, Guiping Li

We consider the manufacturer's quality decisions for outlet stores and regular malls.

4 - Pricing Decisions with Low-carbon Responsibility and Remanufacturing Competition in Closed-loop Supply Chain

Juhong Gao, Dr., Tianjin University, College of Management and Economics, 92 Weijin Road, Nankai, Tianjin, 300072, China, gaojuhong@tju.edu.cn, Zhen Huo, Mengmeng Li

Under the consideration of uncertain demand and remanufacturing, introduce the low-carbon responsibility, establish the pricing models of CLSC with remanufacturing competition with the goal about the system expected profit maximization, it is concluded that the pricing strategy of CLSC. Then, considering the low-carbon responsibility factor, the numerical examples further respectively analyze the influence of the uncertain demand and remanufacturing competition to pricing strategies and expected profits of CLSC. It is concluded that the pricing strategies of CLSC are under the condition of different market demand and remanufacturing competition.

5 - Managing Product Returns in Online Retailing

Hasmukh Gajjar, Associate Professor, Indian Institute of Management Indore, Rau-Pithampur Road, C-208, Prabandh Shikhar, Indore, 453331, India, hasmukh135@gmail.com, Bhavin J. Shah

We study the forward and reverse supply chain for product returns in online retailing. The first part of the study investigates the prominent reasons of it and seeks to identify the improvement areas to minimize the returns. Second part discusses ways to handle the return process more efficiently and effectively.

Invited: Project Management and Scheduling

Invited Session

Chair: Zhixin Liu, University of Michigan-Dearborn, Dearborn, MI, 48126-4100, United States, zhixin@umich.edu

1 - Production and Pricing Decisions in a Dual-channel Supply Chain under Remanufacturing Subsidy and Carbon Tax Policies

Ping He, Associate Professor, South China University of Technology, A309, Shantou Alumni Building, 381 Wushan Road, Guangzhou, 510641, China, phe17@scut.edu.cn, Kaiying Cao, Zhixin Liu

In recent years, governments pursue multiple policies to promote remanufacturing practice. We investigate the optimal production and pricing strategies of a manufacturer and a retailer in a dual-channel supply chain under two policies, i.e. remanufacturing subsidy policy (RSP) and carbon tax policy (CTP). We also explore which policy is better for the society by comparing the social welfares achieved under the two policies. The impacts of two policies on the production quantities of new and remanufactured products are presented. It is found that when the environmental cost coefficient is relatively low, RSP leads to greater social welfare; otherwise, CTP does.

2 - Scheduling of Continuous Slab Casters

Hairong Zhao, Purdue University Northwest, 2200 169 Street, Hammond, IN, 46323, United States, hairong@pnw.edu

The steel industry faces increasing competitive challenges. It is imperative for the steel manufactures to drastically cut costs while improving product quality and customer satisfaction in order to maintain their market positions. One of the tools in the drive to cut costs, increase quality and improve customer satisfaction has been improved planning and scheduling systems. This talk will describe a decision support system for the problem that is faced by a steel company. The system integrates the customer orders selection, and the planning and scheduling of continuous casters, thus makes synchronized production.

3 - Risk-adjusted NPV for Project Evaluation and Selection

Zhixin Liu, University of Michigan-Dearborn, 19000 Hubbard Drive, Dearborn, MI, 48126-4100, United States, zhixin@umich.edu, Nicholas G.Hall, Wenhui Zhao

We consider a company that schedules the tasks of its projects to maximize project net present value (NPV) under risk, and also selects from among its available projects using this measure. We model decreasing project risk by removing from the discount rate the risk factor associated with each task when it is completed. We formulate and solve the resulting problem of maximizing the risk-adjusted NPV of a project. We validate our contribution using two computational studies: the first demonstrates a significant increase in maximum project NPV from improved project scheduling; and the second demonstrates a significant increase in total project portfolio value from improved project selection.

Theoretical Studies in Economics of Information Systems

Sponsored: EBusiness

Sponsored Session

Chair: Lin Hao, University of Notre Dame, Notre Dame, IN, 46556, United States, lhao@nd.edu

1 - Reward Scheme Design Decision under the Multinomial Logit Model in Online Reward-based Crowdfunding Market

Tongxin Zhou, University of Washington, 3927 Adams Lane NE, Seattle, WA, 98105, United States, txzhou5@uw.edu, Shengsheng Xiao

We study the reward scheme design decision for projects in reward-based crowdfunding market. Backers' reward item selection behavior follows the Multinomial Logit choice model with general utility function. Our basic reward design model shows that creators' modified profit margins from each reward item are the same at the optimal backing prices. We also extend the basic model by considering crowdfunding participants' behavior such as backers' altruism, heterogeneous beliefs on project's success probability and creators' reward updating, and derive similar quantitative properties to guide the optimal design decision. Finally, we provide sensitivity analysis of the model parameters.

2 - Mobile App Pricing Models

Jie Zhang, University of Texas, 701 South West Street, Room 520, Arlington, TX, 76019, United States, jiezhang@uta.edu, Xiaoxiao Luo

In the new App Economy, mobile apps market is becoming very crowded with apps in different categories. We theoretically model and compare three different types of common mobile app pricing models to derive implications for mobile developers.

3 - Real Currency or Virtual Currency: Selling Virtual Items in Digital Games

Zixuan Meng, University of Washington, 5000 25th Avenue NE, Room 6201C, Seattle, WA, 98105, United States, zxmeng@uw.edu, Lin Hao, Yong Tan

Providers of free-to-play games often gain profits from two sources - selling in-game virtual items and monetizing players' playtime (e.g. through advertising). Regarding selling virtual items, providers have choices between two popular strategies - (i) selling through real currency only, and (ii) selling through virtual currency only while allowing players to earn virtual currency through their playtime or real currency purchase. This paper studies the provider's optimal choice between those two strategies.

Novel Research Contexts in Behavioral Operations

Sponsored: Behavioral Operations Management

Sponsored Session

Chair: Enno Siemsen, University of Wisconsin-Madison, Madison, WI, 53706, United States, esiemsen@wisc.edu

1 - Production Process Moves and the Impact of Functional Diversity and National Culture

Pettis Kent, University of Minnesota, 321 19th Avenue S, Suite 3-150, Minneapolis, MN, 55455, United States, kentx143@umn.edu

Changing customer demand, increasing production costs, and emerging growth opportunities often generate pressure on firms to relocate their production processes. Although it would be ideal if manufacturing plants could be moved quickly and easily, moving a process is disruptive and involves coping with a new learning curve to ramp-up production. Using behavioral experiments, we examine whether variables such as Functional Diversity and National Culture impact the effectiveness of a proven process template during a production move. Our findings help characterize how a firm's managers should leverage workforce diversity and how they should factor in cultural differences when planning a move.

2 - A Behavioral Study on Abandonment Decisions in Multi-stage Projects

Xiaoyang Long, HKUST.Business School, LSK.Business School, HKUST, Kowloon, Hong Kong, xlongaa@connect.ust.hk, J avad Nasiry, Yaozhong Wu

We experimentally investigate continuation/abandonment decisions in a multi-stage project under two conditions: when the project is reviewed at every stage and when review opportunities are limited. We find systematic deviations from the optimal solution: subjects may wrongly continue or abandon the project, and their decisions are path dependent. We propose a behavioral model which explains the behavioral regularities.

3 - A Behavioral Perspective on Inventory Sharing

Liang Xu, The Pennsylvania State University, 419A Business Building, Penn State University, State College, PA, 16801, United States, lzx103@psu.edu, Hui Zhao, Enno Siemsen

We examine inventory sharing effectiveness from a behavioral perspective. Using behavioral experiments, we show that decision makers do not stock enough to benefit from sharing, and the opportunity to share inventory leads to an even further reduction in the initial inventory stock. Further, decision makers are more likely to under-request inventory, leading to reduced demand signal processing among decision makers. We provide evidence that by reducing inventory transparency in the system and providing decision support, inventory sharing can become effective and increase profitability for participants.

4 - Biased Forecasts: the Impact of Service Level and Product Shelf Life

Tarkan Tan, Eindhoven University of Technology, School of Industrial Engineering, Den Dolech 2 Paviljoen F-07, Eindhoven, 5612AZ, Netherlands, t.tan@tue.nl, Meysam Arvan, Behnam Fahimnia, Enno Siemsen

Sales forecasts produced by the forecasting team are assumed to simply display the most likely value for product demand. This study aims to understand the extent to which this assumption holds in reality. We want to know if forecasts - in a real-world context for highly-perishable products - are treated as "the most likely values" or more like "decisions". We refer to the latter as "biased forecasts". We design an experiment to explore answers to the following questions: to what extent service level requirement and waste minimization are taken into account when developing the base forecasts, and is there a clear relationship between a forecaster's sustainability beliefs and under-forecasting?

Cognitive Modelling & Experimentation

Invited: InvitedBehavioral Aspects of OR

Invited Session

Chair: Juan Pablo Torres, Universidad De Chile, Santiago, Chile, jtorresc@unegocios.cl

Co-Chair: Martin Kunc, University of Warwick, Coventry, CV4 7AL, United Kingdom, martin.kunc@wbs.ac.uk

1 - Neurocognitive Sources of Misperception of Feedbacks in Managerial Decisions

Juan Pablo Torres, Universidad de Chile, 257 Diagonal Paraguay, #1204, Santiago, Chile, jtorresc@unegocios.cl, René San Martin

This article explores some cognitive sources of misperception of feedback in dynamic environments. Operational Research literature has highlighted two key failures, which explain misperception of feedback: Stock-flow failure and failure to account for time delays. We develop a cognitive neuroscience experiment based on the traditional beergame to understand how the brain processes the stock and flow signals. We recorded and analysed brain electrical responses to the presentation of stock and flow information in an adapted version of the classical beer game. Our preliminary results suggest that, neurally, participants process stock and flow information differently in terms of their recruitment of both attentional and reward-processing circuits in the brain. We discuss how this might be a source of misperception of feedback.

2 - Microfoundation of Pricing Capabilities and its Performance

Juan Pablo Torres, Universidad de Chile, 257 Diagonal Paraguay, #1204, Santiago, Chile, jtorresc@unegocios.cl, Claudio Aqueveque, Pablo Tapia

We focus on analyzing how business decision-makers implement pricing decisions in complex environments. We developed a simulation-based experiment to test our hypotheses with 124 middle managers. We identified three microfoundations of pricing decisions: pricing flexibility, risk taking on pricing decisions, and strategic consistency of pricing decisions. Preliminary results suggest that information, which is structured as causal maps improve pricing decisions related to pricing flexibility and strategic consistency. This causal map also reduces inconsistencies in strategy implementation.

3 - Improving Mental Models by Haptic Perception of Internal System Dynamics

Martin Fg Schaffernicht, Universidad De Talca, Avenida Lircay S/N, Talca Maule, 34600, Chile, martin@utalca.cl, Stefan N. Groesser, Bärbel Fürstenau

We consider firms as dynamic resource systems. Internal and external interdependencies influence the development of the resources. The strength of interdependencies and their changes over time cannot be directly perceived in real systems or in on-screen experimental settings. Decision makers perform poorly. We conjecture that interdependency dynamics are more perceivable, performance and understanding improve. Physical levers which require continuous effort to control resources allow improved perception. A simulation with on-screen and haptic interfaces allows to test this hypothesis. We present the theoretic context and initial data.

4 - Effort Reduction in Repeated Rule-based Choices

Andres I. Musalem, U. de Chile, Beauchef 851, Santiago, 8370456, Chile, amusalem@duke.edu

We explore processes of effort reduction in repeated choices. Decision makers are asked to follow a set of lexicographic rules that are tedious, but easy to get right. Eye tracking reveals the processes that lead to effort reduction with experience. Major gains come from learning the locations and meaning of information in the choice tasks, and from limiting repeated attention to needed information. Smaller gains come from focusing fixations on needed information and spending less time per fixation. Rewards for speed enhance these gains but do not decrease accuracy, and greater effort reduction emerges when a trial period permits learning.

Road and Parking Pricing and Coordination

Sponsored: TSL, Urban Transportation

Sponsored Session

Chair: Sayeeda Ayaz, University of Massachusetts-Amherst, 990 North Pleasant Street, Apt B24, Amherst, MA, 01002, United States, sbayaz@umass.edu

1 - A Sensitivity Analysis Approach to Robust Toll Pricing Considering Boundedly Rational Network Users

Mahdi Takalloo, University of South Florida, Tampa, FL, 33620, United States, mtakalloo@mail.usf.edu, Changhyun Kwon

Considering an ambiguous system of preferences and lack of complete information, decision makers are not perfectly rational, but boundely rational. Under such behavior, users do not necessarily choose the shortest path, and system travel time can be greater than in the case of rational behavior. In this research, we study a robust toll pricing strategy in congested networks under boundedly rational behavior. Using sensitivity analysis approach, our goal is to find a toll vector that minimizes the system travel time of the worst-case tolled boundedly rational user equilibrium.

2 - Cooperative Scheme - An Alternative Approach to Equitable and Pareto-Improving System Optimum

Sayeeda Ayaz, University of Massachusetts-Amherst, 990 North Pleasant Street, Apt B24, Amherst, MA, 01002, United States, sbayaz@umass.edu, Song Gao, Hyoshin Park

An alternative approach is adopted to achieve equitable and Pareto-improving system optimum (SO) based on cooperation among travelers assisted by defector penalty. Preliminary analysis shows that under mild conditions, a cooperative scheme always exists for a single-origin-destination two-route network to ensure equitable and Pareto-improving SO. A cooperative scheme without financial transactions always exists where all travelers are cooperators due to high defector penalty. A more practical case is also discussed where a certain number of defectors exist. A constrained optimization problem ensuring equity among cooperators is formulated.

3 - A Bi-level Parking-pricing Problem

Hossein Fotouhi, George Mason University, 4630 Buckhorn Ridge, Fairfax, VA, 22030, United States, hfotouhi@gmu.edu, Elise Miller-Hooks, S.Bekhor

A bi-level, multi-period, parking-pricing problem is formulated with applicability for online reservation systems. In the upper level, multiple parking operators seek to maximize their own profits. User response to these upper-level decisions are obtained from a lower-level, parking-choice problem.

4 - Optimal Pricing for Priced Managed Lanes with Multiple Entrances and Exits

Venktesh Pandey, The University of Texas at Austin, Austin, TX, 78712, United States, venktesh@utexas.edu, Stephen D.Boyles

Priced managed lanes are being implemented in many cities. Dynamic pricing can be incorporated to achieve several objectives, such as maximizing system level throughput or revenue. We propose and compare different approximate dynamic programming algorithms for solving an optimal distance-based pricing for a managed lane corridor with multiple entrances and exits for a time dependent demand with varying value of time across the travelers. The results are compared against other non-optimal methods used in practice.

Information Systems in Healthcare

Sponsored: Information Systems

Sponsored Session

Chair: YeongIn Kim, University of Texas-Dallas, Richardson, TX, 75080, United States, yxk130930@utdallas.edu

1 - The Effect of Online Reviews on Physician Demand: A Structural Model of Patient Choice

Yuqian Xu, University of Illinois at Urbana-Champaign, Champaign, IL, United States, yxu@stern.nyu.edu, Mor Armony, Anindya Ghose

In this paper, we wish to derive the impact of online information on patient choice of outpatient care doctors. We are especially interested in how operational factors influence demand. To do so, we study a unique data set from one of the leading appointment booking websites in the United States, that contains online doctors' appointments made over a five-month period, along with other online information. We propose a random coefficient logit model to characterize consumer heterogeneity in doctor choices, taking into account both numeric and textual user-generated content with text mining techniques.

2 - The Impact of Health Information Exchanges on Physicians' Referral Patterns

Saeede Eftekhari, State University of New York-Buffalo, 304 Jacobs Management Center, Buffalo, NY, 14228, United States, saeedeef@buffalo.edu, Niam Yaraghi, Ram Gopal, Ram Ramesh

The objective of this research is to study how Health Information Exchanges (HIE) improves physicians' referral processes. Mainly, we argue that a primary care physician who has adopted HIE has access to a larger number of specialists than another physician who has not adopted HIE. This enables her to make a better decision in a referral process with regards to selecting an appropriate specialist. Second, we argue that a primary care physician who has adopted HIE tends to refer to the specialists who have also adopted HIE. This leads to better quality of care since HIE renders patient information readily available at the point of care. This study has significant implications for healthcare policy-making.

3 - Supervised Learning Methods for Predicting Healthcare Costs

Mohammad Amin Morid, University of Utah, 130 University Village, Salt Lake City, UT, 84108, United States, amin.morid@utah.edu

This study conducted a systematic literature review and identified five methods for predicting healthcare costs. We empirically evaluated the predictive performance of each reported approach, as well as other state-of-the-art supervised learning methods. In this comparative analysis, gradient boosting had the best predictive performance overall and for low to medium cost individuals. For high cost individuals, Artificial Neural Network (ANN) and the Ridge regression model, which have not been previously reported for use in healthcare cost prediction, had the highest performance.

4 - Physician and Patient Hybrid Community-based Recommender System for General and Diabetic Preventative Care

Pamella Howell, University at Buffalo, Buffalo, NY, United States, pamellah@buffalo.edu, Mohamed A.Abdelhamid

An under-explored area of recommender system research is e-health. Technology is essential in the lives of the aging population and millennials. Integrating technology with healthcare services using recommender systems could help providers transition to a Merit-based payment incentive system. We propose a recommender system that will provide general preventative care prescriptions based on context, personal health information, and domain knowledge.

5 - Standardization, Interoperability and the Patient Interest: How EHRS Influence the Hit Marketplace

Nicola Mountford, Director, UCD Connected Health, University College Dublin, Dublin, Ireland, nicola.mountford@ucd.ie, Rajiv Kohli, Georgiana Ifrim

Encouraged by EHR adoption incentives such as the Health Information Technology for Economic and Clinical Health (HITECH) Act, healthcare providers held bargaining power as buyers of HIT. As EHRs began to promote quality measurement and reimbursement that power shifted toward an oligopoly of EHR vendors. We explore an emerging power shift toward patients that is driven by consumerism and patients' control of information. We track this emergent power shift and the evolving role of EHR and discuss implications for providers, vendors and patients.

Energy

Contributed Session

Chair: Shigeki Toriumi, Chuo University, Tokyo, Japan, toriumi@ise.chuo-u.ac.jp

1 - Coal Inventory Optimization for Electric Power Utilities

Chung-Hsiao Wang, LG&E and KU, 102 Spruce Lane, Louisville, KY, 40207-1701, United States, chunghsiao@hotmail.com, K. Jo Min

Electric power utilities that own coal power plants maintain coal inventory to hedge against coal burn and delivery uncertainties. Coal burn uncertainties are caused by fluctuations in load and generation unit availability. Delivery uncertainties are primarily caused by transportation disruptions. In this paper, we develop a mathematical model that considers those root causes to determine optimal coal inventory levels for electric power utilities.

2 - Evaluation of Risks for Power Plant Operators through Reconfiguration of Price Zones in Central Western Europe (CWE) using a Recombining Scenario Tree

Robin Leisen, Research Assistant, University Duisburg-Essen, Berliner Platz 6-8, Essen, 45127, Germany, robin.leisen@uni-due.de, Tim Felling, Caroline Deilen, Christoph Weber

In CWE a new price zone configuration (PZC) for electricity is discussed. A frequent change of PZC affects the risk for power plant operators as their expected net present value (NPV) varies depending on the PZC. Thereby the PZC is assessed using a hierarchical cluster algorithm. Using the new zonal prices, the contribution margin is determined. The net present value results from the probability-weighted average of the contribution margin of each scenario discounted to today. Among others, the scenario tree considers time steps, grid development, fuel prices and different zonal configurations.

3 - Evaluation of Importing Countries and Transportation Mode of Energy Resources Considering Uncertainty

Shigeki Toriumi, Chuo University, 1-23-27 Kasuga, Bunkyo-ku, Tokyo, 112-8551, Japan, toriumi@ise.chuo-u.ac.jp, Ryuta Takashima

In this study, we evaluate country risk and transport risk of importing energy resources using two mathematical model. First, we develop a mathematical model that determines the quantity of imports considering country risk. Next, we develop a mathematical model that determines transportation mode and route considering transport risk. Then, we analyze import cost and risk using these models. As a result, for Japan, it was found that although the cost of pipeline transport is lower than that of ship transportation, the transport risk increases.

Arterial and Highway Traffic Operations

Sponsored: TSL, Intelligent Transportation Systems (ITS)

Sponsored Session

Chair: Roger Lloret-Batlle, ITS Irvine, 7430 Palo Verde Road, Irvine, CA, 92617, United States, rlloretb@uci.edu

1 - Dynamic Optimal Realtime Algorithm for Isolated Signals

Xiubin Wang, Associate Professor, Texas A&M.University, 3136 TAMU, College Station, TX, 77845, United States, bwang@tamu.edu, Mark Cao, Changjun Wang

This work studies intersection signal control . The optimal control policy minimizes the overall intersection delay by deciding the green intervals for signal phases dynamically . It proposes an analytical model for intersection vehicle delay and derives optimal conditions for green signal switch. Two numerical algorithms are proposed: optimum based (DORAS) and queue-based heuristic respectively. Numerical tests are conducted via simulation.

2 - Connected Vehicle Enabled Proactive Signal Control for Congestion Mitigation on Arterial Corridors

Hao Yang, Visiting Assistant Professor, Lamar University, 2622 Cherry Engineering Building, Beaumont, TX, 77710, United States, yhharold@gmail.com, Xing Wu, Mm Haque

With increasing penetration rates of connected vehicles, signals are able to interact with real-time traffic conditions and to be operated more proactively with traffic prediction models to mitigate road congestions and to improve road capacities. This paper develops a proactive signal control system based on connected vehicles to minimize vehicle delay at multiple intersections. The system utilizes connected vehicles to predict the volumes entering the intersection accurately and to optimize phase sequence and durations of the intersections. The simulations and field experiments illustrate the effectiveness of the algorithm on reducing vehicle delays.

3 - Core-stable Queue Routing Policies for Multiserver Queue Facilities and Highway Control

Roger Lloret-Batlle, PhD Candidate, ITS.Irvine, 7430 Palo Verde Road, Irvine, CA, 92617, United States, rlloretb@uci.edu, R. Jayakrishnan

Transportation supply in multiserver queues and freeways is generally consumed in an FCFS basis. We explore game-theoretical solution concepts that allow agents to cooperate with each other and efficiently violate FCFS in a core-stable fashion. In particular, we develop a dynamic allocation as an n-level Stackelberg game, characterized as a partition function game which is strong-core stable.

Challenges and Opportunities of Establishing Data-driven Agronomic Services to Smallholder Farmers Across the World

Invited: Agricultural Analytics

Invited Session

Chair: Daniel Ricardo Jimenez, International Center for Tropical Agriculture (CIAT), KM 17 recta Cali-Palmira, KM 17 recta Cali-Palmira, Palmira, 0057, Colombia, d.jimenez@cgiar.org

Co-Chair: Andrew Jarvis, a.jarvis@cgiar.org

1 - Increasing Agricultural Production and Resilience through Data Services and Decision Support Systems

Brenda Ortiz, Associate Professor, Auburn University, 201 Funchess Hall, Auburn, AL, 36849, United States, bortiz@auburn.edu, Wendy-Lin Bartels, Clyde Fraisse, David Zierden

The farming community is currently being challenged to build resilience to climate change and to increase crop productivity through the adoption of practices and technology. Our extension efforts have showed that low adoption of decision support systems is due to the lack of engagement with farmers during the conceptualization and development process. A success farmers engagement story is the Tri-state Climate Learning Network for Row Crop Agriculture. Through bi-annual meetings, we learned that awareness on the limitations of the data, the applicability of climate information to crop management, and the co-development of usable decision support tools are key elements of farmers' adoption.

2 - Simulation Based Fungal Disease Modeling in Agriculture using Big Data

Drew Marticorena, aWhere, Inc., Broomfield, CO, United States, drewmarticorena@awhere.com

The FAO estimates that over 1B MT of food are lost due to the fungal diseases yearly. In addition, associated toxins cause harmful health effects to both animals and people that consume the contaminated food. These issues are especially prevalent amongst smallholder producers. The ability to predict where and when fungal diseases are likely to occur would be of great value across the agricultural value chain and would improve the lives of smallholder producers. Using field datasets and modern parameter optimization techniques coupled with biological based models, aWhere has developed simulation based models that predict the incidence of fungal diseases with both high sensitivity and specificity.

3 - Agriculture 3.0: Crowed Sourced Data for Decision Making and Taking in Resilient Agrifood Systems

Bram Govaerts, CIMMYT, Mexico City, Mexico, b.govaerts@cgiar.org

Managing the hugely complex risks that are associated with the food system of the 21st century is a major challenge for decision makers in government, civil society and the private sector alike, and one that has been neglected for the past 30 years. Therefore complex agricultural innovation systems (AIS) that can support agrifood systems for nutrition, nature conservation and national and international security are required. While Knowledge Management (KM) is an important component of AIS, previous KM frameworks did not account for the fact that agricultural systems are complex systems and did not integrate innovation with KM. The results presented will show a case of an AIS that was implemented in Mexico including crowd sourcing of field scale data to develop complex decision support systems. The case presented shows that these approaches can boost performance and steer complex systems in ways that benefit all stakeholders.

4 - Data-driven Agro-climatic Services Improve Farmer Responses to Climate Variability

Julian Ramirez-Villegas, University of Leeds, Leeds, United Kingdom, Julian.ramirezvillegas@gmail.com

Climate is one of the most important factors influencing the performance farming systems. In Colombia, climate variability explains between 30-60 % of rice yield. Farmers, however, make decisions in their farms including issues related to planting date, what variety to plant, or whether to plant, at best, on the basis of no information. We develop data-driven seasonal crop-climate prediction analyses that feed into the development of a climate services platform. The analyses demonstrate that the combination of skillful seasonal climate forecasts, calibrated crop models, and a forecast platform tailored to users' needs can prove successful in establishing a climate service for agriculture.

1 - Estimating Dynamic Option Pricing Models using Large Panels
Kris Jacobs, University of Houston, Houston, TX, United States, kjacob@bauer.uh.edu

We estimate option valuation models on returns and large panels of option data using the particle filter.

2 - State-varying Factor Models of Large Dimension
Markus Pelger, Stanford University, 312 Huang Engineering Center, 475 Via Ortega, Stanford, CA, 94305, United States, mpelger@stanford.edu, Ruoxuan Xiong

This paper develops an inferential theory for state-varying factor models of large dimension. Unlike constant factor models, the loadings are general functions of some recurrent state process. Our estimator combines nonparametric methods with principal component analysis. We derive the rate of convergence and limiting normal distribution for the factors, loadings and common components. We develop a statistical test for the constancy of factor loadings in different states. In an empirical study on U.S. Treasury securities data, we find that the systematic factor structure is different in boom and recession times and in periods of high market volatility.

3 - The Discretization Filter: A Simple Way to Estimate Nonlinear State Space Models
Leland E. Farmer, University of Virginia, Charlottesville, VA, United States, farmer.leland@gmail.com

Existing methods for estimating nonlinear dynamic models are either too computationally complex to be of practical use, or rely on local approximations which often fail to adequately capture the nonlinear features of interest. I develop a new method, the discretization filter, for approximating the likelihood of nonlinear, non-Gaussian state space models. I apply results from the statistics literature on uniformly ergodic Markov chains to establish that the implied maximum likelihood estimator is strongly consistent, asymptotically normal, and asymptotically efficient (see paper for full abstract).

4 - Long-run Risk or Disasters? New Evidence from an Efficient Estimation Method for Multivariate Jump-diffusions
Gustavo Schwenkler, Boston University, 595 Commonwealth Ave, Boston, MA, 02215, United States, gas@bu.edu, Andrea M. Buffa, Yunjeen Kim

We study the dynamics of consumption growth in a series of countries over a time span of 200 years. We seek to answer whether long-run risk or disasters are features of models that yield good fit to consumption data. To accomplish this goal, we develop a new methodology for filtering and estimation of multivariate jump-diffusion processes with incomplete data. Our methodology is both statistically and computationally efficient, and enables the empirical analysis of previously intractable multidimensional models. Our estimates suggest that long-run risk is a predominant feature of consumption data, albeit of low persistence. Disasters are estimated to be small and frequent, yet necessary for a good model fit.

1 - An Integer Programming Model of Route Assignment Problem for Reducing Traffic Congestion in Urban Area
Naoya Uematsu, Osaka University, Suita, Japan, naoya.uematsu@ist.osaka-u.ac.jp, Shunji Umetani, Hiroshi Morita

Despite of the spread of navigation services through smartphones, it has been still hard to resolve traffic congestion in urban area.We consider a large-scale combinatorial optimization problem that finds optimal routes for six million people to minimize the peak of congestion in the urban area, instead of solving shortest path problem for each user in individual.To avoid solving a large number of shortest path problems, we enumerate plausible candidate routes for each pair of origin and destination in advance and formulate this problem as a variant of the assignment problem.

2 - On the Spatial Separability of Uncapacitated Single Allocation P-hub Median Problems
Taghi Khaniyev, University of Waterloo, 200 University Ave., CP.H.3669, Waterloo, ON, N2L.3G1, Canada, thanalio@uwaterloo.ca, Samir Elhedhli, F. Safa Erenay

The spatial separability property of uncapacitated single assignment p-hub median problems (USApHMP) is studied. We illustrate that the optimal solutions to the well-known USApHMP instances can be partitioned into p allocation clusters, defined as the set of nodes which are allocated to the same hub, such that the convex hulls of the allocation clusters are disjoint. To exploit this property, a data driven approach to group the network nodes into regions and to obtain high quality solutions based on the solution of a smaller (low resolution) USApHMP is proposed. Experiments indicate the effectiveness of the proposed approach in generating high quality solutions within a reasonable amount of time.

3 - Solution Methods of Safe Walking Route Design Problem
Yuichiro Miyamoto, Sophia University, Tokyo, Japan, miyamoto@sophia.ac.jp, Ryuhei Miyashiro, Ken-ichi Tanaka

In the previous study, we proposed the safe walking route design problem (SWRDP) and analyzed exact optimal solutions using medium-sized problem instances. In this talk, we propose several solution methods of SWRDP for solving larger problem instances. We will also mention some variants of SWRDP.

4 - A Lagrangean Relaxation Algorithm for the Radius Formulation of the P-median Problem
Sergio Garcia Quiles, University of Edinburgh, School of Mathematics, James Clerk Maxwell Bldg, King's Building, Edinburgh, EH9 3FD, United Kingdom, sergio.garcia-quiles@ed.ac.uk, Minerva Martin del Campo Barraza

The p-median problem is a well-known problem in Discrete Facility Location, but at the same time still very challenging to solve for problems of large size. One of the proposed methods in recent years is the so-called radius formulation, which is based on using variables that rank the distances for each customer. This formulation has allowed to solve very large instances for some values of p but it fails for some others (e.g., for small values of p). In this paper we explore the usefulness of applying Lagrangian relaxation to the radius formulation.

Sponsored Session

Chair: Mohammad Dehghani, Northeastern University, M.dehghani@northeastern.edu

1 - Triggering an Optimization Module within the Simulation Run: Introducing a New Iterative Optimization-based Simulation (IOS) Framework
Mohammad Dehghanimohammadabadi, Northeastern University, 170 Brookline Avenue, Unit 1025, Boston, MA, 02115, United States, mdehghani@neu.edu, Thomas K. Keyser, Hossein Cheraghi

A unique Iterative Optimization-based Simulation (IOS) framework is presented by integrating simulation, optimization and database managers. With this IOS model, optimization occurs frequently at the operational level in order to optimize system configuration during the simulation run. A trigger event momentarily pauses the simulation and prompts the optimization manager to solve a mathematical model in order to update the simulation model configuration. This promising IOS framework is applied in a manufacturing system and its results are compared with Simulation-Based Optimization (SBO).

2 - A Stochastic Flow Shop Maintenance Scheduling using a Simulation-optimization Approach
Javad Seif, University of Tennessee-Knoxville, 411 B.H. Goethert Parkway, Tullahoma, TN, 37388, United States, jseif@utsi.edu, Mohammad Dehghanimohammadabadi, Andrew Junfang Yu

In this study, preventive and corrective maintenance (PM and CM) activities are incorporated into a permutation flow shop scheduling problem. A set of usage-based and diverse PMs as well as random variables with different probability distributions that represent potential CMs are applied to the model. A hybrid simulation-optimization (SO) approach using mixed integer programming (MIP) and discrete event simulation (DES) is utilized to solve the problem. Finally, a numerical experiment is conducted to evaluate the performance of the provided methodology and its potentialities.

3 - Use of Simulation Optimization Technique in Operating Room Scheduling

Musa Demirtas, PhD, Western New England University, Springfield, MA, 01119, United States, musa.demirtas@wne.edu

Due to increasing number of patients, surgeries, and the healthcare industry needs to use their limited resources efficiently. Operating rooms (ORs) are considered among the most important and costly departments, and generate a significant portion of revenues. Also, planning and scheduling of surgeries for ORs is not an easy task due to uncertainties and limited resources. This study focuses on maximization of utilization of ORs and minimization of the patients' length of stay so that hospitals can decrease their costs while increasing the satisfaction of patients. We developed a simulation-optimization model to allocate limited resources to improve utilization and minimize the patients stay.

Emerging Modalities and Multimodal Systems in Transportation

Sponsored: Transportation Science & Logistics

Sponsored Session

Chair: Kostas Zavitsas, Imperial College London, 615, Skempton Building, Imperial College Road, London, SW72AZ, United Kingdom, k.zavitsas@gmail.com

1 - Optimization for Campaign-level Human Space Mission Design

Koki Ho, University of illinois at Urbana-champaign, Urbana, IL, United States, kokiho@illinois.edu, Takaya Ukai, Hao Chen

This presentation introduces an integrated method for campaign-level space mission design and optimization. Human space mission design process has become increasingly complex, and there is a larger demand for a rigorous optimization method to support it. Particularly, with more space infrastructure technologies such as lunar mining and on-orbit propellant depot, we need a multi-mission campaign-level design method to find an optimal deployment and utilization strategy of those infrastructure technologies. This presentation develops a method based on approximate dynamic programming and network optimization to efficiently optimize multi-mission space campaign over time.

3 - What Mode Should I Choose? Offering Travel Packages in Mobility-as-a-Service Era

Ali Arian, University of Arizona, 415 N.Park Avenue, Tucson, AZ, 85719, United States, arian@email.arizona.edu, Alireza Ermagun, Yi-Chang Chiu

Mobility as a Service (MaaS) concept aims at changing individual's mode choice from personal owned vehicles towards options that are consumed as a service, and offered by combination of private and public transportation providers. Users of this service can subscribe to packages or pay by trip. This study considering individual's activity pattern, proposes suitable personalized mobility packages. Algorithmic details alongside a case study using Metropia app data are presented.

4 - Optimal Multimodal Transport Networks Beyond Physical Infrastructures

Kostas Zavitsas, Research Associate, Imperial College London, 615, Skempton Building, Imperial College Road, London, SW72AZ, United Kingdom, k.zavitsas@imperial.ac.uk

Transport services have become increasingly complex in recent years with dynamic pricing strategies, smart path finding algorithms, live & personalised user notification, as well as new infrastructure and modes kicking in like automation and drones. The increasing complexity of transport services beyond the physical domain, make several of the systemic approaches dealing with multimodality in transport obsolete. Recognising that a major drive for this complexity is the increased availability and utilisation of data, this research attempts to establish a link between transport system performance and data utilisation.

Joint Session RAS/Practice: Roundtable B - Driverless Technology Implications to Freight Railways

Sponsored: Railway Applications

Sponsored Session

Chair: Dharma Acharya, GE Transportation, Ponte Vedra, FL, 32081, United States, dharma.acharya@ge.com

Co-Chair: Carl D. Van Dyke, TransNetOpt, West Windsor, NJ, 08550, United States, carl@cvdzone.com

1 - Rail Renaissance: Responding to the Threat of Autonomous Trucks

David T. Hunt, Oliver Wyman, One University Square, Suite 100, Princeton, NJ, 08540, United States, david.hunt@oliverwyman.com, Jason Kuehn

SuperTrucks, platooning, and self-driving trucks will erode a large portion of the cost advantage rail intermodal currently holds for longer distance freight trips. Railroads will need to aggressively pursue cost reduction programs of their own to remain competitive in many large markets. This presentation will look ahead 10 years at the relative competitiveness of rail and truck under different scenarios, including implementation of a possible multi-phase strategy for lowering rail costs.

2 - Avoiding Irrelevance - A Future State of Railroading

Daniel Plonk, Norfolk Southern Corporation, 1200 Peachtree Street, Atlanta, GA, United States, dan.plonk@nscorp.com

Truckers have an "in" with Silicon Valley as well as with legislators and regulators. Meanwhile, railroads have been dragged by PTC to the technology table. This view presents not too "far out" ideas on how to achieve better competitiveness while reducing the operating ratio.

3 - The Evolution of Planning and Dispatching to Support Driverless Trains

Giampaolo Orrigo, GE Transportation, 1990 W. Nasa Boulevard, Melbourne, FL, 32904, United States, giampaolo.orrigo@ge.com

Autonomous train operation has been a desire of the rail industry for many years. The economics of it make it easy to see why: asset optimization, cost reduction, and safety. Autonomous systems are in use since the 90's in the rail transit industry. It has been difficult though to apply it to freight networks, due to size, openness of the network, cost of infrastructure, and lack of "intelligent" systems to plan and control. Thanks to recent introduction of new main line ATO, ATP, optimized planning and automatic routing, driverless freight trains now seem more in reach. This presentation will explore how the evolution of the centralized planning and dispatching system will help this transformation.

4 - A Possible Railroad Response to Autonomous Trucks: Higher Quality of Service

James Brooks, GE Global Research Center, Niskayuna, NY, United States, brooksja@ge.com

The railroad industry has long had a significant cost advantage over the trucking mode of transportation. With the possible onset of autonomous trucks, this advantage may significantly erode forcing the rail industry to evolve to provide higher quality of service. In this talk, we will discuss some key barriers and technology needs for the industry to dramatically improve their transportation service levels.

Assessment Processes for OR/MS Education

Sponsored: INFORMEd

Sponsored Session

Chair: Sadan Kulturel-Konak, Penn State Berks, Reading, PA, 19610, United States, sadan@psu.edu

1 - Examining Student Attitudes Toward Statistics

Ping Wang, James Madison University, 1235 Sparrow Court, Harrisonburg, VA, 22802, United States, wangpx@jmu.edu, Susan Wright Palocsay

Statistics is receiving renewed attention in the "analytics movement". One avenue of investigation into student learning of statistics comes from educational psychology. Research findings suggest that students' psychological attributes play an important role in statistics education. We will describe an instrument for measuring attitudinal factors shown to affect acquisition and retention of statistical skills and present test results from a sample of undergraduate business students.

2 - Peer Assessment of Teamwork: Challenges & Solutions

Abdullah Konak, Penn State Berks, Tulpehocken Road, P.O. 7009, Reading, PA, 19610, United States, konak@psu.edu

Student peer evaluations have several problems such as very high peer and self-ratings inconsistent with students' expected skill levels. We redesign a peer assessment instrument from the literature based on behaviorally anchored rating scores in order to address some of these problems. In addition, we introduce new methods to identify anomalies in peer evaluations and incorporate them into the Peer Evaluation and Assessment Resource (PEAR) system, which is an online tool for peer evaluations.

3 - Assessing Engineering Students' Intercultural Competence
Sadan Kulturel-Konak, Penn State Berks, Tulpehocken Road, P.O Box 7009, Reading, PA, 19610, United States, sadan@psu.edu

Students must now be globally aware in order to remain competitive in today's globalized society. In order to effectively assess engineering students' intercultural competence development and engagement throughout their education, an instrument was developed. In this study we focus on students' responses to knowledge-based questions regarding different global content/issues. Our findings using the proposed assessment framework will be presented, and factors affecting engineering students' intercultural competence will be analyzed.

Topics for PhD Students

Sponsored: Minority Issues

Sponsored Session

Chair: Maria Esther Mayorga, North Carolina State University, Raleigh, NC, 27695, United States, memayorg@ncsu.edu

1 - Topics for PhD Students
Maria Esther Mayorga, North Carolina State University, 400 Daniels Hall, Dept. of Industrial & Systems Engineering, Raleigh, NC, 27695, United States, memayorg@ncsu.edu

In this session, a group of panelists will discuss topics of interest to PhD students. The list of topics include: finding your research topic, mentoring, choosing a career path, preparing for the job market, and tips for success. Panelists range from new graduates to full professors, and are from business and engineering schools as well as industry. The amount of time spent on each topic will depend on questions from the audience.

2 - Panelist
Gabriel Zayas-Caban, University of Michigan, 1731 Broadview Lane, Ann Arbor, MI, 48105, United States, gzayasca@umich.edu

3 - Panelist
Shannon Harris, The Ohio State University, 1005 W. 5th Avenue, Unit 535, Columbus, OH, 43212-3085, United States, harris.2572@osu.edu

4 - Panelist
Mark E. Lewis, Cornell University, School of Ops Research & Information Engin., 221 Rhodes Hall, Ithaca, NY, 14853, United States, mark.lewis@cornell.edu

5 - Panelist
William Christian, US.Dept of Defense, Washington, DC, United States, wchristia@gmail.com

IISE-Transaction Session

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Jianjun Shi, Georgia Institute of Technology, Atlanta, GA, 30332-0205, United States, jianjun.shi@isye.gatech.edu

1 - A Multi-response Multilevel Model with Application in Nurse Care Coordination
Bing Si, Arizona State University, Tempe, AZ, 85287, United States, bingsi@asu.edu, Jing Li

The recently developed Nurse Care Coordination Instrument (NCCI) enables data to be collected for measuring nurse care coordination, which plays a vital role in promoting patients' safety and quality outcomes by a recent report by the Institute of Medicine. Driven by this, we propose a novel multi-response multilevel model with joint fixed/random effect selection across multiple responses and apply it to a dataset collected across four U.S. hospitals using the NCCI. Our study conducts the first quantitative analysis that links multiple care coordination metrics with multilevel predictors, and thus providing important insight into how care coordination might be impacted or improved.

2 - Identifying Multistage Nanocrystal Growth using in Situ TEM Video Data
Yanjun Qian, Texas A&M.University, 1501 Harvey Rd, Apt 806, College Station, TX, 77840, United States, qianyanjun09@gmail.com, Jianhua Z Huang, Yu Ding

The in situ transmission electron microscopy (TEM) technique is receiving considerable attention as it provides the capability of directly observing nanocrystal growth processes. As more and more TEM video data become available, one of the bottlenecks appears to be the lack of automated and dynamic processing tools. We introduce a method that analyzes the in situ TEM videos in an automated and effective way, which tracks the normalized particle size distribution and identifies the change points delineating the stages in nanocrystal growth. Using the outcome of the change-point detection, we propose a hybrid multi-stage growth model and test it on an in situ TEM video published in 2009 by Science.

3 - Scalable Prognostic Models for Large-scale Condition Monitoring Applications
Xiaolei Fang, Georgia Institute of Technology, 1546 Woodlake Dr NE, Apt F, Atlanta, GA, 30329, United States, xfang33@gatech.edu, Nagi Gebraeel, Kamran Paynabar

Capturing degradation of high-value engineering assets usually entails the use of various types of sensors, which generate massive amounts of data. Building a prognostic model for such large-scale datasets often presents two key challenges: how to effectively fuse the signals from a large number of sensors and how to make the model scalable to the large data size. To address the challenges, we present a scalable model designed for fusing multistream signals using two fusion algorithms developed from functional PCA. Using the algorithms, we identify fused features and predict the RUL via an adaptive (log)-location-scale regression framework. We validate our model using numerical and case studies.

Energy and Climate 11

Invited: Energy and Climate

Invited Session

Chair: Ross Baldick, University of Texas at Austin, Austin, TX, 78712, United States, baldick@ece.utexas.edu

Co-Chair: Vaidyanathan Krishnamurthy, University of Texas-Austin, vaidyanathan@utexas.edu

Co-Chair: Sambuddha Chakrabarti, University of Texas-Austin, sambuddha.chakrabarti@gmail.com

1 - Contingency Analysis During Extreme Events for Electric Power Systems
Sambuddha Chakrabarti, University of Texas-Austin, Austin, TX, United States, sambuddha.chakrabarti@gmail.com, Vaidyanathan Krishnamurthy

Extreme events such as natural disasters and weapon of mass destruction attacks have a major impact on electric power resiliency. This talks discusses contingency analysis for the electric transmission grid considering the physical impact of extreme events on electric power infrastructure.

2 - The University of Texas at Austin - A Microgrid in Practice
Rossen Tzartzev, UT.Austin Utilities and Energy Management, Austin, TX, United States, tzartzev@gmail.com

The University of Texas at Austin has selected the microgrid approach to serving all of the campus energy needs - power, cooling, and thermal. The talk will explore the benefits, opportunities, and challenges presented by these interconnected energy systems, as well as their effect on the overall system resiliency.

3 - Enhancing Grid Resiliency
Robert Hebner, University of Texas-Austin, Austin, TX, United States, r.hebner@cem.utexas.edu

: Achieving the level of resilience needed in the future electricity grid requires hardening against aging infrastructure, malicious attacks, and disasters. Developing a more robust system requires modeling of the physics of failure, robust controls, and a grid that can quickly disaggregate. These are necessary, but not sufficient. There is also a need to understand the interconnection of disparate systems such as transportation, telecommunications, and power.

4 - Contingency Constrained Day-ahead Scheduling of Large-scale Power Systems
Ramtin Madani, Assistant Professor, The University of Texas at Arlington, Arlington, TX, United States, ramtin.madani@uta.edu, Edward Quarm

A computational method will be introduced for solving power system scheduling problems under load and generation uncertainty as well as contingency constraints. A polynomial-time solvable model is created, whose scalability is beyond the reach of standard branch and bound methods. It either fully determines the globally optimal decision or, in the worst case, offers a vastly simplified input to standard solvers.

5 - A Risk Hedging Strategy for Wind Power Producers in U.S. Electricity Markets via Financial Risk Exchange

Hunyoung Shin, University of Texas at Austin, 10050 Great Hills Trail, Unit 1218, Austin, TX, 78759, United States, hunyoung@utexas.edu

Wind power producers (WPPs) participating in forward electricity markets are exposed to real-time (RT) market risks from uncertain generation outputs and RT market prices. To mitigate this joint volume-price risks, we propose a financial instrument referred to as a risk exchange (REX) that enables the WPPs to trade random net payments from uncertain RT prices and MW outputs, after the day-ahead (DA) market is cleared. A negotiation of the REX is analyzed by a bargaining game based on a conflict of interest in determining the REX amounts. Numerical examples show that the REX can reduce RT market risks successfully and encourages the WPPs to sell more energy to the DA market.

Predictive Medicine on Electronic Health Record

Sponsored: Data Mining

Sponsored Session

Chair: Kazim Topuz, Oklahoma State University, ktopuz@okstate.edu

1 - Cleaning Challenges and Algorithms for Electronic Health Record Data

Zhuqi Miao, Health Data Analyst, Oklahoma State University, 345 Business Building, Stillwater, OK, 74078, United States, zhuqi.miao@okstate.edu, Shrieraam Sathyanarayanan, Elvena Fong, William Paiva

Rich health data created via electronic health record (EHR) systems is stimulating the rapid development of EHR-based health research. EHR data can be very "dirty," but there is little discussion in the literature regarding specific summaries and taxonomies of dirty EHR data and associated cleaning methods. By leveraging Cerner Health Facts, one of the nation's largest EHR data warehouses, we identified prominent data cleaning challenges and developed algorithms to address these issues. Given the considerable similarities among various EHR systems, it is expected that the findings and algorithms based on Health Facts can be extended to cleaning EHR data in general.

2 - Developing a Synthetic Informative Minority Over-sampling (SIMO) Algorithm Embedded in Support Vector Machines to Learn from Imbalanced Datasets

Saeed Piri, Oklahoma State University, School of Industrial Engineering & Management, Engineering North, Stillwater, OK, 74078, United States, saeed.piri@okstate.edu, Dursun Delen, Tieming Liu

A dataset is called imbalanced when the distribution of different classes in the data is not similar. While a standard machine learning technique could have a good performance on a balanced dataset, when applied to an imbalanced dataset its performance deteriorates dramatically. In this study, we propose a synthetic informative minority over-sampling (SIMO) algorithm imbedded into support vector machine (SVM). In this algorithm, minority examples close to the SVM decision boundary are over-sampled. We assessed SIMO in comparison to other existing algorithms by using 15 benchmark datasets and it outperformed all of them. We also applied SIMO to a real-word dataset to predict diabetic nephropathy.

3 - Predicting 30-day Hospital Readmissions of COPD: A Data Mining Approach to Study the Effects of COPD Drug Therapies

Andrea Blair, Graduate Research Assistant, Oklahoma State University - Center for Health Sciences, 1111 W. 17th Street, Tulsa, OK, 74107, United States, andrea.blair@okstate.edu, Shrieraam Sathyanarayanan

Chronic obstructive pulmonary disease (COPD) is a leading cause of 30-day readmissions. Using data extracted from Cerner Health Facts, we built logistic regression, decision tree, and neural network models to predict 30-day readmissions using comorbidities, demographics, and drug therapies. Inpatients with COPD, prescribed one of three common COPD drug therapies (Advair, Symbicort, and Spiriva) or combination of drugs were included in analysis. We used SMOTE (synthetic minority oversampling) to balance the data. Of 52 variables modeled, 28 emerged as important in predicting 30-day readmission for COPD. Decision tree model performed better than other models (AUC DT=0.67, NN=0.66, LR=0.62).

4 - A Decision Support System to Predict Mortality in Sepsis

Akash Gupta, Oklahoma State University, 40 South University Place, Stillwater, OK, 747075, United States, akashg@okstate.edu, Tieming Liu, Scott Shepherd, William Paiva

We developed a decision tree frame work to predict 28-day mortality among suspected infected patients (58,231 encounters extracted from Cerner's health fact data) using the vital signs and laboratory tests observed within 24 hours of the admission time. A survival ensemble approach was also used to predict the time to mortality. Our model discriminate (AUROC) non-survival from survival with a accuracy of 0.77 (95% CI = 0.75-0.79). We performed sensitivity analysis to identify the relevant predictors of sepsis mortality. Compare to SOFA, our model uses fewer variables and perform equally well.

5 - Surgery Scheduling under Uncertainty

Vikrant Vaze, Dartmouth College, 14 Engineering Drive, Murdough Center, Hanover, NH, 03755, United States, vikrant.s.vaze@dartmouth.edu, Kazim Topuz, William Paiva

Surgery scheduling should account for uncertainty in the duration of surgical procedures to minimize delays and maximize resource utilization. We develop a data-driven approach to inform the surgery scheduling optimization process under uncertainty

Planning Logistics Systems under Uncertainty

Sponsored: TSL, Freight Transportation & Logistics

Sponsored Session

Chair: Michael Hewitt, mhewitt3@luc.edu

1 - Multimodal Capacity Planning with Uncertainty on Contract Fulfillment

Mariangela Rosano, PhD Student, Politecnico di Torino, Corso Duca degli Abruzzi 24, Turin, 10129, Italy, mariangela.rosano@polito.it, Guido Perboli, Guido Perboli, Teodor Gabriel Crainic, Teodor Gabriel Crainic

Contracting with carriers or third-party logistics firms is a way to secure transportation or warehousing capacity for the next planning period. However, contracts are concluded under uncertainty regarding the demand of loads to be transported, the availability of contracted capacity and of the extra one if needed. The question is how much to contract of each type of capacity to minimize the costs of the contract and of ad-hoc future actions to redress an unfavorable situation. We model this planning problem by extending the Stochastic Variable Cost and Size Bin Packing Problem. Extensive numerical experiments are conducted considering the case of an express courier in a City Logistics environment.

2 - A Learning-based Matheuristic for Stochastic Network Design

Teodor Gabriel Crainic, Université du Quebec à Montreal, School of Management, Department of Management & Technology, QC, H3C 3P8, Canada, TeodorGabriel.Crainic@cirrelt.net, Walter Rei, Fatemeh Sarayloo

We consider the two-stage stochastic programming formulation of the fixed charge multicommodity capacitated network design problem with uncertain demands. We aim to identify promising design decision variables, common to high-quality solutions. We propose a learning mechanism that systematically extracts such information when scenarios are gradually considered. This mechanism and the information it provides are the core elements of a variable-fixing-based matheuristic. Extensive computational experiment show the efficiently of proposed approach in obtaining high-quality solutions in reasonable computational times, particularly as the instance dimensions increase.

3 - Meso-parametric Value Function Approximation for Dynamic Customer Acceptance

Barrett Thomas, University of Iowa, W272 PBB, Iowa City, IA, 52242-1000, United States, barrett-thomas@uiowa.edu, Marlin W. Ulmer

We consider a problem in which a dispatcher decides whether to accept delivery requests given resource constraints and the possibility of additional future requests. To solve the problem, we present a novel method of approximate dynamic programming, the offline, meso-parametric value function approximation (VFA). This method combines parametric and non-parametric VFA to estimate future rewards. We compare the approach with the individual VFAs and online rollout algorithms. For a variety of instance settings, we show that the presented method combines the advantages and alleviates the shortcomings of parametric and non-parametric VFAs.

4 - Service Network Design at the Polish Post
Maciek A.Nowak, Loyola University Chicago, Department of Information Systems, Graduate School of Business, Chicago, IL, 60611, United States, mnowak4@luc.edu, Mike Hewitt, Bogumil Kaminski, Michal Pliszka

Solving the Service Network Design (SND) problem assists a freight transportation firm by prescribing the choice of paths for shipments and the services or resources necessary to execute them, while achieving the economic and service-quality targets of the carrier. This research presents an algorithm that applies SND to assist the Polish Post in developing a more efficient and effective network. The algorithm extends previous research in this area through the consideration of a heterogeneous vehicle fleet and driver pool, providing insight into the large scale, stochastic network operated by the largest employer in Poland.

Resource Allocation in Port Operations I

Sponsored: Transportation Science & Logistics

Sponsored Session

Chair: Xi Xiang, Tsinghua University, Hai Dian, Beijing, 100084, China, xiangx16@mails.tsinghua.edu.cn

1 - A Decomposition Approach for the Continuous Berth Allocation Problem
Ramez Kian, Istanbul Bilgi University, Department of Industrial Engineering,, Istanbul Bilgi University, Istanbul, Turkey, ramezk@bilkent.edu.tr

Berth allocation problems arise in the maritime logistics which address the schedule and the location of berthing for vessels in many container terminals. This class of problems is shown to be NP-hard in the literature and usually, are dealt with heuristics. In this work, I propose a decomposition approach to providing a relatively fast solution approach for the real moderate-sized problem instances. A numerical computation analysis is provided to compare the efficiency of the solution algorithms.

2 - Assignment and Scheduling of Disrupted Barges
Liliana Delgado Hidalgo, Doctoral Candidate, University of Arkansas and Universidad del Valle, 4207 Bell Engineering Center, Fayetteville, AR, 72701, United States, ld002@uark.edu, Heather Nachtmann, Chase Rainwater

We study the assignment and scheduling of disrupted barges to inland ports to minimize the value loss during inland waterway disruptions. Initially, we formulated our problem as a vehicle routing problem with time windows (VRPTW) and then reformulated the VRPTW via Dantzig-Wolfe decomposition method (DW), which yields better linear-relaxation bounds. The DW reformulation decomposes the problem into an upper level master problem and a lower level subproblem that is more tractable to solve. The subproblem corresponds to an elementary shortest path problem with resources constraints (ESPPRC). A case example is presented to illustrate a ESPPRC solution technique.

3 - Port Pilotage Discrete Event Simulation with GIS in Anylogic
Weihang Zhu, Associate Professor, Lamar University, PO Box 10032, Beaumont, TX, 77710, United States, weihang.zhu@lamar.edu, Mohammed Altayeb

Port pilotage is an important step in vessels arrival or departure process. For pilotage, a local pilot boards a vessel and navigates it through the water channels. This talk presents a simulation model on the process of vessel arrival, waiting for the pilot to be boarded, and navigating through waterway to certain docks for port operation. This model is created in AnyLogic with Geographical Information System (GIS) support and user interface. It helps the port management and decision making based on the simulation results.

4 - Pilot and Chemical Tanker Scheduling Problem in a Port
Berna Tokgoz, Assistant Professor, Lamar University 4400 MLK Blvd. P.O. Box 10009, Beaumont, TX, 77705, United States, btokgoz@lamar.edu, Burak Cankaya, Ezra Wari

Chemical tankers differ from many other types of vessels by carrying up to 30-40 different types of liquid loads to different terminals in a port. One of the constraints in port scheduling in canal type of ports is Pilot Scheduling. It is a sequence dependent pre-setup time. Another one of the parameters in scheduling chemical vessels is the tank-cleaning time after each operation. Which is the sequence-dependent post-setup times. The research problem setting in this study contributes to the job shop scheduling and transportation scheduling literature with an open-shop scheduling problem with sequence-dependent pre and post-setup times for vessels.

5 - A Bi-objective Robust Model for Berth Allocation Scheduling under Uncertainty
Xi Xiang, Dr., Tsinghua University, Tsinghua University,Hai Dian, Beijing, Beijing, 100084, China, xiangx16@mails.tsinghua.edu.cn

This paper examines a berth allocation problem with consideration of uncertainty factors, mainly including arrival and operation time of the calling vessels, and formulates a bi-objective robust berth model which focuses on economic performance and customer satisfaction. The model aims to optimize the robustness of berth allocation policy for the two objectives. An adaptive grey wolf optimizer algorithm is developed to solve the proposed model. Finally, the performance of the heuristic is evaluated by a large number of random generated instances and the experimental results show that the proposed heuristic has good solution quality and calculation efficiency.

Design for Resilience in Emerging Complex Systems

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Zhaojun Li, Western New England University, Springfield, MA, 01119, United States, zhaojun.li@wne.edu

Co-Chair: Tongdan Jin, Texas State University, San Marcos, TX, 78666, United States, tj17@txstate.edu

1 - A General Framework for Evaluating Supply Chain Resilience
Xi Chen, University of Michigan-Dearborn, 2290 Engineering Complex, 4901 Evergreen Rd, Dearborn, MI, 48128, United States, xichenxi@umich.edu, Zhimin Xi, Pengyuan Jing

As the complexity of supply chain structures and the frequency of their disruptions rise, businesses are increasingly recognizing the value of supply chain reliability and resilience (SCRR). A number of efforts have been devoted to define SCRR or to develop risk mitigation strategies for their improvement. However, a key question remaining to be answered is how SCRR should be quantified. This work aims to fill this gap by proposing a unified framework for evaluating SCRR that internalizes design inputs and is flexible to varying degrees of data availability.

2 - Enhancing Resilience of Distribution Grids via Intermittent Renewable Power
Tongdan Jin, Texas State University, 601 University Drive, Ingram School of Engineering, San Marcos, TX, 78666, United States, tj17@txstate.edu, Honggang Wang

Reliability and resilience are the key to designing and operating complex power systems. We propose to integrate distributed wind and solar power to achieve four objectives: (1) bidirectional power flow; (2) customized service reliability; (3) high resilience against extreme weather; and (4) (2) zero-carbon emissions. A 13-node distribution network is used to illustrate the conceptual idea and the preliminary findings are also discussed.

3 - Physical Unclonable Function Based Implementation and Application for Securing IoT Devices
Ruolin Zhou, Assistant Professor, Western New England University, 1215 Wilbraham Rd, Springfield, MA, 01119, United States, ruolin.zhou@wne.edu, Jed Briones, Yuan Liu, Zhaojun Li

To defend against threats of bitstream decoding and hijacking the system, we encrypt the bitstream to enhance the security of FPGA (Field Programmable Gate Array) based IoT (Internet of Things) devices. FPGAs can enable vastly growing IoT applications since they can interface with the outside world easily with low power, low latency, high determinism with re-programmable and re-configurable capabilities. A completely unique key for encryption through a physical unclonable function (PUF) is implemented on an IoT device. Such an implementation leverages the intrinsic physical characteristics of the FPGA in order to generate a secure, reliable, and unclonable encryption key.

Data Analytics for System Improvement I

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Xiaochen Xian, UW-Madison, Madison, WI, 53705, United States, xxian@wisc.edu

Co-Chair: Kaibo Liu, UW-Madison, Madison, WI, 53706, UW-Madison, United States, jacoblkb@gmail.com

1 - Improving Food Assistance System Service by Considering Measurement Error

Haomiao Yang, University of Arizona, Tucson, AZ, United States, haomiaoyang@email.arizona.edu, Daoqin Tong, Jian Liu

Generalized linear regression models are usually used to model the service quality of food assistance systems. Conventional estimation methods are based on the assumption that the model covariates are free of errors. In this research, a new algorithm is proposed to explicitly consider two type of errors associated with regression covariates and improve model estimation accuracy. The case study shows the effectiveness.

2 - A Multimodality Factor Mixture Model with Hierarchically-structured Sparsity for Disease Subtype Discovery

Bing Si, Arizona State University, Tempe, AZ, 85287, United States, bingsi@asu.edu, Jing Li

Medical imaging technology has revolutionized health care and plays a pivotal role in Precision Medicine (PM). Disease subtype discovery paves the way toward PM by stratifying patients into subgroups with similar clinical characteristics, prognostics, or/and treatment response. To enable subtype discovery from multimodality imaging data, we propose a Multimodality Factor Mixture Model with a double-L21 penalty to achieve hierarchical selection of informative modalities and features and adopt an efficient Group-wise Majorization Descent algorithm for model estimation. Its performance is demonstrated by both simulation studies and a dataset collected by 2 U.S. medical institutions.

3 - Multifractal and Lacunarity Analysis of Image Profile from UW-Madison, **Ultra-precision Machining**

Farhad Imani, PhD Student, Pennsylvania State University, 233, Leonhard Building, 310 S.Barnard St, University Park, PA, 16802, United States, fxi1@psu.edu, Hui Yang

In this research, we developed a novel method of multifractal and lacunarity analysis which can capture the defects from the in-situ image of ultra-precision machining. Multifractal measures the variation in a layer of image and lacunarity measures heterogeneity to complement multifractal analysis and work together these statistical quantities can characterize patterns extracted from images and very precisely detect the existence of an underlying multiplicative process. The multifractal and lacunarity analysis have shown to have strong potential to be generally applicable as new process monitoring and control tool in a variety of domains such as bioengineering and nanoengineering.

4 - Online Monitoring Big Data Streams: A Rank-based UW-Madison, **Sampling Algorithm**

Xiaochen Xian, UW-Madison, 936 Eagle Heights Apt. C, Madison, WI, 53705, United States, xxian@wisc.edu, Kaibo Liu

With the rapid advancement of sensor technology, a huge amount of data is generated in modern engineering applications, which poses new and unique challenges for Statistical Process Control (SPC). In this paper, we propose an online sampling strategy to online monitor big data streams in the context of limited resources, where only partial observations are available at each acquisition time. Both simulations and case studies are conducted under different scenarios to illustrate and evaluate the performance of the proposed method.

Optimizing Water Resources

Sponsored: Energy, Natural Res & the Environment Environment & Sustainability

Sponsored Session

Chair: Alexandra M Newman, Colorado School of Mines, Golden, CO, 80401, United States, anewman@mines.edu

1 - Designing River Basin Storage using Optimization

Andy Burrow, MS, Colorado School of Mines, Golden, CO, 80401, United States, aburrow@mymail.mines.edu

The ways in which a growing population increases hydrologic demand are often evaluated using simulation models. This research uses data produced by the State of Colorado's Stream Simulation Model as input to an optimization model to determine the flow of unappropriated water so as to minimize the cost of water shortage mitigation while adhering to constraints that force the physical and topographical structures of the river. Solutions combine upstream pumping and new storage in existing reservoirs, as well as storage in new surface and subsurface reservoirs, and provide prescriptive, rather than descriptive, information.

2 - Coordinated Long-term Planning of Interdependent Energy and Water Systems

Shanshan Hou, University Of Arizona, 1670 N.Forgeus Avenue, Tucson, AZ, 85716, United States, shanshanh@email.arizona.edu, Neng Fan

Water is an important player for decisions in energy system, and energy network supply power for water distribution and extraction. These two infrastructure systems could be modeled as interdependent network. We consider both their operations, and planning period, which analyzes building the possible facilities, adding generators and transmission lines. As long-term planning and real-time operations have mutual and conflicting impacts in their decision making, we propose optimization model to simulate the coordinated system. The objective is to save money for planning and operations. We test the model in the example of IEEE 6-Bus and EPANet 1-Tank, as well as IEEE RTS-96 and EPANet 3-Tank.

3 - Data-Driven Distributionally Robust Water Allocation under Climate Uncertainty

Jangho Park, The Ohio State University, 1971 Neil Avenue, Columbus, OH, 43210-1271, United States, park.1814@osu.edu, David Love, Guzin Bayraksan

We apply data-driven distributionally robust stochastic optimization to a real-world water resources allocation model. We allocate Colorado River water to different users by considering possible extreme water shortages and construction of additional water treatment infrastructures until 2050. The system has two main uncertainties, future water demand, and supply. They are interconnected with other uncertain factors such as population growth and climate variability. We provide a statistical framework to predict the future uncertainties. Our data-driven decision provides a cost-benefit analysis for the government to make the long-term city plans and introduce new infrastructures.

4 - A Methodology to Assess the Energy-water Nexus in the UW-Madison, **United States**

Roshi Nategh, PhD, Purdue, West Lafayette, IN, United States, Rnateghi@purdue.edu

Despite the high level of interdependency in energy-water systems, they have been designed, managed and operated by separate entities, and researched independently. However, ensuring the reliability and resiliency of both resources commands knowledge of their interconnectedness. While many research endeavors have focused on addressing the energy-water nexus on the supply side, there is a scant body of knowledge on energy-water demand. In this talk, we present a multivariate, nonparametric technique - leveraging data from various publicly available sources such as the EIA, USGS and US Census - to assess the energy-water nexus in the U.S.

Data Mining

Contributed Session

Chair: Jilei Zhou, Guanghua School of Management, Peking University, Beijing, China, 1501110963@pku.edu.cn

1 - Sustainable Transportation Planning

Mohammad Ali Asudegi, UTK, 525 John D. Tickle Building, 851 Neyland Drive, Knoxville, TN, 37996-2315, United States, masudegi@vols.utk.edu, Rapinder Sawhney

A new perspective of sustainable transportation planning is introduced to help with expanding acceptance of green transportation solutions.

2 - Mining Consumer Shopping Patterns with Mobility and Social Network Data

Sharon Xu, Massachusetts Institute of Technology, UW-Madison, 235 Albany Street, #3023A, Cambridge, MA, 02139, United States, sharon_x@mit.edu, Marta C.Gonzalez

The majority of work in matrix factorization has focused on factorizing a single matrix, making it difficult to exploit the numerous data sources often available. In this talk, we present a collective factorization approach to predict shopping behavior through the addition of consumer mobility and network data. We model how shopping preferences change temporally, jointly factorizing the monthly user-purchase matrix (UVT), user-location matrix (UWT) and social network (UZT) with a shared user latent feature space U. Through this approach, we improve upon single matrix factorization while connecting multiple perspectives of user factors to better understand consumer lifestyles.

3 - Employee or Contractor: A Study of Courts' Misclassification Decisions

Mohammad Javad Feizollahi, Assistant Professor, UW-Madison, Georgia State University, Atlanta, GA, 30303, United States, mfeizollahi@gsu.edu, Charlotte Alexander

In this research, we study federal district court decisions in worker misclassification cases, 2008-2016. Independent contractors lack the benefits and protections available to employees. They may file suit, seeking "employee" classification, but the law poorly defines the two categories. Moreover, judges' classification opinions have never been studied systematically. We use text mining and analytical tools to understand how courts distinguish between employees and independent contractors and the factors that influence their decisions.

4 - Margin-based Pattern Selection for Support Vector Machines

Dongil Kim, Korea Institute of Industrial Technology, 89 Yangdaegiro-gil, Ipjang-myeon, Seobuk-gu, Cheonan, Korea, Republic of, dikim01@kitech.re.kr, Seokho Kang, Sungzoon Cho

Support Vector Machines (SVM) is a widely used training algorithm in data mining and machine learning. However, as the size of the dataset increases, the training complexity of the SVM has become a limit to apply SVM to real applications. In this paper, we propose a margin-based pattern selection method for SVM. Margin of each training pattern is estimated from multiple SVMs trained with smaller sample sets. Based on the estimated margin, the proposed method selects patterns that are likely to be support vectors. Experiments conducted on various datasets show that the proposed method has good generalization performance.

5 - Data Mining for Individual Consumer Credit Default Prediction under E-commence Context: A Comparative Study

Jilei Zhou, Guanghua School of Management, Peking University, No.5 Yiheyuan Road Haidian District, Beijing, 100871, China, 1501110963@pku.edu.cn

This paper explored the relative effectiveness of alternative classifiers (decision tree, logistic regression, random forests and extreme gradient boosting) to estimate how likely an applicant is to default in individual consumer credit services offered by e-commerce platform. Specifically, our work contributes to the following research questions: (i) What kind of features should be introduced in the new context of e-commence? Which features plays important roles in credit scoring model? (ii) How to tuning classification algorithms to avoid model inefficiency? (iii) Do ensemble classifiers real improve classification ability? Data used came from an financial services platform in China.

Chair: Akshay Gupte, Clemson University, Clemson, SC, 29634-0975, United States, agupte@clemson.edu

1 - Outer-product-free Sets for Polynomial Optimization and Oracle-based Cuts

Chen Chen, Columbia University, chen.chen@columbia.edu, Daniel Bienstock, Gonzalo Munoz

We consider valid inequalities for the intersection of a closed set S with a polyhedron P. Given an oracle providing the distance to S we propose a pure cutting plane algorithm; if the initial relaxation is a polytope, the algorithm converges. Cuts are generated from convex forbidden zones, or S-free sets derived from the oracle. A special case is polynomial optimization represented with a symmetric matrix of decision variables. In this lifted representation we let S be the set of real, symmetric outer products, and accordingly develop a theory of outer-product-free sets. We identify two families of maximal outer-product-free sets; associated intersection cuts can be generated in polynomial time.

2 - On Branching-point Selection for Triple Products in Spatial Branch-and-bound: the Hull Relaxation

Emily Speakman, University of Michigan, 2222 Fuller Court, Apt 702A, Ann Arbor, MI, 48105, United States, eespeakm@umich.edu, Jon Lee

Having three or more expressions multiplied together occurs frequently in factorable global-optimization models. For these triple products, we present some analytic results regarding the choice of branching variable and branching point in the context of sBB for factorable formulations. Following the approach we previously introduced to compare various common relaxations associated with trilinear monomials, we use 4-dimensional volume as a comparison measure to evaluate the sBB choice of branching variable and branching point in this context. For branching-point selection, we also compare our results to common practice in software.

3 - Computational Approaches to Mixed Integer Second Order Cone Optimization

Aykut Bulut, Lehigh University, Bethlehem, PA, United States, aykut@lehigh.edu, Ted Ralphs

We introduce a framework for solving Mixed Integer Second Order Cone optimization Problems (MISOCP). We present solver DisCO implemented within COIN-OR's CHiPPS framework. DisCO is a flexible library that implements different algorithms to solve MISOCP.

4 - Cutting Plane Techniques via Decision Diagrams

Danial Davarnia, Carnegie Mellon University, ddavarni@andrew.cmu.edu, Willem-Jan Van Hoeve

We develop cutting plane techniques for certain classes of discrete problems based on their decision diagram formulation. For linear IPs, these cutting planes provide a natural generalization of Gomory and intersection cuts. For convex IPs, they dominate the linearized cuts used in the outer approximation schemes. These cutting planes can also be derived for nonconvex IPs which allows for an adaptation of outer approximation algorithms. Computational experiments show significant gap improvement upon the traditional cutting plane methods.

1 - A Closed-loop Supply Chain Equilibrium Model with Random and Price-sensitive Demand and Return

Qiang Qiang, Penn State, Management Division, 30 E Swedesford Rd, Malvern, PA, 19355, United States, qzq10@psu.edu, Younes Hamdouch

This paper proposes a decentralized closed-loop supply chain network model consisting of raw material suppliers, manufacturers, retailers, and recovery centers. The demands for the product and the corresponding returns are random and price-sensitive. Retailers and recovery centers face penalties associated with shortage demand and supply, respectively.The optimality conditions of the various decision-makers are derived. The governing equilibrium conditions can be formulated as a finite-dimensional variational inequality problem. The qualitative properties of the solution to the variational inequality are discussed. Numerical examples are provided for illustration purpose.

2 - Supply Chain Network Capacity Competition with Outsourcing: A Variational Equilibrium Framework

Deniz Besik, Master's, Isenberg School of Management, University of Massachusetts Amherst, Amherst, MA, 01003, United States, dbesik@som.umass.edu, Anna Nagurney, Min Yu

This paper develops a supply chain network game theory framework with multiple manufacturers/producers, with multiple manufacturing plants, who own distribution centers, which are distinguished by brands, to demand markets, while maximizing profits and competing noncooperatively. The manufacturers avail themselves of external distribution centers for storing their products and freight service provision. We impose capacities on the links. We utilize a special case of the Generalized Nash Equilibrium problem, known as a variational equilibrium. A case study on apple farmers in Massachusetts is provided to illustrate the potential benefits of outsourcing in this sector.

3 - Mergers and Acquisitions in Blood Banking Systems: A Supply Chain Network Approach

Amir H. Masoumi, Assistant Professor of Management, Manhattan College, School of Business, De La Salle Hall 508, Riverdale, NY, 10471, United States, amir.masoumi@manhattan.edu, Min Yu, Anna B.Nagurney

We develop a methodological framework for the assessment of total cost efficiency (synergy) associated with a merger or acquisition in the blood banking industry, which is experiencing a volatile environment. The network optimization pre- and post-merger models handle perishability of the life-saving product of blood, include both operational and discarding costs of waste, capture the uncertainty associated with the demand points, as well as the expected total blood supply shortage cost and the total discarding cost at demand points. The models incorporate capacities on the links and their solution yields the optimal link flows plus frequencies of activities throughout the blood supply chain.

4 - Consumer Learning of Product Quality with Time Delay: Insights from Spatial Price Equilibrium Models with Differentiated Products

Dong Li, Arkansas State University Jonesboro-College of Business, P.O. Box 59, State University, AR, 72467, United States, dli@astate.edu, Anna B. Nagurney, Min Yu

We present spatial price equilibrium network models with differentiated products under perfect quality information for producers and consumers and under quality information asymmetry with consumer learning of product quality with a time delay. In addition, we provide measures of consumer welfare under perfect quality information and under information asymmetry as well as the value of perfect quality information for consumers. The models are especially relevant to agricultural products where spatial price equilibrium models have found wide application. We also present several numerical examples with insights provided.

Underground Mine Planning

Sponsored: Energy, Natural Res & the Environment, Natural Resources Mining

Sponsored Session

Chair: Alexandra M Newman, Colorado School of Mines, Golden, CO, 80401, United States, anewman@mines.edu

1 - Optimally Locating Support Pillars in an Underground Mine

Levente Sipeki, 8805 W. Geddes Pl, Littleton, CO, 80128, United States, levente.sipeki@gmail.com, Alexandra M.Newman, Candace Arai Yano

In underground mining, specifically, in top-down, open-stope retreat operations, blocks are designated as pillars (and left in situ) or stopes (and extracted and processed) so as to maximize profit. Safety is ensured by abiding by geotechnicalrestrictions on (i) the hydraulic radius of a stope, (ii) the length-to-width ratio of a pillar, (iii) the ratio between adjacent pillar and stope lengths, and (iv) the proximity between veins. We present a methodology consisting of (i) preprocessing, (ii) solving an optimization model,and (iii) employing a heuristic to determine structurally stable pillars locations.

2 - Production Scheduling in Underground Mining Operations Incorporating Heat Loads

Oluwaseun Babatunde Ogunmodede, MS, Colorado School of Mines, Golden, CO, 80401, United States, setotravel@gmail.com, Andrea Brickey, Levente Sipeki, Gregory Bogin, Alexandra M. Newman

A problem in the mining industry is production scheduling, or determining when, if ever, notional three-dimensional blocks of ore should be mined. Often lacking in underground production scheduling models are heat limitations, driven largely by the equipment used for underground activities such as development, extraction, and backfilling. To correct this, we attribute a specific heat load to each mining activity owing to equipment use, auto compression, broken rock and strata rock. We incorporate heat into a knapsack constraint in an integer programming model that produces more realistic schedules; adhering to them could increase revenue by lowering refrigeration costs for the mine.

3 - Production and Construction Optimization in Underground Mining

Nelson Morales, DIMIN.& AMTC, Av Tupper 2069, Santiago, Chile, nmorales@ing.uchile.cl

The planning and design of underground mines is a very complex task that requires to balance multiple considerations like economical value and geotechnical constraints in order to generate an extraction and a construction plan. Due to this complexity, the problem is solved in different stages and scopes, which lead to suboptimal solutions or even infeasibilities. In this work we present a MIP model which aims to optimize mine plans in underground mines. We show how this model can then be coupled with other models in order to generate more comprehensive plans that integrate aspects like geomechanics or operational uncertainty.

4 - Optimizing the Cutoff Grade at an Underground Mine

Alexandra Newman, Colorado School of Mines, Golden, CO, 80401, United States, anewman@mines.edu, Barry kING

An important strategic decision for any operational mine is the differentiation between ore and waste material, referred to as the cutoff grade. Our mixed-integer programming optimization framework determines the cutoff grades in three different, predetermined zones for a soon-to-be-operational underground mine by exploiting an underlying mathematical structure; current industry practice would produce solutions with lower net present value, would require six to eight weeks, and would preclude scenario analysis.

1 - Supervalid Inequalities for Network Interdiction Problems

Ningji Wei, 4303, Chestnut Ridge Rd., Buffalo, NY, 14228, United States, ningjiwe@buffalo.edu, Jose Luis Walteros

We focus on attacker-defender network interdiction problems in which: 1) the objective minimizes the attacker's cost of achieving a fixed disruption level over the defender's problem; 2) the defender's problem is to select an optimal graph structure (e.g., a shortest path, a spanning tree) over the residual graph; 3) the attacker strategies are defined over the same ground set of the graph structures. e.g., if the structures are defined over the edges, the attacker also interdicts edges. We develop a cut-generating framework that produces a general class of supervalid inequalities that remove non-trivial suboptimal solutions. We show how to addapt our framwework to tackle a wide variety of problems.

2 - On the Impact of Decentralization in Interdependent Network Restoration Scheduling

Thomas Sharkey, sharkt@rpi.edu, Hongtan Sun

We consider the problem of restoring disrupted services across multiple interdependent networks after extreme events. We consider integer programming approaches to determine the equilibrium (stable) solutions for this decentralized scheduling system. These approaches help to calculate the price of anarchy and the price of stability as well as allocate incentives to improve the loss from the centralized objective.

3 - Bi-level Optimization Model for Assortment Planning under Worst-case Customer Order of Preferences

Saharnaz Mehrani, Arizona State University, 1500 E Broadway Road, Apt B2128, Tempe, AZ, 85282, United States, smehrani@asu.edu, Jorge A.Sefair

One of the main challenges in assortment planning is to capture the customer choice behavior for substitutable products. We model customer behavior using a general ranking-based choice approach with a modified multinomial logit model to incorporate the effect of product unavailability on customer decisions. We present a bi-level optimization approach to maximize the expected revenue and protect it against the worst possible customer preferences. Our solution approach includes a single-level reformulation, which we tighten using problem-specific properties, and then solve using a cutting plane algorithm.

4 - Robust Location of Transparent Interdictions on a Shortest Path Network

Nail Orkun Baycik, Rensselaer Polytechnic Institute, Troy, NY, United States, baycin@rpi.edu, Kelly Sullivan

We study a shortest path network interdiction problem in which the follower seeks to find a path of minimum length on a network and the leader seeks to maximize the follower's path length by interdicting arcs. We consider placement of interdictions that are not visible to the follower; however, we seek to locate interdictions in a manner that is robust against the possibility that some information about the interdictions becomes known to the follower. We formulate the problem as a bi-level program, and apply a Benders decomposition approach to optimally solve it. We derive supervalid inequalities to improve the performance of the algorithm and test the algorithm on randomly generated grid networks.

Methods for Large-scale Convex Optimization

Sponsored: Optimization, Nonlinear Programming

Sponsored Session

Chair: Paul Grigas, pgrigas@berkeley.edu

1 - Variants of the ADMM for Block Optimization

Xiang Gao, University of Minnesota, 609 Oak Street, Apt 1-11, Minneapolis, MN, 55403, United States, gaoxx460@umn.edu

In this talk we present a suite of first-order algorithms which can be characterized as variants of the ADMM. In terms of the informational structure, we propose several ADMM-type methods that are applicable on a much broader class of problems where only noisy estimations of the gradient or the function values are accessible. For problems involve multi-block and non-separable objective with linear constraint, both deterministic and randomized ADMM variants are introduced. Under different conditions, sublinear convergence rates of all the aforementioned variants will be presented.

2 - Globally Convergent Algorithms for Two Layer Neural Network Problems

Digvijay Boob, Georgia Institute of Technology, digvijaybb40@gatech.edu, Guanghui Lan

Neural network can be trained with stochastic gradient descent to achieve good performance in many applications. Central problem in their training involves optimizing a nonconvex loss function whose theoretical analysis is hard. In this work, we give an algorithm to converge to global optimal solution with high probability under some assumptions about activation functions, distribution of the data and width of neural network.

3 - A Convex Gradient-based Approach for Profit Optimization in Online Advertising Demand-side Platforms

Paul Grigas, UC Berkeley, 4177 Etcheverry Hall, University of California, Berkeley, CA, 94720-1777, United States, pgrigas@berkeley.edu, Alfonso Lobos, Zheng Wen, Kuang-chih Lee

We develop an optimization model for the management of a demand-side platform (DSP), whereby the DSP aims to maximize its own profit while acquiring valuable impressions for its advertiser clients in a real-time bidding environment. We use convex relaxation to develop a tractable convex dual problem, which, due to the properties of second-price auctions, may be solved efficiently with non-smooth stochastic gradient methods. We propose a two-phase solution procedure and demonstrate evidence of strong performance guarantees.

4 - Approximation Algorithms for Bilevel Programming

Saeed Ghadimi, Princeton University, Princeton, NJ, United States, sghadimi@princeton.edu, Mengdi Wang

In this talk, we consider the classical setting for bilevel programming where the objective function of the outer problem depends on the optimal solution of inner one. We present gradient type algorithms for solving this class of problems and obtain an optimal iteration complexity for the outer problem and (nearly) optimal one for the inner problem. We also discuss convergence of stochastic approximation algorithms for solving this class of problems under stochastic setting.

Integrated Methods and Decomposition Approaches

Sponsored: Optimization, Integer and Discrete Optimization

Sponsored Session

Chair: Joris Kinable, Carnegie Mellon University, Pittsburgh, PA, 15213, United States, jkinable@cs.cmu.edu

1 - Discrete Nonlinear Optimization by State-Space Decomposition

David Bergman, McKinsey & Company, 4106 Stearns HIll Road, Waltham, MA, 02451, United States, david.bergman@business.uconn.edu

In recent years the use of decision diagrams for discrete optimization has grown in popularity, with a focus on linear integer optimization. In this talk, an expansion to nonlinear objective functions will be discussed. The work proposes the use of decision diagrams to model the objective function, which are then linked together through a network flow linearization. Experimental results on problems arising in revenue management, portfolio optimization, and healthcare exhibit orders-of-magnitude improvement in solution times compared with state-of-the-art nonlinear solvers.

2 - Dynamic Programming Bounds from Decision Diagrams

John Hooker, Carnegie Mellon University, Tepper School of Business, Pittsburgh, PA, 15213, United States, jh38@andrew.cmu.edu

We investigate the potential of relaxed decision diagrams to provide bounds on the optimal value of dynamic programming formulations. We prove general conditions under which a node merger operation in the diagram yields a valid relaxation. We then focus on job sequencing problems with state-dependent processing times, because no useful bounding mechanism currently exists for these problems. Computational experiments show that, surprisingly, relaxed diagrams prove the optimal value when their size is only a small fraction of the size of an exact diagram.

3 - Integer and Constraint Programming for Batch Annealing Process Planning

Willem-Jan Van Hoeve, Carnegie Mellon University, Tepper School of Business, 5000 Forbes Avenue, Pittsburgh, PA, 15213, United States, vanhoeve@andrew.cmu.edu, Sridhar R.Tayur

We describe an optimization application in the context of steel manufacturing, to design and schedule batches for annealing furnaces. Our solution approach uses a two-phase decomposition. The first phase groups together orders into batches using a mixed-integer linear programming model. The second phase assigns the batches to furnaces and schedules them over time, using constraint programming. Our solution has been developed for operational use in two plants of a steel manufacturer in North America.

4 - A Unified Decomposition Matheuristic for Assembly, Production and Inventory Routing

Jean-Francois Cordeau, HEC Montreal, 3000 Cote-Sainte-Catherine, Montreal, QC, H3T.2A7, Canada, jean-francois.cordeau@hec.ca, Masoud Chitsaz, Raf Jans

We introduce a decomposition-based heuristic for the assembly-routing problem and two related problems: the production-routing problem (PRP) and the inventory-routing problem (IRP). The heuristic relies on the iterative solution of different subproblems. The first phase determines a setup schedule while the second phase optimizes production quantities, supplier visit schedules and shipment quantities. The third phase solves a vehicle routing problem for each period in the planning horizon. Using the same parameter setting for all problems and instances, we obtained 818 new best known solutions out of 2,628 standard IRP and PRP test instances.

5 - Vehicle Routing Problems with Synchronized Visits and Stochastic Travel or Service Times: Applications in Healthcare

Louis-Martin Rousseau, Polythechnique Montreal, Cp 6079 Succ Centre-Ville, Montreal, QC, H3C 3A7, Canada, louis-martin.rousseau@polymtl.ca, Seyed Hossein Hashemi Doulabi, Gilles Pesant

We study the vehicle routing problems with synchronized visits (VRPS) where travel and service times are stochastic or time-dependent. We formulate VRPS as a two-stage stochastic programming model with integer variables in both stages. An advantage of the proposed model is that it does not have any big-M constraints. We consider applications in home-health care scheduling problem, as well as operating room scheduling with stochastic durations. We prove that the integrality constraints on second-stage variables are trivial, and therefore we can apply the L-shaped algorithm and its branch-and-cut implementation to solve the problem.

Joint session OPT/Practice: Applications of Conic Optimization for Energy Systems

Sponsored: Optimization, Linear and Conic Optimization

Sponsored Session

Chair: Ramtin Madani, The University of Texas at Arlington, Arlington, TX, 76015, United States, ramtin.madani@uta.edu

1 - Polynomial Optimization, Interpolation, and its Application to Power Systems

Cédric Josz, ERC Postdoctoral Fellow, Laboratory for Analysis and Architecture of Systems LAAS.CNRS, 7 Avenue du Colonel Roche, Toulouse, 31400, France, cedric.josz@gmail.com

Polynomial optimization in complex numbers is used to model oscillatory phenomena in various applications such as electric power systems, imaging science, signal processing, and quantum mechanics. We propose a hierarchy of complex semidefinite programs as well as a semidefinite programming solver in complex numbers to find global solutions with reduced computational burden. We apply these to large-scale sections of the European HV electricity grid. We also propose an algorithm for extracting global solutions once optimality has been reached, and show that it provides a variant to Prony's method, which is used for instance to determine inter-area oscillations from phasor measurement units.

2 - Power System State Estimation Problem: Optimal Sensor Placement

Salar Fattahi, PhD Candidate, University of California-Berkeley, Berkeley, CA, United States, fattahi@berkeley.edu, Javad Lavaei

This talk is concerned with the power system state estimation (PSSE) problem. Given a set of noisy measurements, PSSE aims at estimating the complex voltages at all buses of the network. Recently, we have shown that a conic optimization problem could effectively estimate the state of the system. In this talk, we use the notion of weighted algebraic connectivity to devise a sparsity-promoting technique that would determine where to place the sensors so that the estimation error associated with the conic formulation of PSSE is minimized.

3 - A Massively Scalable Approach to Power System Scheduling

Ramtin Madani, Assistant Professor, The University of Texas at Arlington, 3004 Franciscan Dr, Apt 1835, Arlington, TX, 76015, United States, ramtin.madani@uta.edu, Alper Atamturk, Ali Davoudi

A computational method is introduced, which is capable of approaching power system scheduling problems with a considerably large number of binary variables, while handling nonlinear equations that govern the flow of electricity. We design a family of linear and conic inequalities to form a polynomial-time solvable surrogate, with the aim of finding a near globally optimal point for the original problem. The proposed method is demonstrated on large-scale problems based on real-world European grid data, for which feasible decisions are obtained within provably small gaps from global optimality.

4 - On the Identification of Optimal Partition for Second Order Cone Optimization

Tamás Terlaky, Lehigh University, 200 W. Packer Ave, Bethlehem, PA, 18015, United States, terlaky@lehigh.edu, Ali Mohammad-Nezhad

The concept of optimal partition was originally introduced for LO and LCP and subsequently extended to SDO. Terlaky and Wang specialized the concept for SOCO. In this paper, we present a fast iterative procedure, which uses the optimal partition information to generate a pair of maximally complementary optimal solutions. We are interested in the local convergence of the iterative procedure near the optimal set. In this regard, we show that, under the primal and dual nondegeneracy conditions, the iterative procedure is quadratically convergent to a maximally complementary optimal solution when starting from a strictly interior pair of solutions close to the optimal set.

Electricity Markets

Sponsored: Energy, Natural Res & the Environment Electricity

Sponsored Session

Chair: Todd Levin, Argonne National Laboratory, 9700 S. Cass Ave, Bldg 202, Lemont, IL, 60439, United States, tlevin@anl.gov

1 - A Multistage Stochastic Dynamic Programme for Major Consumers' Demand Response in Electricity Markets

Mahbubeh Habibian, University of Auckland, 439-325, 70 Symonds, Auckland, 1010, New Zealand, mhab735@aucklanduni.ac.nz, Golbon Zakeri, Anthony Downward

We optimize the bidding policy for a major consumer of energy in an energy and reserve co-optimized electricity market. In our model, the major consumer has dispatchable demand, and it is able to offer interruptible load reserve. The large consumer is a strategic player, maximizing its profit, while meeting its required level of consumption over a long-time horizon. By reformulating the equilibrium constraints, we present a multi-stage stochastic dynamic programming. In order to solve our mixed integer program in an adequate time-frame we use heuristics while utilizing the intuition of stochastic dual dynamic programming.

2 - Demand Response to Electricity Prices in Flexible Manufacturing

Kazem Abbaszadeh, The University of Auckland, Room F, level 1,11 Mount St, Auckland, 1010, New Zealand, kabb955@aucklanduni.ac.nz, Golbon Zakeri, Geoffrey Pritchard

Large manufacturers are often also large users of electricity. This includes Aluminium and Steel manufacturers as well as paper and dairy processing plants in New Zealand. We consider a major consumer of electricity whose decision to contract for production could depend on electricity prices. We describe our stochastic dynamic programming approach for a steel mill in New Zealand with some flexibility in their operations, and utilize this flexibility to provide an optimal production plan. As a part of this model, we need to develop electricity price models over the short and medium time horizon. We will describe these models as well.

3 - Key Drivers of Prices for Ancillary Services

Todd Levin, Energy Systems Engineer, Argonne National Laboratory, 9700 S. Cass Ave, Bldg 362, Lemont, IL, 60439, United States, tlevin@anl.gov

We apply AURORAxmp, a commercial power systems model, to forecast how prices for ancillary services (AS) in PJM are affected under various future scenarios. We find that doubling the natural gas price increases the average frequency regulation price by 41% and decreases the average price for synchronized and primary reserves by 75% and 23% respectively. Increasing wind generation capacity by a factor of 15 decreases average AS prices by 8%, 25% and 90% for regulation, synchronized and primary reserves. Several additional sensitivities including increased AS requirements, unit retirements and natural gas supply constraints are also considered and revenue sufficiency implications are discussed.

Contributed Session

Chair: Hesam Shams, University of Tennessee, Knoxville, TN, United States, hesam@utk.edu

1 - Bias in Balance Optimization Subset Selection

Hee Youn Kwon, PhD Student, University of Illinois at Urbana-Champaign, 104 S.Mathews Avenue, Transportation Building, Urbana, IL, 61801, United States, hkwon14@illinois.edu, Jason Sauppe, Sheldon H. Jacobson

When estimating a treatment effect from observational data, researchers encounter bias regardless of estimation methods. By focusing on a particular method of estimation called Balance Optimization Subset Selection (BOSS), we investigate all the possible cases that may lead to bias in the context of BOSS and try to mitigate the bias. While doing so, we define a balance hierarchy and a correct imbalance measure which corresponds to a functional form of the responses.

2 - Service Placement Optimization in Mobile Edge Computing

Hossein Badri, Graduate Teaching Assistant, Wayne State University, 4185 4th Street, Manufacturing Building, Detroit, MI, 48202, United States, fq2529@wayne.edu, Kai Yang

Service placement is a very important and at the same time a super complex problem in Mobile Edge Computing (MEC). Dynamisms of users' location and uncertainties in their demands are the main source of complexity in this problem. In this research, we develop a stochastic programming model for the service problem in MEC and conduct an extensive computational analysis to evaluate the performance of the proposed approach.

3 - Two-stage Stochastic Mathematical Model for Inventory Management of Red Blood Cells Accounting for Age-differentiated Demand

Bayan Hamdan, Masdar Institute, Abu Dhabi, United Arab Emirates, bhamdan@masdar.ac.ae, Ali Diabat

Blood Supply Chain inventory management has recently become one of the most important fields in operations research due to the perishability of blood. This paper forms a mathematical model that determines an optimal inventory ordering policy for red blood cells (RBCs). The model accounts for the perishability of the red blood cells and the age-differentiation and stochasticity of the demand. This paper proposes an (R,S) inventory policy where R is the review frequency and S is the target level, to minimize system outdate, shortage, substitution and holding costs.

4 - Surrogate Modeling Recommendations

Reza Alizadeh, Graduate Research Assistant, University of Oklahoma, Norman, OK, 73019, United States, reza.alizadeh-2@ou.edu, Janet K. Allen, Farrokh Mistree

Models describing engineering systems are often simplified, thus creating uncertainty. Surrogate models with their reduced computational costs allow us to manage uncertainty by substantially reducing computational expense. Much has been done to compare different methods; however, there is a gap in providing guidance for the choice of appropriate surrogate modeling methods. We ask these questions: 1) What are the critical characteristics of a model to be approximated? 2) What are desirable characteristics of the DOE, surrogate model and model fitting methods to achieve useful surrogate models? Answering these questions leads to a toolbox to choose appropriate surrogate modeling methods.

5 - Enhancing Optimization Algorithm via Machine Learning

Hesam Shams, University of Tennessee, 851 Neyland Drive, 525 John D. Tickle Engineering Building, Knoxville, TN, 37996, United States, hesam@utk.edu, Oleg Shylo

We explore an application of classification techniques to binary optimization. Given a set of solutions and the corresponding objective values, the goal is to classify each solution component either as zero or one. We implement statistical models based on random forests, convolutional neural networks, and logistic regression and compare their performance on a set of scheduling problems. A learning module based on an efficient logistic regression model is embedded into the tabu search method. The comparison with standard tabu algorithm implementations reveals significant gains in efficiency.

1 - Computational Challenges in RTO Markets

Yonghong Chen, Midwest ISO, 720 City Center Drive, Carmel, IN, 46032, United States, ychen@misoenergy.org

Optimization techniques and algorithms are at the core of electricity market operations with the goal of minimizing system operation cost while ensuring system security. The industry evolution has posed unprecedented challenges to the existing optimization and computation techniques. This panel will discuss the latest advances in formulating optimization problems and developing new algorithm and solution techniques. It includes the development of tighter Mixed Integer Programming (MIP) models and exploration of novel algorithms in solving MIP problems on traditional hardware as well as with distributed and high performance computers.

Co-Chair: Destenie Nock, destenienock5@gmail.com

1 - Long Term Generation and Transmission Co-optimization: Infrastructure Planning to Accommodate Renewables
Patrick Maloney, Iowa State University, 2405 Aspen Road, # 210, Ames, IA, 50010, United States, patrickm@iastate.edu, Ping Liu, James McCalley

This work investigates deterministic and stochastic long term planning models for the Pacific Northwest using a 300 bus reduced model of a WECC TEPPC dataset. NREL toolkit profiles and resource capacities are used to model realistic wind and PV candidate generation. To compete remote renewable resources against traditional generation near load centers, the model co-optimizes generation and transmission. A major thrust of the tools developed for this work is to enable energy decision makers to explore the decisions that allow them to adapt systems to the future; especially in response to increasing interest in and competiveness from renewable technologies.

2 - Pricing Wind: A Revenue Adequate, Cost Recovering Market Clearing Mechanism to Facilitate Volatile Renewables
Golbon Zakeri, University of Auckland, Dept of Eng Science, Private Bag 92019, Auckland, New Zealand, g.zakeri@auckland.ac.nz, Geoffrey Pritchard, Endre Bjorndal, Mette Bjorndal

With the increasing penetration of volatile renewable energy into the power grid, it is imperative to ensure sufficient, economical regulation is available to compensate for any excess or short fall of electricity generated from renewables. To this end, we have developed a stochastic programming market mechanism that is an improved version of Pritchard et al's 2010 model. In this talk we will discuss the properties of our model, that include revenue adequacy in each scenario and expected cost recovery. We have implemented our model on the New Zealand system. Will provide the numerical results that we have obtained thus far.

3 - Effects of Grid-scale Electricity Storage on System Carbon Dioxide Emissions as a Power System Decarbonizes
Michael Craig, Carnegie Mellon University, Pittsburgh, PA, United States, mtcraig@andrew.cmu.edu, Paulina Jaramillo, Bri-Mathias Hodge

While grid-scale electricity storage may be crucial for decarbonizing the electric power system, studies find it would currently increase net carbon dioxide (CO_2) emissions across the U.S. We quantify the effect of storage participating in reserve and/or energy markets on net CO_2 emissions as a power system decarbonizes. To do so, we use two optimization models: a capacity expansion model to forecast generator fleet changes and a unit commitment model to quantify net CO_2 emissions with and without storage. We preliminarily find that storage reduces net CO_2 emissions well before full decarbonization and that storage affects net CO_2 emissions more when participating in reserve than in energy markets.

4 - Evaluation of Generation Portfolios for the New England Power System
Destenie Supreece Nock, University of MA-Amherst, 132 Middle Street, Unit 3, Hadley, MA, 01035, United States, dnock@umass.edu, Erin Baker

As power systems evolve there has been a shift towards sourcing electricity from more sustainable generation sources. This push combined with the need to ensure the system can reliably supply electricity throughout the year makes the generation capacity planning question more complex. In this paper we propose a method for evaluating a portfolio of generation technologies in terms of their sustainability and a pre-integration metric for reliability. Preference scenarios for sustainability are defined in terms of economical, technological, societal, and environmental factors.

Distributional Robust Optimization with Marginals

Sponsored: Optimization, Optimization Under Uncertainty

Sponsored Session

Chair: Karthik Natarajan, Singapore, 439959, Singapore, karthik_natarajan@sutd.edu.sg

1 - Using Marginal Distribution Choice Models in Traffic Equilibrium
Selin D. Ahipasaolgu, Assistant Professor, Singapore University of Technology and Design, Singapore, Singapore, ahipasaoglu@sutd.edu.sg, Ugur Arikan, Karthik Natarajan

Traffic equilibrium models are fundamental to the analysis of transportation systems. We develop a new user equilibrium model, the MDM-SUE model, that uses the marginal distribution model (MDM) for the underlying route choice. In MDM, the marginal distributions of the path utilities are specified but the joint distribution is not. We show that MDM-SUE exists, is unique under mild assumptions, has a convex optimization formulation, and can be computed efficiently. The MDM-SUE model can be used to recreate logit SUE and weibit SUE. Moreover, the model is flexible as it can capture perception variance scaling at the route level and allows for modeling with skewed and heavy tailed distributions.

2 - Distributionally Robust Markovian Traffic Equilibrium
Ugur Arikan, Singapore University of Technology and Design, Singapore, Singapore, ugur_arikan@sutd.edu.sg

A class of link based models under a Markovian assumption has been proposed to deal with the drawbacks of route based models in traffic assignment. However, the application has been thus far restricted to the multinomial logit model. We propose a distributionally robust Markovian traffic equilibrium model assuming that marginal distributions of link utilities are known but the joint distribution is unknown. We develop a convex optimization formulation and propose an efficient algorithm to compute equilibrium flows. Our formulation is completely link based, relaxes the assumption of independence and identical distributions, and provides modeling flexibility and computational tractability.

3 - Scenario Reduction Revisited: Fundamental Limits and Guarantees
Napat Rujeerapaiboon, Ecole Polytechnique Federale de Lausanne, EPFL.CDM.MTE I.RAO, ODY 1 19 (Odyssea), Station 5, Lausanne, 1015, Switzerland, napat.rujeerapaiboon@epfl.ch, Kilian Schindler, Daniel Kuhn, Wolfram Wiesemann

The goal of scenario reduction is to approximate a discrete distribution with another discrete distribution that has fewer atoms. We distinguish continuous scenario reduction, where the new atoms may be chosen freely, and discrete scenario reduction, where the new atoms are chosen from among the existing ones. Using Wasserstein distance to measure proximity between distributions, we analyze the added benefit of continuous over discrete scenario reduction. We also propose polynomial-time constant-factor approximations and exponential-time exact algorithms for both types of scenario reduction.

4 - Revisiting the Marginal Distribution Model for Discrete Optimization: Extensions and Generalizations
Louis L. Chen, Massachusetts Institute of Technology, Cambridge, MA, United States, llchen@mit.edu, Karthik Natarajan, David Simchi-Levi

Building on previous work which incorporated the Marginal Distribution Model to examine the persistency problem for discrete optimization, we provide extensions in two ways. Firstly, we extend the distributionally robust problem to now incorporate completely arbitrary marginal distributions, and we find a dual optimization problem that not only points the way to tractable cases but also presents a basic multi-marginal transport problem with a story not unlike that found in the assignment game from mathematical economics. Secondly, we investigate the role of the discrete constraint set's structure in tractability. As well, we consider how the results generalize/unify some other works.

Optimizing Network Robustness under Uncertainty

Sponsored: Optimization, Optimization Under Uncertainty

Sponsored Session

Chair: Tanveer Hossain Bhuiyan, tb2038@msstate.edu

1 - Chance Constrained Distributional Robust Optimization for Capacity Expansion of Wind Generation

Wei Wang, Doctoral Student, University of Pittsburgh, 1025 Benedum Hall, Pittsburgh, PA, 15261, United States, w.wei@pitt.edu, Bo Zeng

To handle uncertainties in wind energy generation in capacity expansion, a chance-constrained distributional robust optimization model is developed and solved. Numerical results will be reported.

2 - Algorithm for a Stochastic Bilevel Optimization

Chaosheng Dong, University of Pittsburgh, 4200 Fifth Avenue, Pittsburgh, PA, 15260, United States, chaosheng@pitt.edu, Bo Zeng

For a bilevel optimization problem with multiple lower level problem, we analyze its property and develop a distributed computational algorithm. Numerical results will be presented.

3 - Network Design and Facility Protection when the Effect of Protection is Uncertain

Tanveer Hossain Bhuiyan, Mississippi State University, P.O. Box 5227, Room 321, Starkville, MS, 39762, United States, tb2038@msstate.edu, Hugh Medal

We study a facility location and network design problem that involves protecting facilities subject to random disruptions where the protection is imperfect, multi-level, and the effect of disruption is imperfect. The goal of our study is to optimally allocate protection resources to the facilities, and construct links in the network to minimize the expected total transportation cost. We model the problem as a two-stage stochastic programming with decision dependent uncertainty where the post-disruption capacity states of the facilities depends probabilistically on the resource allocation decision and the disruption intensity. We implement an L-shaped algorithm to solve the model.

4 - Two-stage Robust Optimization for Single-commodity Network Design with Potential Edge Failures

Logan R. Matthews, Princeton University, Princeton, NJ, United States, loganm@princeton.edu, Yannis G. Kevrekidis, Chrysanthos E. Gounaris

The single-commodity network design problem with potential edge failures is formalized as a two-stage robust optimization problem with an uncertainty set of binary random variables representing uncertain edge failures. A column-and-constraint generation algorithm is tailored to this application and implemented to gain minimum cost networks which remain feasible for a given number of simultaneous edge failures. Problems adapted from the Survivable Network Design Library are solved to measure the cost increases and computational efforts required due to various levels of robustness.

Stochastic Optimization with Learning

Sponsored: Optimization, Optimization Under Uncertainty

Sponsored Session

Chair: Daniel Jiang, University of Pittsburgh, University of Pittsburgh, Pittsburgh, PA, 15261, United States, drjiang@pitt.edu

1 - Optimal Online Learning for Nonlinear Belief Models with Physical State Information

Weidong Han, Princeton University, 35 Olden Street, Sherrerd Hall, Princeton, NJ, 08544, United States, whan@princeton.edu, Warren Powell

We consider an optimal learning problem with nonlinear belief models and physical state information such as a finite budget or resource. We assume the parameter vector in the belief model follows a discrete prior distribution. We formulate the problem into a dynamic program, and propose a lookahead policy called the OC-correction that is shown to be optimal for two-stage problems. We prove asymptotic convergence properties of the proposed policy for infinite-horizon problems. Adopting this framework, we find an approach to the real-time bidding problem for online advertising.

2 - Statistical Optimality and Model Assessment for SP in Learning Enabled Optimization (LEO)

Yunxiao Deng, PhD Student, University of Southern California, Los Angeles, CA, 90089, United States, yunxiaod@usc.edu

For Learning Enabled Optimization problems, we can obtain solutions with statistical guarantees using concepts of statistical optimality. Model assessment and selection are also critical parts of the modeling process. We present a collection of hypothesis tests, metrics and comparisons between alternative LEO models to assess solution quality.

3 - Ensemble Bayesian Optimization for Partially Controllable Sequential Information Processes

Yingfei Wang, Princeton University, Department of Computer Science,, Princeton University, 35 Olden Street,, Princeton, NJ, 08540-5233, United States, yingfei@princeton.edu, Warren B.Powell

An important element in sequential decision making problems is stochastic models of the environment and proper statistical models and inferences to represent our changing beliefs about the environment as new information is collected. We design an ensemble optimal learning method to respond quickly and robustly to complex data streams. In our ensemble system, multiple models, such as classifiers, are strategically generated and combined to minimize the incorrect selection of a particularly poorly performing statistical model. Similar to the idea of online boosting, we use Bayesian learning with expert advice as the belief model, aiming to spend the limited measurement budget more wisely.

4 - Learning Rare-event Probabilities and Applications to Automated Vehicle Testing

Zhiyuan Huang, University of Michigan, Ann Arbor, MI, 48109, United States, zhyhuang@umich.edu, Henry Lam, Ding Zhao

This talk discusses the estimation of rare-event probabilities where learning takes place in the measurement of the hitting set of interest. Because of the rare-event nature, the estimation requires the use of variance reduction techniques that are sequentially optimized. This problem arises from the safety testing of automated vehicles using simulation-based estimation of critical events such as crashes or conflicts, where the vehicles' behaviors are analytically intractable or not fully observable.

Modeling, Decisions, and Sensitivity

Sponsored: Decision Analysis

Sponsored Session

Chair: Emanuele Borgonovo, Bocconi University, Milano, 20136, Italy, emanueleborgonovo@unibocconi.it

Co-Chair: Alessandra Cillo, Bocconi University, Milan, 20136, Italy, alessandra.cillo@unibocconi.it

1 - Multinomial Logit Processes and Preference Discovery

Fabio Maccheroni, Università Bocconi, Milan, Italy, fabio.maccheroni@unibocconi.it, Simone Cerreia-Vioglio, Massimo Marinacci, Aldo Rustichini

We study and axiomatically characterize the dependence of choice probabilities of an agent on the time available to decide by means of a Multinomial Logit Model with time independent (systematic component of the) utility and time dependent scale parameter. This is the most widely used model of preference discovery in all fields of decision making from Quantal Response Equilibrium theory to Discrete Choice Analysis, from Psychophysics to Combinatorial Optimization. Our axiomatic characterization permits, on the one hand, to understand its conceptual underpinnings as a theory of agents behavior, on the other to empirically test its descriptive validity.

2 - Domain Dependent Attitudes
Veronica Roberta Cappelli, PhD Student, HEC Paris, Jouy en Josas, France, veronica.cappelli@hec.edu

Many everyday decisions can be framed as choices between streams of multicriteria alternatives. At the same time, there is by now substantial evidence that decision makers may have domain-specific attitudes toward outcomes. In particular, different categories of outcomes may be discounted differently and associated with different levels of risk aversion. This work aims at providing an axiomatized model of choice between streams of multicriteria alternatives. Our objective is to allow for an evaluation functional that takes into account the fact that, not only utility, but also discounting may be attribute, or domain, dependent.

3 - Accelerated Kriging for Global Sensitivity Analysis
Xuefei Lu, Bocconi University, Via Sarfatti 25, Milan, 20136, Italy, xuefei.lu@phd.unibocconi.it, Emanuele Borgonovo, Lorenzo Andrea Rosasco, Alessandro Rudi

In global sensitivity analysis, kriging is commonly applied as a metamodeling technique, especially when the analyst is dealing with time-consuming computer codes. We study an improved kriging improving estimation with an acceleration procedure coming from Machine Learning. We apply this method to global sensitivity analysis and compare the results with standard kriging.

4 - Information Density in Decision and Sensitivity Analysis
Emanuele Borgonovo, Bocconi University, Bocconi University, Via Sarfatti 25, Milano, 20136, Italy, emanueleborgonovo@unibocconi.it, Gordon B. Hazen, Victor Richmond R.Jose

This work discusses the use of the notion of information density in decision and sensitivity analysis.

5 - On the Relationship Between Safety and Decision Significance
Alessandra Cillo, Bocconi University, Via Roentgen 1, Milan, 20136, Italy, alessandra.cillo@unibocconi.it, Emanuele Borgonovo, Curtis L. Smith

Risk analysts are often concerned with identifying key safety drivers, i.e., the systems, structures and components (SSCs) that matter the most to safety. SSCs importance is assessed both in the design phase and in the implementation phase using the same importance measures. However, in a design phase it would be necessary to appreciate whether, the failure/success of a given SSC can cause the overall decision to change from accept to reject. This work addresses the search for the conditions under which SSCs which are safety significant are also decision significant. To address this issue, the work proposes the notion of teta-importance measure.

1 - Modeling Multi-target Defender-attacker Games with Quantal Response Attack Strategies
Jun Zhuang, University at Buffalo, SUNY, 317 Bell Hall, Buffalo, NY, 14260, United States, jzhuang@buffalo.edu, Jing Zhang

Due to the growing interest in incorporating behavior models within thedefender-attacker game literature, the perfect rationality assumption of adversary has been relaxed. We study four multi-target defensive resource allocation in defender-attacker games by using quantal response model, in which the attacker might be bounded rational. We compare the our model results with the traditional game theoretic model where the attacker behaves rationally. We studied the impacts of the attacker's rationality level on the defender's optimal defense strategies. This paper provides some novel insights to defensive resource allocation when considering the attacker's bounded rationality.

2 - A Roadmap for OR Research in Homeland Security
Detlof von Winterfeldt, USC, 3710 McClintock Ave, RTH 316A, Los Angeles, CA, 90089-3926, United States, detlof@aol.com

On the occasion of 15th anniversary of 9/11, we will summarize the evolvement and analyze strengths and weaknesses of OR methods in homeland security, in particular in decision and risk analysis, optimization, game theory as well as in simulation and stochastic methods. On the other hand, we will identify in a survey the needs of current key decision makers in homeland security. Finally, we will bring the status quo in theory and the practical needs together in order to develop a roadmap for research on OR methods in counterterrorism in the future.

3 - Public Response to the Security Threat to Aviation
Richard S. John, University of Southern California, Dept of Psychology MC 1061, Los Angeles, CA, 90089-1061, United States, richardj@usc.edu, Heather Rosoff

Important to the effectiveness of airport security measures is public response to the implemented policies. We will present three studies that have assessed public reaction to varying aspects of the security threat to aviation. The first is a longitudinal study looking at the psychological effects of the events of 9/11 over 5 years. The second study examines how travelers value the principle of equal protection by quantifying their willingness to sacrifice to avoid different screening procedures. The third study looks at public perception of traditional airport security schedules that search everyone versus randomized security schedules that randomly deploy security measures.

4 - Understanding Terrorist Attacks with Learning Models
Gilberto Montibeller, Loughborough University, School of Business & Economics, Loughborough, LE11 3TU, United Kingdom, g.montibeller@lboro.ac.uk, Johannes Jaspersen

In this paper we adopt the perspective of the terrorist group as an economic agent learning from reinforcement and calibrate different learning models to study the target selection of terrorists using empirical data. Terrorists display the power law of learning and discount prior information, but show no tendency to have an aspiration level or reference point. Our results show learning models from laboratory experiments in behavioral economics to be applicable to naturally occurring human conflicts and let us draw implications for counterterrorism strategies.

5 - A Hybrid Spatio-temporal Model for Wildlife Poaching Prediction Evaluated through a Controlled Field Test
Shahrzad Gholami, PhD Student, University of Southern California, Los Angeles, CA, 90089, United States, sgholami@usc.edu, Milind Tambe

Worldwide, conservation agencies employ rangers to protect conservation areas from poachers. However, agencies lack the manpower to have rangers effectively patrol these vast areas frequently. While past work has modeled poachers' behavior so as to aid rangers in planning future patrols, those models' predictions were not validated by extensive field tests. We present a hybrid spatio-temporal model that predicts poaching threat levels and results from a five-month field test of our model in Uganda's Queen Elizabeth Park.

Dynamic Ridesharing

Invited: Tutorial

Invited Session

Chair: Jiming Peng, University of Houston, Houston, TX, 77204, United States, jopeng@Central.uh.edu

Chair: Rajan Batta, University at Buffalo (SUNY), 410 Bell Hall, Buffalo, NY, 14260, United States, batta@buffalo.edu

1 - Dynamic Ridesharing
Fernando Ordonez, DII, Univeridad de Chile, Santiago, Chile, fordon@dii.uchile.cl, Maged M.Dessouky

Recent technological developments such as GPS, mobile devices and increases in data storage and computation capacity have greatly enhanced the communication capabilities of travelers, facilitating ridesharing in real-time. This opportunity has created a new ridesharing industry built on making use of the unused vehicle capacity moving about on the roads. There are however still important barriers for widespread dynamic ridesharing adoption. It therefore becomes important to better understand the problems and challenges of ridesharing, creating the need for novel research that explicitly takes into account dynamic ridesharing. In this tutorial we review recent research on new vehicle routing models, cost sharing mechanisms, and planning models that incorporate ridesharing.

Energy in Applied Probability

Sponsored: Applied Probability

Sponsored Session

Chair: Bert Zwart, Eindhoven, 5629RD, Netherlands, Bert.Zwart@cwi.nl

1 - Estimating Line Failure Probability in Power Grids under Uncertainty
Tommaso Nesti, CWI, Amsterdam, Netherlands, TNesti@cwi.nl

The advent of renewable energy has huge implications for the control of power

grids. Due to increasing uncertainty, traditional reliability constraints must be replaced by probabilistic guarantees. We investigate the probability of line current overloads assuming stochastic power injections, using techniques from large deviations theory and concentration inequalities, both in a static and in a dynamic scenario. We derive analytic expressions for the set of admissible power injections profiles such that line overloads are sufficiently rare events, and we show how enforcing constraints on line temperature, rather than on current, can lead to capacity gains.

2 - Learning to Price in Demand Response Programs

Kia Khezeli, Cornell University, Ithaca, NY, 14853, United States, kk839@cornell.edu, Eilyan Bitar

Electric power utilities offer demand response (DR) programs where consumers are paid to curtail their electricity consumption when electricity is scarce and expensive. The most basic challenge that a utility faces in implementing DR programs is the prediction of how customers will adjust their demand in response to different prices. In this talk, we'll discuss the role of adaptive control in guiding the design of DR pricing polices that effectively balance the tradeoff between the utility's need to learn the unknown customer response model and the need to minimize its expenditure over time.

3 - Estimation of Stochastic Process Parameters Implied by Financial Transmission Rights

Boris Defourny, Lehigh University, 200 W Packer Ave, Bethlehem, PA, 18015, United States, defourny@lehigh.edu

This work hypothesizes that Financial Transmission Right (FTR) prices in electricity markets express the assessment by market participants of the grid congestion risk, as determined by parameters of stochastic processes such as load levels, generation and transmission grid state driving the underlying day-ahead hourly price differences. We propose a methodology to infer parameters consistent with FTR contract prices, based on a relation between state occupation measures and the contract value. More broadly, this work is concerned with the inverse mapping from occupation measures to stochastic processes, and the stability of the estimates.

4 - Random Graph Models for Power System Controllability

Linqi Guo, California Institute of Technology, Pasadena, CA, United States, lguo@caltech.edu, Steven H.Low

We give a full characterization in terms of spectral graph theory for the controllability of the swing and power flow dynamics when we can only inject control signals to a subset of the buses. In particular, we show the controllability of the system depends on two orthogonal conditions: 1) intrinsic structure of the system graph 2) algebraic coverage of buses with controllable loads. Both conditions can be verified using the eigenvalue and eigenvectors of the graph Laplacian matrix. We then employ random graph models and uncertainty principle to explain why in practice we only need sporadic controllers for full controllability.

Economic Models on Markets, Firms and Information

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Shuya Yin, University of California-Irvine, shuya.yin@uci.edu

1 - When Does a Supply Chain Member Benefit from Vendor Managed Inventory?

Ruixia Shi, University of San Diego, San Diego, CA, United States, rshi@sandiego.edu, Jun Ru, Jun Zhang

This paper studies the effects of VMI on a supply chain consisting of one manufacturer and one retailer. We show that whether the two supply chain members benefit from VMI depends on how the holding or shortage cost increment from the manufacturer to retailer compares with two corresponding critical values. We then develop comparative statics results on how these critical values change with respect to different parameters. Interestingly, the retailer is more likely to benefit from the adoption of VMI when its inventory holding cost is low, and the manufacturer is more likely to benefit from VMI adoption when its inventory holding cost is high, contradicting what our intuitions would suggest.

2 - Inventory Allocation in the Presence of Store Switching Caused by Stock Outs

Elcin Ergin, McGill, 3465 Hutchison Street, Apt 905, Montreal, QC, H2X 2G3, Canada, elcin.ergin@mail.mcgill.ca, Mehmet Gumus

In this study, we focus on inventory allocation of fast fashion products between the stores of the firm when there is an evidence of store switching behaviour of customers in the case of stock outs. Examining an extensive dataset taken from a fast fashion retailer company which has more than 300 stores showed that some of the customers visit other stores to find the product they look for. We present an inventory allocation model considering this behavior. We analyze how this behavior would affect the total sales and accordingly how a firm should shape the initial allocation decisions under this model.

3 - Strategic Inventories when Competing Manufacturers Sell through a Common Retailer

Abhishek Roy, University of Texas-Austin, 2110 Speedway Stop B6500, Austin, TX, 78712-1277, United States, abhishek.roy@utexas.edu, Stephen M. Gilbert, Guoming Lai

Although the effects of strategic inventory in dynamic contracts on supply chain agents are well known, most existing research on strategic inventory focuses on bilateral monopolies. When the partially substitutable products of different manufacturers are sold through a common retailer, we find that those effects are altered in significant ways. Among other things, the retailer's and the manufacturers' preferences between commitment and dynamic contracts can be reversed.

4 - Distribution Channel Entry Strategies with Intra-and Inter-channel Demand Learning

Shuya Yin, University of California-Irvine, Paul Merage School of Business, Irvine, CA, 92697-3125, United States, shuya.yin@uci.edu, Jing Hu, Christopher S.Tang

When a rm introduces a new product to market, making it available in multiple channels can achieve higher market coverage and learn market uncertainty better so as to improve subsequent decisions, while selling it in a single channel exclusively can save slotting fees and avoid channel cannibalization. This paper considers a model where a rm needs to determine its distribution channel entry strategy on whether to sell its product in one or two channels over a two-period time.

5 - Incentives for Information Transparency under Vertical Information Asymmetry

Sammi Tang, Associate Professor, University of Miami, Miami, FL, 33146, United States, ytang@miami.edu, He Huang, Hongyan Xu

This paper studies the incentives for horizontal information transparency between competing downstream firms when upstream suppliers possess private information. Information is modeled along two dimensions: vertical information on suppliers' reliability level and horizontal information on suppliers' production cost. Our findings provide novel insights for managers to handle two-dimensional information asymmetry.

Sustainable Operations

Sponsored: Manufacturing & Service Oper Mgmt, Sustainable Operations

Sponsored Session

Chair: Greys Sosic, University of Southern California, Los Angeles, CA, 90089-0809, United States, sosic@marshall.usc.edu

Co-Chair: Hailong Cui, University of Southern California, Los Angeles, CA, 90089-0809, United States, Hailong.Cui.2019@marshall.usc.edu

1 - Lemons, Trade-ins and Remanufacturing

Ximin Huang, Assistant Professor, University of Minnesota, 321 19th Ave S, Ste 3-150, Minneapolis, MN, 55455, United States, huangx@umn.edu, Atalay Atasu, Beril L.Toktay

Trade-in programs have been shown to partially mitigate the lemons problem in secondary markets. We show when and how remanufacturing traded-in products can further improve the efficiency in secondary markets.

2 - Complementary Product Design and Process Technology Choices in Recycling

Luyi Gui, The Paul Merage School of Business, University of California-Irvine, Irvine, CA, 92697-3125, United States, luyig@uci.edu, Morvarid Rahmani, Atalay Atasu

Motivated by the Japanese implementation of the Home Appliance Recycling Law, we study the complementarity between product design and technology choices for recycling. We evaluate the environmental benefit of recycling capacity sharing between producers and of producers' investment in recycling facilities.

3 - Choice of E-waste Recycling Standard under Recovery Channel Competition

Gokce Esenduran, Ohio State University, 2100 Neil Avenue, 656 Fisher Hall, Columbus, OH, 43210, United States, esenduran@gmail.com, Yen-Ting (Daniel) Lin, Wenli Xiao, Minyue Jin

There are two recycling standards for e-waste recyclers that are different in stringency: E-stewards and R2. E-stewards is more stringent and costlier but attracts more e-waste from environmentally conscious donors. We model the competition between recovery channels and examine how secondary market sales and economies of scale affect recyclers' choice. We find that a recycler may choose e-Stewards only when facing competition. Our results also show that recyclers with strong scale economies in e-waste processing choose e-Stewards only when incurring processing costs significantly higher than R2 would require.

4 - To Recycle or Not: An Analysis of the Environmental and Financial Impact of Recycling

Hailong Cui, University of Southern California, Marshall School of Business, Data Sciences and Operations, Los Angeles, CA, 90089-0809, United States, Hailong.Cui.2019@marshall.usc.edu, Greys Sosic

We evaluate the conditions under which recycling of simple products (made of common materials) has positive impact across three dimensions: GHG emissions, operational costs, and societal costs. Our study contains both an analytical model and empirical validation of our results. We then consider different decision makers when decision variables are collection and yield rates: we start with centralized models wherein a single entity (local government, manufacturer, or independent recycler) determines both values, and then we move to decentralized models in which collection and yield rates are chosen by two different parties. We also discuss incentive mechanisms for achieving social optima.

Behavioral, Incentive and Policy Issues in Healthcare

Sponsored: Health Applications

Sponsored Session

Chair: Tinglong Dai, Johns Hopkins University, Baltimore, MD, 21202, United States, dai@jhu.edu

Co-Chair: Song-Hee Kim, University of Southern California, Los Angeles, CA, 90089, United States, songheek@marshall.usc.edu

1 - Search Among Queues under Quality Differentiation

Luyi Yang, Johns Hopkins University, Baltimore, MD, United States, luyi.yang@jhu.edu, Laurens G.Debo, Varun Gupta

We examine a setting in which customers looking for service providers face search frictions and service providers vary in quality and availability. We find that reducing either the search cost or customer arrival rate may strictly increase the average waiting time in the system as customers substitute toward high-quality service providers. We discuss policy implications of our results in the context of public surgical waits.

2 - Upcoding in Medicare Reimbursement for Hospital-acquired Infections

Joel Goh, Harvard Business School, Morgan Hall 420C, Soldiers Field Road, Boston, MA, 02163, United States, jgoh@hbs.edu, Hamsa Sridhar Bastani, Mohsen Bayati

Since 2008, Medicare has levied financial penalties to providers for hospital-acquired infections (HAIs). However, Medicare relies on providers' self reported HAIs to assess these penalties. Consequently, providers may upcode, i.e., mis-report HAIs in a manner that increases reimbursement. One form of upcoding involves incorrectly classifying HAI conditions as being present-on-admission (POA). In this empirical study, we use nationally-representative claims data to investigate the whether such POA upcoding occurs. Our results suggest that the level of state-level regulation and enforcement is an important determinant of POA upcoding.

3 - Designing Response Supply Chain Against Bioattacks

Peter Yun Zhang, Massachusetts Institute of Technology, Cambridge, MA, United States, pyzhang@mit.edu, David Simchi-Levi, Nikolaos Trichakis

We study the problem of designing supply chain against bioattacks. We propose a model that integrates key facets of the problem in a way not done before, with decision variables spanning medical countermeasure stock level, capacity, shipment, and dispensing. We also explicitly capture the interaction between defender and attacker. We present a tractable and provably strong heuristic capable of solving large networks with high fidelity (100,000s nodes). Compiling data on supply, population, lead times, health effects, and costs, we analyze the design of a comprehensive biodefense supply chain in the United States and generate new policy insights.

4 - A Contract Mechanism for the Opioid Prescription Epidemic

Alireza Boloori, Arizona State University, 505 W. Baseline Rd, Apt 2158, Tempe, AZ, 85283, United States, alireza.boloori@asu.edu, Soroush Saghafian, Stephen J. Traub

Hospital EDs are in part responsible for the overprescription of opioid painkillers. To analyze the impact of different contracts (between an insurer (e.g., Medicare and a hospital) on the opioid prescription in EDs, we propose a principal-agent model where pharmaceutical incentives from opioid manufacturers cause asymmetric information (i.e., adverse selection) in the model. Utilizing data from Mayo Clinic, we establish a data-driven contracting approach to not only alleviate the negative consequences of opioids, but also address patients who really need these medications. We also provide implications for healthcare policy makers.

Healthcare Decision Making under Uncertainty

Sponsored: Health Applications

Sponsored Session

Chair: Hadi El-Amine, George Mason University, George Mason University, Fairfax, VA, 22030, United States, helamine@gmu.edu

1 - Adaptive Risk-based Pooling in Public Health Screening

Hrayer Y. Aprahamian, Virginia Tech, 1145 Perry Street, Blacksburg, VA, 24060, United States, ahrayer@vt.edu, Ebru Korular Bish, Douglas R.Bish

Pooled testing is commonly used in public health screening for classifying subjects in a large population as positive or negative for an infectious or genetic disease. Pooling is especially useful when screening for low prevalence diseases under limited resources. We propose and study an adaptive risk-based pooling scheme, which considers important test and population level characteristics often overlooked in the literature. We characterize important structural properties of optimal subject assignment policies, and provide key insights. Our case study demonstrates the effectiveness of the proposed pooling scheme, with false classifications reduced substantially over current policies.

2 - Multi-objective Two-stage Stochastic Programming for Adaptive Interdisciplinary Pain Management with PLN Transition Models

Jay Michael Rosenberger, University of Texas-Arlington, Arlington, TX, 76010, United States, jrosenbe@uta.edu, Gazi Md Daud Iqbal, Victoria Chen, Robert Gatchel

This research uses a two-stage stochastic programming approach to optimize personal adaptive treatment strategies for pain management. The goal is to generate adaptive treatment strategies using statistics based optimization approaches that can be used by physicians to prescribe treatment to the patients. Five pain outcomes has been considered in objective function. This research uses Piecewise Linear Networks (PLN) to represent transition models. A mixed integer linear program is developed to integrate those PLN transition models into an optimization problem.

3 - Comparative Effectiveness of Incorporating a Hypothetical DCIS Prognostic Marker into Breast Cancer Screening

Mehmet Ergun, University of Wisconsin, 7429 Old Sauk Road, Madison, WI, 53717, United States, mergun@wisc.edu, Oguzhan Alagoz, Amy Trentham-Dietz, Ronald E. Gangnon, Natasha Stout, John M.Hampton, Kim Dittus, Ted A. James, Pamela M. Vacek, Sally Herschorn, Elizabeth S. Burnside, Anna N. Tosteson, Donald L. Weaver, Brian L. Sprague

Due to the lack of a reliable test to identify a non-progressive disease, most of the ductal carcinoma in situ (DCIS) cases are treated with similar treatment regimens to localized invasive breast cancers. Thus, most of the patients with a non-progressive disease receive unnecessary treatments that result in decrements in their quality of life as well as an extra financial burden. To assess the potential impact of a hypothetical test that identifies non-progressive DCIS cases, we used the University of Wisconsin Breast Cancer Simulation model. Our results show that a perfect test would reduce the treatment costs as much as 40% and lead to a modest increase in discounted quality-adjusted life years.

4 - Robust Post-donation Blood Screening under Prevalence Rate Uncertainty

Hadi El-Amine, George Mason University, 4310 Cotswolds hill ln, Fairfax, VA, 22030, United States, helamine@gmu.edu, Ebru Korular Bish, Douglas R. Bish

Blood product safety, in terms of being free of transfusion-transmittable infections, is crucial. Under prevalence rate uncertainty, various objective functions, including minimization of a mean-variance objective and minimization of the maximum regret, were considered in order to determine a "robust" post-donation blood screening strategy that minimizes the risk of releasing an infected unit of blood into the blood supply. Efficient and exact algorithms are provided.

New Scheduling and Capacity Management Approaches to Improve Patient Access to Medical Services

Sponsored: Health Applications

Sponsored Session

Chair: Mustafa Y Sir, Mayo Clinic, Rochester, MN, 55905, United States, sir.mustafa@mayo.edu

1 - Acuity Based Demand Management

Bjorn Berg, Mayo Clinic, KPSL 21, 200 First Street SW, Rochester, MN, 55905, United States, berg.bjorn@mayo.edu, Brian Klute, Tarun Mohan Lal

Outpatient specialty practices, notably at large medical centers, face a matrix of uncertainties and objectives when making planning and operational decisions. Uncertainties include requests for new appointments, the mix of services required, and patient preferences. The effects of these uncertainties need to be managed to pursue criteria such as ensuring that the right patients are provided care based on their acuity and needs, the time patients must wait for an appointment, and utilization rates of provider calendars. We present a series of predictive analyses, capacity management models, and simulation-based approaches used to manage demand at an outpatient quaternary care practice.

2 - Online Surgery Reservation to Optimize Surgical Day Utilization

Maria Martinez, Mayo Clinic, Rochester, MN, United States, Martinez.Maria@mayo.edu, Alexander Mafusalov, Mustafa Y. Sir, Kalyan Pasupathy

This paper proposes a novel surgical scheduling optimization method within the general framework of a resource allocation problem. In the clinical setting, a patient enters the department with a diagnosis, which, after a clinical consultation, is linked to a specific surgical procedure. Surgery time slot is reserved upon arrival, when the procedure information is not available. The paper studies the long-run allocation policies, based on the demand in diagnoses, the stochastic relationship linking a diagnosis to a procedure, and on the surgical capacity. The objective is to minimize the surgeons' overtime hours. Numerical experiments on real data illustrate the effectiveness of the methods.

3 - Improving Patient Access of Back Pain Patients

Derya Kilinc, Arizona State University, 1975 E University Dr, Apt 162, Tempe, AZ, 85281, United States, dkilinc@asu.edu, Esma S.Gel, Bernard Bendok

Back pain is one of the leading health problems that affect a significant portion of the population. Identifying the patients that needs a surgical intervention and improving the access of those patients to right providers are crucial in healthcare delivery. We present our results on improving patient access based on of our year-long study in a neurosurgery clinic. Our results suggest that by prioritizing the patients need surgery and managing the capacity, we can achieve improvements in patient access.

4 - A Decision-support Tool for Capacity Management of Two-step Service Calendar

Phichet Wutthisirisart, Mayo Clinic, 200 First Street SW, Rochester, MN, 55905, United States, Wutthisirisart.Phichet@mayo.edu, Maria Gabriela Martinez, Kalyan Pasupathy, Mustafa Y. Sir

This works assess the performance of clinical and surgical calendars in an elective surgical practice. A simulation-based approach is proposed to score the efficiency of calendar with respect to the length of the planning horizon. Our approach generates key performance metrics to assists the identification of potential inefficiencies in the calendar.

System Dynamics in Healthcare

Sponsored: Health Applications

Sponsored Session

Chair: Nasim Sabounchi, State University of New York at Binghamton, Systems Science and Industrial Engineering, Binghamton, NY, 13902, United States, sabounchi@binghamton.edu

1 - Medicaid Access to Primary Care in Broome County, NY – A Combination of GIS and System Dynamics Methodology

Nasim S. Sabounchi, State University of New York at Binghamton, 4400 Vestal Parkway East, P.O. Box 6000, Systems Science and Industrial Engineering, Binghamton, NY, 13902, United States, sabounchi@binghamton.edu, Nasser Sharareh, Serdar Atav

The effect of Medicaid expansion on primary care access is studied from the spatial aspect. We built a system dynamics model using the constructs of the Health Belief Model to explain the dynamics of primary care access that captures the different stages of getting qualified, enrolling in Medicaid, seeking primary care services, and utilizing preventative care. Finally, the results of simulation model were applied to create a dynamic GIS map which shows the growth of Medicaid enrollees throughout the County, and the distance of patients to primary care providers will be investigated.

2 - Analyzing Optimal Screening Policies for Post-traumatic Stress Disorder in the Presence of Social Stigma

Mohammad S. Jalali, Massachusetts Institute of Technology, 77 Massachusetts Avenue, Cambridge, MA, 02139, United States, jalali@mit.edu, Navid Ghaffarzadegan, Richard C. Larson

Post-traumatic stress disorder (PTSD) stands out as a major mental illness and screening policies have played a critical role in mitigating the effects of PTSD. However, little agreement exists on the optimal cutoff value—a threshold above which screening scores should be considered as PTSD positive. We develop a simulation model of PTSD screening which includes social forces that inhibit accurate screening. Our analysis shows that with the presence of public stigma, current dichotomous screening policies are not effective to minimize the number of false positive and false negative.

3 - Combination of System Dynamics Modeling and Social Marketing for Increasing Colorectal Cancer Screening

Brian Biroscak, PhD, MS, MA, Yale School of Medicine, New Haven, CT, 06519, United States, brian.biroscak@yale.edu, Peter Hovmand

Human learning in and about complex systems is a feedback process. Yet in the world of social action, feedback processes often do not operate well. We will present our experience using a social marketing approach as one potential means for overcoming the implementation challenge in system dynamics modeling, within the context of an initiative to increase colorectal cancer (CRC) screening. We applied a modeling approach called 'community based system dynamics'. The primary purpose of the model (Stella ArchitectTM; Stella OnlineTM) is to help this academic-community partnership design a social marketing strategy for implementing evidence-based interventions that will increase CRC screening.

4 - Towards Optimal Antibiotic Prescribing for Acute Respiratory Tract Infections in Ambulatory Settings by Applying System Dynamics Modeling

Hamed Kianmehr, State Univerity of New York, Binghamton, NY, 13905, United States, hkianme1@binghamton.edu, Nasim S. Sabounchi, Leon E. Cosler, KarenBeth H. Bohan

Antibiotic resistance is a growing public health concern. There are several conditions for which antibiotics are prescribed excessively including acute respiratory tract infections (ARTIs). The goal of this study is to find key factors that lead to excessive antibiotic prescriptions among ARTI patients. We developed a system dynamics model to reproduce antibiotic prescriptions for ARTI, from the National Ambulatory Medical Care Survey (NAMCS), 1993-2014. The best-fit model captures the relationship between patient and physician decision making properly. The simulation results indicate that patient expectation has a strong effect on physician intention for prescribing antibiotics.

Structural Modeling and Estimation in Operations Management

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Jun Li, Ross School of Business, University of Michigan, Ann Arbor, MI, 48109, United States, junwli@umich.edu

Co-Chair: Yixin Wang, University of Michigan, Ann Arbor, MI, 48104, United States, iriswang@umich.edu

1 - Manufacturing and Regulatory Barriers to Generic Drug Competition: A Structural Model Approach

Yixin Wang, University of Michigan, 701 Tappan Street R4323, Ross School of Business, Ann Arbor, MI, 48104, United States, iriswang@umich.edu, Jun Li, Ravi Anupindi

Understanding the drivers of market concentration in the generic pharmaceutical industry is essential to guarantee the accessibility of low-cost generics. In this paper, we develop a structural model to capture the determinants of manufacturers' entry decisions and estimate the model using data collated from six disparate sources. In particular, this study focuses on the impact of production cost and regulatory barrier. We find that production complexity, as reflected for example in the administration route, significantly reduces the likelihood of generic entries. An increase in the processing time of production applications due to government capacity issue also deters firms from entering.

2 - Route Preferences in Bike-sharing Systems
Pu He, Columbia University, Uris Hall, Cub 4H, New York, NY, 10027, United States, phe19@gsb.columbia.edu, Fanyin Zheng, Elena Belavina, Karan Girotra

Over 300 cities have implemented large scale bike-share systems, including London, Paris and New York city. Using transaction-level trip and bike-availability data from London's bike sharing system, we construct a structural model of commuters' preferences over different routes that captures the effects of two components of route-length: the biking and the walking distances, along with the service-levels experienced at both ends. We illustrate the use of our estimates for system design, e.g. to choose between adding stations to increase station density in existing coverage areas or to expand the coverage area, to compare a docking station model with a dock-less model, etc.

3 - Managing Flexibility and Relationships in an Online Marketplace: Experiment and Prescriptions for Pricing and Matching
Ken Moon, The Wharton School, Philadelphia, PA, 19104, United States, kenmoon@wharton.upenn.edu, Elena Belavina, Karan Girotra

Exploiting the recent introduction of relationship-specific pricing by the largest online intermediary connecting freelancers to jobs, we present empirical evidence relating the operational performance of the platform's pricing and matching regimes to a simple market characteristic: whether clients derive greater relative value (A) by pursuing repeat relationships with trusted freelancers or (B) by exploiting the platform as an intermediary to flexibly hire different freelancers. We discuss how platforms can follow intuitive rules to tailor their pricing and matching policies based on how participants value relationships and flexibility, respectively.

4 - A Structural Estimation Approach to Study Agent Attrition
Seyedmorteza Emadi, University of North Carolina at Chapel Hill, 221 Tremont Cir, Chapel Hill, NC, 27516, United States, seyed_emadi@kenan-flagler.unc.edu, Bradley R.Staats

We use a structural estimation approach to investigate involuntary and voluntary attrition decisions of agents in a call center. We estimate different parameters of agents including their sensitivity to salary and their degree of forward looking behavior.

Personnel Scheduling

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Rachid Hassani, Polytechnique Montreal/Gerad, rachid.hassani@gerad.ca

Co-Chair: Dalia Attia, Gerad, 1, Montreal, QC, Canada, dalia.attia@gerad.ca

1 - Employee Scheduling with Inter Departments Transfers
Dalia Attia, Polytechnique Montreal & GERAD, Montreal, QC, Canada, dalia.attia@gerad.ca, Guy Desaulniers, Francois Soumis

Employee scheduling with inter-department transfers integer program is intractable for large instances. We propose a three-phase heuristic, each phase solves a small integer program. The first phase is a pre-processing phase which identifies probable inter-departments transfers needs. The second phase creates for each department apart, employee schedules using previously gathered information. The third phase, globally fulfills any remaining demand. Several variations for each phase are implemented and compared showing promissing results along with quick execution time.

2 - Real-time Personnel Re-scheduling After a Minor Disruption
Rachid Hassani, Polytechnique Montreal & GERAD, Montreal, QC, Canada, rachid.hassani@gerad.ca, Issmail El Hallaoui, Guy Desaulniers

This talk is about a real-time optimization method to adapt a pre-set schedule after a small disruption that can result from delay or absence of employees. The method provides schedule's rectification choices to the decision-maker taking into account the immediate and a deterministic future costs. This method considers five types of decision and is based on the dual values of the linear relaxation of the personnel scheduling problem . We also propose a procedure exploiting a multivariate adaptive regression splines method for updating the dual values after each disruption when several ones occur in the same week.

Chair: Carri Chan, Columbia Business School, New York, NY, 10027, United States, cwchan@columbia.edu

Co-Chair: Fanyin Zheng, Columbia University, New York, NY, 10027, United States, fz2225@gsb.columbia.edu

1 - Why do Automakers Initiate Recalls?
Robert Louis Bray, 830 Hinman Ave., 2s, Evanston, IL, 60202, United States, robertlbray@gmail.com, Ahmet Colak

Are automakers averse to consumer complaints or to the government recalls they attract? We study this question with 8,439 manufacturer recalls, 5,685 government recalls, and 976,062 defect reports submitted to the government. We model the agents' joint recall decisions as an asymmetric dynamic discrete choice game. Our estimates suggest (i) there is a little overlap in the sets of products the agents recall and in the types of complaints they respond to, (ii) the cost of a recall does not depend on who initiates it, and (iii) auto manufacturers recall faulty products to avoid receiving defect reports but not to preempt anticipated government recalls.

2 - Estimating Dynamic ICU Admission Decision
Fanyin Zheng, Columbia University, Columbia Business School, 412 Uris Hall, New York, NY, 10027, United States, fz2225@gsb.columbia.edu, Carri Chan

We study physician's ICU admission decisions using structural estimation methods.

3 - Understanding the Impact of Remote Patient Monitoring in the Hospital ICU: An Empirical Study
Lesley Meng, The Wharton School, University of Pennsylvania, 3730 Walnut Street, Suite 500 JMHH, Philadelphia, PA, 19104, United States, lmeng@wharton.upenn.edu, Christian Terwiesch

Innovation in healthcare technology has led to new healthcare delivery methods such as the addition of remote patient monitoring in the hospital intensive care unit. We utilize data on patient vitals to study the effect of remote monitoring on provider responsiveness to adverse patient health states in the ICU.

4 - Forecasting Product Life Cycle Curves: Practical Approach and Empirical Analysis
Jan A. Van Mieghem, Northwestern University, Kellogg School of Mgmt (MEDS.Dept), Leverone Hall 2001 Sheridan Rd, Evanston, IL, 60208-2009, United States, vanmieghem@northwestern.edu, Kejia Hu, Jason Acimovic, Francisco Erize, Douglas Thomas

We present an approach to forecast customer orders of ready-to-launch new products that are similar to past products. The approach fits product life cycle (PLC) curves to historical customer order data, clusters the curves of similar products, and uses the representative curve of the new product's cluster to generate its forecast. We propose three families of curves to fit and forecast the PLC: Bass diffusion curves, polynomial curves and simple piecewise-linear curves (triangles and trapezoids). We evaluate our approach using a large data set of customer orders for 4,037,826 units of 170 Dell computer, representing several billion dollars in revenue.

Field Experiments in Service and Retail Operations

Sponsored: Manufacturing & Service Oper Mgmt, Service Operations

Sponsored Session

Chair: Qiuping Yu, Kelley School of Business, Indiana University, Bloomington, IN, 47405-1701, United States, qiupyu@indiana.edu

1 - The Reference Effect of Delay Announcements: A Field Experiment

Qiuping Yu, Kelley School of Business, Indiana University, 1309 E. Tenth Street, Bloomington, IN, 47405-1701, United States, qiupyu@indiana.edu, Gad Allon, Achal Bassamboo

We explore whether customers are loss averse in time and how the amount of delay information available may impact such reference-dependent behavior by conducting a field experiment at a call center. Our results show that customers exhibit loss averse regardless of the availability or accuracy of the delay information. While delay announcements may not alter the fact that customers are loss averse, they do seem to impact the reference points customers use when the announcements are accurate. However, when those announcements are not accurate, customers may completely disregard them.

2 - Low-acuity Patients Delay High-acuity Patients in the ED

Danqi Luo, Stanford University, Stanford, CA, United States, dluo@stanford.edu, Sara Kwasnick, Mohsen Bayati, Erica Plambeck

Causal analysis of data from 4 different hospitals shows that an additional low-acuity patient in the ED significantly increases the wait time to start of treatment for a high-acuity patient. Through a pseudo-randomized experiment at 1 hospital, we estimate that arrival of a low-acuity patient increases the aggregated wait time for high-acuity patients by 55 minutes on average. We identify 2 mechanisms by which low-acuity patients delay high-acuity patients, analyze a novel model of a priority queue with transition delays, and recommend ways to mitigate delays for high-acuity patients.

3 - Setting Retail Staffing Levels: Methodology and Implementation

Serguei Netessine, University of Pennsylvania, Philadelphia, PA, United States, netessin@wharton.upenn.edu, Marshall L.Fisher, Santiago Gallino

We describe a three-step process that a retailer can use in setting retail store sales staff level. First, use historical data on revenue and planned and actual staffing levels by store to estimate how revenue varies with staffing level at each store. We disentangle the endogeneity between revenue and staffing levels by focusing on randomly occurring deviations between planned and actual labor. Second, using historical analysis as a guide, validate these results by changing the staffing levels in a few test stores. Finally, implement the results chain-wide and measure the impact. We describe the successful deployment of this process with a large specialty retailer.

4 - Stable Schedules for Retail Associates: Field Experiment at the Gap

Saravanan Kesavan, University of North Carolina-Chapel Hill, Kenan-Flagler Business School, Cb 3490 Mccoll Building, Chapel Hill, NC, 27599-3490, United States, skesavan@unc.edu, Susan Lambert, Joan Williams

Employer scheduling practices are an important source of employment instability that can limit earnings, impede worker performance, and create stress and work-life interferences that undermine worker health and well-being. Widespread acknowledgement of the impact of these challenges on thousands of working class households has triggered several policy debates regarding the need for more stable schedules across a variety of industries. In this study, we ran a field experiment in 30 stores of the Gap to improve stability in workers' schedules without affecting the store performance.

Game Theory

Contributed Session

Chair: Xiaojun (Gene) Shan, UHCL, Houston, TX, United States, shan@uhcl.edu

1 - Cost Allocation Mechanisms in a Peer-to-peer Network

Basak Altan, Ozyegin University, Istanbul, Turkey, basak.altan@ozyegin.edu.tr, Okan Orsan Ozener

We consider a P2P network where the service provider broadcasts the content across the network and the users collaborate to seed the content to a subset of users in the network. The objective of the service provider is to determine the minimum cost network solution and to allocate this joint-cost fairly among the users. The minimum cost network solution can be determined by solving a minimum cost Steiner Tree problem. We propose four cost allocation mechanisms: a dual linear programming based mechanism, an approximation mechanism to the Shapley Value, a partition-based mechanism, and an approximation mechanism to the nucleolus.

2 - Safe and Nested Subgame Solving for Imperfect-Information Games

Tuomas W. Sandholm, Professor, Carnegie Mellon University, Gates Center for Computer Science, Carnegie Mellon University, Pittsburgh, PA, 15213, United States, sandholm@cs.cmu.edu, Noam Brown

Unlike perfect-information games, imperfect-information games cannot be solved by solving subgames independently: decisions must consider the strategy for the whole game. Yet one can improve strategies by solving subgames. We introduce subgame-solving techniques that outperform prior methods in theory and practice. We also adapt them to respond to opponent actions that are outside the action abstraction; this significantly outperforms the prior state of the art, action translation. Finally, we show that subgame solving can be repeated as the game progresses down the tree, leading to lower exploitability. These techniques are key components of Libratus, the first AI to beat top humans in no-limit poker.

3 - Tiered Cloud Storage Pricing via Two-stage, Latency-aware Bidding

Vaneet Aggarwal, Purdue University, 315 N Grant St., West Lafayette, IN, 47906, United States, vaneet@purdue.edu, Yang Zhang, Arnob Ghosh, Lan Tian

In this paper, we wish to maximize the overall profit of the Cloud Service Providers (CSPs) that utilize a tiered storage architecture (with hot and cold storage tiers) with file placement and access request scheduling flexibilities. To this end, we propose a scheme where the CSP offers a two-stage auction process for (a) requesting storage capacity, and (b) requesting accesses with latency requirements. Our two-stage bidding scheme provides a hybrid storage and access optimization framework with the objective of maximizing the CSP's total net profit over four dimensions: file acceptance decision, placement of accepted files, file access decision and access request scheduling policy.

4 - Empirical Study on Effects of Defense Resource Allocations

Xiaojun (Gene) Shan, UHCL, Houston, TX, United States, shan@uhcl.edu, Jun Zhuang

In this paper, we use the method of statistical analysis based on data from Global Terrorism Database, which is available at National Consortium for the Study of Terrorism and Responses to Terrorism (START) and the Urban Area Security Initiative (UASI) grant allocations from FY 2004 to FY 2012 to study the effects of defense resource allocations. We conclude that ingeneral, effects of defense resources onreducing success probability of attack are mixed due to scarcity of terrorism data.

Personalized Medicine

Sponsored: Manufacturing & Service Oper Mgmt, Healthcare Operations

Sponsored Session

Chair: John Silberholz, University of Michigan, josilber@mit.edu

1 - Personalized Medicine in Cost-effective Management of Diffuse Large B-cell Lymphoma

Qiushi Chen, Massachusetts General Hospital, 101 Merrimac St., 10th FL, Boston, MA, 02114, United States, qchen@mgh-ita.org, Turgay Ayer, Christopher Flowers

Diffuse large B cell lymphoma (DLBCL) is the most common type of aggressive lymphoma. There are various treatment options available, and evidence shows that patients with DLBCL experience widely divergent outcomes. Recent findings imply that treatment tailored by biological subtypes represents a promising treatment strategy for DLBCL patients. In this study we assess the potential benefit of personalized treatment based on subtype with respect to health and cost outcomes, and compare with the one-size-fits-all treatment strategies.

2 - Personalized Treatments for Breast Cancer Patients

Emma L.Gibson, MIT, 60 Woodsworth Street, Cambridge, MA, 02142, United States, emgibson@mit.edu

There are many treatment options available to breast cancer patients, but it is often difficult to predict how successful these treatments will be for individual cases. We have developed a personalized treatment algorithm to select and evaluate treatment options based on individual diagnostic factors and existing medical conditions. When applied to cases in the SEER-Medicare dataset, our algorithm recommended alternative treatment options for approximately 10% of test subjects, resulting in an average estimated increase in survival time of 8 months within the first 8 years after diagnosis.

3 - The Price of Simplicity in Personalized Prostate Cancer Screening Strategies

John M.Silberholz, Assistant Professor, University of Michigan, 701 Tappan Street R5468, Ann Arbor, MI, 48109, United States, josilber@umich.edu

Patient preferences for different health states can significantly impact their best course of action in screening for diseases like prostate cancer. Patients with a relatively small disutility for treatment side effects might benefit from aggressive screening, while others might benefit from less aggressive screening or no screening at all. In this work, we use a mathematical model to quantify the benefit of fully personalized prostate cancer screening versus a one-size-fits-all strategy. Further, we identify simpler, more interpretable personalized screening strategies that could be easier to implement in practice, and we quantify the price of this simplicity in strategies.

4 - Personalised Treatment for Coronary Heart Disease Patients using Electronic Medical Records and Machine Learning

Agni Orfanoudaki, MIT, 77 Massachusetts Avenue, Cambridge, MA, United States, agniorf@mit.edu

Coronary Heart Disease is the most common type of heart disease and the leading cause of death in the United States. However, a common approach to determine which treatment to prescribe to which patient has not yet been established. On that basis, we recognized the substantial benefit that machine learning and algorithmic approaches could bring to this field. We developed a personalized prescriptive algorithm that uses EMR to maximize the expected time to an adverse event from the time diagnosis. Overall, we achieve 15,2% improvement for the overall population, performing particularly well in the female (17,5% improvement) and in the Hispanic subpopulation (24,8% improvement).

1 - Crowdfunding via Revenue-sharing Contracts

Soraya Fatehi, University of Washington, 5215 15th Avenue, Apt 15, 15, Seattle, WA, 98105, United States, sfatehi@uw.edu, Michael R.Wagner

We present a new model of crowdfunding where a platform acts as a matchmaker between a firm needing funds and a crowd of investors willing to provide capital. Once the firm is funded, it pays back the investors using revenue sharing contracts. The firm determines its optimal contract parameters to maximize its expected net present value, subject to investor participation constraints and platform fees. We use approximate firm solutions in a game-theoretic setting to analyze the platform's problem, which sets its optimal pricing structure, in the form of origination and servicing fees, to maximize its net present value, subject to firm participation constraints.

2 - Guarantor Financing in a Three-stage Supply Chain

Gangshu Cai, Santa Clara University, Department of OMIS, 216n Lucas Hall, Santa Clara, CA, 95053, United States, gcai@scu.edu, Weihua Zhou, Tiantian Lin

Based on a supply chain model with a manufacturer, a capital-constrained retailer, a third-party logistics (3PL) firm, and a bank, this paper investigates two types of guarantor financing, manufacturer guarantor and 3PL guarantor, and compares them to traditional bank financing.

3 - Inventory Risk and Financing Frictions for SME Suppliers

Fasheng Xu, Washington University in St. Louis, Saint Louis, MO, 63130, United States, fasheng.xu@wustl.edu, Panos Kouvelis, Wenhui Zhao

Most of the financing initiatives revolve around post-shipment approved-invoice financing. But SME suppliers would have cash flow difficulty financing production activities upfront. To fill this gap, we study a pull-structure supply chain with a large retailer and a SME supplier. The bank offers a fairly-priced loan for relevant operational risks and failure of loan repayment leads to costly bankruptcy. We identify the Stackelberg equilibrium and find the supplier's riskiness always dampen the retailer's profit, however may benefit the supplier itself. Interestingly, the supplier's riskiness may benefit the system and increase the supply chain's expected profit.

4 - Financial Pooling in a Supply Chain

S. Alex Yang, London Business School, Regent's Park, London, NW1 4SA, United Kingdom, sayang@london.edu, Qu Qian, Ming Hu

We study a supply chain in which the buyer uses trade credit to purchase from the supplier. The embedded stretch option of trade credit allows supply chain partners to pool their liquidity buffers. Due to this pooling effect, even as the supplier's financing costs are higher than the buyer's, trade credit can be more effcient than cash on delivery when the supplier's cost for collecting trade credit is low or when the supplier does not have access to a low-cost financing channel when facing liquidity shocks. The benefit of pooling increases as the buyer has a more diversified supplier portfolio. As an innovative financing scheme, reverse factoring further enhances the effciency of this pooling effect.

1 - Innovation Opportunities Emerging from Responsiveness and Co-located Manufacturing

Lauri Saarinen, University of Lausanne, Bâtiment Anthropole 3016, Lausanne, CH-1015, Switzerland, lauri.saarinen@unil.ch

Co-locating manufacturing with either the market or with R&D encourages innovation: Customer ideas are more easily communicated, and product and process innovations are more rapidly tested. We develop a system dynamics model of the interaction between responsiveness and innovation. We demonstrate that the real options created when responsiveness makes it possible to postpone the decision about what will be produced until demand information is available also generate follow-on options through innovation.

2 - Antecedents of New Venture Financing

Thomas Zehren, Assistant Lecturer and PhD Candidate, Technical University of Dortmund, Vogelpothsweg 87, Dortmund, 44227, Germany, Thomas.Zehren@udo.edu

It is widely acknowledged that traditional capital market theories do not apply to the initial capital structure of new ventures. However, empirical evidence on the actual behavior is very limited. Drawing on a novel sample of over 4,000 new business owners, this paper examines the influence of founder- and venture-related characteristics on the initial capital structure. Our central contribution is that the provision of personal assets by the owner represents a central element of start-up financing. Additionally, we demonstrate that the access of external capital sources is mainly related to venture and not - as one would expect - to founder-related characteristics.

3 - Difficulties of Nascent Entrepreneurs: What Prevents Individuals from Starting a New Venture?
Jessica Moser, Assistant Lecturer and PhD Candidate, Technical University of Dortmund, Vogelpothsweg 87, Dortmund, 44227, Germany, Jessica.Moser@udo.edu

This research analyzes the influences of multiple barriers nascent entrepreneurs (NEs) encounter on their outcome status - still trying, disengaged or started - and on their start-up intention after disengaging. Drawing upon a novel and recent sample of 872 NEs, this paper finds that recently disengaged individuals have faced significantly more barriers than other NEs. A deeper analysis displays that financing difficulties and especially personal barriers hinder a venture creation. In addition, barriers beyond a NE's own control are identified to be lethal for the continuance of the intention to create a new business. Major implications for NEs and policymakers regarding barriers are derived.

4 - Dimension of VC-E Trust Based on the "Guanxi" Culture in China
li haiyan, Harbin Engineering University, Harbin, 000451, China, 643076746@qq.com, Yang hongtao

The dimension of VC - E trust is divided into three aspects: computational trust, knowledgeable trust and relational trust. The results show that relationship trust is particularly important to the performance of start-ups in China. VC and E can share resources in the phase of relational trust.Acknowledgement: This paper is funded by the International Exchange Program of Harbin Engineering University for Innovation-oriented Talents Cultivation.

Random Graphs and Learning in Applied Probability

Sponsored: Applied Probability

Sponsored Session

Chair: Jiaming Xu, Purdue University, West Lafayette, IN, 47907, United States, xu972@purdue.edu

1 - The Lovasz Theta Function of Random Graphs and Community Detection in the Hard Regime
Cris Moore, Santa Fe Institute, Santa Fe, NM, United States, moore@santafe.edu

Community detection and graph coloring is believed to have a hard regime, in between an informational threshold and a computational one, where inference is possible but exponentially hard. In particular, in this range it should be hard to refute the existence of a community structure in a null random graph model. We confirm this for refutations that use the Lovasz theta function, or equivalently degree-two sum-of-squares proofs. This is joint work with Jess Banks and Robert Kleinberg.

2 - Estimating the Number of Connected Components of Large Graphs Based on Subgraph Sampling
Yihong Wu, Yale University, yihong.wu@yale.edu, Jason Klusowski

Learning properties of large graphs from samples is an important problem in statistical network analysis. We revisit the problem of Frank '78 of estimating the numbers of connected components based on subgraph sampling, where a subgraph induced by vertices drawn uniformly at random is observed. The key question is whether accurate estimation is possible if we only sample a vanishing fraction of the vertices. We show that this is impossible if the graph contains high-degree vertices or long induced cycles; otherwise, it is possible by accessing only sublinear number of vertices. Optimal sample complexity are obtained for several classes of graphs including forests, cliques and chordal graphs.

3 - Optimal Community Recovery on the Weighted Stochastic Block Model
Varun Jog, University of Wiscconsin-Madison, vjog@wisc.edu

The Stochastic Block Model (SBM), which is one of the most well-studied statistical models for community detection, has an important limitation: it assumes that each network edge is drawn from a Bernoulli distribution. This is rather restrictive, since weighted edges are ubiquitous in scientific applications, and disregarding edge weights results in a loss of information. In this talk, we study a weighted generalization of the SBM. We propose and analyze a novel algorithm for community estimation and show that it is optimal in terms of its rate of convergence.

4 - On the Local Minima of Nonconvex Matrix Completion with Arbitrary Condition Numbers and General Sampling Patterns
Xiaodong Li, University of California, Davis, CA, United States, xdgli@ucdavis.edu, Ji Chen

In recent years much progress has been made in the theory of nonconvex matrix completion. However, strong conditions are usually required for the condition numbers and sampling patterns. In this work, we study the properties of local minima of nonconvex matrix completion with general sampling patterns and arbitrary condition numbers. We apply this general framework to some specific random graph-based sampling patterns to obtain novel approximate recovery results for all local minima. As a byproduct, we also improve the state-of-the-art no-spurious-local-minima results in the literature under strong conditions of the condition numbers and sampling patterns.

Chair: Xiting Gong, The Chinese University of Hong Kong, Hong Kong, xtgong@se.cuhk.edu.hk

Co-Chair: Xiuli Chao, University of Michigan, Ann Arbor, MI, 48109, United States, xchao@umich.edu

1 - Asymptotic Optimality of Constant Order Policies for Lost Sales Inventory Models with General Supply Functions
Jinzhi Bu, The Chinese University of Hong Kong, Hong Kong, njujzhbu@gmail.com, Xiting Gong, Dacheng Yao

In this paper, we study the constant-order policies (COP) for the lost-sales inventory system with positive lead times and general supply functions. Besides analyzing the asymptotic properties of the best COP with large lead times and large penalty costs, we construct a simple while asymptotically optimal heuristic COP and carry out extensive numerical studies to investigate the COP's performances.

2 - Joint Assortment and Pricing Optimization with Demand Learning
Sentao Miao, University of Michigan, Ann Arbor, MI, 48104, United States, semiao@umich.edu, Xiuli Chao

We study a joint assortment and pricing optimization problem where customers arrive sequentially and make purchasing decisions based on a multi-nomial logit (MNL) model. Without prior information about customers' demand for products, the retailer selects subset of products for display and set their prices through learning customer behavior to maximize its expected total profit over a finite selling horizon. By a special structure of the MNL model, we design an algorithm that estimates the consumer's demand and sets the assortment and price for each period. The algorithm balances the trade-o ff between learning the demand and maximizing the revenue, and is shown to be asymptotically optimal.

3 - Optimality of Order-up-to Policies for Serial Inventory Systems with Lost Sales
Woonghee Tim Huh, University of British Columbia, Sauder School of Business, Operations and Logistics Division, Vancouver, BC, V6T.1Z2, Canada, tim.huh@sauder.ubc.ca, Marco Bijvank, Ganesh Janakiraman

We study how to manage a serial inventory system under periodic review when excess demand at the most downstream stage is lost. First, we show that there is an echelon order-up-to policy that is asymptotically optimal as the lost-sales penalty cost parameter grows large. We also show that this asymptotic optimality result is robust in the sense that there is a large family of order-up-to policies such that it continues to hold. Next, we propose a heuristic rule to set the order-up-to levels based on the algorithm of Clark and Scarf where the resulting policy performs close to the best order-up-to policy even when the penalty cost is not large. Finally, we extend the optimality results to (R,nQ) policies.

4 - Performance Bounds and Asymptotic Optimality of Modified (R,Q) Policies for Stochastic Distribution Inventory Systems
Frank Y. Chen, City University of Hong Kong, Dept of Management Sciences, AC1, Tat Chee Avenue, Hong Kong, youhchen@cityu.edu.hk, Han Zhu, Ming Hu, Yi Yang

We study a classic one-warehouse multi-retailer distribution system, in which any inventory replenishment at each location incurs a fixed-plus-variable cost and takes a constant lead time. The optimal policy is unknown. We identify an easy-to-compute heuristic policy within the class of modified echelon (r, Q) policies that does not require an integer-ratio property or a synchronized, nested ordering property, yet has easily computable performance bounds. The proposed heuristic policy is asymptotically optimal.

1 - Cash Conversion Systems in Corporate Subsidiaries

Weiwei Chen, Rutgers Business School - Newark and New Brunswick, Piscataway, NJ, United States, wchen@business.rutgers.edu, Benjamin Melamed, Ben Sopranzetti, Oleg Sokolinskiy

This paper models a cash conversion system in a subsidiary of a parent company, where there is an active internal capital market, but otherwise the subsidiary has no access to additional external funds. The cash conversion system implements a perpetual flow cycle, where funds convert to product and back to funds. We model this system as a discrete-state continuous-time Markov process, and compute statistics of the equilibrium cash conversion cycle. We further optimize the financial and operational designs of the system, so as to maximize its financial rate metrics. Finally, we study numerically the impact of friction in such parent-subsidiary relationship.

2 - Dynamic Financial Hedging and Inventory Management for a Storable Commodity

Zhan Pang, City University of Hong Kong, Hong Kong, zhan.pang@cityu.edu.hk

Managing demand and price risks for commodity inventory remains a major challenge for firms facing volatile raw material prices. Consider a firm purchasing a raw material from a spot market with the access to a financial derivative market where derivative contracts can be used to hedge the price risk. We formulate this problem as a dynamic program in the Markowitz mean-variance framework. Recognizing the time-inconsistency of the mean-variance objective, we analyze a class of time-consistent policies and identify the market conditions under which an optimal time-consistent policy can be optimal. The roles and relationship of inventory and derivatives in hedging are discussed.

3 - On a Firm's Optimal Response to Pressure for Gender Pay Equity

David Anderson, Baruch College, City University of New York, 55 Lexington Ave, Office 9-251, New York, NY, 10010, United States, DavidRybergAnderson@gmail.com, Margret V. Bjarnadottir, Cristian Dezsö, David Gaddis Ross

We present a theory of how a firm would rationally respond to pressure for gender pay equity. We show that (a) employees in low-paying jobs and whose job-related traits typify men at the firm are most likely to get raises; (b) counterintuitively, some men may get raises and giving raises to certain women would increase the pay gap; (c) a firm can reduce the gender pay gap as measured by a much larger percentage than the overall increase in pay to women at the firm; and (d) "ghettoizing" women in select jobs can help a firm reduce its pay gap.

4 - Operational Risk Management of Commercial Institutions

Yuanqiao Chen, Nanjing University, Nanjing City, China, ccyykalcc@163.com, Michael L.Pinedo

Operational risk is the risk of losses caused by failed internal processes, people, systems or external events. We propose a process-based model to help organizations predict potential operational losses and determine capital reserves. The model enables us to use available data to predict via a probabilistic network based on process.

Sponsored Session

Chair: Zhili Tian, Florida International University, Weston, FL, 33327-2444, United States, ztian99@gmail.com

1 - An Empirical Analysis of the Effects of Personnel Scheduling on Hospital Performance

Bogdan C. Bichescu, The University of Tennessee, 229 Stokely Management Center, 916 Volunteer Blvd, Knoxville, TN, 37996-0525, United States, bbichescu@utk.edu, Randy V. Bradley, John E. Bell, Joonwhan In, Wei Wu

Despite efforts to improve scheduling and resource allocation via the adoption of disparate technologies in hospitals, there is still a lack of empirical evidence that indicates where, and if, the value proposition of such investments exists. We employ regression modeling to analyze a panel of 268 hospitals. Our findings suggest which scheduling applications impact which specific measures of hospital performance. This study offers several theoretical and managerial implications, which contribute to a better understanding of the potential benefits of the use of technology applications for personnel scheduling.

2 - Optimal Investment in Support of Current Drug and Development of New Drug

Zhili Tian, Florida International University, Miam, FL, 33139, United States, ztian99@gmail.com

The marketing spending on the drugs is often equal to or even higher than that for developing a new drug. Despite so much investment in the new drug development, only around twenty new drugs are approved every year for the entire pharmaceutical industry. To boost their revenues, firms often emphasize marketing of the current drugs at the expense of developing new drugs. However, the source for the two competing investments is from the revenues of the existing drugs. Hence we develop models to address the investment in the existing drugs and development of new drugs. Our methods optimally allocate the fund between marketing communication and new drug development for the following three scenarios.

3 - Outsourcing Strategy for Intermediate Production Steps

Yang Wang, University of California-Berkeley, Berkeley, CA, United States, yangwang0803@gmail.com, Philip Kaminsky

Biopharmaceutical firms often outsource their final filling, labeling and packing operations to a third party outsourcer, leaving these firms susceptible to long and variable lead time due to queuing at the outsourcer. To address this issue, a so-called capacity reservation policy is proposed, in which means the firm reserves some fixed capacity at the outsourcer at given intervals to guarantee short and less variable lead time. We show the benefit of such a policy compared to the traditional polices when the lead time is intrinsically random, and conclude that the policy not only reduces the inventory and ordering cost at the firm, but also increases the profit of the outsourcer.

1 - Modeling the Values of Private Sector Agents in Humanitarian Supply Chains

Jarrod D. Goentzel, Massachusetts Institute of Technology, 77 Massachusetts Avenue, E38-650, Cambridge, MA, 02139, United States, goentzel@mit.edu, Corinne Carland, Gilberto Montibeller

Humanitarian organizations (HOs) increasingly engage the private sector to achieve their goals but must understand the different objectives and priorities of such agents to be effective. To develop such knowledge, we formalize an approach based on multi-attribute value analysis and apply it with agents across a multi-echelon health supply chain in Uganda, with a focus on malaria rapid diagnostic tests. Our findings show that objectives are not aligned in this supply chain, but also reveal how our approach can improve private sector engagement, which may be crucial for humanitarian outcomes.

2 - The Post-disaster Debris Clearance Problem with Resource Allocation and Learning

Seyma Guven-Kocak, Georgia Institute of Technology, 1235 Parkway Circle N, Atlanta, GA, 30340, United States, seymaguven@gatech.edu, Pinar Keskinocak

In the aftermath of a disaster, debris blocks roads and hampers critical response operations such as search-and-rescue and relief transportation, so that it needs to be cleared quickly and efficiently. However, debris management is expensive and complicated. This work, motivated by the debris clearance operations in a post-disaster situation, addresses a problem of establishing connectivity between the nodes on a disrupted network with inherent uncertainty and learning. We explore structural results on various special networks, which provide insight for the problem on more general networks.

3 - A Variational Equilibrium Network Framework for Humanitarian Organizations in Disaster Relief: Effective Product Delivery under Competition for Financial Funds

Anna B. Nagurney, University of Massachusetts Amherst, Isenberg School of Management, Dept of Operations & Information Mgmt, Amherst, MA, 01003, United States, nagurney@isenberg.umass.edu, Patrizia Daniele, Emilio Alvarez Flores, Valeria Caruso

In this paper, we present a new Generalized Nash Equilibrium (GNE) model for post-disaster humanitarian relief that captures competition and with novel financial funding and altruism functions. The common shared constraints associated with the relief item deliveries at points of need are imposed by an upper level humanitarian organization or regulatory body and consist of lower and upper bounds to ensure the effective delivery of the estimated volumes of supplies to the victims of the disaster. We formulate the variational equilibrium and illustrate the game theory model through a case study focused on tornadoes hitting western Massachusetts, a highly unusual event that occurred in 2011.

4 - Practice-based Heuristics for Humanitarian Transportation Planning

Erica L. Gralla, George Washington University, 800 22nd st NW, Rm 2680, Washington, DC, 20052, United States, egralla@gwu.edu

Transportation is a critical challenge in humanitarian response, but adoption of optimization-based decision support has been limited due to the difficulty of implementation. We evaluate the performance of heuristics based on current planning practices, identify key weaknesses, and suggest ways to improve planning while maintaining implementability.

5 - Supply Chain Modeling of Large Scale Humanitarian Food Aid Operations with Different Transfer Modalities

Keziban Rukiye Tasci, Northeastern University, 77 Westland Avenue #5, Boston, MA, 02115, United States, tasci.k@husky.neu.edu, Ozlem Ergun

Large humanitarian organizations strive to serve millions of beneficiaries spread around the globe by delivering many different commodities and services on time while abiding by organizational and governmental regulations. This study describes a time expanded network model that determines the cost-effective ways to supply pre-decided basket of commodities via using traditional food delivery and cash & voucher modalities for one of the largest humanitarian aid agencies in the world. Through these models and analysis of historic procurement data we identify significant improvement opportunities for the organization's supply chain operations.

Applications of Revenue Management

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Maxime Cohen, maxccohen@gmail.com

1 - Price and Availability Discrimination, Exclusive Goods and Social Networks

Ruslan Momot, INSEAD, Boulevard de Constance, Fontainebleau, 77305, France, ruslan.momot@insead.edu, Elena Belavina, Karan Girotra

We study the value of price and availability discrimination when selling goods whose value derives from exclusive ownership in a social network. We build a stylized model of socially interacting customers who differ in their network position (degree) and their proclivity for social comparisons (conspicuity). We find that firm's optimal strategy is to set price proportional to product of customer's degree and conspicuity and exclusively offer the product to only high conspicuity customers with sufficiently low degree. We find that price and availability discrimination are substitutes. While availability is useful instrument on its own, it has limited values when price discrimination is possible

2 - Pricing and Assortment Strategies with Product Exchanges

Laura Wagner, IESE Business School, Calabria, Barcelona, Spain, LWagner@iese.edu, Victor Martinez de Albeniz

Return policies enable consumers to return or exchange products they are unsatisfied with. We develop a search framework where consumers sequentially learn about products' true value and decide whether to keep, exchange or return them. We show that when pricing is not a decision, the assortment problem is NP-complete. When pricing is endogenous, the optimization becomes tractable and it is not necessarily optimal to set all products at equal margins. Finally, we find that retailers prefer to pass all return costs on to the consumers, and that this decision can also be beneficial to consumers.

3 - Earning and Learning with Varying Cost

Ying Zhong, City University of Hong Kong, Kowloon Tong, Hong Kong, yzhong4-c@my.cityu.edu.hk, Jeff Hong, Guangwu Liu

The earning-and-learning problem refers to the profit maximization problem where one optimizes the profit by choosing a price and learns the demand at the same time. Traditionally, the cost is fixed and the problem may be formulated as a multi armed bandit problem, which is known to have an O(logT) lower bound on the expected regret, where T is the number of periods. In this paper, we consider the case where the cost changes over periods. Then, the optimal pricing decision becomes a function of the cost. We propose an upper-confidence-bound type of algorithm to solve the problem. We find that, surprisingly, the expected regret may be bounded by a constant under certain conditions.

4 - Forecasting and Price Optimization for a Beverage Company: Theoretical Questions Arising from Practice

Will Ma, Massachusetts Institute of Technology, 71 School Street, Cambridge, MA, 02139, United States, willma353@gmail.com, Hanwei Li, David Simchi-Levi, Jinglong Zhao

We discuss our experience conducting demand forecasting and price optimization at a global beverage company, which controls its pricing through multiple retailers. We discuss many different substitution patterns observed in the data: internally within the company's products, externally with competitors' products, over time, and between different retailers. The business contstraints on pricing also give rise to various unsolved theoretical questions.

Chair: John G Turner, University of California-Irvine, Irvine, CA, 92697-3125, United States, john.turner@uci.edu

1 - Optimal Signaling Mechanisms in Unobservable Queues with Strategic Customers

David Lingenbrink, Cornell University, Ithaca, NY, United States, dal299@cornell.edu, Krishnamurthy Iyer

We consider an unobservable M/M/1 queue offering a service at a fixed price to a Poisson arrival of delay-sensitive customers. The service provider can observe the queue, and may share information about the queue with arriving customers. The customers incorporate this information into their prior beliefs before making the decision to join or balk. We pose the following question: which signaling mechanism and what price should the service provider select to maximize her revenue? We formulate this problem as an instance of dynamic Bayesian persuasion, characterize the structure of the optimal signaling mechanism, and compare its revenue with that of the optimal state-dependent pricing mechanism.

2 - Price Discrimination over Quality via Aggregate Rebate Programs

Amir Ajorlou, Massachusetts Institute of Technology, 32 Vassar Street, 32-D569, Cambridge, MA, 02139, United States, ajorlou@mit.edu, Ali Jadbabaie, David Simchi-Levi

Firms selling network goods can enjoy a marginal gain in profit due to the network effect. Early adopters improve the social value of the product and firm can raise the price when the product becomes more popular. Motivated by this observation, we pose the question as to whether it is beneficial to a firm selling a product with no network effect to artificially inject externality? To this end, we propose an aggregate reward program where the reward paid to the consumers is a function of the sales volume. By analyzing the equilibria of the induced global game among consumers, we show that the optimal reward program pays back the buyers a fixed rebate, if the product fails to reach certain level of popularity.

3 - Waterfall Yield Optimization for Online Advertising

Dmitri Arkhipov, University of California, 23 Bethany Drive, Irvine, CA, 92603, United States, darkhipo@ics.uci.edu, John G. Turner, Michael Dillencourt, Ameila C. Regan

In programmatic advertising, advertisements are matched to users. Quality matches may take time to compute, time being a scarce resource particularly for publishers who would like their webpages to load quickly. Policies for ad placement must execute very quickly; this necessitates policies are either simple or are pre-computed offline. The order in which advertisers are offered ad spaces as these become available is referred to as a waterfall and the process of finding a good or optimal such ordering is referred to as yield optimization. We formulate a stochastic optimization problem to solve a publisher's waterfall yield optimization problem.

Mean Field Approaches and Applications

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Gabriel Weintraub, Stanford Graduate School of Business, Stanford, CA, 94304, United States, gweintra@stanford.edu

1 - Pairwise Comparisons for Online Reputation Systems

Nikhil Garg, 825 Menlo Avenue, Apt G, Menlo Park, CA, 94025, United States, nkgarg@stanford.edu, Ramesh Johari

Modern online marketplaces rely on reputation systems to assess participants, and enable search and matching. Typically, these systems rely on cardinal ratings — e.g., the ubiquitous five star rating system. Inspired by a number of issues that these systems have encountered in practice, we suggest an alternative: reputation systems based on pairwise comparisons. We use a mean field model to compare and contrast such a rating system with cardinal ratings, and present theoretical results, simulations, and empirical analysis that suggest that such rankings can be significantly more informative than cardinals ratings.

2 - An Empirical Framework for Sequential Assignment Allocating Deceased Donor Kidneys

Itai Ashlagi, Stanford University, Department of Management Sci. and Engr., Stanford, CA, 94305, United States, iashlagi@stanford.edu

We provide an empirical framework for designing the allocation of cadaver organs.

3 - Transitional Market Dynamics in Complex Environments

Gabriel Weintraub, Stanford Graduate School of Business, Knight Management Center, Stanford University, 655 Knight Way, E364, Stanford, CA, 94304, United States, gweintra@stanford.edu, Lanier Benkard, Przemek Jeziorski

Recent work in dynamic oligopoly models uses mean-field approaches to approximate long-run Markov perfect industry dynamics. In several applications though, one is interested in the short-run dynamic behavior of an industry after a policy or environmental change. We introduce a mean-field approach for these settings and show that a "resolving" version provides accurate approximations even in concentrated industries. We illustrate our methods with several dynamic oligopoly models relevant to IO and also in a model of network effects.

4 - On Matching in Ridesharing Systems

Amy R. Ward, University of Southern California, Marshall School of Business, Bridge Hall BR.I.401H, Los Angeles, CA, 90089-0809, United States, amyward@marshall.usc.edu, Erhun Ozkan

In a ridesharing system such as Uber or Lyft, arriving customers must be matched with available drivers. These decisions affect the overall number of customers matched, because they impact whether or not future available drivers will be close to the locations of arriving customers. A common policy used in practice is the closest driver policy that offers an arriving customer the closest driver. This is an attractive policy because it is simple and easy to implement. However, we expect that a forward-looking parameter-based policy can achieve better performance. We prove asymptotic optimality of a matching policy based on a continuous linear program in a large market regime

Recent Advances in Oil and Gas I

Invited: Energy Systems Management

Invited Session

Chair: Leah Kaffine, GE Energy Consulting, 16100 W 62nd Dr, Arvada, CO, 80403, United States, leah.kaffine@ge.com

1 - Integrated Gas Electric Modeling with GE MAPS and RBAC GPCM

Leah Kaffine, GE Energy Consulting, 16100 W. 62nd Dr, Arvada, CO, 80403, United States, leah.kaffine@ge.com

Examine the importance of a time varying price elasticity assumption of natural gas demand for power in RBAC's GPCM model. By default, these assumptions are homogenous and independent of time. Coal retirements, renewables and increased gas fired generation are impacting the ability to respond to price signals.

2 - Economic and Environmentally Conscious Supply Chain Network Optimization for Determination of Potential Infrastructure and Production of Biogas

Yong Shin Park, North Dakota State University/UGPTI, 1940 Dakota Drive N, Apt 203, Fargo, ND, 58102, United States, yong.park@ndsu.edu, Joseph Szmerekovsky

Supply chain network design for the animal waste including biogas facility have not been addressed in the previous research. In response, we develop economic and environmentally conscious supply chain design of cattle manure to energy by incorporating carbon policy including carbon tax and cap and trade scheme. Mixed Integer Linear Programming (MILP) approach identify the optimal location of biogas plants and capacities to treat cattle waste from farm, and investigate the impact of the carbon policy on tactical and strategic supply chain decisions. A case study of North Dakota is adopted where there is high potential for biogas production based on number of cattle inventory.

3 - Black Carbon Projection in Energy Model

Cheng (Marshal) Wang, Economist, Environment and Climate Change Canada, 200 Sacré-Coeur Blvd., Office 1053, Gatineau, QC, J8X 4C6, Canada, cheng.uot@gmail.com

Black Carbon is both a short-lived climate pollutant and an air pollutant linked to adverse health effects. Canada, as a member of an Arctic Council, so far has submitted black carbon inventories for 2013 and 2014 in the last two years to the Arctic Council following Convention on Long Range Transboundary Air Pollution guidelines. The objective of this presentation is to provide background information on black carbon and its relationship to climate change, explain the new BC reporting requirements, and provide a progress report on the development of black carbon projections, collective BC target and challenges.

4 - The Causality between Prices and Operating-equipment Costs in the Oil and Gas Industries

Sergio Cabrales, Visiting Professor, Universidad de los Andes, Calle 19 A.no 1-37 Este, ML-758, Bogota, 111711, Colombia, s-cabral@uniandes.edu.co, Laura Herrera, Jesús Godoy

Is there a bidirectional causal relationship between prices and costs in oil and gas markets? This paper studies the causality between prices and operating and equipment costs in oil and gas industries, using annual indexes (1976—2009). In oil market, we find a bidirectional Granger causality relationship between prices and operating costs. By contrast, in gas market, we observe the Granger causality only in one direction, indicating a causality of operating costs on gas prices. Finally, in contrast to operating costs, we do not find Granger causal relationship between prices and equipment costs in oil and gas industries.

Operational Implications of 3D Printing

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Lingxiu Dong, Washington University, Saint Louis, MO, 63130-4899, United States, dong@wustl.edu

Co-Chair: Duo Shi, Olin Business School, Washington University-St Louis, St. Louis, MO, 63130, United States, dshi@wustl.edu

1 - Stock or Print? Impact of 3D Printing on Spare Parts Logistics

Yue Zhang, Duke University, 5507 Butterfly Ln Apt 207, Durham, NC, 27707, United States, yueyue.zhang@duke.edu, Jing-Sheng Jeannette Song

We present a general framework to analyze and quantify the impact of 3D printing on spare parts logistics. We consider multiple parts facing stochastic demands. To minimize long-run average system cost, our model determines which parts should be printed and which should be stocked and the corresponding base-stock levels. We derive various structural properties and characterize the optimal policy for several special systems, which lead to efficient near-optimal heuristic solutions for the general system. We demonstrate that adopting 3D technology can yield significant cost savings and this impact increases in part variety.

2 - Personal Fabrication as an Operational Strategy: Value of Delegating Production to Customer

Nagarajan Sethuraman, PhD Candidate, University of North Carolina, Campus Box 3490, McColl Building, Chapel Hill, NC, 27599, United States, Nagarajan_Sethuraman@kenan-flagler.unc.edu, Ali Kemal Parlakturk, Jayashankar M.Swaminathan

In this paper, we study an operational strategy enabled by 3D printing—- Personal Fabrication (PF) —-in which a firm focuses on product's design and delegates its production to customers. We characterize the conditions under which, such a strategy benefits the firm. We study the implications of various roadblocks for such a strategy: high production costs of 3D printing, intellectual property concerns and product liability issues.

3 - Evaluating the Potential of Additive Manufacturing for Spare Parts Supply

Rob Basten, Eindhoven University of Technology, P.O. Box 513, IE&IS.- OPAC, Eindhoven, 5600 MB, Netherlands, r.basten@utwente.nl, Bram Westerweel, Geert-Jan Van Houtum

We investigate the decision of whether or not to replace a regularly produced spare part with an alternative produced via additive manufacturing (AM), also called 3D printing. Such a transition requires a one-time investment and changes characteristics such as procurement lead time, production costs and component reliability. We consider the entire product lifecycle and take into account performance benefits and design, inventory, maintenance and downtime costs. We derive analytical properties of the required reliability and production costs of the AM part such that its lifecycle costs break even with that of its regular counterpart.

4 - 3D Printing vs. Traditional Flexible Technology: Implications for Operations Strategy

Duo Shi, Olin Business School, Washington University-St Louis, K.H.401, Olin Business School, 1 Brookings Drive, St. Louis, MO, 63130, United States, dshi@wustl.edu, Lingxiu Dong, Fuqiang Zhang

We study a firm's operational strategy under two types of flexible production technologies: the traditional flexible technology and 3D printing. Under the traditional flexible technology, capacity becomes more expensive as it handles more product variants; under 3D printing, however, capacity cost is independent of the number of product variants processed. The firm possesses a dedicated technology and may additionally adopt one or both of the two types of flexible technologies. Our results demonstrate that the rising 3D printing has significantly different implications for firms' assortment and production strategy than the traditional flexible technology.

Network Analysis with Social Media Data

Invited: Social Media Analytics

Invited Session

Chair: Alexander Nikolaev, University at Buffalo, Buffalo, NY, 14260-2050, United States, anikolae@buffalo.edu

1 - Explaining the Emergence of Power Laws in Online Social Networks

Rakesh Nagi, SUNY- Buffalo, Buffalo, NY, United States, nagi@illinois.edu, Sushant Khopkar, Alexander Nikolaev

We present a method for parameterizing a network formation model that explains how the information about "socially contagious" individuals/items propagates into the masses, and the power law in degree emerges as these individuals/items reach new followers. We report the inferred model parameter values for several real-world social media datasets.

2 - Clustering of Ordered Restaurant Rankings on Yelp.com

Alexander Semenov, University of Jyväskylä, Jyväskylä, Finland, alexander.v.semenov@jyu.fi, Alexander Nikolaev

The ease of posting anonymous reviews online has created many opportunities for people to express their opinions about products and services in social media sites. The difference in opinions may or may not imply malicious behavior; in any case, identifying multiple groups of users, sharing different distinct views on how the evaluated items fair against each other, may help us better understand the diversity in tastes. We present a method to identify distinct user groups based on how they rank restaurants on Yelp.com, and interpret the results.

3 - Network Analysis of Social Media Portal VK.com

Vladimir Boginski, University of Central Florida, Orlando, FL, 32541, United States, Vladimir.Boginski@ucf.edu, Alexander Nikolaev, Alexander Veremyev, Eduardo Pasiliao, Alexander Semenov

The "post-Soviet space" includes a group of countries with a substantial fraction of the world's population and spans multiple time zones and cultures, creating a unique geopolitical mixture. We present the study of the social network of VK.com (also known as VKontakte), which is the largest European (mainly Eastern-European) social portal, with over 300 million nodes. We analyze several aspects of the VK network structure, including its global connectivity patterns and community composition and draw conclusions about the "social media landscape" of the post-Soviet space.

4 - Engagement-based Predictive Analyses of the Growth of Online Health

Rahul Gopalsamy, University at Buffalo, 409 Bell Hall, Buffalo, NY, 14260-2050, United States, rahulgop@buffalo.edu, Alexander Nikolaev, Scott McIntosh, Alexander Semenov, Eduardo Pasiliao

The research on nurturing the growth of online communities posits that it is in part attributed to the network externality effects. This study uses the data of a large online portal to show that user engagement - measurable using the recently introduced metric "engagement capacity" - has a positive causal effect on online health community growth, opening the door to exploiting network externality effects in calculated ways.

Behavioral Models in Auctions

Invited: Auctions

Invited Session

Chair: Kyle Woodward, University of North Carolina at Chapel Hill, Chapel Hill, NC, 27599-3305, United States, kyle.woodward@unc.edu

1 - Auctions with Max-min Players

Kyle Woodward, University of North Carolina at Chapel Hill, Department of Economics, Gardner Hall, CB #3305, Chapel Hill, NC, 27599-3305, United States, kyle.woodward@unc.edu, Marek Pycia

Multi-unit auctions are commonly used to allocate government debt and electricity generation, but little is known about equilibrium strategies under private information. We show that when bidders have max-min beliefs over opponents' information, equilibrium is analytically tractable; our results apply to both private- and interdependent-values models. We define a natural equilibrium selection, upside dominance, implying equilibrium uniqueness; we show upside dominance to be equivalent to limiting forms of risk and ambiguity aversion. In upside-dominant equilibrium pay-as-bid auctions revenue-dominate uniform-price auctions, offering novel evidence favoring pay-as-bid auctions.

2 - Declining Prices Across Second-price Reverse Auction Formats

Marion Ott, RWTH Aachen University, Templergraben 64/V, Aachen, 52062, Germany, marion.ott@rwth-aachen.de, Karl-Martin Ehrhart

In four experimental reverse second-price auction formats for procuring a good for which bidders have uncertain private values, we find declining auction prices across the four formats. Pseudo-endowment effect arguments on psychological ownership, detachment, and willingness-to-pay/willingness-to-accept disparity predict the order of the declining prices. We conclude that auctions that foster detachment from an item may lead to lower payments.

3 - Empirical Relevance of Ambiguity in First-price Auctions

Gaurab Aryal, University of Virginia, VA, United States, aryalg@virginia.edu

We study the identification and estimation of the first-price auction model with IPV when risk averse bidders face ambiguity about the value distribution and have maxmin expected utility. We use variation in the number of bidders to nonparametrically identify the true value distribution and the lower envelope in the bidders' set of priors. We propose a flexible Bayesian estimation method based on Bernstein polynomials. MC experiments show that our method estimates parameters precisely and chooses the reserve prices with (nearly) maximal revenues. We apply our method to U.S. timber auctions and find evidence of ambiguity in auctions from the Pacific Northwest region.

4 - Threshold Problems in Ascending Combinatorial Auctions

Bart Vangerven, KU. Leuven, Naamsestraat 69, Leuven, 3000, Belgium, bart.vangerven@kuleuven.be, Dries Goossens, Frits C.Spieksma

We experimentally study bidding behavior in ascending combinatorial auctions with threshold problems, using human bidders. We vary feedback from very basic information about provisional allocations, to more advanced concepts as winning/deadness levels, and even coalitional feedback, aimed at helping bidders to overcome threshold problems. The main question we address is the following: `Does additional feedback help bidders overcome threshold problems in ascending combinatorial auctions?' We test this in different auction environments, investigating the effects on economic efficiency, auction revenues, duration, etc.

Artificial Intelligence Problems in Real World

Sponsored: Artificial Intelligence

Sponsored Session

Chair: Jiaheng Xie, University of Arizona, 1130 E Helen Street, Tucson, AZ, 85721, United States, xiej@email.arizona.edu

1 - Genetic Algorithms for Electrical Harness Routing During Satellite Conception

Eliott Roynette, PhD Student, Airbus Defence and Space, 31 Rue des Cosmonautes, Toulouse, 31400, France, eliott.roynette@gmail.com, Cedric Pralet, Vincent Vidal, Bertrand Cabon

In the space industry, every satellite is unique and customized for its mission. In this presentation, we introduce a multi-criteria genetic algorithm for helping in the conception of the 3D routing of the electrical harness, which is responsible for establishing physical connections between several thousands of devices of the satellite. This algorithm is used for obtaining a tradeoff between the total weight of the harness and the complexity of its manufacturing. In the end, we show how using OR tools brings a strong advantage to space engineers both for speeding and optimizing the conception process of real satellites.

2 - Forecasting Crude Oil Price: A Novel Decompose-ensemble Methodology with AIC-ANN Approach

Yishan Ding, Shanghai Jiaotong University, Huashan Road 1954, Xuhui District, Shanghai Jiaotong University, Zhongyuan, Shanghai, 200030, China, dys90@163.com

Forecasting international crude oil is a well-known issue. Hybrid methodology has been widely used in current research. In this study, a novel decompose-ensemble prediction process is proposed. This method, adds the decompose-ensemble to the single AI model to further improve the predicting accuracy. It has been confirmed that "decompose-ensemble" models are better than the normal hybrid one, in terms of prediction accuracy (both level and directional measurement) and Diebold-Mariano test. What's more, the EEMD-based one outperforms the empirical mode decomposition(EMD) one. At last but not the least, AIC gives us reasonable and convincing statement about determining the value of lag.

3 - Advantages of the Parameter Control Strategy Over the Parameter Tuning: A Case Study for the Berth Scheduling Problem at Marine Container Terminals

Maxim A.Dulebenets, Florida A&M.University-Florida State University, 2300 Bluff Oak Way, Apt. 8408, Tallahassee, FL, 32311, United States, mdlbnets@gmail.com, Eren Erman Ozguven, Ren Moses, Thobias Sando

This study proposes a novel Evolutionary Algorithm to assist with berth scheduling at marine container terminals, which unlike published to date studies on berth scheduling applies a parameter control strategy. Specifically, an adaptive mechanism is developed for the mutation operator, where the mutation rate is altered based on feedback from the search. A set of numerical experiments are conducted to assess performance of the developed algorithm based on a comparison against a typical Evolutionary Algorithm that relies on the parameter tuning analysis.

4 - Path Planning for Multiple UAVs in Dynamic Environment Considering Uncertainty of Threats

Mengqi Hu, University of Illinois at Chicago, 842 W. Taylor Street, MC 251, 3023 ERF, Chicago, IL, 60607, United States, mhu@uic.edu, Di Wang

Path planning for multiple interconnected unmanned aerial vehicles (UAVs) especially for fixed-wing UAVs in dynamic environment has attracted great attention. Considering motion characteristics of dynamic artificial and natural threats, a probability predictive method based on Bayesian theory is presented to modify cost functions. A non-cooperative game model is formulated in which UAVs are modeled as Homo Egualis agents that aim at predicting a sequence of future actions and then a novel reinforcement learning method is proposed to solve the game model to converge to a Nash equilibrium. Finally, the feasibility and effectiveness of the proposed approach is evaluated using simulations.

Invited: Social Media Analytics

Invited Session

Chair: Fouad H. Mirzaei, Santa Clara University, Santa Clara, CA, 95050, United States, fhmirzaei@scu.edu

1 - Attracting Investors in Equity Crowdfunding Campaigns

Anna Lukkarinen, Aalto University, Helsinki, 00100, Finland, anna.lukkarinen@aalto.fi, Jyrki Wallenius, Hannele Elina Wallenius, Tomi Seppälä

While many equity crowdfunding campaigns succeed in reaching their funding goals, many also fail. Using campaign and investor level data, we aim to build an understanding of what attracts the crowd to invest. We find that campaign characteristics and networks are more important for success than traditional factors. Furthermore, investors form distinct clusters that differ in their motivations and decision criteria. Donors and supporters place importance on personal acquaintance, while pure investors look at the target company and campaign features. The findings can assist crowdfunding platforms and entrepreneurs in selecting and targeting relevant segments of potential investors.

2 - Social Media Competitiveness

Fouad H. Mirzaei, Santa Clara University, Unit 3, 559 Alviso St, Santa Clara, CA, 95050, United States, fhmirzaei@scu.edu

In this study, we investigate what factors are vital in the short term and the long term success of social media networks.

3 - Do Financial Incentives Induce More Online Participatory Behaviors?

Lini Kuang, Beijing Institute of Technology, 5TH, Zhongguan Street, Haidian District, Beij, Beijing, 100081, China, 3120160689@bit.edu.cn, Zhijun Yan, Han Yang, Yan Liu

Online community-based Question and Answer (Q&A) websites is popular in recent years. The main challenge for Q&A websites is how to motivate users' participation. Using a natural experimental dataset collected from a Chinese Q&A site, we apply difference-in-differences model with propensity score matching to evaluate the impact of paid knowledge sharing activity on free knowledge sharing behaviors and social activities in Q&A sites. Our results show that the paid activity induces more free knowledge sharing and social ties in the site. The results suggest that the financial incentive can increase users' participatory behaviors significantly.

Chair: Yen-Ju Chiang, National Cheng Kung University, Tainan, Taiwan, r48031016@mail.ncku.edu.tw

1 - Corporate Bankruptcy Prediction a Penalized Semiparametric Index Hazard Model Approach

Shaobo Li, PhD Student, University of Cincinnati, 5470 Erie Station Lane, Apt.51, Cincinnati, OH, 45227, United States, lis6@mail.uc.edu, Shaonan Tian, Yan Yu

We introduce a parsimonious yet flexible double-index hazard model for corporate bankruptcy prediction under a semiparametric modeling framework. The two indices are naturally constructed by market and accounting based variables respectively. Penalized estimation is considered variable selection. Our empirical results demonstrate the existence of nonlinearity between predictors and default risk, and improvement of predictive power comparing to Shumway's hazard model. Furthermore, we find that the variables in each index vary as the prediction horizon changes. The proposed model framework sheds new light on modeling flexibility and sparsity in various financial applications.

2 - Efficient Hybrid Candlestick Technical Analysis Model for Stock Market Timing on the Basis of the Support Vector Machine and Heuristic Algorithms

Milad Jasemi, Wayne State University, 4815 4th Street, Detroit, MI, 48201, United States, milad@wayne.edu, Leslie Monplaisir, Elham Ahmadi

Here, two hybrid models are used for timing of stock markets based on the technical analysis of Japanese Candlestick by Support Vector Machine (SVM) and Heuristic Algorithms of Imperialist Competition and Genetic. In the first model, ICA is used to optimize the SVM parameters'. In the second model, Genetic Algorithm is used for feature selection in addition to SVM parameters' optimization. To generate the input data, the Raw-based and Signal-based standard approaches of the literature are applied. According to the Hit Rate for periods of 1-6 day, SVM-ICA prevails them all.

3 - Steel B2b Electronic Market in China: Does it Really Matter?

Wen Fang, PhD, Lecturer, Xidian University, Mailbox 106,No.266, Xifeng Road, Xi'an 710126, PR China, Xi'an, 710126, China, Ph.D.,az-moju@163.com

China steel industry has emerged a typical market, which is B2B electronic market, while other countries usually have only steel futures market and spot market. Many commodities prices fluctuating followed by steel price changes. The development of steel markets plays an important role in the development of China's commodity market as well as global commodity market. Steel electronic market is in the process of vigorous development. There are three kinds of steel price signals: forward transaction price from electronic market, futures price and spot price. Research on price discovery in steel markets has important theoretical significance and practical application value.

4 - Game Theory and Weighted Cash-to-cash Metric: Optimizing Economic Value of Seller-buyer Transaction

Mazen Hammady, PhD, University of North Texas, 201 Inman St, Apt# 6305, Denton, TX, 76205, United States, mazen.hammadybrho@unt.edu, Aaron Glassburner, PhD, Wesley Randall, David Nowicki, Brian Sauser

The use of joint metrics between a seller and buyer allows differences in inventory carrying cost and capital costs to be sources of economic value added (EVA). This research models seller-buyer transactions as a collaborative game with a joint weighted cash-to-cash metric as the payoff function. The model uses strategies of shifting inventory and payment to increase firm and supply chain EVA, thus it is posited as a collaboration decision tool. Also, the developed model optimizes operation and finance functions, lowers trading risk, and increases profitability without additional investment.

5 - Can We Understand the Macroscopic Behavior of the Equity Markets?

Abdullah AlShelahi, University of Michigan, 2410 Leslie Circle, Ann Arbor, MI, 48105, United States, shelahi@umich.edu, Romesh Saigal

In this research, we aim to build a market-based framework from the viewpoint of fluid dynamics and its physics. We seek to develop physical sensors made up of an algorithm in the markets that alerts regulators to unusual activities in the flow of stocks. The fluid flow in physics will be used to measure the irregularities found in the behavior of the financial markets. This marriage between physics and finance will bring greater clarity to those who run the stock markets, as well as regular investors who will no longer worry that they are trading in a losing or rigged game.

6 - Market Anomalies of Credit Rating

Yen-Ju Chiang, Student, National Cheng Kung University, No.1, University Road, Tainan, 701, Taiwan, r48031016@mail.ncku.edu.tw, Shuang-Shi Chuang

Our aims to examine the market anomalie of credit rating in Taiwan stock market. we test whether investors can get abnormal returns by different credit rating or not. Especially, we contribute with new knowledge about how investors choice undervalue stocks by credit rating in many situations. Furthermore, our sample includes listed firms on the Taiwan Stock Exchange during 1th of January 2000 to 31th of December 2016. Our regression model is Fama- French Five factor Model, consisting overall market, size, value, profitability and investment factor can predict future stock price. we found creding rating could predict stock return.

1 - Price Delegation or Not? the Effect of Heterogenous Sales Agents under Asymmetric Information

Hongyan Xu, Chongqing University, School of Economics & Business Admin, Chongqing, 400030, China, xuhongyan@cqu.edu.cn, Jian Chen, Liming Liu

This study examines the impact of heterogeneous sales agents with private information about type-dependent reservation on price delegation decision. The firm prefers centralized pricing when the reservation difference is small or large, and prefers delegated pricing with moderate reservation difference. Specially, when only equilibrium pooling can be offered for two pricing schemes, delegation outperforms centralization, due to the fact that the benefit from pricing flexibility by delegation dominates the hurt from less effort incentive.

2 - Seeding Strategies for New Product Launch in the Presence of Negative WOM

Fang Cui, Xi'an Jiaotong Univercity, Xi'an, China, cuifang2011@stu.xjtu.edu.cn

Taking negative WOM into account, this paper examines the impact of seeding programs on firm profit and market penetration and explores the optimal seeding targets. We use the agent-based modeling method to explore performances of three seeding targets: early adopters, hubs and randomly chosen consumers and the influences of three factors, mean and variance of the probability of consumers spreading negative WOM, and consumer homophily, which represents the similarity of adjacent consumers. The findings suggest that in the presence of negative WOM, on average, seeding early adopters can generate highest profit and largest market penetration, followed by seeding hubs and then by randomly seeding.

3 - Warranty Pricing with Consumer Learning

Yong Lei, Southwestern University of Finance and Economics, IELM Dept, Chengdu, 611130, China, leiyong@swufe.edu.cn, Qian Liu, Stephen Shum

We consider a problem in which a firm dynamically prices a product and its warranty service over time. Consumers can learn about the reliability of products based on warranty prices. We find that warranty sales will not generate profits directly. However, offering a modest warranty still benefits the firm's overall profits. We also show that consumers' beliefs and the firm's warranty policy converge in the long run. In a steady state, either a fraction of consumers will purchase a warranty or no consumer will purchase a warranty. Lastly, we note a firm benefits from consumer learning by hiding the information about the true product reliability only when the true product failure rate is relatively high.

4 - The Market Entry Strategy of Contract Manufacturers

Houcai Shen, Professor, Nanjing University, Department of Management Science, and Engineering, Nanjing, 210093, China, hcshen@nju.edu.cn, Jiahui Zhou

In this paper, we consider a supply chain consists of an original equipment manufacturer (OEM) who outsources its production process to a contact manufacturer (CM). The main issues we address are, should the CM enter the market with vertical differential product where the OEM sells products to. We develop two game theoretical models when CM entry the market or not, and then make comparative analysis of the equilibrium outcomes.

Airline Schedule Design

Sponsored: Aviation Applications

Sponsored Session

Chair: Vikrant Vaze, Dartmouth College, Hanover, NH, 03755, United States, vikrant.s.vaze@dartmouth.edu

1 - An Approximate Dynamic Programming Approach for Aircraft Maintenance Scheduling

Qichen Deng, Delft University of Technology, Delft, Netherlands, Q.Deng@tudelft.nl

An approximate dynamic programming (ADP) approach is proposed to optimize the aircraft A-check and C-check schedule. It aims at minimizing the total unused flight hours of a fleet considering aircraft type, status and operational constraints. For each calendar day, the ADP approach evaluates all possible actions (no check, A-check or C-check etc.) and find the best one. This study is one of the few works optimizing both A-check and C-check schedule at the same time and presents the first application of ADP on aircraft maintenance planning. It also shows that ADP makes large scale application feasible and produces promising results in terms of computational time and solutions quality.

2 - Robust Airport Stand Allocation

Bert Dijk, Beontra, Karlsruhe, Germany, dijk.bert@gmail.com, Bruno F.Santos, João P. Pita

This paper presents an innovative approach to the tactical planning of aircraft remote and contact stands allocation at airports. We use the concept of recoverable robustness to test the robustness of the plans and to select the most robust allocation plan, without compromising its efficiency. This is the first work to discuss airport commercial revenues as a metric for the stand allocation problem. Six days of operations at the Guarulhos Airport (Sao Paulo) are used to test the approach. The solutions obtained show that the proposed approach outperform the solutions of a traditional robust approach.

3 - Integrated Timetable Development and Fleet Assignment Model Incorporating Passenger Choice

Vikrant Vaze, Dartmouth College, 14 Engineering Drive, Murdough Center, Hanover, NH, 03755, United States, vikrant.s.vaze@dartmouth.edu, Keji Wei, Alex Jacquillat

We present a mixed-integer linear programming model for integrated timetable development and fleet assignment, where the passenger itinerary flows are modeled using a multinomial logit model. Even for small to moderate network sizes, this is a very challenging problem to solve and has never been addressed in prior literature. We develop multiple exact and heuristic solution approaches and test their performance against the performance of a state-of-the-art off-the-shelf commercial solver. Our computational results using real-world airline networks provide several new insights into the structure of highly profitable airline timetables.

4 - Multi-stage Airline Scheduling Problem with Stochastic Passenger Demand and Non-cruise Times

Ozge Safak, Bilkent University, Department of Industrial Engineering, Ankara, 06800, Turkey, ozge.safak@bilkent.edu.tr, Ozlem Cavus, Selim Akturk

We introduce an airline scheduling problem that determines flight timing, fleeting and routing decisions while considering the randomness of demand and non-cruise times. We assign aircraft by considering not only flight timing and demand but also fuel and emission costs associated with cruise speed adjustments. We propose a mixed-integer multi-stage stochastic programming model with nonlinear fuel cost function, where the nonlinearity is handled by MISOCP. We employ a scenario group-wise decomposition algorithm to obtain lower and upper bounds for the optimal value of the proposed model. We suggest a cutting plane algorithm for solving group subproblems. Supported by TUBITAK [Grant 116M542].

Chair: Brian J Lunday, Air Force Institute of Technology, Air Force Institute of Technology, WPAFB, OH, 45433, United States, brian.lunday@afit.edu

1 - On Truthful, Stable and Proportionate International Alliance Burden Sharing

William Caballero, Air Force Institute of Technology, WPAFB, OH, 45433, United States, William.Caballero@afit.edu, Brian J. Lunday, Darryl K. Ahner

We propose cost sharing mechanisms for an international alliance such that burden shares are allocated based on declarations of the alliance's worth, probabilistic inspection efforts, and deception penalties. We develop a set of multiobjective nonlinear optimization problem formulations that are budget balanced, proportional and in the core. Any feasible solution to these problems corresponds to a single-stage Bayesian stochastic game wherein a collectively honest declaration corresponds to varying forms of Nash Equilibria, but the optimal solution considers the alliance's central authority preferences between inspection and penalization.

2 - Automating Mission Essential Task List Crosswalks with Data Science

Dan Koban, United States Military Academy, donald.koban@usma.edu, Michael S. Scioletti

A Mission Essential Task List (METL) crosswalk is a unit's primary analysis tool to plan training; however, it is often improperly executed. We contend improper execution is not a function of training, but rather an unreasonable expectation to solve a difficult problem by hand. By modeling task relationships as a network, we are able to automated the crosswalk and provide descriptive measures of the payoff and complexity associated with tasks included in a Unit Task List (UTL). These measures can then be used to assist commanders with selecting and prioritizing tasks when developing a Unit Training Plan (UTP). We demonstrate the effectiveness of our method by applying it to an infantry company.

3 - Air Force Comprehensive Core Capability RiskAssessment Framework (C3RAF)

Charles Glaze, Headquarters US.Air Force Pentagon, Washington, DC, charles.b.glaze.mil@mail.mil, Shane N. Hall, John R. Lepird, Robert Henson, Donald Allen

This paper examines risk within the United States Air Force (AF) by modeling the AF as a network of core capabilities. This model provides a better understanding of what factors drive risk across the AF and its overall contribution to the United States' ability to win wars. This decision framework provides key insights on strategic investment decisions by linking core capability risk with budgeting decisions on military systems. Application of this effort is utilized to provide repeatable, defendable results informing budget decisions over a 30 year, $3 trillion resource allocation plan.

Supply Chain Management

Contributed Session

Chair: Naser Nikandish, California State University-Fullerton, Fullerton, CA, United States, n.nikandish@gmail.com

1 - Value of Information-sharing in a Supply Chain under a Revenue-sharing Contract

Tal Avinadav, Bar-Ilan University, Webb 1, Ramat-Gan, Israel, tal.avinadav@biu.ac.il, Tatyana Chernonog, Yael Perlman

We investigate the value of vertical information-sharing in a supply chain whose members interact via a revenue-sharing contract. Demand is uncertain, and both the manufacturer and the retailer receive signals about the demand, which are correlated. We analyze the value of information-sharing in this supply chain under the assumption of truth telling. We show that (i) to obtain equilibrium, the leader has to disclose the signal he received or his lack of information; (ii) the leader does not derive any benefit from the information that has been signaled to him, or from knowing what has been signaled to the follower; (iii) the leader does benefit when the follower has knowledge of both signals.

2 - Supply Chain Integration, Advanced Manufacturing Technology, and Operational Performance

Birasnav Muthuraj, New York Institute of Technology, Northern Boulevard, Old Westbury, NY, 11568, United States, bmuthura@nyit.edu, Disha Nair

This study examines the relationship between supply chain integration, implementation of advanced manufacturing technology, and operational performance. Data were collected from Indian manufacturing industries to understand the relationships among the studying variables.

3 - The Influence of Network Resources and Absorptive Capacity on Productive Efficiency

Hung-Chung Su, University of Michigan-Dearborn, Dearborn, MI, 48126, United States, hcsu@umich.edu, Ta-Wei Kao

This study considers the relationships between network resources, exploitative absorptive capacity, and a firm's productive efficiency. This research examines the effects of network positions that relate to three types of informational resources obtained from the network: information volume, information velocity, and information diversity on a firm's productive efficiency. Furthermore, we examine the moderating role of absorptive capacity on the relationship between network resources and productive efficiency.

4 - Evaluation of End-to-end Strategies with Omnichannel Retailing: A Model and Application for Apparel Supply Chains

Shardul Phadnis, Malaysia Institute for Supply Chain Innovation, 2A, Persiaran Tebar Layar, Seksyen U8, Shah Alam, 40150, Malaysia, sphadnis@misi.edu.my

We advance an extant model of end-to-end supply chain to omnichannel retailing to evaluate sourcing and sales strategies as components of one supply chain strategy. We develop demand models for two omnichannel settings—Buy-Online-Pickup-in-Store, and Try-in-Store-Buy-Online. We develop conditions for optimal inventory placement, and evaluate four end-to-end strategies, combinations of two omnichannel settings with offshore and nearshore sourcing to describe the conditions in which each strategy outperforms the others. We test the model using a computer simulation and describe how the optimum end-to-end strategies of omnichannel merchants differ from those of single channel merchants.

5 - Occurrence of Bullwhip Effect in Pricing in the Case of a Revenue-sharing Contract

Ertunga Ozelkan, University of North Carolina-Charlotte, 9201 University City Boulevard, Charlotte, NC, 28223, United States, ecozelka@uncc.edu, Ziaul Haq Adnan

Bullwhip effect in pricing (BP) refers to the amplified variation in pricing. We analyze the occurrence of BP in the case of a revenue-sharing contract with both the deterministic and the stochastic demand. We model the deterministic case as a Stackelberg game, and the stochastic model as a Newsvendor problem with both an additive and a multiplicative uncertainty in demand. The results show that the ratio of the standard deviations of the retail and the wholesale prices (i.e. BP ratio) is inversely proportional to the retailer's profit share. We also discuss the cost-pass-through rates in the case of a revenue-sharing contract with a stochastic demand under a linear and an isoelastic demand form.

6 - Capacity Planning Analysis for Amazon.com Lockers
Naser Nikandish, Assistant Professor, California State University, Fullerton, 800 North State College Boulevard, Fullerton, CA, 92831, United States, n.nikandish@gmail.com, Lawrence W. Robinson

Amazon.com's lockers are this company's innovation to control their increasing fulfillment costs by decreasing last-mile distribution costs and to improve their shoppers' experience by bringing convenience and safety to the package delivery process. In this project, we investigate online shoppers' package retrieval behavior from an Amazon.com locker location and research its impact on capacity decisions at the Amazon.com locker locations.

Recent Progress in Efficient Algorithms in Convex Optimization

Sponsored: Optimization, Nonlinear Programming

Sponsored Session

Chair: Qihang Lin, University of Iowa, Iowa City, IA, 52245, United States, qihang-lin@uiowa.edu

1 - New Results for Sparse Methods for Logistic Regression and Related Classification Problems
Robert Michael Freund, MIT, MIT Building E62-567, 77 Massachusetts Ave., Cambridge, MA, 02139, United States, rfreund@mit.edu, Paul Grigas, Rahul Mazumder

We propose and analyze methods in logistic regression that induce sparse solutions. We introduce a novel condition number associated with the data for logistic regression that measures the degree of non-separability of the data, and that naturally enters the analysis and the computational properties of methods. We take advantage of very recent new results in first-order methods for convex optimization due to Bach and others, to present new computational guarantees for the performance of methods for logistic regression. In the high-dimensional regime in particular, these guarantees precisely characterize how the methods impart both data-fidelity and implicit regularization, for any dataset.

2 - Sliding Techniques for Large-scale Optimization
Guanghui (George) Lan, Georgia Institute of Tehnology, Newberry, FL, 32669, United States, george.lan@isye.gatech.edu

We provide an overview of gradient/operator sliding techniques which lead to signifiant improvement on optimization algorithms. This includes savings on gradient computation, accesses to dataset and communication costs etc.

3 - Feasible Level Set Method for Constrained Convex Optimization Problems
Negar Soheili Azad, University of Illinois-Chicago, 601 S.Morgan Street, University Hall 2416, Chicago, IL, 60607, United States, nazad@uic.edu, Qihang Lin, Selvaprabu Nadarajah

First order methods have emerged as an effective solution strategy for tackling large scale convex optimization problems. The success of these methods has been greatest for such problems with simple feasible sets. We propose a novel feasible level set method that extends the applicability of these methods to convex optimization problems with potentially complicated constraint sets.

4 - Searching the Growth Rate: Adaptive SVRG Methods under Error Bound Conditions
Qihang Lin, University of Iowa, Iowa City, IA, 52245, United States, qihang-lin@uiowa.edu, Yi Xu, Tianbao Yang

Error bound condition (EBC), an intrinsic property of an optimization problem, can be exploited for developing algorithms with surprisingly fast global convergence. However, many existing approaches utilizing EBC requires knowing a growth parameter in the statement of EBC, which is usually very difficult to estimate, leading to a gap between the theoretical convergence and practical implementation. To address this issue, we propose a variance reduced stochastic gradient method that automatically searches for this unknown parameter on the fly of optimization, while still maintaining almost the same convergence rate just as the parameter is known.

Design and Operation of Interdependent Infrastructure Systems

Sponsored: Service Science

Sponsored Session

Chair: Ann Suhaimi, Northeastern University, Somerville, MA, 02145, United States, nmsuhaimi@gmail.com

Co-Chair: Jacqueline Griffin, Northeastern University, Boston, MA, 02115, United States, jacqueline.griffin@gmail.com

1 - Effect of Constructing Utility Tunnels on Interdependent Critical Infrastructure Resilience to Malicious Attacks
Min Ouyang, Huazhong University of Science and Technology, Wuhan, China, min.ouyang@hust.edu.cn, Min Xu, Liu Hong

We propose a bilevel attacker-defender model to analyze the effect of constructing utility tunnels on interdependent critical infrastructure resilience under the worst-case malicious attack. Results show that designing utility tunnels may largely reduce system resilience to the worst-case malicious attack. But if the utility tunnels are designed with sufficient redundancy or well hardened, interdependent system resilience could be well improved.

2 - An Interdiction-based Approach to Identify Damage in Interdependent Critical Infrastructures
N. Orkun Baycik, PhD Student, Rensselaer Polytechnic Institute, 110 8th Street Center for Industrial Innovation, Suite 5015, Troy, NY, 12180, United States, baycin@rpi.edu, Thomas Sharkey

We study the problem of determining the damage in multiple interdependent infrastructures given outage reports from the customers (or service receivers). Demand nodes within these infrastructure networks may have an outage either from damage that occurred within its infrastructure or due to cascading failures across infrastructures. We present a network interdiction based approach to identify the order in which components should be inspected in order to determine the damage within these networks based on the outages reported by customers.

3 - Employing a Mixed-strategy for Effective Response to Vulnerable Populations in Short-notice Disasters
Rana Azghandi, Northeastern University, 360 Huntington Avenue, Boston, MA, 02115, United States, rana.azghandi@gmail.com, Jacqueline Griffin

A mixed integer programming model is developed for applying a mixed-strategy framework to respond to needs of vulnerable populations in short-notice disasters. The mixed-strategy approach focuses on the joint deployment of resources for sheltering-in-place and evacuation assistance. Moreover, social features, such as the physical and emotional needs of target population, and physical features, such as infrastructure systems, will affect the optimal strategy. We examine the effect of these features on the effectiveness of the mixed strategy policy.

4 - Emergency Response Operations Accounting for Interdependent Infrastructures
Ann Suhaimi, Northeastern University, 30 Adams St, Apt 7, Boston, MA, 02145, United States, nmsuhaimi@gmail.com, Jacqueline Griffin

Demand for emergency response personnel is tightly coupled with the operation of other infrastructures, including power and communication systems, as well as the behaviors of citizens, particularly with respect to evacuation. Additionally, the demand for these services changes dynamically throughout an extreme event (e.g. snowstorm, hurricane, etc.). Using MIP model, we examine effects of coordinated decision making across infrastructures on the efficiency and effectiveness EMS deployment, accounting for the dynamics of demand for services.

5 - Optimizing the Resilience of Interdependent Infrastructure Networks under Pre-and Post-event Uncertainty
Andres David Gonzalez, Assistant Professor, The University of Oklahoma, Norman, OK, 73071, United States, andres.gonzalez@ou.edu, Leonardo Dueñas-Osorio, Andres L. Medaglia, Mauricio Sánchez-Silva, Andrew J. Schaefer

Optimizing the resilience of any given infrastructure system requires optimizing decisions for pre-event enhancement and damage mitigation, as well as for post-event efficient recovery. Moreover, it is imperative to consider the multiple interdependencies that these infrastructure systems depict, which directly impact their vulnerability and recoverability. In this work, we present a comprehensive optimization framework that allows optimizing both pre- and post-event decisions, based on the stochastic Interdependent Network Design Problem (sINDP), while taking into account diverse sources of uncertainty, associated with the failure of components and the demands and costs involved.

Multi-Criteria Decision Making: Can we Always Know that we have Made the Right Decision?

Sponsored: Multiple Criteria Decision Making

Sponsored Session

Chair: Evangelos Triantaphyllou, Louisiana State University, Baton Rouge, LA, 70803, United States, etriantaphyllou@yahoo.com

Co-Chair: Juri Yanase, Complete Decisions, LLC, Baton Rouge, LA, 70810, United States, jurijuriy@aol.com

1 - How to (and not) Apply Multi-Criteria Decision Analysis (MCDA) to Medical Decisions

Edouard Kujawski, 1159 Miller Ave., Berkeley, CA, 94708, United States, edkuj@comcast.net

MCDA is increasingly being implemented in shared medical decision-making. Medical professionals and patients face a quagmire of deceitfully attractive methods that can substantially impact alternative rankings. Medical decision-making is often a problem under uncertainty: tests provide imperfect information and outcomes are probabilistic. A significant effort is required to develop realistic and mathematically valid models for making reliable life-critical medical decisions.

2 - Some Important Issues Regarding the use of a Number of Well-known MCDM Methods

Fujun Hou, Beijing Institute of Technology, No.5 South Street Zhongguancun, Haidian, Beijing, 100081, China, houfj@bit.edu.cn

Recent findings on the way some popular MCDM methods rank and prioritize alternatives, raise questions on the validity of their results. We examine these issues comprehensibly. We consider three types of preference data for MCDM problems and identify some isomorphic relations. We use these results to design some appealing approaches for dealing with the problems that face current MCDM methods.

3 - Can We Always Determine the Best MCDM Method?

Evangelos Triantaphyllou, Louisiana State University, Dept of Computer Science, 298 Coates Hall, Baton Rouge, LA, 70803, United States, etriantaphyllou@yahoo.com, Juri Yanase

The reason there is more than one method to solve a given MCDM problem is the fact that sometimes such methods may yield different results for exactly the same input data. Thus, a critical question is to identify the best MCDM method. This problem may be intractable. We discuss a number of intriguing issues related to this fundamental MCDM question.

Young Researchers

Sponsored: Analytics

Sponsored Session

Chair: Aaron Burciaga, Accenture, Global Analytics Executive, 4305 Majestic Lane, Fairfax, VA, 22033, United States, adburciaga@gmail.com

1 - A Decision Support Prototype for Blood Donation Management

Deepti Bahel, Proxima Analytics, West Lafayette, IN, 47906, United States, baheldeepti@gmail.com, Matthew Lanham

We study the performance of machine learning algorithms that have not been previously investigated to support the problem of blood donation prediction. We build models on clustered data sets using k-means clustering and not using clustering to see if performance can be significantly improved. The motivation for this research is that blood demand is gradually increasing by the day due to needed transfusions due to accidents, surgeries, diseases etc. Accurate prediction of the number of blood donors can help medical professionals know the future supply of blood and plan accordingly to entice voluntary blood donors to meet demand. In addition to predicting demand accurately, we show how to incorporate the costs of targeting a potential donor or not, which provides novel decision support to blood centers in how they can manage their donation efforts.

2 - A Balanced k-Means Clustering Algorithm to Support the Division III Men's Wresting Conference Alignment Problem

Amar Iyengar, Purdue University, West Lafayette, IN, United States, iyengara@purdue.edu, Matthew Lanham

We develop a balanced k-means clustering algorithm that allows the modeler to specify a range of how many observations the modeler would like within each generated cluster. The traditional k-means clustering algorithm is one of the most well-known clustering algorithms used by practitioners today. Unfortunately, it often leads to the generation of groups that have a diverse number of observations in each group. Such scenarios regularly lead to cluster formations that violate the problem context and requirements. Since the k-means algorithm is so intuitive, we modify how the algorithm forms clusters so that cluster formations tend to have a similar number of observations in each group. We apply our algorithm to an industry problem posed by division III men's wresting where they were seeking to form new conference regions that we more competitively and geospatially balanced. We show our algorithm improves their current region assignments. Lastly, we identify additional potential avenues this clustering algorithm could be implemented.

Health Care, Modeling and Optimization

Contributed Session

Chair: Aditya Jain, Baruch College, Zicklin School of Business, New York, NY, United States, aditya.jain@baruch.cuny.edu

1 - Evaluating Cardiac Mortality Rates: An Alternative to the RAMR

Christine Pitocco, Research Professor, Stony Brook University, 333 Harriman Hall, Stony Brook, NY, 11794-3775, United States, christine.pitocco@stonybrook.edu, Acsah Joseph, Thomas Sexton

The risk adjusted mortality rate (RAMR) measures the mortality performance of health care providers such as hospitals and physicians. It is used by health care consumers in selecting providers and policy makers evaluating their mortality performance. However, the RAMR has several serious flaws. We propose an alternative measure and demonstrate its use in measuring performance of cardiac surgeons and hospitals.

2 - Graph Regularized EEG Inverse Program with Total Variation Priors

Feng Liu, UT.Arlington, 19251 Preston Rd, Apt 1214, Dallas, TX, 75252, United States, liufengchaos@gmail.com

As EEG sensors measure electrical potentials on the scalp instead of directly measuring activities of brain sources, many approaches were proposed to infer brain source activation pattern. We propose that by leveraging label information, the task related discriminative sources can be much better retrieved among strong spontaneous background signals. A novel supervised EEG source imaging model was proposed which aims to explicitly extract the discriminative source extents by implicitly coding the label information into the graph regularization term. An ADMM optimization algorithm is given to solve the problem. Numerical results show the effectiveness of our proposed framework.

3 - Modeling the Pre-clinical Phase for Ovarian Cancer using a Conditionally Stationary Markov Process

Jing Voon Chen, University of Southern California, Los Angeles, CA, 90089, United States, jingvooc@usc.edu, Julia L. Higle

Creating a nonstationary natural history (NH) model can overwhelm parameter search methods and exacerbate the problems surrounding calibration uncertainty, especially when data is scarce. We present a conditionally stationary Markov model (CSMM) that decomposes the overall NH into two components: a stationary Markov chain governing the disease progression and a nonstationary process for competing risk mortality. We investigate the window of opportunity for ovarian cancer using a CSMM.

4 - Creating Thickness in Kidney Exchange Markets

Shayan Oveis Gharan, Stanford University, 475 Via Ortega,, Huang Engineering Center, 314K, Stanford, CA, 94305, United States, shayan@stanford.edu, Shengwu Li

We study a dynamic model of kidney exchange in which patient-donor pairs arrive and depart continuously and the composition of the market depends on the matching algorithm. We discuss the role of thickness and information in designing optimal policies.

5 - The Effect of Flexible Service Rates in Appointment Scheduling System

Aditya Jain, Baruch College, Zicklin School of Business, 55 Lexington Ave, Suite 9-240, New York, NY, 10010, United States, aditya.jain@baruch.cuny.edu, William P.Millhiser

Recent empirical evidence suggests that ambulatory care healthcare workers intentionally vary service rates in response to two factors: time of day and queue length, where workers choose work speeds to balance their own overtime and the patient's wait. We explore a theoretical justification of this behavior and show that workers speed up if the cost of patient waiting is relatively small compared to workers' overtime cost. We analyze the implications of such worker behavior on various performance metrics for established appointment systems, and how appointment systems should be adapted.

Nano Manufacturing

Invited: Advanced Manufacturing

Invited Session

Chair: Chiwoo Park, Florida State University, Tallahassee, FL, 32310-6046, United States, cpark5@fsu.edu

1 - Quantifying Nanoparticle Mixing State to Account for Both Location and Size Effects

Yanjun Qian, Texas A&M.University, 1501 Harvey Rd, Apt 806, College Station, TX, 77840, United States, qianyanjun09@gmail.com, Ling Dong, Xiaodong Li, Dan Yu, Hui Zhang, Zhong Zhang, Yu Ding

Ripley's K function is a favored tool in quantifying the homogeneity of the nanoparticles mixing state, a parameter is of close relevance to certain properties of the nanomaterial. Ripley's K function assumes that the spatial points are dimensionless, however the nanoparticles form clusters or agglomerates of various sizes and shapes. Our analysis shows that using the original K function falls short of ranking the homogeneity of nanoparticle mixing. We therefore propose to revise the K function to account for both particle location and size effects. The analysis on electron microscopy images of material samples shows that the revised function is a better index to quantify the mixing states.

2 - Tensor Mixed Effects Model with Applications in Nanomanufacturing Inspection

Xiaowei Yue, Georgia Institute of Technology, 755 Ferst Drive NW, ISYE, Atlanta, GA, 30332, United States, xwy@gatech.edu, Jin Gyu Park, Zhiyong Liang, Jianjun Shi

Raman mapping technique has been used to do quality inspection of nanomanufacturing process. Massive high dimensional data with mixed effects are generated. The existing tensor decomposition methods cannot separate mixed effects, and mixed effects model can only handle matrix data instead of tensor data. We propose a tensor mixed effects (TME) model to handle high dimensional data with complex structure. The TME model can (i) separate fixed effects and random effects in a tensor domain; (ii) exploit the correlations along different dimensions; and (iii) realize efficient parameter estimation by a double Flip-Flop method. Simulation and case study demonstrate the efficiency and accuracy.

3 - Structural Sparsity Regularization for Inference of Lattice Structure

Xin Li, Florida State University, 2525 Pottsdamer St, Building A, Suite A231, Tallahassee, FL, 32310, United States, xl12d@my.fsu.edu, Alex Belianinov, Ondrej Dyck, Stephen Jesse, Chiwoo Park

We presents a regularized regression model with a two-level structural sparsity penalty applied to locate individual atoms in a noisy scanning transmission electron microscopy image (STEM). The applicability of the algorithm on determination of atom structures and identification of imaging distortions and atomic defects was demonstrated using real STEM images. We believe this is an important step toward automatic phase identification and assignment with the advent of genomic databases for materials.

Last Mile Aid Operations

Sponsored: Public Sector OR

Sponsored Session

Chair: Feyza Guliz Sahinyazan, McGill University, Montreal, QC, H3A 1G5, Canada, feyza.sahinyazan@mail.mcgill.ca

1 - Community Healthcare Network in Underserved Areas: Design, Mathematical Models, and Analysis

Marie-Ève Rancourt, HEC Montreal, Montreal, QC, H3T.2A7, Canada, marie-eve.rancourt@hec.ca, Marilène Cherkesly, Karen Smilowitz

In this presentation, we design community healthcare networks in underserved areas. The problem consists of determining the number of community health workers and supervisors, as well as the routing and scheduling of the supervisors. We propose four set-partitioning mathematical models. Computational results are presented for a real-life case study.

2 - Food Assistance Modality Selection Problem: In Kind, Cash or Voucher?

Feyza Guliz Sahinyazan, McGill University, Desautels Faculty of Management, Bronfman Building, 1001 Rue Sherbrooke O, Montreal, QC, H3A 1G5, Canada, feyza.sahinyazan@mail.mcgill.ca, Marie-Ève Rancourt, Vedat Verter

There is a vast empirical literature suggesting that providing food aid in cash or vouchers is significantly more effective compared to in-kind. Yet, ours is the first study that mathematically models the aid modality selection and provides a methodology that can respond the dynamics of the environments requiring food assistance.

3 - On the Cost and Effectiveness of Packaging as a New Lever in Food Aid Supply Chain Design

Mark Brennan, Massachusetts Institute of Technology, 77 Massachusetts Avenue, E38-649, Cambridge, MA, 02139, United States, mbrenn1129@gmail.com, Jarrod D. Goentzel, Prithvi Sundar, Dan Frey

Recent legislation has changed from where and when US food aid can be sourced, and how it can be shipped, affecting the timeless and cost-effectiveness of relief efforts. Using data collected from a $1.7 million US food aid procurement in which new packaging types were piloted, this study shares results of the cost and effectiveness of changing in which packaging food aid is shipped. This study demonstrates how packaging can be a lever of supply chain design, and presents the advantages and limitations of including another "lever" in the US food aid supply chain.

Military Applications

Contributed Session

Chair: Laura Freeman, IDA, Alexandria, VA, United States, lfreeman@ida.org

1 - Model Predictive Control for the Flow Field in an Intermittent Transonic Wind Tunnel

Jian Zhang, City University of Hong Kong, Hong Kong, jzhang398-c@my.cityu.edu.hk

This study aims to design a controller to quickly reject various disturbances for the varying Angle of Attack (AoA) tests in an Intermittent Transonic Wind Tunnel (ITWT). A novel AoA model (i.e., Hammerstein model) with corresponding modeling approach is developed to characterize the influence of varying AoA on the static pressure. Finally, the flow field controller is formed as a simple Quadratic Programming (QP) problem, and the feedforward strategy is employed to compensate for the varying AoA disturbance. Simulation results and practical wind tunnel tests prove that the proposed controller can improve test precision and reduce test costs.

2 - Assessing Risk in a Military Logistics Network

Brandon McConnell, North Carolina State University, 1631 Carywood Drive, Apt 1631, Cary, NC, 27513, United States, bmmcconn@ncsu.edu

The U.S. Army's adoption of an enterprise resource planning (ERP) system provides an opportunity to develop automated decision-support tools and other analytical models designed to use logistical data. This research presents a tool that runs in near-real time to assess risk while conducting capacity planning and performance analysis for a military logistics network. A goal-seeking adaptive simulation is combined with recent advances in transient queue analysis to both account for uncertainty and assess residual risk.

3 - Simulation of a Readiness Based Sparing Optimization

Javier Salmeron, Naval Postgraduate School, 1411 Cunningham Road, Monterey, CA, 93943, United States, jsalmero@nps.edu, Wray John, Arnold H. Buss

We develop a simulation to complement a new optimization tool that establishes inventory levels for aviation weapon systems (WS) in the U.S. Navy. We seek cost minimization while achieving required readiness for hundreds of WS, each comprising thousands of indentured parts. We employ the Vari-Metric model and a variant of a greedy heuristic algorithm. On average, the optimization slightly overestimates availability. Also, 57 of 64 WS simulated yield results within 8% difference, with a worst-case under 11%. We identify factors correlated to these differences. We test another legacy optimization tool currently in use by the Navy and find it has a larger difference in expected readiness.

4 - Robust Allocation of Resources in Reliability Growth Testing

Mohammadhossein Heydari, University of Arkansas, 1898 Caton Dr, Fayetteville, AR, 72704, United States, mhheydar@uark.edu, Kelly Sullivan

Reliability growth testing seeks to identify and remove failure modes in order to improve the reliability of a system. In this study, we consider the robust allocation of testing resources across the components of series and series-parallel systems. We assume that the failures of each component occur according to the AMSAA model (Crow, 1974) with uncertain parameters within a bounded uncertainty set. We develop and analyze exact solution approaches for this problem based on a cutting plane algorithm. A simulation approach is used to compare solutions from our model with solutions from an analogous deterministic optimization model.

5 - Statistical Techniques for Modeling and Simulation Validation
Laura Freeman, IDA, 4850 Mark Center Drive, Alexandria, VA, 22311, United States, lfreeman@ida.org, Kelly Avery

Modeling and simulation (M&S) can augment live testing to provide a more complete evaluation of system performance. It is essential that the usefulness and limitations of the M&S are well characterized, and uncertainty quantified. This talk highlights statistical techniques to compare M&S output with live test data. We will show how design for computer experiments can be used to efficiently cover the simulation domain and inform live testing. A simulation study shows that regression analysis is the most powerful method when paired with experimental design techniques. A Defense system case study shows highlight real world implications.

Revenue Management, Pricing

Contributed Session

Chair: Tulay Flamand, Colorado School of Mines, Golden, CO, United States, tflamand@mines.edu

1 - Tell Me What I Want: A Study of Personalized Assortment Planning for Learning Consumers
Yulia Vorotyntseva, University of Texas at Dallas, 2200 Waterview Parkway, Apt 1627, Richardson, TX, 75080, United States, yxv120230@utdallas.edu, Canan Ulu, Dorothee Honhon

We model the retailer's and consumer's simultaneous learning about the consumer's idiosyncratic preferences in a given product category. In each period the retailer chooses the assortment of products to offer learns about the consumer's preferences by observing her choice. The consumer picks at most one product, gets a noisy signal about its utility and updates her beliefs on her own preferences in Bayesian fashion. We derive structural properties of the firm's optimal assortment policy and quantify the value of information about the consumer's experience, such as feedback surveys.

2 - Novel Ways to Leverage Consumer Choices through Optimization
James Farmer, President of The Harvest Group, 5500 West JB Hunt Drive, Suite 720, Rogers, AR, 72758, United States, jfarmer@harvestgroup.com

Organizations struggle with how to determine appropriate spend. This dynamic reinforces the behavior of beginning with the "what did we do last year" approach - that reduces optimal results. By taking a different perspective that begins bottom-up and ends with practical engineering, brands and retailers can discover more growth. Data driven feedback loops provide executives with an ability to optimize past results based on predictive analytics. This dynamic re-allocation of resources guides managers and executives toward focusing investment where business can improve.

3 - Designing a Centralized Distribution System for Omnichannel Retailing
Jia Guo, the University of Alabama, 311 Reed Street, Apt 8, Tuscaloosa, AL, 35401, United States, jguo23@crimson.ua.edu, Burcu B.Keskin

Shifts in consumer spending toward services and experiences as well as the competition from discounters and online stores force the traditional retailers to reconsider their supply chain designs. We consider a two-stage stochastic integer programming model for designing an omnichannel network integrating brick-and-mortar stores with an online channel by filling online orders through shipping from nearby stores; by offering their customers the option to buy online and pick up in-store or curbside. Using a single period model, we evaluate the effectiveness of these cross-channel strategies for improving profitability, moving store inventory and avoiding markdowns.

4 - Simulation and Analysis of a Grocery Store Layout
Jessica Peggy Dorismond, University at Buffalo, 17DA Creekside Village, Buffalo, NY, 14212, United States, jpdorism@buffalo.edu, Jose Walteros, Rajan Batta

The purpose of this research is to utilize optimization and simulation modeling to yield an optimal supermarket layout. This study focuses on how to optimize the layout of a supermarket in order to increase its gross profit via the maximization of impulse sales. In most supermarkets many items often get unnoticed because on average customers only walk one-third of the store. Since customers use tangible products as a memory cues, increasing the visibility of certain items will prompt customers to purchase items that are not included on their shopping list.

5 - Sales Assistance Search and Purchase Decisions an Analysis using Retail Video Data
Aditya Jain, Baruch College, Zicklin School of Business, 55 Lexington Ave, Suite 9-240, New York, NY, 10010, United States, aditya.jain@baruch.cuny.edu, Nils Rudi, Sanjog Misra

We investigate the roles of sales assistance and search in driving customer's purchase decision using unique observational video data from retail stores. Our analysis reveals that both sales assistance and search play substantial roles which differ based on the context of specific decisions—search has a more dominant role in purchase incidence, whereas the latter in conditional expenditure.

6 - Retail Analytics on Store-wide Shelf Space Allocation
Tulay Flamand, Colorado School of Mines, Engineering Hall 816 15th Street Office #313, Golden, CO, 80401, United States, tflamand@mines.edu, Ahmed Ghoniem, Bacel Maddah

We investigate how to optimize the store-wide shelf space allocation of retailers in a way that guides in-store traffic and induces impulse buying. A predictive model for in-store traffic is formulated based on our data analysis and is embedded into an optimization model that prescribes shelf space allocation solutions.

Scheduling in Operations Management

Invited: Project Management and Scheduling

Invited Session

Chair: Chelliah Sriskandarajah, Texas A&M University, College Station, TX, 77843-4217, United States, chelliah@mays.tamu.edu

Co-Chair: Yunxia Zhu, Rider University, Pennington, NJ, 08534, United States, yuzhu@rider.edu

1 - Outpatient Appointment Block Scheduling under Patient Heterogeneity and Patient No-shows
Yunxia Zhu, Rider University, 101 tuxford ct, Pennington, NJ, 08534, United States, yuzhu@rider.edu, Seung Jun Lee, Gregory R. Heim, Chelliah Sriskandarajah

We study outpatient appointment block scheduling policies for single providers under conditions of patient heterogeneity in service times and patient no-shows. The objective is to find daily appointment schedules that minimize a weighted sum of patients' waiting time, the physician's idle time, and the physician's overtime. We contribute by suggesting new effective sequential block scheduling procedures motivated by actual outpatient clinic practices across the globe and grounded in the successful Toyota Production System load smoothing approach.

2 - Lateral Transshipment Strategy with Customer Switching
Ying Li, Texas A&M.University, College Station, TX, 77843, United States, yli@mays.tamu.edu, Wenjing Shen, Xinxin Hu, Yi Liao

We consider inventory replenishment and transshipment decisions at two retail locations in a single-period setting while allowing the possibility of customers not staying with their initial retail location. Our research identifies the optimal replenishment and transshipment policy. In particular, we show that the surplus retailer should reserve part of its inventory for switching demand, as opposed to satisfy all transshipment demand. Through numerical studies, we examine the impact of random customer switching on profitability and demand fill rate, as well as the value of the optimal transshipment policy.

3 - Network Seeding on Social Media
Rakesh Reddy Mallipeddi, Texas A&M.University, 320 Wehner - 4217, Mays Business School, Dept of Info&Operations, College Station, TX, 77843-4217, United States, rmallipeddi@mays.tamu.edu, Subodha Kumar, Yunxia Zhu, Chelliah Sriskandarajah

With explosive growth in number of users, marketers have embraced social media as a preferred platform to diffuse and advertise their products. In this study, we propose analytical models to identify influencers (or network seeders) to maximize the reach and effect of an advertisement (or seed) on social media platforms.

4 - A Framework for Analyzing the U.S. Coin Supply Chain
Yunxia Zhu, Rider University, 101 Tuxford Ct, Pennington, NJ, 08534, United States, yuzhu@rider.edu, Yiwei Huang, Subodha Kumar, Chelliah Sriskandarajah, Bala Shetty

This study addresses operational issues within a Coin Supply Chain (CSC) and provides an optimal/near-optimal operating policy for the Federal Reserve System and Depository Institutions to increase their efficiency and cost-effectiveness in ordering, producing, packaging, distributing, and managing inventory of coins. We treat the U.S. CSC as a closed-loop supply chain from both supply and demand side perspectives. We devise and perform an extensive computational study to answer managerially relevant questions in the context of improving the efficiency of the U.S. CSC.

Sponsored Session

Chair: Jie Zhang, University of Texas, Arlington, TX, 76019, United States, jiezhang@uta.edu

1 - On the Spillover Effects of User-generated Reviews on Purchases: Evidence from Clickstream Data

Gene Moo Lee, University of Texas at Arlington, 6746 Deseo #112B, Arlington, TX, 75039, United States, gmlee7@gmail.com, Young Kwark, Paul Pavlou, Liangfei Qiu

We analyze the spillover effect of the online reviews of related products on the purchases of a focal product using clickstream data from a large retailer by investigating (a) whether the related, co-visited products are complementary or substitutive; (b) whether the related products are from the same or a different brand, and (c) the choice of media channel (mobile or PC) used. The result shows that the mean rating of the online reviews of substitutive products has a negative effect on the purchasing of the focal product, while the mean rating of complementary products has a positive effect.

2 - Social Processes and Earnings Management: Evidence from Employee Reviews

Feng Mai, Stevens Institute of Technology, 1 Castle Point on Hudson, Hoboken, NJ, 07030, United States, feng.mai@stevens.edu, Xinyan Yan

We study the link between corporate culture and earnings management. Using data from a leading employee review site, we show that the use of discretionary accruals to manipulate reported earnings is more pronounced at those firms having stronger social affiliation among employees. Our results suggest that employee reviews can provide pertinent information about corporate ethics.

3 - Augment Reality Game's Spillover

Jie Zhang, University of Texas at Arlington, Arlington, TX, 76011, United States, jie.zhang2@mavs.uta.edu, Yuan Zhang

This study empirically examined how the introduction of augmented reality games, such as Pokemon Go affects the reputation of local businesses.

4 - Social Learning and Early Purchase under Product Fit Uncertainty and Price Uncertainty

Xuying Zhao, University of Notre Dame, 361 Mendoza College Of Business, Notre Dame, IN, 46556, United States, xzhao1@nd.edu, Zhan Pang, Jie Zhang

The first period buyers make purchase decisions under future price uncertainty. Social learning increases this uncertainty because the second period price may depend on the review valence then, which is uncertain in the first period. So social learning has the increasing-price-uncertainty effect, which changes early buyers' waiting incentives and may hurt or benefit the firm in different scenarios.

5 - Competitive Poaching in Search Advertising: A Randomized Field Experiment

Siddharth Bhattacharya, Temple University, Philadelphia, PA, United States, tug79848@temple.edu, Jing Gong, Sunil Wattal

A key strategy firm's are following in search advertising is to generate traffic by bidding on not only their own keywords but also competitors' keywords. This strategy, known as competitive poaching, is prevalent in multiple industries. However, little research has empirically examined the effectiveness of competitive poaching. The objective of this research is to examine the effect of ad copy variations with respect to competitor keywords on driving click-through and conversion. We further expect this relationship to be moderated by quality and location of competitor. We run a 4-month randomized field experiment in collaboration with a business school.Managerial implications are discussed.

Empirical Behavioral Operations

Sponsored: Behavioral Operations Management

Sponsored Session

Chair: Dennis Zhang, University City, MO, 63124, United States, denniszhang@wustl.edu

1 - Learning from Inventory Availability Information: Field Evidence from Amazon

Ruomeng Cui, Goizueta Business School, Emory University, 1300 Clifton Rd, Atlanta, GA, 30322, United States, ruomeng.cui@gmail.com, Dennis Zhang, Achal Bassamboo

Many online retailers provide real-time inventory availability information. Customers can learn from the inventory level and update their beliefs about product quality. Based on a unique setting from Amazon lightning deals, which displays the percentage of inventory consumed in real time, we explore whether and how consumers learn from inventory availability information. We run randomized field experiments on Amazon and run a panel data analysis. We find evidence of consumer learning from inventory information: a decrease in product availability causally attracts more sales in the future; in particular, a 10% increase in past sales leads to a 2.08% increase in cart add-ins in the next hour.

2 - When You Work with a Super Man, Will You Also Fly? An Empirical Study of the Impact of the Coworkers on Workers' Performance

Fangyun Tan, Southern Methodist University, 6212 Bishop Blvd, Dallas, TX, 75275, United States, ttan@cox.smu.edu, Serguei Netessine

We examine a large operational data set in a casual restaurant setting to study how coworkers' sales ability level affects other workers' sales performance. We find that waiters react non-linearly to their coworkers' ability. Our empirical findings imply that to maximize sales, managers should mix waiters with heterogeneous ability levels during the same shift.

3 - Last Place Aversion in Queues

Ryan Buell, Harvard Business School, Morgan Hall 429, Boston, MA, 02163, United States, rbuell@hbs.edu, Michael Norton, Jay Chakraborty

Waiting in queues is an all-too-common source of customer frustration, disrupting the customer experience and - when queues or waits are sufficiently long - causing customers to switch queues, or forgo the experience altogether by reneging. While the number of people in front of a customer in a queue logically predicts such behaviors - the more people, the longer the wait - we examine an underexplored trigger of frustration: how many people are behind the customer in the queue. In particular, in a series of lab and field experiments, we explore whether being in or near last place in a queue predicts switching and reneging, independent of how many people are ahead in the queue.

4 - Fixed or Random Supplier? Evidence from an Order Allocation Game

Chao Xue, Tsinghua University, Beijing, 100084, China, xuec15@mails.tsinghua.edu.cn, Xiaobo Zhao, Jinghuo Chen

We present an experimental study to investigate the impact of fairness concerns on supplier selection strategies. In the game, a manufacturer needs to allocate its orders to two identical suppliers, and the relationships are established through either fixed or random pairings. It is observed that order allocations over time by the manufacturer follow a U-shaped curve under the fixed matching. To capture such learning dynamics, we propose a behavioral model in which the manufacturer updates his belief about the supplier's fairness preferences through repeated interactions. Our results provides useful insights for how to adopt supplier selection strategies appropriately.

Practice/eBusiness I

Contributed Session

Chair: Rajiv Misra, XLRI-Xavier School of Management, C H Area (East), Jamshedpur, 831001, India, rajiv@xlri.ac.in

1 - How to Compare Two Products? A Framework to Make a Better Decision for Consumers Based on Online Word-of-mouth Information

Song Gao, Tongji University, 1 Zhangwu Road, Tongji Block A, Shanghai, 200092, China, hardygao@outlook.com, Hongwei Wang

It is an essential part for consumers to make a purchase decision by comparing different products. And online WOM can guide consumers to judge which one is better. This paper proposes a framework to compare two products based on three comparison types. The first one is comparing two products using the direct comparison opinions presented by other consumers. If they have no direct relation, we construct stable comparison relation by introducing a common comparison object, which has the direct relation with them respectively. The third type focuses on two products, which have no direct relation and no common object. We compare them using the comparison between consumer's opinion and past experience.

2 - Effects of Certificates on Buyers' Order Cancellations in E-marketplaces

Sang Won Kim, Assistant Professor, CUHK.Business School, The Chinese University of Hong Kong, Shatin NT, Hong Kong, skim@cuhk.edu.hk, Youngsok Bang, Yiying Zhang

Despite a plethora of previous studies on the role of seller certificates in e-marketplaces, we have a limited understanding of their effects in post-order stage where buyers can reverse their purchase decisions. Based on the psychological contract violation theory, we propose hypotheses about potential negative effects of certificates and test them using transaction data from a leading e-marketplace in Korea. Our results suggest that, given the time elapsed from the order, buyers are more likely to cancel their orders from "quick" sellers, whereas the impact is reversed for "quality" or "quantity" sellers. We also examine how the results vary over different product types and purchase channels.

3 - Online Retailer Competition with an Option of Referral Services

Kihoon Kim, Associate Professor, Korea University, Korea Univeristy Business School, LG-POSCO.#316, Anam-dong, Seongbuk-gu, Seoul, 136701, Korea, Republic of, kihoon@korea.ac.kr

We investigate whether two competing online retailers can be better off by adopting a referral service. When they adopt the referral service, a referral-offering online retailer faces a trade-off between generating additional revenues from referral fees and the risk of exposing its loyal consumers to the price of its referred online retailer. We show that the proportion of strongly loyal consumers of the referral-offering retailer among all its (potential) consumers mainly determines the degree to which the referral service will improve the retailers' profits.

4 - Domestic Expansion Strategies for Online Grocery Retailers: Case Study from Emerging Economy

Rajiv Misra, Professor, XLRI-Xavier School of Management, C. H. Area (East), Jamshedpur, 831001, India, rajiv@xlri.ac.in, Sayan Mukherjee, Alok Baveja, Atanu Ghosh

This is a study on the strategies that an Online Grocery Store can consider for expansion in the domestic market. Our overarching research questions are: 1.What strategic options does an online grocery store have when it considers expansion? 2. What factors affect the choice of an expansion strategy? By conducting literature review and by evaluating cases from an emerging economy, we first try to explore the strategic options available for expansion and the factors that affect the choice of each option. Taking the case of a leading online grocery retailer in India, we next longitudinally evaluate the decisions taken by the retailer while expanding into several locations in the domestic market.

Advances in Urban Transportation

Sponsored: TSL, Urban Transportation

Sponsored Session

Chair: Qie He, University of Minnesota, Minneapolis, MN, 55455, United States, qhe@umn.edu

1 - Real Options Switching Strategies in Dynamic Transportation Operations

Joseph Y.J. Chow, New York University, 2 Washington Square Village, Apt. 10i, New York, NY, 10012, United States, joseph.chow@nyu.edu, Qianwen Guo, Paul M. Schonfeld

With increasing ubiquity of real time data in urban transportation, there is a need for dynamic decision-making to switch operational mode based on an underlying stochastic process. Examples include flexible transit that switch between fixed route and on-demand operations; autonomous vehicle fleet management; and taxi surge pricing. We present an analytical optimal policy model based on market entry-exit real options to identify such switching thresholds. The model assumes an Ornstein-Uhlenbeck stochastic process and can reduce up to 72% of the excess cost of a myopic policy. Test cases are presented to illustrate the model.

2 - Continuous Approximation on the Vehicle Routing Problem with Unpaired Pickup and Delivery

Chao Lei, Ph. D., University of Illinois at Urbana–Champaign, 205 N Mathews Ave, Urbana, IL, 61801, United States, chaolei@illinois.edu, Yanfeng Ouyang

We propose a hybrid modeling framework for the vehicle routing problem with unpaired pickup and delivery (VRPPD) of a commodity. Continuum approximation (CA) is used to model internal pickup and delivery within each of multiple subregions, while matching of net excess or deficit of the commodity out of these subregions is addressed in a discrete model. A Lagrangian relaxation algorithm is developed to solve the hybrid model for large-scale VRPPD instances.

3 - Analysis of Two Hybrid Route Choice Models in Stochastic Assignment Paradox

Zhanhong Cheng, Harbin Institute of Technology, Harbin, China, 18369181837@163.com, Jia Yao

This paper compares the stochastic assignment paradoxes of the multiplicative hybrid model and the linear combinatorial hybrid model, both of which can overcome the drawbacks of the multinomial logit/weibit model, in three typical networks (two links, independent links, and three routes with an overlapping link).

4 - Traffic Assignment Paradox Incorporating Congestion and Stochastic Perceived Error

Jia Yao, Harbin Institute of Technology, Harbin, China, yaojia@hit.edu.cn

This paper analyzes how congestion and stochastic perceived error affect traffic assignment paradox simultaneously. The paradox corresponding to the travel cost and the perceived travel cost for marginal improving and adding a link and information paradox in which a higher stochastic perceived error decrease the travel cost are analyzed respectively.

Online Markets

Sponsored: Information Systems

Sponsored Session

Chair: Wei Chen, Tucson, AZ, 85718, United States, weichen@email.arizona.edu

1 - Value of Diversity in Online Equity Crowdfunding

Mingfeng Lin, University of Arizona, 1130 E.Helen St, Tucson, AZ, 85721, United States, mingfeng@eller.arizona.edu

This talk discusses the role and value of diversity in predicting business performance using an extremely detailed proprietary dataset from online equity crowdfunding. Results have implications for investors, entrepreneurs, and policy makers.

2 - The Impact of Store Opening on Customers' Spending in Online Retailing Platform with A Hybrid Model of Reselling and Marketplace

Ling Xue, Georgia State University, Department of Computer Information Systems, J. Mack Robinson College of Business, Atlanta, GA, 30302, United States, lxue5@gsu.edu, Peijian Song, Yanran Liu, Arun Rai

In this study, we examine how the offline channel of the retailer influence the sales in the hybrid online channel with both the reselling section and the marketplace section. We use the opening of offline stores as a research setting to draw causal inferences. Our findings show how the offline channel generates differential impacts on the reselling section and the marketplace section of the online channel. Our study extends the existing understanding of online-offline interaction by bringing the marketplace model into consideration.

3 - Market Segmentation and Software Security: Pricing Patching Rights

Duy Dao, University of Calgary, Calgary, AB, Canada, Duy.Dao@rady.ucsd.edu

The patching approach to security in the software industry has been less effective than desired. A critical issue is that the ability for a consumer to choose whether security updates are applied lacks the incentive structure to induce better security-related decisions. In this paper, we establish how vendors can differentiate their products based on the provision of patching rights and how optimally pricing this right can segment the market in a manner that leads to both greater security for consumers and greater profitability for vendors.

1 - Allocating Distributed Generators for Resilient Distribution System under Uncertain Probability Distribution of Natural Disasters

Sadra Babaei, Oklahoma State University, 322 Engineering North, Industrial Engineering & Mgmt, Stillwater, OK, 74078, United States, sadra.babaei@okstate.edu

A new distributionally robust defender-attacker-defender model is proposed for the planning of line hardening and allocating distributed generators, to hedge against the risk of disruptions caused by natural disasters. We consider the case that the true probability distribution of extreme weather is ambiguous, and minimize the load shedding with the worst-case scenario of weather distribution. Unlike traditional robust models, our approach takes advantage of moment information of the weather distribution that is learned from historical data. We reformulate the proposed model as a tractable two-stage robust optimization and employ a column-and-constraint generation algorithm to solve it.

2 - Decision Criteria for Wave Energy Extraction Characterizing its Temporal and Spatial Variability

Francisco Haces Fernandez, Texas A&M.University-Kingsville, Kingsville, TX, United States, fr.haces@gmail.com, Hua Li, David Ramirez

Wave energy is one of the most promising renewable energy resources. However, its commercial development has been slow and is facing important challenges. Understanding its high temporal and spatial variability will significantly improve its extraction. This research is able to identify how wave energy behaves as a two temporal estate system, with high and low energy periods. Energy Events have distinctive characteristics, allowing them to be identifiable on calendar periods, by its seasonal frequencies and on energy content. This study provides decision criteria for the installation of wave energy extraction equipment that provides the optimal fit for each location.

3 - Improving the Efficiency and Performance of Genetic Algorithm Based Layout Optimization Method on Irregular Shape Wind Farms

Hua Li, Associate Professor, Texas A&M University-Kingsville, 700 University Blvd MSC 191, Kingsville, TX, 78363-8202, United States, hua.li@tamuk.edu, Yan Xu

Layout optimization has become a one of the critical tools to help increase the power output or decrease the cost of a wind farm. Most of the existing layout optimization algorithms are based on regular shape wind farms, while most commercial wind farms have irregular shapes. A layout optimization algorithm that can be applied on different irregular shape wind farm with consideration of different commercial wind turbine models and hub heights is needed to help improve the efficiency and performance of commercial wind farms. This study develops and improves a genetic algorithm based wind farm layout optimization method for irregular shape wind farms with real world parameters.

4 - Optimal Use of the Storage Capacity of a Pool of Electrical Vehicles, Connected to a Micro Grid or a Virtual Power Plant

Jose-Ignacio Munoz-Hernandez, University of Castilla - La Mancha, Edifico Politecnico - UCLM, Avda Camilo Jose Cela, S/N, Ciudad Real, 13071, Spain, joseignacio.munoz@uclm.es, Pablo Diaz-Cachinero, Javier Contreras

Micro grids and Virtual Power Plants consist of several types of generation resources to meet their demand necessities. Electrical vehicles are mobile demands that can plug into the network at different sites but, at the same time, they also can be used as power reservoirs or sources. Due to the increasing penetration of renewable energy sources, electric vehicles, and storage units, the associated uncertainty needs to be properly characterized. This work develops a new approach to optimize the use of this sort of resources in a micro grid and in a virtual power plant.

Improving Energy Efficiency of Personal Transportation

Sponsored Session

Chair: Hesham Rakha, PhD, P. Eng., Virginia Tech Transportation Institute, 3500 Transportation Research Plaza,, Blacksburg, VA, 24061, United States, hrakha@vt.edu

1 - A Web Based Personal Driving Assistant using Real Time Data and a Dynamic Programming Model

Mohammad Ali Alamdar Yazdi, PhD Student, Auburn University, 516 E. Glenn Ave, Apt 128, Auburn, AL, 36830, United States, mza0052@auburn.edu, Fadel Mounir Megahed, Alexander Vinel

This talk presents a web based Eco-Driving Assistance System to improve a vehicle's miles per gallon (mpg) fuel-economy performance. More specifically, a dynamic programming model is constructed to dynamically optimize the current speed, gear, and route based on forthcoming route conditions (weather, traffic, elevation, etc.) collected from different web APIs.

2 - An Algorithm for Incentive Allocation Problem as a Part of Smart Mobility Solutions

Mehrdad Shahabi, University of Michigan, 2350 Hayward St, 205, Ann Arbor, MI, 48109, United States, mshahabi@umich.edu, Yafeng Yin, Chenfeng Xiong, Lei Zhang

Recently, there has been a surge of interest in transportation demand management tools involving incentive provision in order to manage the growing congestion problems in transportation networks. With the goal of decreasing the energy consumption on the system level, our focus in this work is to design a framework through which a number of travelers are offered incentives on some travel alternatives different from their original travel option. The results confirm significant savings in energy consumption as a result of changing travel behavior.

3 - Multi-scale and Multi-modal Agent-based Modeling of Network-wide Energy/Fuel use of Travel Incentive Strategies

Hesham Rakha, Samuel Reynolds, Pritchard Professor of Engineering, Virginia Tech, Blacksburg, VA, 24060, United States, hrakha@vt.edu, Ahmed Elbery, Filip Dvorak, Matthew Klenk, Jinghui Wang, Ahmed Ghanem

The need to objectively and systematically evaluate the network-wide impacts of travel incentive strategies necessitates the development of multi-scale multi-modal agent-based modeling tools. This presentation describes the various building blocks of the proposed modeling tool, namely: (a) traveler behavior modeling; (b) modeling of train dynamics; (c) modeling driver and vehicle longitudinal and lateral movement; (d) modeling of multi-modal energy/fuel consumption (gasoline, electric, and plugin hybrid electric vehicles, CNG buses, and electric trains); (e) integration of microscopic and mesoscopic modeling into a fully-integrated multi-scale multi-modal agent-based modeler.

Operations Research in Plant Breeding

Invited: Agricultural Analytics

Invited Session

Chair: Lizhi Wang, Iowa State University, Ames, IA, 50011, United States, lzwang@iastate.edu

1 - The Extended Predicted Cross Value for Genetic Introgression of Multiple Alleles with Multiple Individuals

Ye Han, Iowa State University, Black Engineering, Room 0076, Ames, IA, 50014, United States, yeh@iastate.edu, Lizhi Wang, William D. Beavis, John N. Cameron

In our recent research, we applied operations research approaches to optimize introgression of multiple alleles from a donor to a recipient genome. We designed a novel metric called the Predicted Cross Value (PCV) for selecting breeding parents. The PCV has been proved to bring in significantly advantages over the existing approaches by simulations. In this research, according to the practical breeding requirements, we extend the PCV idea to introgression process for multiple individuals. The updated metric is referred as PCV for multiple individuals or NPCV. We examine the NPCV in different case studies compared with the PCV or existing approach and demonstrate the results by simulations.

2 - New Genomic Selection Approaches
Lizhi Wang, Iowa State University, IMSE and ECPE, Ames, IA, 50011, United States, lzwang@iastate.edu

Genomic selection is among the most impactful decisions that plant and animal breeders make. It also presents an incredibly complex mathematical challenge: how to select the right breeding parents to produce the next generation of progeny to achieve maximal genetic gains? We will review previously proposed genomic selection approaches, present a new one, and discuss future research directions.

3 - Mathematical Programming Based Training Set Optimization for Genomic Selection
Shiyang Huang, Iowa State University, 0076 Black Engineering, Ames, IA, 50011, United States, shuang@iastate.edu, Guiping Hu

A new method of optimized training set (TRS) selection was proposed for genomic selection. A quadratic optimization model with binary variables is formulated and and solved with a specially designed algorithm to select individuals forming the TRS from a calibration set. A ridge regression best linear unbiased predictor (rrBLUP) model was trained based on selected TRS to calculate genomic-estimated breeding value (GEBV) and predict the corresponding trait. The proposed method significantly outperformed common existing TRS selection methods, and suggested a criterion based on individuals' Identify-By- State (IBS) distances to evaluate training sets.

4 - Optimizing the Size of Training Data for Genomic Prediction
Reka Howard, University of Nebraska-Lincoln, 342B Hardin Hall, Lincoln, NE, 68583, United States, rekahoward@unl.edu

Genomic prediction (GP) is a technique in plant breeding where plants' genotypic and phenotypic information - called training set - are used to predict plant's phenotypic performance for which only marker information is available, also known as testing set. In GP the size, genetic architecture and quality of phenotypic data influence predictability. Herein an algorithm based on genetic similarities that avoids the use of phenotypic data for choosing the optimal training set for GP using a soybean data set containing information for 5600 individuals is presented.

Robust Portfolio Selection

Sponsored: Financial Services

Sponsored Session

Chair: Victor DeMiguel, London Business School, London, NW1 4SA, United Kingdom, avmiguel@london.edu

1 - Long-term Asset Allocation under Time-varying Investment Opportunities: Optimal Portfolios with Parameter and Model Uncertainty
Alex Weissensteiner, Free University of Bolzano Bozen, Universitÿtsplatz 1, Bolzano, 39100, Italy, alex.weissensteiner@unibz.it, Thomas Dangl

We study the implications of predictability on the optimal asset allocation of ambiguity averse long-term investors in a VAR model. While over short periods the model-implied conditional covariance structure of asset-class returns determines the optimal allocation, over longer horizons the optimal asset allocation is significantly influenced by the covariance structure induced by estimation errors. As a consequence, the ambiguity averse long-term investor tilts her portfolio not simply toward the global minimum-variance portfolio but shrinks portfolio weights toward a seemingly inefficient portfolio which shows maximum robustness against estimation errors.

2 - A Portfolio Perspective on the Multitude of Firm Characteristics
Victor DeMiguel, London Business School, Management Science and Operations, Regents Park, London, NW1 4SA, United Kingdom, avmiguel@london.edu

We investigate which characteristics matter jointly for an investor who cares not only about average returns but also about portfolio risk, transaction costs, and out-of-sample performance. We find only a small number of characteristics—six—are significant without transaction costs. With transaction costs, the number of significant characteristics increases to 15 because the trades in the underlying stocks required to rebalance different characteristics often net out. We show investors can identify combinations of characteristics with abnormal out-of-sample returns net of transaction costs that are not fully explained by the Fama and French (2015) and Hou, Xue, and Zhang (2014) factors.

3 - Risk-adjusted Returns and Leverage Efficiency under Market Impact
Chanaka Edirisinghe, Rensselaer Polytechnic Institute, Lally School of Management, Pittsburgh 2118, Troy, NY, 12180-3590, United States, edirin@rpi.edu, Jingnan Chen, Jaehwan Jeong

We model the Pareto-efficient set between portfolio's Sharpe and leverage under risk-aversion in continuous-time trading under market impact. We derive analytical properties for Sharpe-Leverage tradeoff and show the departures from the standard theory that ignores trading costs. We also obtain the minimum variance portfolio and provide empirical testing under market impact. Disregarding market impact leads to severe performance shortfall.

4 - Portfolio Construction by Mitigating Error Amplification: The Bounded-noise Portfolio
Long Zhao, UT.McCombs Business School, 2110 Speedway Stop B6500, CBA 5.334 B, Austin, TX, 78712-1277, United States, longzhao@utexas.edu

This paper focuses on the problem of poor portfolio performance when a minimum-variance portfolio is constructed using the sample estimates. Estimation errors are mostly blamed for this problem. However, we argue that even small unbiased estimation errors can lead to bad performance because the optimization step amplies errors. Instead of trying to independently improve the estimation step or fix the optimization step for robustness, we disentangle the well-estimated aspects from the poorly estimated aspects of the covariance matrix and handle them differently and appropriately. Using a single constant parameter, our method achieves excellent performance in both simulation and real data.

Emerging Topics in Machine Learning: Methodology and Applications

Sponsored: Data Mining

Sponsored Session

Chair: Tong Wang, University of Iowa, Iowa City, IA, 52245, United States, tong-wang@uiowa.edu

1 - Big Data is Small Data
Jessica Clark, University of Maryland Smith School of Business, College Park, MD, 20742, United States, jclark@stern.nyu.edu, Foster Provost

The goal of this work is to explore the ways in which big data and small data are similar in a binary classification setting. We define big data sets as those that represent human behaviors selected from a large set of options, and are therefore not only large in quantity but are also sparse. Conversely, small data sets are dense and comprise few instances and few features. We propose a model for big (and small) data generation and use it to generate sample data sets. We find two key similarities between big and small data. First, models trained on big data generate learning curves that continue to improve as more instances are added. Second, models trained on sparse data tend not to overfit, even with many features.

2 - New Algorithms for Inference in Dynamic Stochastic Block Models
Theja Tulabandhula, UIC, Chicago, IL, United States, tt@theja.org, Mehrnaz Amjadi

Although the computational and statistical trade-offs for modeling single graphs are relatively well understood, extending such results to sequences of graphs is difficult. In this work, we propose two models for such sequences that capture: (a) link persistence between nodes across time, and (b) community persistence of each node across time. In the first model, we assume that the latent community of each node does not change, and in the second model we relax this assumption. For both models, we propose computationally efficient inference algorithms, which leverage community detection methods that work on single graphs. We provide simulation results validating their performance.

3 - Causal Rule Sets for Identifying Subgroups with Enhanced Peer Influence
Tong Wang, University of Iowa, Pappajohn Business Build, 21 East Market Street, Iowa City, IA, 52245, United States, tong-wang@uiowa.edu, Cynthia Rudin, Shan Huang, Haojun Wu

Peer influence is of central importance in social science. The goal of this paper is to identify subgroups where peer influence exerts enhanced effect on users' responses to social advertisements. Our model characterizes such a subgroup using a set of interpretable rules, constructed from information regarding a user (susceptibility), his/her friend (influence), and their relationship. For this study, we partnered with a world leading mobile social network platform, WeChat, and conducted a large-scale randomized controlled field experiment on WeChat Moments on more than 28 million users across 99 ads. Our model showed competitive performance on different types of product ads.

4 - Cost-effective Interpretable Treatment Regimes
Cynthia Rudin, Duke University, Durham, NC, 27708, United States, cynthia@cs.duke.edu, Himabindu Lakkaraju

I will present work on cost-effective interpretable treatment regimes. This is a policy design problem that involves estimating counterfactuals and using tools from interpretable machine learning.

Simulation Optimization and Ranking and Selection

Sponsored: Simulation

Sponsored Session

Chair: Demet Batur, University of Nebraska-Lincoln, dbatur@unl.edu

1 - Ranking and Selection as Stochastic Control
Yijie Peng, George Mason University, Fairfax, VA, United States, ypeng10@gmu.edu, Edwin P.Chong, Chun-Hung Chen, Michael Fu

We propose a new framework for ranking and selection (R&S). The speaker shows an unexpected phenomenon that many popular methods in R&S decrease the probability of correct selection (PCS), which is caused by the imperfect theoretical foundation of these methods. To address the problem, R&S is formulated as a stochastic control problem and efficiently solved in an approximate dynamic programming (ADP) paradigm. Two ADP approaches are provided. One using a single feature of the value function sequentially achieves an asymptotically optimal sampling ratio that cannot be achieved by the many existing methods. Another ADP approach using two features avoids the non-monotonicity of the PCS.

2 - Quantile Based Selection
Demet Batur, University of Nebraska-Lincoln, Department of Management, CBA 209, Lincoln, NE, 68588-0491, United States, dbatur@unl.edu, Fred Choobineh

We study comparison of stochastic simulated systems based on a quantile performance measure. An indifference-zone quantile selection procedure is presented.

3 - Tractable Sampling Strategies for Ordinal Optimization
Dongwook Shin, Hong Kong University of Science and Technology, Kowloon, Hong Kong, dwshin@ust.hk
Dongwook Shin, Columbia University, New York, NY, 10027, United States, dwshin@ust.hk, Mark Nathan Broadie, Assaf Zeevi

We consider a problem of ordinal optimization when the objective is selecting the best of several competing alternatives ("systems"), where probability distributions governing each system's performance are not known, but can be learned via sampling. The objective is to dynamically allocate a finite sampling budget to minimize the probability of selecting a system that is not the best. The aforementioned objective does not possess an analytically tractable solution. We introduce a family of practically implementable sampling policies and show that the performance exhibits (asymptotically) near-optimal performance.

Shipping and Port Operations of the Future

Sponsored: TSL, Facility Logistics

Sponsored Session

Chair: Amir Gharehgozli, Texas A&M University at Galveston, Galveston, TX, 77553, United States, gharehga@tamug.edu

1 - Integrated Planning of Ship Waterway Traversals and Berthing at Maritime Ports using Resource-constrained Project Scheduling
Alessandro Hill, Universidad Adolfo Ibanez, Santiago, Chile, alessandro.hill@uai.cl, Marcos Goycoolea, Eduardo Lalla-Ruiz, Stefan Voss

We consider short-term scheduling of ship traversals of waterways that connect the seacoast with the actual port area in accordance with arrival and departure times. Side constraints arising from the port's geographical situation, traffic and the influence of the tides make this problem challenging when minimizing the total ships' turnaround times. We extend this problem for including ship berthing operations, which have to be completed within pre-assigned time windows, and we show that this problem can be expressed as a multi-mode resource-constrained project scheduling problem. Using mathematical programming, we improve previous results for real-world instances.

2 - A Junction Traffic Coordination in the Large Scale Act Network
Ek Peng Chew, National University of Singapore, 10 Kent Ridge Crescent, Dept of Industrial and Systems Engineering, Singapore, 119260, Singapore, isecep@nus.edu.sg

In the mega transshipment automated container terminal (ACT), there are many potential conflicts and congestion occur in the junctions because of interactions among traffic flows from different direction. We present a scheme for control of AGV traffic flow and coordination of junctions to improve the operation performance in terms of container throughput.

3 - Module Based AGV Routing Algorithms for Automated Container Terminal
Loo Hay Lee, National University of Singapore, 10 Kent Ridge Cresent, Industrial and Systems Engineering, Singapore, 119260, Singapore, iseleelh@nus.edu.sg, Ek Peng Chew, Qitong Zhao

In this talk, we will present a module based routing algorithms for AGV for Automated Container Terminal. This routing algorithm consists of two level planning. The high level planning will determine the rough routing for each AGV by considering congestion, while the low level planning looks into the inner module control which avoids the deadlock for a small section of road.

4 - Developing Reshuffling Free Container Stacking Operations
Amir Gharehgozli, Texas A.& M.University, P.O. Box 1675, Galveston, TX, 77553, United States, gharehga@tamug.edu, Nima Zaerpour

This paper addresses a highly-researched area, the reshuffling problem in container terminals. Container stacking and reshuffling operations can cause ship delays and additional risk. In deep-sea terminals, outbound containers are tightly stacked according to the retrieval sequence. Due to lack of space, terminals stack containers in multiple tiers. This means any delay in the arrival of a ship can impose extra handlings and reshuffling of containers delaying future cargo handling. To address this issue, this study proposes an alternative stacking policy allowing different container types to share the same pile. At the same time, we avoid reshuffling. We aim to minimize the total retrieval time.

Joint Session RAS/Practice: Passenger and High Density Railway Corridor OR/MS

Sponsored: Railway Applications

Sponsored Session

Chair: Shane Wu, National Railroad Passenger Corporation (Amtrak), Washington, DC, 20002, United States, SWu@alumni.pitt.edu

Co-Chair: Steven Harrod, Technical University of Denmark, Kgs. Lyngby, 2800, Denmark, stehar@dtu.dk

1 - CO2REOPT: Real-time Train Dispatching on the Iron Ore Line
Lukas Bach, SINTEF, Forskningsveien 1, 0314 Oslo, Oslo, 0314, Norway, lukas_bach@hotmail.com, Carlo Mannino

On a congested critical railway corridor, the Iron Ore line between Narvik (Norway) and Lluleå (Sweden), we investigate if optimized train dispatching can increase the capacity of the corridor such that more trains can be operated while reducing delays. This is achieved by applying an exact mathematical model as real-time decision support to the dispatchers, given a railway infrastructure and its status, a set of trains and their current position, we find a route for every train from its current position to the destination and a disposition timetable to minimize the cost function.

2 - CO2REOPT: Integrated Planning for Multimodal Networks with Stochastic Demand and Customer Service Requirements
Ioannis Fragkos, Assistant Professor, Rotterdam School of Management, Kralingse Plaslaan 120 bgg, Rottredam, Netherlands, Fragkos@rsm.nl, Joris Wagenaar, Rob A. Zuidwijk

Multimodal networks use multiple modes of transport to carry freight from its origin to its destination. Such networks are more cost efficient than their single-mode counterparts, but their planning is more challenging, as resources have to be coordinated across several modes of transport. Motivated by the operations of a Dutch provider, we integrate strategic, tactical and operational decisions in a single framework, which, on its original form, is intractable. By utilizing a careful reformulation, we develop decomposition heuristics and lower bounding procedures. Our experiments demonstrate that good solutions for realistic instances can be obtained within reasonable time.

3 - A Rapid Modeling Method for High-speed Railway Terminal Simulation

Guangyuan Zhang, Southwest Jiaotong University, Chengdu, Sichuan, 32202, China, gyzhang@swjtu.cn, Yuan Wang

Each railway terminal has many specific features like rail network topology, connectivity structure and route conflicts conditions etc., which makes modeling process complicated and time consuming. This talk will demonstrate a rapid way of modeling the railway terminal simulation, including following procedures: 1) terminal railway network modeling; 2) routes and track connectivity recognition; 3) simulation preprocessing; 4) route conflicts detection; 5) timetable simulation; 6) rapid animation modeling; 7) statistics calculation.

OR/MS Education for MBAs Around the World

Sponsored: INFORMEd

Sponsored Session

Chair: Nilakantan Sundara Raman Narasinganallur, K.J. Somaiya Institute of Management Studies & Research, K.J. Somaiya Institute of Management Studies & Rese, Mumbai, 400082, India, nilakantan@somaiya.edu

1 - A Game of Thrones Optimization Game for Teaching Linear Programming

Jeroen Belien, KU. Leuven, Warmoesberg 26, Brussel, 1000, Belgium, jeroen.belien@kuleuven.be

This paper presents an educational game for teaching LP modeling built entirely around the popular HBO series Game of Thrones. The student takes on the role of a miner's son and encounters various important leading characters from the television series. Every encounter involves formulating and solving a linear programming problem correctly before being allowed to move on to the next one. The game has been used successfully in an introductory course of linear programming for Business Engineering students at KU Leuven (Belgium) in the academic years 2015-2016 and 2016-2017.

2 - O.R./MS Education for MBAS- in India and Around the World

Nilakantan Sundara Raman Narasinganallur, K.J. Somaiya Institute of Management Studies & Research, B.602 Tulip Rachna Garden, Mulund Colony, Mumbai, 400082, India, nilakantan@somaiya.edu

In the modern world, businesses are complex and their study requires quantitative analysis to predict an outcome or prescribe a decision. Operations Research (Management Science) breaks down the problems into a mathematical form and provides optimal or near optimal solutions. All managers are expected to have a good understanding of the OR techniques since such understanding assists in their mastery of the decision-making process. The presentation describes the experiences of researchers in India and around the World and identifies useful tips to deliver the knowledge base and skillsets of Operations Research to MBA students, who are aspiring to be managers in the real world.

3 - Introducing Web-based Spreadsheet Modeling in the MBA Classroom

Neil Desnoyers, Saint Joseph's University, 133 Green Valley Rd, Upper Darby, PA, 19082, United States, ndesnoye@sju.edu

Web-based spreadsheets are different from computer-based spreadsheets. We explore several implications for teaching.

4 - Intelligent Tutoring Systems Driven Management Education

Mark W. Chun, Pepperdine University, 6100 Center Drive, Los Angeles, CA, 90045, United States, mark.chun@pepperdine.edu, Owen P. Hall

Business schools are under growing pressure to engage in significant programmatic reforms in light of the business community's call for web-savvy, problem solving graduates. Some specific benefits for adopting intelligent tutoring systems throughout schools of business include:1) improve learning outcomes; 2) approach Bloom's two-sigma learning goal; and 3) enhance employment opportunities. The purpose of this presentation is to highlight best practices in the use of intelligent tutoring systems throughout the management education universe.

Sports Analytics I

Sponsored: SpORts

Sponsored Session

Chair: Keith A Willoughby, University of Saskatchewan, Saskatoon, SK, S7N 5A7, Canada, willoughby@edwards.usask.ca

1 - 2 Players, 5 Rocks, 8 Ends: Exploring the Analytics of Mixed Doubles Curling

Keith A.Willoughby, University of Saskatchewan, Department of Finance and Mangement Science, Saskatoon, SK, S7N.5A7, Canada, willoughby@edwards.usask.ca, Kent J.Kostuk

As a variant of traditional curling, mixed doubles curling features teams of two players. Each team plays five rocks during an eight-end game. The inclusion of mixed doubles curling in the 2018 Winter Olympics has precipitated an increase in the sport's popularity. The decision-making environment within mixed doubles curling offers significant differences from that observed in traditional curling. We apply quantitative analysis to explore various decisions made during a mixed doubles game.

2 - What Does it Take to Win Consistently in Daily Fantasy Sports?

Ryan Elmore, University of Denver, Denver, CO, United States, Ryan.Elmore@du.edu

Daily fantasy sports (DFS) contests, or fantasy sports contests in general, are at their core a problem of choosing a set of players, or team, that will hopefully outperform the team chosen by one's opponent(s). Individual team construction serves as the basis for variation within games and, hence, a player's team choice is critically important in not going bankrupt. In this talk, we will present several mathematical results related to team choice, DFS player ability, and how good a particular player must be relative to his/her opponents in order to create a positive expected value. We will illustrate our work via a Monte Carlo experiment using hypothetical DFS contests from the 2016-7 NBA season.

3 - Teamwork in e-Sports: Evidence from League of Legends

David Mendonca, RPI, Troy, NY, United States, mendod@gmail.com, W. Gray, M. Sangster, J. Eaton

This talk explores prospects for understanding antecedents and consequences of teamwork through the analysis of data from e-sports: that is, online games that—because they may attract millions of dedicated teams worldwide—produce data of scale and scope that dwarf those of conventional sports. This talk explains how data from one such e-sport, League of Legends, are being used to explore how changes in the membership of teams over fairly long time scales can affect team processes (such as collaboration) and team outcomes (such as winning). Implications for research on conventional sports are also addressed.

4 - Working with Sports Media

James Cochran, University of Alabama, Auburn, AL, United States, jcochran@cba.ua.edu

Members of the various sports media often rely on support from experts for their stories and articles, and as the use of analytics has become more prevalent academics who work in sports analytics have been called on more frequently to provide such support. There are many benefits to providing such support, and one could argue that we are obliged to do so, but this can be daunting the first few (or perhaps several) times you are asked to do so. In this talk we provide guidelines punctuated with discussion of the speaker's experiences.

5 - UFC PPV Buys and the Value of Celebrity Fighters

Thomas Robbins, East Carolina University, 3212 Bate Building, Greenville, NC, 27858, United States, robbinst@ecu.edu

In 2016 the Ultimate Fighting Championship was sold for a reported price of $4 billion, the highest price ever paid for a sports franchise. This was a remarkable turn-around for a promotion that 15 years earlier was saved from bankruptcy by a $2 million buyout. This turnaround was driven by the UFC's ability to mainstream the promotion and the sport while establishing reliable revenue streams through television contracts and massive pay per view events. In this paper we analyze the pay per view record of the UFC and analyze the extent to which it is driven by high profile celebrity fighters with broad crossover appeal. We assess the economic value they generate for the UFC.

Statistical Methods for Degradation Data Analysis

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Qingyu Yang, Wayne State University, Detroit, MI, 48202, United States, qyang@wayne.edu

Co-Chair: Yong Chen, University of Iowa, Iowa City, IA, 52242-1527, United States, yong-chen@uiowa.edu

1 - Physical-statistical Modeling and Quantification of Degradation Rate for Corroding Aluminum Alloy

Xuxue Sun, University of South Florida, 5005 Excellence Blvd 435C, Tampa, FL, 33617, United States, xuxuesun@mail.usf.edu, Mraied Hesham, Wenjun Cai, Guoyuan Liang, Mingyang Li

Corrosion-induced degradation of aluminum alloy is a key causing factor for structure failure of many mission critical systems, such as aircrafts. Successful evaluation of degradation performance is important yet challenging since the degradation rate is not directly measurable. We propose a physical-statistical modeling approach in evaluating the alloy degradation rate. Specifically, the latent degradation rate is first characterized via fractional order system dynamics. Bayesian inference is then carried out to address both data uncertainty and population variability due to the limited data samples. A real case study is further provided to illustrate of the proposed work.

2 - Degradation Analysis of High Strength Dual-phase Steel by using Microstructure Images

Wujun Si, Wayne State University, 4500 Cass Avenue, Apt 1001, Detroit, MI, 48201, United States, fk9456@wayne.edu, Qingyu Yang, Xin Wu

The microstructure of high strength dual-phase steel strongly impacts steel degradation and failure. In this paper, we conduct degradation based reliability analysis of the dual-phase steel by utilizing its microstructure images. A novel functional covariate degradation model is proposed for the analysis. A penalized least square estimation method is developed for the model parameter estimation. Simulation and real case studies are conducted to demonstrate the proposed model. Results show that the failure prediction is more precise by utilizing the microstructure images.

3 - An Integrated Method for Pipeline Fatigue Crack Growth Prediction

Mingjiang Xie, University of Alberta, Edmonton, AB, Canada, mingjian@ualberta.ca, Zhigang Will Tian

Managing fatigue cracks has been a huge challenge in pipeline industry. An integrated method is proposed for predicting pipeline fatigue crack growth considering large defect sizing uncertainty, which can be used for remaining useful life prediction. Stress analysis models, crack propagation models and in-line inspection (ILI) data are fused in this approach. Model parameters are updated based on ILI data through Bayesian approach to achieve a more accurate crack growth prediction. The proposed method is compared with existing physics-based methods.

4 - A Prognostic Framework for Complex Engineering Systems with Multiple Failure Modes

Liexiao Ding, Georgia Institute of Technology, Atlanta, GA, United States, nagi.gebraeel@isye.gatech.edu, Nagi Gebraeel, Xiaolei feng

Complex engineering equipment typically undergoes multifaceted degradation processes. The use of multiple sensors potentially allows the capture of different aspects of such complicated degradation processes, which sometimes exhibit different failure modes. In this talk, we present a statistical prognostic framework for multi-failure modes applications. Specifically, a penalized functional data clustering methodology is first built to select the informative sensor signals corresponding to each failure modes. Next, a prognostic model is built by using the informative sensor signals selected earlier. Numerical studies are used to evaluate the performance of our model.

Causal Data Mining

Sponsored: Data Mining

Sponsored Session

Chair: Michael Lash, University of Iowa, Iowa City, IA, 52242, United States, michael-lash@uiowa.edu

1 - Building Recommenders and Search Engines using Causal Data Mining

Adith Swaminathan, Microsoft, One Microsoft Way, Redmond, WA, 98052, United States, adswamin@microsoft.com

Interactive systems like search engines, recommender systems, and ad placement platforms are ubiquitous. Evaluating and optimizing these systems is hard – users' feedback governs system performance, and gathering their feedback in randomized experiments is costly. Can we re-use logs collected from deployed systems to reliably perform offline evaluation and learning? I will outline two projects (Viewing Recommendations as Treatments, ICML'16 and De-biasing Learning to Rank, WSDM'17) that advance the state of the art for these problems.

2 - Large-scale Model Validation with Negative Controls

Robert Moakler, rmoakler@stern.nyu.edu

Causal models are essential for drawing real-world inferences about cause and effect relationships. Therefore, validating these models is crucial, but unfortunately very difficult. Negative control testing, a method typically employed at small-scales, shows promise when applied to large-scale digital applications. In this work, we build a framework for applying negative control testing and argue that the full potential of negative control testing is only realized when companies and organizations are collecting data for many events they observe. We apply this framework to assess and compare RCTs and observational models built for real-world examples in online advertising.

3 - Prophit: Inverse Classification via Causal Deep Learning

Michael Lash, University of Iowa, 2 West Washington Street, B4 MacLean Hall, Iowa City, IA, 52242, United States, michael-lash@uiowa.edu, Qihang Lin, Nick Street

Past work in the area inverse classification, the process of obtaining instance-specific feature-value updates (recommendations) that optimally improve the probability of a desired classification, focuses on eliciting real-world recommendations, optimization methodology, and classifier inclusion. Ultimately, however, the problem is causal in nature, yet methodologically unexplored. Therefore, we propose Prophit, a deep neural network architecture augmented with causal properties, to solve the inverse classification problem.

4 - Generalized Random Forests

Susan Athey, Stanford University, Stanford, CA, United States, athey@susanathey.com, Stefan Wager

We propose a method based on random forests (Breiman, 2001) can be used to fit any quantity of interest identified as the solution to a set of local moment equations. Our method operates in covariate space by considering a weighted set of nearby examples. We propose a computationally efficient algorithm for growing generalized random forests, develop a sample theory for our method that shows our estimates are consistent and asymptotically Gaussian and provide an estimator for asymptotic variance. Our approach to develop estimators: non-parametric quantile regression, conditional average partial effect estimation, & heterogeneous treatment effect estimation via instrumental variables.

Planning Logistics Systems Under Uncertainty II

Sponsored: TSL, Freight Transportation & Logistics

Sponsored Session

Chair: Mike Hewitt, Loyola University Chicago, Glen Ellyn, IL, 60137, United States, mhewitt3@luc.edu

1 - Covering Path Problem on Grid with an Application to School Bus Routing

Liwei Zeng, Northwestern University, 2145 Sheridan Road, IEMS.Department, Evanston, IL, 60208, United States, liweizeng2015@u.northwestern.edu, Karen Smilowitz, Sunil Chopra

We will present work from a collaboration with a large public school district, related to bus transportation to reduce budget pressure. We focus on bus stop selection and route design, two key components of the School Bus Routing Problem identified in the literature. We model the joint problem as a covering path problem. We further exploit the underlying grid-like structure of the road network and obtain robust and easy-to-implement solutions.

2 - Anticipatory Synchromodal Transportation Planning

Martijn Mes, University of Twente, Building Ravelijn, P.O. Box 217, Enschede, 7500 AE, Netherlands, m.r.k.mes@utwente.nl, Arturo E. Pérez Rivera

We study the problem of selecting transport modes and transfers in a synchromodal network over a multi-period horizon. Freights with different characteristics become known over time. Using probabilistic knowledge of freight arrivals, the planner balances current and future costs at each period. We model this problem as a Markov Decision Process (MDP) and solve it using Approximate Dynamic Programming (ADP) in combination with various exploration strategies. Using different problem settings, we show that our look-ahead approach has significant benefits compared to benchmark heuristics.

3 - Approximate Dynamic Programming for the Multi-Period Technician Scheduling with Experience-based Service Times and Stochastic Customers (MTSP-ESTSC)

Xi Chen, Beijing Foreign Studies University, Beijing, China, chenxi0109@bfsu.edu.cn, Barrett Thomas, Mike Hewitt

In this work, we explore the value of integrating future information into the current period decision-making process for the MTSP-ESTSC. We propose an approxi- mate dynamic programming solution approach that uses a basis function to reduce the dimensionality of the state. We benchmark the performance of the ADP solution ap- proach with the basis function against a one-day lookahead approach that minimizes the recent two periods' costs. Our computational results demonstrate the value of proposed approach.

4 - A Benders Decomposition Method for Two-stage Stochastic Network Design Problems

Walter Rei, University of Quebec-Montreal, 10673 Larose, Montreal, QC, H2B 3C4, Canada, rei.walter@uqam.ca, Ragheb Rahmaniani, Teodor Gabriel Crainic, Michel Gendreau

In this presentation, we describe a Benders decomposition algorithm capable of efficiently solving large-scale instances of the multi-commodity capacitated network design problem with demand uncertainty. This problem is relevant to a wide gamut of real-world applications in the telecommunications, transportation and logistics fields. To obtain a state of the art Benders method, we propose various acceleration techniques, including the use of cutting planes, partial decomposition, heuristics, stronger cuts, reduction and warm-start strategies. Extensive computational experiments conducted on benchmark instances confirm the superiority of the proposed algorithm over existing ones.

Network Design in Freight Logistics

Sponsored: Transportation Science & Logistics

Sponsored Session

Chair: Lokesh Kalahasthi, Rensselaer Polytechnic Institute, Troy, NY, United States, kalahl@rpi.edu

1 - Scheduling Optimization of Local Farmers

Sefakor Fianu, North Carolina A&T.State University, 1601 .Market St, Greensboro, NC, 27401, United States, sfianu@aggies.ncat.edu, Lauren Berrings Davis

Local farmers face challenges such as; seasonality, transportation, food safety, and packaging requirements that prevent them from meeting the demand of institutions like universities. This research is part of the University Food Systems project aimed at connecting local farmers and universities in North Carolina. We solve the transportation problem by developing weekly schedules that minimizes the distance traveled by farmers to drop off their produce at crossdocking facilities. The schedules addresses capacity, collection frequency and food spoilage constraints.

2 - The Dynamic Shortest Covering Path Problem

Jimena Pascual, Pontificia Universidad Catolica de Valparaiso, Av Brasil 2241, Casilla 4059, Valparaiso, 2362807, Chile, jimena.pascual@pucv.cl, Andrea Leticia Arias, Dario Canut De Bon, Ricardo Gatica, Timothy I. Matis

We consider a variant of the Shortest Covering Path Problem (SCPP) in which the arc costs change over time due to dynamic environmental conditions. In this problem, the aim is to determine a minimum cost path from a starting to an ending position, such that all the nodes in the network are covered by at least one node selected to be in the path. We present an integer programming formulation for the Dynamic SCPP and explore solution methodologies.

3 - Freight Demand Synthesis with Mode Choice; A Combined Estimation Procedure

Lokesh Kumar Kalahasthi, Rensselaer Polytechnic Institute, 22, College Ave,, Troy, NY, 12180, United States, kalahl@rpi.edu, Jose Holguin-Veras, John E.Mitchell

This research develops a combined model for freight demand synthesis (FDS) that incorporates the estimation of modal split between rail and truck. A gravity model is adopted for the estimation of trip distribution; a binary logit model for modal split between rail and truck; and Noortman and van E's model is used for empty trips. It is assumed that the total productions and attractions, the network data, and the link flows by both modes are available. Application on a sample network shows that, the model provides reasonably good estimates for O-D table and modal split. This research serves as a potential tool for transportation planners in evaluating various policy outcomes.

1 - A Class of Bayesian Hierarchical Models with Conjugate Full-conditional Distributions for Dependent Data

Jonathan Bradley, Florida State University, Tallahassee, FL, United States, bradley@stat.fsu.edu

We introduce a class of models for Bayesian analysis of high-dimensional dependent data. In particular, we introduce something we call the "conjugate multivariate distribution." Furthermore, we provide substantial theoretical and methodological development including: results regarding conditional distributions, an asymptotic relationship with the multivariate normal distribution, conjugate prior distributions, and full-conditional distributions for a Gibbs sampler. The results in this manuscript are extremely general, and can be adapted to many different settings. We demonstrate the methodology through several illustrations.

2 - Estimation of Sparse Vector Autoregressive Moving Averages

Ines Wilms, KU. Leuven, Naamsestraat 69, Leuven, 3000, Belgium, Ines.Wilms@kuleuven.be, Sumanta Basu, Jacob Bien, David Matteson

The Vector Autoregressive Moving Average (VARMA) model is a fundamental tool for modeling multivariate time series. However, as the number of time series increases, the VARMA model becomes heavily overparameterized. For such high-dimensional VARMA models, estimation is generally considered intractable, leading people to favor simpler approaches such as Vector Autoregressive (VAR) models. We propose a new framework for learning parsimonious VARMA models in high-dimensional settings and show that it has good forecast accuracy both in simulation and in various application domains.

3 - A Statistical Modeling Approach for Large-scale Spatio-temporal Data

Xiao Liu, Assistant Professor, University of Arkansas, Department of Industrial Engineering, 4207 Bell Engineering Center, 1 University of Arkansas, Fayetteville, AR, 72701, United States, liuxiao314923@gmail.com

The research presents a statistical modeling approach for large-scale spatio-temporal data. In particular, we show the connection of the statistical model to physical models which are given by Stochastic Partial Differential Equations.

Chair: Hongyue Sun, University at Buffalo, Buffalo, NY, 1, United States, hongyues@buffalo.edu

1 - Heterogeneous Recurrence Monitoring of Dynamic Transients in Ultraprecision Machining Processes

Chen Kan, Pennsylvania State University, University Park, PA, United States, cjk5654@psu.edu, Changqing Cheng, Hui Yang

In-situ monitoring and control of process variations are important for quality assurance in ultraprecision machining (UPM) processes. However, conventional approaches are limited in their ability to address the complex dynamics in the nonlinear and nonstationary processes. This paper presents a heterogeneous recurrence monitoring approach to detect dynamic transients in UPM processes. Experimental results showed that the proposed approach effectively detects transitions with a small magnitude in the Lorenz system, and identifies the shift from stable cutting to unstable cutting in the real-world study of UPM processes.

2 - Sensor Fusion and on-line Monitoring of Friction Stir Blind Riveting for Lightweight Materials Manufacturing

Weihong Guo, Rutgers, The State University of New Jersey, 96 Frelinghuysen Rd, CoRE Rm 220, Piscataway, NJ, 08854, United States, wg152@rutgers.edu, Zhe Gao

Friction stir blind riveting (FSBR) is a recently developed manufacturing technique for joining lightweight materials for wider adoption in the automotive sector. Using FSBR to join carbon fiber-reinforced polymer (CFRP) composite and aluminum alloy sheets has been studied experimentally, however, the quantitative relationship between FSBR and joint quality remains unclear. To gain a better understanding of FSBR lightweight materials manufacturing, the proposed method effectively models this relationship by integrating data de-noising, dimension reduction, feature extraction, feature selection, and classifier fusion. The proposed method is demonstrated with real data from FSBR.

3 - Remaining Useful Life Prediction Based on Model Integration for Broaching Tools

Wenmeng Tian, Virginia Tech, 415 New Kent RD, Blacksburg, VA, 24060-6507, United States, tian0414@vt.edu, Lee J. Wells, Jaime Camelio

Remaining useful life prediction is a critical task for various multi-edged machining processes such as broaching. Tool wear occurs when cutting edge and machining surface rub each other, leading to material loss from the cutting edge. A system-level health index and the parametric form of its degradation path are derived simultaneously based on the physical process model. Then the degradation path is used for remaining useful life prediction. A Bayesian update framework is used to combine in-situ observations of a testing sample and historical degradation model parameter distributions considering possible correlation between the degradation path parameters and the random failure threshold.

4 - Online Monitoring of Line Resistance in Aerosol Jet Printing Process

Rao Prahalada, University of Nebraska-Lincoln, Lincoln, NE, 68588, United States, rao@unl.edu, Roozbeh Salary, Mark Poliks, Jack Lombardi

The goal of this research is online monitoring of functional electrical properties, e.g., resistance, of electronic devices made using aerosol jet printing (AJP) additive manufacturing (AM) process. In pursuit of this goal, the objective is to recover the cross-sectional profile of AJP-deposited electronic traces (called lines) through shape-from-shading (SfS) analysis of their online images. The aim is to use the SfS-derived cross-sectional profiles to predict the electrical resistance of the lines.

1 - Optimizing Water Pollution Monitoring Systems: Regulation Policy Guideline for Curbing Nutrient Pollution

Michael K. Lim, Univ of Illinois Urbana-Champaign, Champaign, IL, United States, mlim@illinois.edu, Xin Chen

We examine regulatory guidelines of surface water quality to curb nutrient pollution resulting from various farming activities. We formulate an optimization model that captures the government's regulation decision taking into account farmers' moral hazard issue. We obtain policy insights and guidelines, along with a solution method for the problem.

2 - Theoretical and Simulation Analysis of Electricity Market for Integrative Evaluation of Renewable Energy Policies from Social Welfare Aspect

Masaaki Suzuki, Tokyo University of Science, 2641 Yamazaki, Noda-shi, Chiba, Japan, m-suzuki@rs.tus.ac.jp, Mari Ito, Ryuta Takashima

Governments have introduced various policies for promoting renewable energy technologies such as feed-in tariff and renewable portfolio standard. Our purpose is to clarify how the relationships among policy, market power, and number of producers impact social welfare. In this work, multi-agent system is constructed for integrative evaluation of renewable energy policies. Multi-agent simulations enable us to evaluate more realistic market and to observe emergent processes of equilibrium states. By comparing the results obtained from the simulation and the equilibrium analysis, we comprehensively examine the policies from both bottom-up and top-down viewpoints.

3 - Analysis of Climate-induced Vulnerability of Northern California Natural Gas System

Sepehr Ramyar, University of California-Santa Cruz, 1156 High Street, Santa Cruz, CA, 95064, United States, sramyar@ucsc.edu, Yihsu Chen, Andrew Lu Liu

This talk will discuss an ongoing project that analyzes the vulnerability of the Northern California natural gas system, considering delivery contracts and engineering aspects. The study is formulated as an optimization problem that minimizes the operational and contractual energy delivery costs while at the same time accounting for the physical characteristics of the network to guarantee reliable delivery of natural gas to customers. The model will be coupled with the downscaled outputs from climate change models to evaluate its vulnerability and identify possible resilience options.

4 - When Agents Trade in Electricity Attributes, Who Benefits?

Janiele Custodio, George Washington University, Washington, DC, United States, janiele@gwu.edu, Ekundayo Shittu

The integration of RPS programs has been suggested as a way to accomplish renewable goals at low cost. However, issues such as market power and overlapping regulatory mechanisms are critical to the performance of such systems. The purpose of this research is to explore the viability and the implications of integrated markets for renewable certificates. We formulate a series of MPECs to analyze how imperfect competition and redundant renewable policies would affect the economics of an inter-regional market. Lastly, we estimate aggregate supply and demand curves using data from existing RPS programs to explore the viability of an integrated market for renewable certificates.

Data Mining

Contributed Session

Chair: Samuel Davis, Northeastern University, Boston, MA, United States, davis.sam@husky.neu.edu

1 - A Data Mining Approach to Identify Third Party Subrogation in the Health Insurance Industry

Naveen Kumaresan, Data Mining Analyst, West Corporation, 11808 Miracle Hills Drive, Omaha, NE, 68154, United States, nkumaresan@west.com, Shruti Palasamudram Ramesh

Every year, health insurance companies pay billions of dollars in excess to medical providers. An average of up to 5% of medical claims paid by insurers are the responsibility of other payers which leads to subrogation. Subrogation is the recovery of an insurance claim from a third party that was originally paid by a patient's medical plan. Traditional subrogation process is laborious and time consuming. This paper discusses how WEST Corporation's Center for Data Science utilized predictive analytics to predict the probability of a claim to be third party liable (TPL) with highest recovery chances. The predictive model has increased the identification of TPL claims by 5 times.

2 - Analyzing Patterns of Multiple Chronic Conditions and Their Associated Behavior in Temporal Direction using Multi-level Temporal Bayesian Network

Syed Hasib Akhter Faruqui, Graduate Research Assistant, The University of Texas at San Antonio, One UTSA Circle, San Antonio, TX, 78249, United States, syed-hasib-akhter.faruqui@utsa.edu, Adel Alaeddini, Mary Jo Pugh, Jaramillo Carlos

The rising prevalence of multi-morbidity raises the complexity of health care management, Medicaid co-ordination and treatment planning. The domain knowledge of underlying pattern among the Multiple Chronic Conditions (MCC) from the existing longitudinal co-morbid patient dataset can be used for building a decision support system. Multi-Level Temporal Bayesian Networks can be used to reveal and analyze hidden patterns present in co-occurring MCC and any risk factor associated with it along the temporal abstraction. This study describes the prevalence of and patterns of co-morbidity among patients of different age groups receiving Medicaid assistance.

3 - A Semi-markov Mixture Model Clustering Method for Multi-state Partially Censored Data

Geet Lahoti, Graduate Research Assistant, Georgia Tech, 1038 Mcmillan St. NW, Atlanta, GA, 30318, United States, glahoti6@gatech.edu, Chitta Ranjan, Zih Huei Wang, Zhen Qian, Chuck Zhang, Ben Wang

Semi-Markov model is used to model the state transition dynamics in spatio-temporal data widely found in the web, marketing, reliability, and healthcare. The main challenge in modeling this data is the underlying (unobserved) heterogeneity with respect to the behaviors in the transition dynamics. We propose a semi-Markov mixture model based methodology and develop an EM algorithm that stratifies the partially censored data into homogeneous groups. The transition dynamics of all the subjects within a stratified group will be similar; thus, a predictive model built for a group will have a better accuracy. We demonstrate the validation and application on synthetic and real data sets.

4 - Using an Integrated System Approach in Finding the Optimal Simulation Model Based on Healthcare Case Study

Tannaz Khaleghi, Wayne State University, Detroit, MI, 48202, United States, fj6710@wayne.edu, Alper E. Murat

Nowadays predicting the system architecture and its corresponding core attributes at a specific time slice is valued the most. Simulation experts usually simulate the system based on the data they receive and observing some processes. However, in many cases one may not be able to gather prior information about the system design. In this study the attempt is to propose 3-stage analysis namely, process mining, dynamic Bayesian network and discrete event simulation, to discover the best system design model which is not only exclusively grantees infinitesimal deviation from the real model, but also reduces the time complexity of finding the optimal model significantly for large systems.

5 - Data Analytics & Modeling in Medical Imaging Analysis & Decision Making

Shouyi Wang, Assistant Professor, University of Texas-Arlington, 500 West First Street, Woolf Hall 420, Arlington, TX, 76019, United States, shouyiw@uta.edu, Feng Liu, Kin Ming Puk, Rahilsadat Hosseini

The advances in computing and advanced data analytics techniques have led to powerful and promising data-driven tools to solve complex healthcare and medical decision making problems based on increasingly large amounts of data. This session provides a collection of talks in the field to present several most recent research studies that develop data-driven approaches and machine learning techniques for comprehensive decision modeling in medical imaging analysis and decision making.

6 - Application of Conditional Binary Decision Tree to Develop Improved Hospital Length of Stay Prediction

Samuel Davis, PhD Candidate, Northeastern University, Boston, MA, United States, davis.sam@husky.neu.edu

Managing the variable demand and relatively fixed supply of hospital bed and nurse resources is critical for maintaining safe and efficient operations. Level-loading daily patient census requires a firm understanding of patient arrival and length of stay (LOS) patterns. This work shows that traditional LOS prediction methods are less accurate at the individual and aggregate level than the proposed method, and does so by using a novel conditional binary decision tree. Predictions are produced and validated using data from a large Boston metro area hospital. Aggregate demand predictions are created from the individual patient predictions and are shown to be accurate and rigorous.

7:30 - 8:15 Syncopation /8:15 - 9:30 Mathworks

Invited: Vendor Tutorial

Invited Session

1 - DPL Portfolio and DPMX(tm): A Decision Analysis based System for Better Portfolio Decisions

Chris Dalton, Syncopation Software, Inc, Bangor, ME, United States, cdalton@syncopation.com

This demonstration will show how the DPMX(tm) System can improve portfolio decision quality by bringing better analytics and data management to your portfolio analysis process. We'll start with an overview of DPL Professional, a widely used modelling environment for decision analysis, risk analysis and Monte Carlo simulation. Next, we'll cover DPL Portfolio, the platform for portfolio analysis, visualization and prioritization. Finally we'll show DPMX, a web-based based system for managing project data and presenting portfolio results in attractive, management-ready reports. The motivating examples will be drawn from the prioritization of an R&D portfolio.

2 - Data Analytics with MATLAB

Mary C.Fenelon, MathWorks, 3 Apple Hill Dr., Natick, MA, 01760-2098, United States, mary.fenelon@mathworks.com

Join us to see how MATLAB can help you explore data, develop predictive and prescriptive models, and integrate analytics into enterprise applications. We'll illustrate this through a load forecasting and unit commitment demo on Big Data following this workflow. Merge historical demand and weather data into a time series. Explore machine learning models interactively to find the best model to predict demand. Prescribe how to satisfy demand by formulating and a solving mixed-integer linear program. Deploy an application to the web or enterprise systems to empower business analysts.

Network Dynamics and Inference

Sponsored: Optimization, Network Optimization

Sponsored Session

Chair: Chris Quinn, Purdue University, Purdue, West Lafayette, IN, United States, cjquinn@purdue.edu

1 - Identification of Peer Effects in Networked Panel Data

Daniel Rock, Massachusetts Institute of Technology, Sloan School of Management, 100 Main Street, Cambridge, MA, 02142, United States, drock@mit.edu, Sinan Aral, Sean J. Taylor

After product adoption, consumers make decisions about product use. These choices can be influenced by peer decisions in networks, but identifying causal peer influence effects is challenging. Extending the work of Bramoullé et al. (2009), we apply proofs of peer effect identification in networks under a set of exogeneity assumptions to the panel data case. With engagement data from simulation and two mobile applications, we estimate usage peer effects, comparing the performance of a variety of regression models under simulated homophily conditions. Though violation of exogeneity assumptions can bias regression estimates, there are contexts where such IV analysis can be usefully applied.

2 - Coevolutionary Latent Feature Processes for Continuous-time User-item Interactions

Le Song, Georgia Institute of Technology, Atlanta, GA, United States, lsong@cc.gatech.edu

Matching users to the right items at the right time is a fundamental task in recommendation systems. Traditional models based on static latent features or discretizing time into epochs become ineffective in capturing the fine-grained and complex temporal dynamics in the time-varying user-item interaction networks. We propose both parametric and nonparametric coevolutionary latent feature process models which accurately captures the coevolving nature of users' and items' features. Extensive experiments on diverse real-world datasets demonstrate significant improvements in user behavior prediction compared to state-of-the-arts.

3 - A Relational Event Approach to Modeling Continuous Network Change

Aaron Schecter, University of Georgia, Athens, GA, United States, aschec@gmail.com, Noshir Contractor

The increasing availability of continuous event data, such as emails or clickstreams, has made interaction processes significantly more visible. These interactions are driven by short-term and long-term patterns of directed events. To analyze this data with traditional network approaches, event data would have to be transformed into static links. However, this process would reduce the sequential and temporal information available. We present a method which directly utilizes this data, the relational event model, to infer the effect of event patterns on network change.

4 - Network Model Selection and Tuning by Cross-validation

Tianxi Li, University of Michigan, Ann Arbot, MI, United States, tianxili@umich.edu

Though many models and methods are now available for network analysis, model selection and tuning remain challenging. Cross-validation, a general tool for these tasks in many settings, is not directly applicable to networks since network splitting destroys some of the network structure. We propose a network cross-validation strategy which avoids losing information and is applicable to a wide range of network problems. We provide a theoretical justification for our method. Numerical results on both simulated and real networks show that our approach performs well for a number of model selection and parameter tuning tasks.

Open Pit Mine Planning

Sponsored: Energy, Natural Res & the Environment, Natural Resources Mining

Sponsored Session

Chair: Alexandra M. Newman, Colorado School of Mines, Golden, CO, 80401, United States, anewman@mines.edu

1 - Scheduling Optimization for a Continuous Steel Caster

Alexandra Newman, Colorado School of Mines, Golden, CO, United States, anewman@mines.edu, Joshua Betz

In continuous steel casting operations, molten steel is batched into heats inside a ladle that is cast into slabs, which are then rolled into coils. We present a mixed integer program to produce a daily casting schedule that is solved using state-of-the art software. This model minimizes penalties incurred by violating plant best practices while strictly adhering to safety and logical constraints. A heuristic produces an initial feasible solution to expedite solutions, which we compare to current plant practice.

2 - A Study of Problem Specific Cutting Planes for the Open Pit Strategic Mine Scheduling Problem

Orlando Rivera Letelier, Universidad Adolfo Ibanez, Santiago, Chile, orlando.rivera@uai.cl

We study four types of problem specific cutting planes for the Open Pit Strategic Mine Scheduling Problem: Cliques, Early Starts, VRHS and Hourglass cuts. Two of them, the Cliques and the Early Start cuts are well-known cuts in the literature for the Precedence Constrained Knapsack Problem, while the other two types, the VRHS and the Hourglass cuts are new cuts developed for this work that make use of the production capacity constraints of the problem. We make computational tests in a set of real mines instances of the production scheduling problem, showing that the root node gap can be improved in average from 9.21% to 0.74%, which allows to solve to near optimallity instances of this problem.

3 - Revisiting Lane's Model: An Optimization Approach

Patricio Lamas, Universidad Adolfo Ibanez, Santiago, Chile, plamas@alumnos.uai.cl, Marcos Goycoolea, Bernardo Kulnig Pagnoncelli, Adriana Piazza

In 1964 Kenneth, Lane proposed an algorithm for optimizing the cutoff grade in an open pit mining project. Lane's algorithm has made their way into multiple commercial software systems. However, the algorithm is regarded as a heuristic since no convergence proof is available in the literature. We present a formal description of Lane's algorithm, and present theoretical results regarding the behavior of the optimal cut-off grade. Moreover, we propose a new mathematical optimization formulation for the problem, and use it as a benchmark to test the performance of Lane's algorithm. Our computational results for real-world mines show that Lane's algorithm finds the optimal solution for all instances.

4 - An Efficient Frontier Analysis to Determine Final Pit under Geological Uncertainty

Enrique Jelvez, PhD, Advanced Mining Technology Center, Santiago, Chile, ejelvez@delphoslab.cl
Enrique Jelvez, PhD, Delphos Mine Planning Lab & Department of Mining Engineering, University of Chile, Santiago, Chile, ejelvez@delphoslab.cl, Nelson Morales, Nelson Morales, Julian Ortiz

The final pit problem consists of finding the set of blocks that maximizes the undiscounted value of exploitation subject to precedence constraints. Although there exist efficient algorithms to compute it in a deterministic setting, the information on which this decision is made is subject to uncertainty. In this work, we present a comparison of several options to calculate final pit, including geological uncertainty given by a number of conditional simulations. In particular, we develop a model that allows us to generate the efficient frontier of final pit alternatives in the expected return-risk context, when the risk is measured in terms of Conditional Value at Risk.

Network Problems with Hop Constraints

Sponsored: Computing

Sponsored Session

Chair: Austin Buchanan, Oklahoma State University, Stillwater, OK, 74078, United States, buchanan@okstate.edu

1 - Why is Maximum Clique Easy on Real-life Graphs?

Jose Luis Walteros, University at Buffalo, SUNY, 413 Bell Hall, Buffalo, NY, 14260, United States, josewalt@buffalo.edu, Austin Buchanan

Recently, researchers have developed algorithms that solve maximum clique rather quickly for real-life graphs despite the computational intractability of the problem. An explanation for the success of these approaches on these graphs is their sparsity, allowing one to delete low-degree vertices in a preprocessing step. We provide an alternative explanation based on the empirically observed proximity of the clique number to the graph's degeneracy d. We develop an algorithm that runs in time polynomial in the graph's size, but exponential in d - . When this difference is a constant, the running time is O(dm) = O(m1.5). Since 70% of common instances have d - ≤ 3, our algorithm is highly competitive.

2 - The Optimal Design of Low Latency Virtual Backbones

Hamidreza Validi, Oklahoma State University, Stillwater, OK, 74078, United States, hamidreza.validi@okstate.edu, Austin Buchanan

In wireless networks, two nodes may not be close enough to communicate directly, necessitating the use of intermediate nodes for relaying information. Often, one seeks a (smallest possible) subset of nodes to serve as designated relay nodes. In this talk, we discuss a hop-constrained variant of this optimization problem and propose an integer programming approach to solve it.

3 - On the 2-club Polytope of Graphs

Foad Mahdavi Pajouh, University of Massachusetts Boston, 100 Morrissey Boulevard, Boston, MA, 02125-3393, United States, foad.mahdavi@umb.edu, Balabhaskar Balasundaram, Illya V. Hicks

A k-club in a graph is a subset of its vertices such that the subgraph induced by this set has diameter at most k. Polyhedral study of the k-club model is a challenging task as this property is not hereditary. This talk presents a new class of facets for the 2-club polytope that contains all known nontrivial facets as special cases. Computational results addressing the effectiveness of these new inequalities will also be presented.

4 - Parsimonious Formulations for Low-diameter Clusters

Hosseinali Salemi, Oklahoma State University, 15 North University Place, Apartment Number 2, Stillwater, OK, 74075, United States, hosseinali.salemi@okstate.edu, Austin Buchanan

In the analysis of social and biological networks, one often searches for tightly knit clusters. One property of a "good" cluster is that it have a small diameter, which leads to the concept of a k-club. We propose a new IP formulation for detecting k-clubs and show that a relatively simple implementation of it often outperforms previous approaches.

1 - Linear Convergence of Gradient and Proximal-gradient Methods under the Polyak-lojasiewicz Condition

Mark Schmidt, 201 2366 Main Mall, Vancouver, BC, V6T1Z4, Canada, schmidtm@cs.ubc.ca

In 1963, Polyak proposed condition that is sufficient to show gradient descent has a global linear convergence rate, without strong-convexity. We show that this condition is weaker than the main conditions used to relax strong-convexity over the last 25 years. We also it to give new analyses of coordinate descent and stochastic gradient methods. We give a natural generalization of the inequality that applies to proximal-gradient methods for non-smooth optimization, and show this gives a simple linear convergence proof for LASSO and SVMs. Along the way, we give new convergence results for a wide variety of problems in machine learning.

2 - An Optimal Randomized Incremental Gradient Method Independent of Exact Gradient Evaluations

Yi Zhou, Georgia Institute of Technology, 3209 Druid Hills Reserve Dr, Atlanta, GA, 30329, United States, yizhou@gatech.edu, Guanghui Lan

In this talk, we consider a class of finite-sum convex optimization problems whose objective function is given by the average of m smooth components together with a strongly convex term. We first present a deterministic predictive accelerated gradient descent (PAGED) method that achieves the optimal black-box iteration complexity for solving these problems. We then develop a randomized variant, Rand-PAGED method, which needs no exact gradient evaluations and computes the gradient of one randomly selected smooth component iteratively but can possibly achieve better complexity bounds than optimal deterministic first-order methods in terms of the number of gradient evaluations.

3 - On the use of L-BFGS in Derivative-Free Optimization
Albert S.Berahas, Northwestern University, Evanston, IL, 60208, United States, albertberahas@u.northwestern.edu, Jorge Nocedal, Richard Byrd

The efficiency and efficacy of using finite-differencing to estimate derivatives in the Derivative-Free Optimization (DFO) setting still remains an unexplored domain. In this talk, we present a finite-difference quasi-Newton method for minimizing smooth deterministic, and noisy, black-box functions, and illustrate the performance of the method on several test-problems. We argue that popular model-based trust-region methods may not, for certain classes of problems, be more efficient in their use of function information than the finite-difference BFGS method, and that these problems have special identifying characteristics.

1 - Benders Decomposition for Uncapacitated Multicommodity Network Design
Carlos Zetina, Concordia University, 1455 De Maisonneuve, Montreal, QC, H2L.4H1, Canada, c_zetina@encs.concordia.ca, Ivan Contreras, Jean-Francois Cordeau

In this study, we present a Benders based exact algorithm to solve the uncapacitated multicommodity network design problem. Our algorithm combines the use of a modified Benders reformulation, lower bound strengthening and upper bound heuristics. We analyze the performance of the algorithm on benchmark instances and compare them with current solution methods

2 - A layer-Based Branch-and-price Approach for 3D Bin Packing
Samir Elhedhli, University of Waterloo, Department of Management Sciences, 2000 University Street West, Waterloo, ON, N2L.3G1, Canada, elhedhli@uwaterloo.ca, Burak Can Yildiz, Fatma Gzara

We propose a new formulation and a branch-and-price solution approach where the subproblems are two dimensional layers, a feature that is highly desirable in practice. The approach allows the inclusion of important practical constraints such as support, family groupings, isle friendliness, and load bearing. We conduct extensive computational experiments and compare against existing approaches. We also use industrial data to train and propose a realistic data set. The proposed approach outperforms the best performing algorithm in the literature and succeeds in solving practical size instances in very reasonable computational times.

3 - Network Planning of Green Telecommunication Networks
Joe Naoum-Sawaya, Ivey Business School, 1255 Western Road, London, ON, N6G 0N1, Canada, jnaoum-sawaya@ivey.ca

We present the network planning problem of an LTE cellular network with switchable base stations, ie. where the configuration of the antennae is dynamic, depending on demand. This is formulated as a two-stage stochastic program under demand uncertainty with integers in both stages. We develop its Dantzig-Wolfe reformulation and solve it using column generation. Preliminary results confirm the efficiency of the approach.

4 - Data Driven Robust Order Batching for Warehouse Management: A Branch and Price Approach
Vedat Bayram, Assistant Professor, TED University, Endustri Muhendisligi Bolumu, Ziya Gokalp Caddesi No:48, Kolej Cankaya, Ankara, 06420, Turkey, vedat.bayram@tedu.edu.tr, Gohram Baloch, Fatma Gzara, Samir Elhedhli

In this presentation, we report on data analytics solutions for a warehouse management and control systems company. We present data driven robust order batching solutions by developing an optimization model and a state of the art branch and price algorithm that employs simultaneous column and row generation procedures.

Sponsored Session

Chair: Ziteng Wang, Northern Illinois Universtiy, DeKalb, IL, 60115, United States, zwang3@niu.edu

1 - Quadratic Programs with Hollows
Boshi Yang, PhD, Clemson University, Clemson, SC, United States, boshiy@clemson.edu, Kurt M.Anstreicher, Samuel Burer

Let F be a quadratically constrained bounded set, and let E1, ... , El denote ellipsoids contained in F with non-intersecting interiors. We prove that minimizing an arbitrary quadratic q() over G := F \ (\cup_{k=1}^l int(Ek)) is no more difficult than minimizing q() over F in the following sense: if a given SDP relaxation for min{ q(x) : x in F } is tight, then the addition of l linear constraints derived from E1, ... , El yields a tight SDP relaxation for min { q(x) : x in G }. Inspired by these results, we resolve a related question in a seemingly unrelated area, mixed integer nonconvex quadratic programming.

2 - A Completely Positive Programming Approach to the Cardinality Constrained Quadratic Programming
Ziting Wang, Northern Illinois University, DeKalb, IL, United States, zwang3@niu.edu, Ye Tian

In this paper, we propose a completely positive programming reformulation of the cardinality constrained portfolio selection problem. By constructing a sequence of computable cones of nonnegative quadratic forms over a union of second-order cones, an -optimal solution of the original problem can be found in nite iterations using semidenite programming techniques. In order to obtain a good lower bound eciently, an adaptive scheme is adopted in our approximation algorithm. The numerical results show that the proposed algorithm can nd better approximate and feasible solutions than other known methods in the literature.

3 - A New Linear Reformulation for Binary Quadratic Programming Problems
Shan Jiang, North Carolina State University, sjiang8@ncsu.edu, Tiantian Nie, Shu-Cherng Fang, Qi An

This paper presents a new 0-1 mixed-integer linear reformulation of a binary quadratic programming (BQP) problem. The proposed $O(n)$-sized linear reformulation is distinguished from other known $O(n)$-sized linear reformulations by a new linearization strategy that simultaneously treats symmetric quadratic terms. Besides the new structure embedded, the proposed reformulation also reduces the number of required continuous variables and linear constraints. Numerical experiments on various BQP instances demonstrate the superior computational efficiency of the proposed reformulation over other state-of-the-art linear reformulations.

1 - Combining the L-shaped Method and Lagrangian Relaxation for Expansion Planning with Energy Storage Devices and Renewable Portfolio Standard Constraints
Roderick Go, Johns Hopkins University, Baltimore, MD, 21218, United States, rgo1@jhu.edu, Francisco David Munoz, Jean-Paul Watson

We propose a convergent solution algorithm to solve capacity expansion planning problems that co-optimize transmission, generation, and energy storage investment decisions on a transmission network subject to linking policy constraints like Renewable Portfolio Standards. In the proposed algorithm, we introduce a novel hybridization of Lagrangian relaxation and the L-shaped method that allows us to efficiently compute upper and lower bounds on optimal system cost. Additionally, we introduce a heuristic method to accelerate the solution while maintaining bounds. We illustrate the performance of these algorithms using the IEEE 24-bus test case with 52 weeks of hourly data.

2 - Understanding the Decision Making in a Long-term Electric Power Sector Capacity Expansion Models

Kelly Eurek, National Renewable Energy Laboratory, Golden, CO, United States, Kelly.Eurek@nrel.gov

Long-term capacity expansion model are used for exploring the potential evolution of the electric power sector. Often formulated using linear and mixed integer optimization, these models choose the mix of technologies that minimize the cost to reliability balance supply and demand of electricity. This presentation highlights a method for understanding the decision making in NREL's Regional Energy Deployment System (ReEDS) capacity expansion model.

3 - Stochastic Transmission Expansion Planning: Computational Challenges

Mohammad Majidi-Qadikolai, The University of Texas at Austin, 1616 Guadalupe UTA 2.304, Austin, TX, 78701, United States, majidi_mohammad@yahoo.com, Ross Baldick

Increasing uncertainties in future generation generation mix, output of high penetration intermittent resources, contribution of demand response and energy storage capacity significantly increase complexities of transmission expansion planning (TEP), and traditional experienced based methods may not be efficient anymore. Stochastic programming can be used to model and integrate these uncertainties into TEP decision making process. Being computationally expensive is the main drawback of this method. In this work we proposed a generalized decomposition framework that allows us to solve a two-stage stochastic TEP problem with security constraints for real-size problems.

4 - Using Multihorizon Stochastic Programming to Analyze the Potential Trade-off Between Demand Response and Transmission

Asgeir Tomasgard, Norwegian University of Science and Technology, Dept. of industrial economics, Alfred getz vei 3, Trondheim, 7491, Norway, asgeir.tomasgard@iot.ntnu.no, Christian Skar, Hector Maranon-Ledesma

The objective of this work is to analyse to what demand response (DR) can contribute to the transition to an European low emission power system. The capabilities of DR are studied through the multi horizon stochastic programming model EMPIRE, an electricity sector model with a time span of 30 years and hourly market clearing. The model includes uncertainty at the operational level and energy economics dynamics at a strategic level. The investment-operation DR module models several classes of shiftable and curtailable loads in residential, commercial, industrial and transport sectors for 31 European countries.

1 - Finding Patterns in Pareto Optimal Solutions and its Applications

Abhinav Gaur, Doctoral Candidate, Michigan State University, 428 S Shaw Lane, East Lansing, MI, 48824, United States, gaurabhi@msu.edu, Kalyanmoy Deb

Multi-objective optimization (MOO) problems lend themselves to not one but a set of optimal solutions also called Pareto-optimal (PO) solutions. Such P.O. solutions carry information on patterns that make these solutions concurrently optimal for multiple objectives. Discovering such patterns from the P.O. solutions is called 'Innovization' or innovation through optimization. Some of the uses of carrying out an Innovization exercize are discovering design principles for the MOO design problem, automatically discovering optimization heuristics for a problem and, expediting black box MOO algorithms.

2 - Redundancy Allocation of Standby Components in Repairable K-out-of-N Systems

Hanlin Liu, City University of Hong Kong, Hong Kong, hanlinliu2-c@my.cityu.edu.hk, Rui Peng, Min Xie

In system design process, standby redundancy is a widely-used technique to improve system reliability and availability. In this paper, we investigate the repairable K-out-of-N system with both warm and cold standby redundancy. In the proposed system, each component can be in failure, cold, warm and active states and the components are assumed to be repairable. The systems are modeled by continuous time Markov chain (CTMC) and the system long run availability is derived. Furthermore, optimal number of warm standby is studied by considering system availability and average long run cost. Illustrative examples are also given to show the applications of the proposed model.

3 - An Incentive Mechanism to Improve Engineering Design Process under Requirement Based Engineering Design

Soodabeh Yazdani, PhD Student, George Mason University, 4400 University Dr, Fairfax, VA, 22030, United States, syazdan2@masonlive.gmu.edu, Edward Huang, Daniel Lin

Large-scale complex engineering systems are mostly carried out by requirement based engineering design where project manager at higher levels flow-down requirements and design resources to design teams at lower levels. Under this scheme, incentive alignment and efficient resource allocation are crucial factors in the success of design outcome. This paper explores economics incentives to control and improve the system-level design outcome. A mathematical framework by using mechanism design theory is proposed to analyze the effect of incentives on system wide design outcome.

4 - Determining Decoupling Points in a Network Associated with Different Design Preferences using Exploration of the Solution Space

Lin Guo, Graduate Research Assistant, University of Oklahoma, 202 W. Boyd Street, Room 218, Norman, OK, 73019, United States, lin.guo@ou.edu, Reza Alizadeh, Janet Katherine Allen, Farrokh Mistree

In this paper, we propose an approach using exploration of the solution space of a multi-goal compromise Decision Support Problems model to determine the decoupling points of a three-echelon supply chain. Facing different design preferences of the supply chain, the goals should be satisfied in different degree, and the change of the design preference may take place rapidly, which requires the decoupling points flexible enough to be moved through the supply chain.

5 - Axiomatic Design in Early Product Design a Case of Outdoor Sports Equipment

Rhythm Wadhwa, Professor, NTNU, Teknologiveien 22, Gjoevik, 2821, Norway, rhythmwadhwa@hotmail.com

The paper presents the application of Axiomatic design for the early product development of outdoor sporting equipment. The design parameters were used to decouple the functional and customer requirements. The product developed after multiple iterations and was field tested. The results of the simulation and field trials have been compared and discussed.

1 - Batch Scheduling of Multi-Product Pipeline Networks

Sander J. Vlot, ORTEC, Zoetermeer, Netherlands, Sander.Vlot@ortec.com

In this research, we propose a novel method for scheduling pipeline networks. The method consists of a planning and a scheduling phase that are coupled in a hierarchical decomposition scheme. In the planning phase, global transportation volumes are determined for each pipeline. In the scheduling phase, we use the planning output to generate complete schedules. Both phases are based on discrete-time MILP formulations. The method is successfully tested on two case studies involving up to 4 products, 8 pipelines, 8 tank farms, 2 supply locations, and 5 demand locations. The proposed method is flexible in terms of network configurations, supply and demand requirements, and cost structures.

2 - A Mixed-complementarity Approach to Assess the Potential Gain from Intra-regional Electricity Transmission Utilizing the GCC Interconnector

David Wogan, Research Associate, King Abdullah Petroleum Studies and Research Center, P.O. Box 88550, Riyadh, 11672, Saudi Arabia, david.wogan@kapsarc.org

The GCC Interconnector links the electricity systems of the six countries of the Gulf Cooperation Council. Potential economic and technical gains could be realized by utilizing the Interconnector to deliver electricity from lower-cost sources across the region. We formulate a bottom-up mixed-complementarity problem to capture market distortions that arise from subsidized fuel prices for power and water producers. We assess the impact on volume of transmission and marginal costs of supply and demand by considering electricity production for domestic consumption at administered prices and for export to the Interconnector at prices reflecting fuel opportunity costs.

3 - Gas Storage Valuation via Least Squares Monte Carlo and Support Vector Regression

Alexander Malyscheff, University of Oklahoma, 110 W Boyd Street, Devon Energy Hall 150, Norman, OK, 73019-1102, United States, malyscheff@gmail.com, Theodore B.Trafalis

Least squares Monte Carlo (LSMC) approaches represent a computationally efficient method for the valuation of natural gas storage facilities. LSMC methods are computationally tractable while they simultaneously allow for a decoupling of the price path simulation from the optimization of the decision vector. We study the impact of additional pricing information in the form of a forward contract on the value of a gas storage facility. Value function approximation is carried out by employing a kernel-based regression technique in the form of support vector machine regression (SVR).

4 - Optimal Control of Tank Levels with Constrained Chance of Pipeline Shutdown

Tianyuan Zhu, University of Calgary, Scurfield Hall, 2500 University Dr NW, Calgary, AB, T2N.1N4, Canada, zhut@ucalgary.ca

In a petroleum pipeline network, when unexpected power failure or other malfunctions happens during a predetermined shipping and maintenance schedule, the unusual change of pipeline flow rate may lead to excessively high or low inventory level in tank farms, which will result in connecting pipeline shutdowns and network throughput missing. To address this problem, an optimization model is developed to study the optimal tank levels and associated pipeline flow rate adjustment policy with the objective of minimizing the missing throughput, while the chance of pipeline shutdown is bounded. The model is tested on a simplified real-world network owned by a Canadian pipeline company.

Modeling Interdependent Infrastructures

Sponsored: Energy, Natural Res & the Environment, Energy

Sponsored Session

Chair: Feng Qiu, Argonne National Laboratory, Lemont, IL, 60439, United States, fqiu@anl.gov

Co-Chair: Spada Matteo, Paul Scherrer Institute, Villigen PSI, 5232, Switzerland, matteo.spada@psi.ch

1 - Enhancing Resilience of Powergrid-cyber-transportation Interdependent Infrastructures

Yunhe Hou, University of Hong Kong, CYC Building, Room 522, Hong Kong, Hong Kong, yhhou@eee.hku.hk

This presentation discusses the coordinating strategies for enhancing the resilience of energy systems. The interaction among power network, cyber system, and transportation systems are modeled. Cyber-attack and extreme weather events trigger the disruptive event of a power system. Some sequential resilient operating strategies to absorb the impacts and to restore the system are discussed. Due to the essential interdependent characteristics of three systems and stages after the trigger events, the proposed strategies are constructed based on a multi-level optimization framework. The solution methods are discussed as well.

2 - Resilience Planning and Operations of Energy and Water Systems

Neng Fan, University of Arizona, 1127 E James E. Rogers Way, PO Box 210020, Tucson, AZ, 85721, United States, nfan@email.arizona.edu

In this talk, multilevel optimization model will be constructed to model the interdependency between energy and water systems. To ensure the resilience planning and operations, failure scenarios in both systems will be integrated into the model with their respective planning/operations standards. To solve the complicated model, decomposition based algorithms will be designed and validated on some test cases.

3 - Computable Equilibrium Model Analysis for Energy-water Nexus

Feng Qiu, Argonne National Laboratory, 9700 S Cass Ave, Building 202, Room C205B, Lemont, IL, 60439, United States, fqiu@anl.gov, Andrew Schreiber, Jianhui Wang

Many studies on energy and water are rightfully interested in the interaction of water and energy, and their projected dependence into the future. While many studies are beginning to ask the right questions, the lack of numerical rigor raises questions of concern in conclusions discerned. In this study, we will perform economic analysis using computable general equilibrium models with energy-water interdependencies captured as an important factor. We atempt to answer important and interesting questions in the studies: how can we characterize the economic choice of energy technology adoptions and their implications on water use in the domestic economy.

4 - Modeling Recovery of Interdependent Civil Infrastructure Systems

Eun Jeong Cha, Assistant Professor, University of Illinois at Urbana-Champaign, 205 N.Mathews Ave., Room 2207, Urbana, IL, 61801, United States, ejcha@illlinois.edu, Xian He

Civil infrastructure systems depend on each other for product input and/or information sharing and properly modeling such dependencies is essential in assessing the performance of the civil infrastructure systems during and following a disruptive event, which lays the foundation of assessing the community resilience. This presentation introduces the Dynamic Integrated Network model which has been developed under the NIST's Center for Risk-Based Community Resilience Planning. The model assesses the damage and recovery of a civil infrastructure network consisting of different systems following a disruptive event with considering the facility-level dependencies.

Distributionally Robust Optimization

Sponsored: Optimization, Optimization Under Uncertainty

Sponsored Session

Chair: Grani Hanasusanto, The University of Texas at Austin,grani.hanasusanto@utexas.edu

1 - Two-stage Distributionally Robust Linear Programming Over Wasserstein Balls

Grani Adiwena Hanasusanto, The University of Texas at Austin, ETC 5.120, Austin, TX, 78712, United States, grani.hanasusanto@utexas.edu, Daniel Kuhn

We study two-stage stochastic linear programming problems where the distribution of the uncertain parameters is ambiguous and is only known to belong to a family of all distributions that are close to the empirical distribution with respect to the Wasserstein metric. We derive an exact copositive program for the generic problems and formulate a tractable linear program for instances with only right-hand side uncertainty. We illustrate the effectiveness of our reformulations in numerical experiments and demonstrate their superiority over the classical sample average approximation scheme and the state-of-the-art moment-based model.

2 - Distributionally Robust Mechanism Design

Cagil Kocyigit, Ecole Polytechnique Federale de Lausanne (EPFL), Lausanne, Switzerland, cagil.kocyigit@epfl.ch, Garud N. Iyengar, Daniel Kuhn, Wolfram Wiesemann

We study a mechanism design problem for auctioning a single good, where the bidders' values are random variables that may follow any distribution in a commonly known ambiguity set. We assume that the seller is ambiguity averse and the bidders have Knightian preferences. If the bidders' values are independent, then the added value of the optimal mechanism over a simple second price auction is offset by just attracting one extra bidder. If the bidders' values are dependent and characterized through moment bounds, we provide a new class of randomized mechanisms, the highest-bidder-lotteries, whose revenues cannot be matched by any second price auction with a constant number of additional bidders.

3 - From Data to Decisions: Distributionally Robust Optimization is Optimal

Daniel Kuhn, Ecole Polytechnique Federale de Lausanne (EPFL), EPFL.CDM.MTE I.RAO, ODY 1 01 B.(Odyssea), Lausanne, 1015, Switzerland, daniel.kuhn@epfl.ch, Bart Paul Gerard Van Parys, Peyman Mohajerin Esfahani

Data-driven stochastic programming aims to find a procedure that transforms time series data to a near-optimal decision (a prescriptor) and to a prediction of this decision's expected cost under the unknown data-generating distribution (a predictor). We propose a meta-optimization problem to find the least conservative predictors and prescriptors subject to constraints on their out-of-sample disappointment. Leveraging tools from large deviations theory, we prove that the best predictor-prescriptor pair is obtained by solving a distributionally robust optimization problem.

4 - Robust Map Inference in Markov Random Fields

Areesh Mittal, University of Texas at Austin, 1626 West 6th St, Apt F, Austin, TX, 78703, United States, areeshmittal@utexas.edu, Grani Adiwena Hanasusanto

In the maximum a posteriori (MAP) inference on Markov Random Fields (MRFs), we seek for the most likely assignment to the given Markov network. The underlying parameters of the MRFs, however, are typically estimated from data and can be subject to substantial errors. In this work, we introduce a new MAP inference model that endeavors to alleviate these estimation errors by leveraging on techniques from robust optimization. We show that the arising optimization model is amenable to standard integer programming solution schemes, and we assess its effectiveness via numerical experiments.

Joint Session OPT/Practice: Optimizing Power System Operations under Uncertainty

Sponsored: Optimization, Optimization Under Uncertainty

Sponsored Session

Chair: Bita Analui, Arizona State University, Tempe, AZ, United States, bita.analui@asu.edu

1 - Evaluating Power Plant Operation and Maintenance Policies for Concentrated Solar Power

Alexander Zolan, University of Texas, Austin, TX, United States, na, Jennifer DiCarlo

We simulate maintenance and component failure events (i.e., for a salt-to-heat steam exchanger, three sizes of turbines, water pumps, and a generator) in a Concentrating Solar Power plant, when provided component specifications and hourly dispatch decisions from an independent optimization model; a collection of stochastic realizations of failure, repair and maintenance events, each of which includes intervals of forced plant downtime, characterize the failure events. An iterative approach takes these as inputs to suggest an improved dispatch strategy that mitigates loss of revenue associated with expected downtime, cold starts (and, more generally, cycling), and maintenance.

2 - A Dynamic Multistage Stochastic Unit Commitment Formulation for Intraday Markets

Bita Analui, AZ, United States, bita.analui@asu.edu, Anna Scaglione

As net-load becomes less predictable there is a lot of pressure in changing decision models for power markets such that they account explicitly for future scenarios in making commitment decisions. This paper proposes to make commitment decisions with multiple gate closures. Our proposed model also leverages a state-space formulation for the commitment variables, through which the operational constraints of generation units participating in the market are respected. We also study the problem of constructing scenario tree approximations for both original and residual stochastic processes and evaluate our algorithms on scenario tree libraries derived from real net-load data.

3 - Condition-based Generation Maintenance and Operations Scheduling under the Uncertainty of the Unexpected Failures

Beste Basciftci, Georgia Institute of Technology, Atlanta, GA, United States, beste.basciftci@gatech.edu, Shabbir Ahmed, Nagi Gebraeel

In this study, our aim is to effectively model and solve the integrated condition-based maintenance and operations scheduling problem of a fleet of generators by explicitly considering the unexpected failures. We formulate this problem as a stochastic mixed-integer program and introduce a chance constraint to ensure a reliable maintenance plan. We propose a data-driven approach by explicitly considering the degradation levels of the generators within the optimization model through their estimated remaining life time distributions. Finally, we present computational experiments demonstrating the effectiveness of the proposed approach.

Two-stage Stochastic and Distributionally Robust MIPs: Algorithms and Applications

Sponsored: Optimization, Optimization Under Uncertainty

Sponsored Session

Chair: Manish Bansal, Virginia Tech., Blacksburg, VA, 24060, United States, bansal@vt.edu

1 - Analysis of Power Grid Attacks

Mauro Escobar, Columbia University, 502 W. 122nd St, Apt 23, New York, NY, 10027, United States, me2533@columbia.edu, Daniel Bienstock

This research project focuses on power grid attacks. The problem setting is as follows: an adversary has the ability of altering the supply/demand of a set S of buses in the network and report a different angle phase of a set T of buses (containing S), while a set R of buses (disjoint of T) responds to the total supply/demand change. This study analyzes the conditions in which the adversary could report phase angles that are consistent with a network flow that satisfies branch capacities and models frequency response, while the real flow would not. So far, the analysis has consisted of DC formulated simulations using cases from 'Matpower.'

2 - New Solution Approaches for the Maximum-reliability Stochastic Network Interdiction Problem

Eli Towle, University of Wisconsin-Madison, Madison, WI, United States, etowle@wisc.edu

We investigate methods to solve the maximum-reliability stochastic network interdiction problem (SNIP). In this problem, a defender interdicts arcs on a directed graph to minimize an attacker's probability of undetected traversal through the network. The attacker's origin and destination unknown to the defender and assumed to be random. We introduce a new extensive formulation that is more compact than the existing extensive formulation. We propose a new path-based formulation of SNIP and a branch-and-cut algorithm to solve it. Computational results demonstrate that both approaches provide a significant improvement over a state-of-the-art implementation of Benders decomposition for SNIP.

3 - On Continuous Mixing Cuts for Two Stage Mean Risk Stochastic Mixed Integer Programs

Hideaki Nakao, University of Michigan, Ann Arbor, MI, United States, nakaoh@umich.edu, Simge Kucukyavuz, Siqian Shen

We study a class of two-stage mean-risk stochastic mixed-integer linear programs (SMILP) which involve mixed-integer variables in the first stage and continuous variables in the second stage. The objective is to minimize the weighted sum of the expected value and the conditional value-at-risk (CVaR) of a random cost function dependent on first-stage decisions and realizations of uncertain parameters. A common approach for solving the two-stage optimization problem is to apply the Benders decomposition algorithm. We show how the CVaR-based Benders cuts lead to a structure that can be used to derive continuous mixing (CMIX) cuts to tighten the relaxed master problem.

4 - Decomposition Algorithms for Two-stage Distributionally Robust Mixed Binary Programs

Manish Bansal, Virginia Tech., 227 Durham Hall, 1145 Perry Street, Blacksburg, VA, 24060, United States, bansal@vt.edu, Kuo-Ling Huang, Sanjay Mehrotra

We present a decomposition algorithm to solve two-stage distributionally robust mixed binary problems (TSDR-MBPs) where the random parameters follow the worst-case distribution belonging to an uncertainty set of probability distributions. We investigate conditions and families of uncertainty set for which our algorithm is finitely convergent. In addition, we present a cutting surface algorithm to solve TSDR-MBPs. We computationally evaluate the performance of our algorithms in solving distributionally robust versions of a few instances from the Stochastic Integer Programming Library, in particular stochastic server location and stochastic multiple binary knapsack problem instances.

Plenary: How Analytics Powers the Uber Marketplace

Invited Session

1 - How Analytics Powers the Uber Marketplace

Robert Phillips, Director of Data Science, Uber Technologies

Uber – the leading ride-sharing company in the world – faces the challenge of efficiently managing both sides of a two-sided market in which it has no direct control over either demand or supply. The challenges include determining real-time prices for both riders and drivers, matching riders and drivers and providing signals to drivers that incentivize efficient movement. In this talk we describe how Uber uses a wide variety of approaches drawn from operations research, management science, statistics, economics and machine learning to address these challenges in a highly dynamic temporospatial marketplace.

Portfolio Decision Analysis

Sponsored: Decision Analysis

Sponsored Session

Chair: Alec Morton, University of Strathclyde, Glasgow, G1 1XQ, United Kingdom, alec.morton@strath.ac.uk

Co-Chair: Liesio Juuso, juuso.liesio@aalto.fi

1 - Out of Sample Comparison of SSD and Directionally SSD Constrained Portfolio Choice

Nasim Dehghan Hardoroudi, Aalto University School of Business, Runeberginkatu 22-24, Chydenia (4th floor), Helsinki, 00100, Finland, nasim.dehghan.hardoroudi@aalto.fi

In this paper we compare out-of-sample performance of second order stochastic dominance (SSD) and directionally SSD constrained portfolio optimization using stock market data of the US. When the market index is taken as benchmark, out-of-sample tests show that both SSD and DSSD constrained optimization with a variety of objective functions out-perform the benchmark in terms of average return, and DSSD based approach compares favorably against SSD based, given that risk aversion exhibited by the objective function is relatively mild.

2 - Sparse Dynamic Portfolios with Regret-based Selection

David Puelz, University of Texas, 6309 Burns Street, Austin, TX, 78752, United States, david.puelz@utexas.edu

This paper considers portfolio construction in a dynamic setting. We present a new decision theoretic approach based on a loss function comprised of utility and portfolio complexity components. These components are related by an unknown tradeoff parameter, and we develop a novel regret-based criterion for selecting the tradeoff parameter to construct optimal sparse portfolios over time. We demonstrate the procedure under a variety of modeling and preference scenarios using data from exchange traded funds.

3 - Allocation Rules for Global Donors

Alec Morton, University of Strathclyde, Management Science, University of Strathclyde, Glasgow, G1 1XQ, United Kingdom, alec.morton@strath.ac.uk, Ashwin Arulselvan, Ranjeeta Thomas, Peter C. Smith

A vitally important part of ensuring that recent improvements in global health are sustained is financial aid from rich countries to poor ones. Aid donors must also ensure that countries build the financial capacity to deliver healthcare for their own population on a sustainable basis, and the allocation rules used by aid donors must reflect this. We present a game theoretic analysis of the relationship between a donor and a country. The donor has a healthcare related mission and the country cares about healthcare but also about other things. We show how our model produces both insight and operationalisable rules for guiding aid donation.

Multicriteria Decision Making

Sponsored: Decision Analysis

Sponsored Session

Chair: Canan Ulu, Georgetown University, Washington, DC, 20057, United States, cu50@georgetown.edu

1 - An Additive Model of Decision Making under Riskand Ambiguity

Ying He, University of Southern Denmark, Campusvej 55, Odense, M, 5230, Denmark, yinghe@sam.sdu.dk, James S. Dyer, John C. Butler, Jianmin Jia

We develop preference conditions to separate "value', "risk" and "ambiguity" to obtain a descriptive, additive model of decision making under risk and ambiguity. This model explicitly captures the tradeoff between the magnitude of risk and the magnitude of ambiguity when making a choice over ambiguous lotteries. Combining this model with the standard risk-value model, we obtain a value-risk-ambiguity preference model.

2 - Where do We Stand on Multi-objective Decision Making?

Ali E. Abbas, Director, DECIDE Center, University of Southern California, OHE 310R, 3650 McClintock Ave, Los Angeles, CA, 90089, United States, aliabbas@usc.edu

The construction of a representative multi-attribute utility function is is an essential step in the analysis of many decisions. This talk with discuss some advances in the field of multi-attribute utility (including graphical representations and connections with artificial intelligence). The talk will also discuss some misuses of the theory, and some subtleties and approaches that still persist.

3 - An Interactive Bayesian Method for Multicriteria Sorting Problems

Canan Ulu, Georgetown University, McDonough School of Business, Operations and Information Management Area, Washington, DC, 20057, United States, cu50@georgetown.edu, Tom Shively

We build a Bayesian learning model for the multicriteria sorting problem.

4 - Robust Multicriteria Decision Analysis

Fabio Maccheroni, Universita Bocconi, Via Sapfath, 25, Milan, Italy, fabio.maccheroni@unibocconi.it, Veronica Roberta Cappelli, Salvatore Corrente, Salvatore Greco

In MCDA, often an alternative can be represented by a vector of probabilities, its i-th component representing the distribution of scores of attribute i. Typically (Keeney and Raiffa, 1976), alternatives are evaluated by an expected additively separable utility. Yet, in many situations the DM's utility is unknown to the DA: available data only leads to an incomplete ranking of alternatives. We provide necessary and sufficient conditions to represent this ranking by a family of additively separable utility functions, so that an alternative outranks another alternative if and only if its expected utility is greater than that of the other alternative for every utility in the representing family.

Quantitative Imaging System for Cancer Diagnosis and Treatment Planning: An Interdisciplinary Approach

Invited: Tutorial

Invited Session

Chair: Jiming Peng, University of Houston, Houston, TX, 77204, United States, jopeng@Central.uh.edu

Co-Chair: Rajan Batta, University at Buffalo (SUNY), 410 Bell Hall, Buffalo, NY, 14260, United States, batta@buffalo.edu

1 - Quantitative Imaging System for Cancer Diagnosis and Treatment Planning: An Interdisciplinary Approach

Teresa Wu, Arizona State University, Tempe, AZ, United States, Teresa.Wu@asu.edu

During the past decade, with breakthroughs in systems biology, precision medicine has emerged as a novel paradigm that has transformed healthcare. Precision medicine is an approach for disease treatment and prevention that takes into account individual variability where medical imaging is a key component. This tutorial focuses on research investigating the roles of medical imaging in cancer diagnosis and treatment planning. While the cornerstone of the imaging research is mathematical and statistical modeling, the research has to take a multidisciplinary and systematic approach due to the nature of the problem. We offer a comprehensive review and discussion on four important components that form an imaging pipeline: imaging pre-processing, imaging feature extraction, feature dimensionality reduction and classification. To illustrate the clinical relevance, our in-house developed system, the imaging Multi-Texture Disease Diagnosis System (iMT-DDS) is presented with two clinical case studies, one on breast cancer diagnosis using contrast enhanced digital mammography imaging, and the other on cholangiocarcinoma using computed tomography imaging. The future directions of the imaging research are highlighted in the end.

Financial Engineering in Applied Probability I

Sponsored: Applied Probability

Sponsored Session

Chair: Tomoyuki Ichiba, University of California-Santa Barbara, Santa Barbara, CA, 93106, United States, ichiba@pstat.ucsb.edu

1 - Systemic Risk in Financial Markets

Andrey Sarantsev, University of California, Santa Barbara, CA, United States, sarantsev@pstat.ucsb.edu

We study behavior of utility-maximizing private banks borrowing from the central bank and investing in risky assets. The central bank is risk-averse, and sets the interest rate to control the amount of risk in the system.

2 - Option Pricing with Delayed Information

Tomoyuki Ichiba, University of California-Santa Barbara, South Hall 5607A, Santa Barbara, CA, 93106, United States, ichiba@pstat.ucsb.edu, Mostafa Mousavi

We study the effects of delayed information on option pricing. First, we discuss absence of arbitrage and super replication problem with delayed information in discrete time, binomial-tree models. For contingent claims with convex payoff we present a closed-form formula. Then we also consider continuous time models as the limit of binomial tree models when the time steps and delay steps go to zero. Finally, we explore how delayed information exagerates the volatility smile.

3 - Pricing Various Swaps

Indranil SenGupta, North Dakota State University, Department of Mathematics, Fargo, ND, 58108-6050, United States, indranil.sengupta@ndsu.edu, William Wilson, William Nganje

One of the major challenges in arbitrage free pricing of swap is to obtain an accurate pricing expression which can be used with good computational accuracy. In this presentation we obtain various approximate expressions for the pricing of volatility, variance and covariance swaps. We show that with the approximate formulas obtained from the Barndorff-Nielsen and Shephard model the error estimation in fitting the delivery price is much less than the existing models with comparable parameters.

4 - Pricing Spread Options using a Variance Gamma Copula Paradigm

Kyle Meerscheidt, University of Houston, 4800 Calhoun Rd, Houston, TX, 77004, United States, kmeerscheidt@gmail.com, Edward Kao

A spread option is a contingent claim whose value depends on the difference between the value of one asset and a constant multiple of the value of a second asset. This paper examines the valuation of a spread call option where the prices of the two assets are driven by a bivariate dependent Lévy process, with a two-dimensional Lévy copula describing the dependence structure. This method can be extended to other bivariate Lévy processes, including those whose marginal (component) processes are not of the same family.

Sponsored Session

Chair: Adam J Mersereau, University of North Carolina, Chapel Hill, NC, 27599-3490, United States, ajm@unc.edu

Co-Chair: Gah-Yi Ban, London Business School, London, NW1 4SA, United Kingdom, gban@london.edu

1 - Data-driven Percentile Optimization for Multi-class Queueing Systems with Model Ambiguity: Theory and Application

Austin Steven Bren, Arizona State University, 5151 Guadalupe Road, Apt 2061, Phoenix, AZ, 85044, United States, hasbren@gmail.com, Soroush Saghafian

Multi-class queueing systems often experience ambiguity in the form of unknown parameters. To incorporate robustness in the control policies we apply a novel data-driven technique that can express different levels of robustness and utilize incoming data parameter learning. Optimal policies are found to be related to a closed-form priority-based policy, with connections traditional priority policies. We also apply our approach to a hospital Emergency Department (ED) using real-world data, and demonstrate the benefits of using our framework for improving current patient priority policies.

2 - Pricing for Reusable Resources

Yunjie Sun, Columbia University, 500 West 120th Street, 535 S.W. Mudd Building, New York, NY, 10027, United States, ys2888@columbia.edu, Omar Besbes, Adam Elmachtoub

We consider price optimization of reusable resources. We develop results on structural properties of the optimal dynamic pricing policy as well as provably good heuristics for this class of problems. We also discuss initial implementation efforts of a large scale pricing project at an industry partner, Dassault Falcon Jet, for rotable spare parts.

3 - Learning Single-peaked Ranking Preferences from Choice Data

Mohammed Ali Aouad, Massachusetts Institute of Technology, 856 Massachussetts Avenue, Flat 9, Cambridge, MA, 02139, United States, aaouad@mit.edu, Vivek Farias, Retsef Levi

We develop an efficient estimation procedure to learn single-peaked preferences from assortment choice data. The latter choice model assumes that individual ranking preferences form a « peak » according to a central permutation over items. This structure is popular in social choice theory, assortment optimization and matrix completion. While searching over the space of permutations is generally hard, we show that rank aggregation (corresponding to the column generation step in the estimation problem) can be solved in polynomial time under the single-peaked structure. We showcase the relevance of the proposed methodology in experiments on real choice data, in several product categories.

4 - Dynamic Procurement of New Products with Covariate Information: the Residual Tree Method

Adam J. Mersereau, University of North Carolina, Kenan-Flagler Business School, CB 3490, Chapel Hill, NC, 27599-3490, United States, ajm@unc.edu, Gah-Yi Ban, Jeremie Gallien

We study a practice-motivated problem of dynamically procuring a new, short life-cycle product under demand uncertainty. The firm does not know the demand for the new product but has data on demand histories and covariate information for similar products sold in the past. We propose a new data-driven combined forecasting and optimization algorithm called the residual tree method, and we analyze its performance via epi-convergence theory and computations. Numerical validations on realistic data confirm the tractability of the approach and the value of covariate information.

Sustainable Operations and Policy

Sponsored: Manufacturing & Service Oper Mgmt, Sustainable Operations

Sponsored Session

Chair: Krishnan S. Anand, University of Utah, Salt Lake City, UT, 84112, United States, anand@eccles.utah.edu

1 - Food Wastage in Commercial Kitchens

Varun Karamshetty, INSEAD, Boulevard de Constance, Fontainebleau, 77300, France, Varun.Karamshetty@insead.edu, Elena Belavina

Kitchens are wasting as much on food waste as they make in profits. With an estimated $1 trillion in food being wasted every year, food waste is not only a huge economic loss, but also has a major impact on our environment accounting for nearly 15% of global GHG emissions. We analyze proprietary data to understand key drivers of food wastage in commercial kitchens. We identify the controllable factors, and quantify the impact of each of them. We then propose changes in their operations that minimize wastage while maintaining their service quality and bottom-line.

2 - Are Hazardous Substance Rankings Effective?

Basak Kalkanci, Georgia Institute of Technology, 3151 Stillhouse Creek Dr SE, Apt 25517, Atlanta, GA, 30339, United States, basak.kalkanci@scheller.gatech.edu, Wayne Fu, Ravi Subramanian

We empirically investigate the relationship between changes in the relative assessed hazard levels of chemicals and emissions reductions (including the use of source reduction and end-of-pipe treatment) by facilities that use these chemicals. We also examine the moderating effects of operational leanness - an attribute that prior studies have found to be associated with better environmental performance - in the setting wherein the relative assessed hazard levels of chemicals change over time.

3 - Fairness in Pollution Regulation

Krishnan S. Anand, University of Utah, David Eccles School of Business, Ois Department, University Of Utah, Salt Lake City, UT, 84112, United States, anand@eccles.utah.edu, Francois C. Giraud-Carrier

Fairness in pollution regulation is an important and much-debated question, especially given multiple stake-holders with conflicting objectives, including polluting firms, industry lobby groups, consumers, environmentalists, doctors and the government. While there is a vast literature on the notion of fairness in general, we use the term precisely to mean that the polluter pays for the entire pollution damage it causes, and no more— the so-called 'polluter pays' principle. We develop a novel benchmark-mechanism to implement fairness, and assess the fairness of Cap-and-Trade and Taxes against this benchmark.

Beyond the Unit - Holistic Approach to Demand-Based Staffing in Hospital Systems

Sponsored: Health Applications

Sponsored Session

Chair: Hari Balasubramanian, University of Massachusetts-Amherst, Amherst, MA, 01003, United States, hbalasubraman@ecs.umass.edu

Co-Chair: Ekin Koker, University of Massachusetts, Amherst, MA, 01003, United States, ekoker@umass.edu

1 - Forecasting Demand and Staffing Fluctuations in Hospital Operations

Jeffrey Jung, Navigant Consulting, Inc., jeffrey.jung@navigant.com

A critical component of labor optimization is the ability to predict short and long term forecasts of demand variations as well as the supply /staffing variations. By projecting fluctuations in demand, hospital leaders are equipped to accurately reflect proportional changes to staffing needs. A variety of different algorithms (e.g. vector auto-regression, ARIMA), provide different approaches to minimize the forecasting error. These predictions lead to hiring decisions in anticipation high volume times and flight risk. The forecasted demand complements the optimal staffing plans to enable our clients to plan their future staffing in a dynamic environment with a higher level of precision.

2 - Creating Optimized Hospital Workforce Solutions

Jeffrey Jung, Senior Consultant, Navigant Consulting, Inc., New York, NY, 60606, United States, Jeffrey.jung@navigant.com, Hannan Abdi, Yaqiong Li, Asli Kayaalp

Hospitals are faced with the challenge of staffing to demand; however, the demand is sometimes hard to predict until just before a shift starts. Managers are therefore inclined to staff to capacity, or use expensive resources to fill gaps. These methods are inefficient and costly. Using mixed integer programming, we model the needs of a group of like-units and determine the optimal numbers of core and flexible resources (float pool vs. per diem, overtime, etc.) required to satisfy demand while minimizing cost. The results allow managers to allocate the best mix of resources (core vs. flexible, part-time vs. full-time) and plan schedules to meet the varying demand throughout the day/week.

3 - Sustaining Performance using Workforce Management Tools

Asli Kayaalp, PhD, Navigant Consulting, Inc., Washington, DC, 20036, United States, asli.kayaalp@navigant.com, Vamshi Gunukula, Hannan Abdi, Jeffrey Jung

To achieve and sustain the value of labor optimization, it is critical for hospital operational leaders to use tools and technologies that allows them to measure and track their performance. These tools include a well-defined position control process with mechanisms to track the impact of decision-making, predictive hiring plans and schedule planners all informed by the optimal staffing models. These tools are complemented by standardized productivity reporting analytics across functional areas. We work with the client to assess the optimal utilization of existing management tools and technologies and identify additional tools to supplement those currently available.

Healthcare Operations

Sponsored: Health Applications

Sponsored Session

Chair: Hessam Bavafa, Wisconsin School of Business, Madison, WI, 53706, United States, hbavafa@bus.wisc.edu

1 - The Impact of E-visits on Visit Frequencies and Patient Health: Evidence from Primary Care

Hessam Bavafa, Wisconsin School of Business, 4284C Grainger Hall, 975 University Avenue, Madison, WI, 53706, United States, hbavafa@bus.wisc.edu

Secure messaging, or "e-visits," between patients and providers has increased sharply in recent years, and many hope they will help improve healthcare quality while increasing provider capacity. Using a panel dataset from a large healthcare system in the United States, we find that e-visits trigger about 6% additional office visits, with mixed results on phone visits and patient health. These additional visits come at the sacrifice of new patients: physicians accept 15% fewer new patients each month following e-visit adoption. Our data on nearly 100,000 patients spans from 2008 to 2013, which includes the rollout and diffusion of e-visits in the health system we study.

2 - Black Swans in Patient Costs: Evidence and Implications for Patient Allocation and Reimbursement

Michael Freeman, INSEAD, 1 Ayer Rajah Avenue, 138676, Singapore, mef35@cam.ac.uk, Stefan Scholtes

Using a unique data set of patient-level clinical information and costs, we identify "black swan" events — i.e. the admission to hospital of patients who cost significantly more than expected — and study their distribution across over 50 hospitals in England. We show that while emergency black swans appear to be allocated at random across hospitals, there is evidence that for planned patients the black swans are concentrated in certain hospitals. We estimate the quality and productivity implications of a black swan patient beeing seen at a hospital that rarely treats such patients, and recommend how these patients might be better allocated to hospitals and how to reimburse for them appropriately.

3 - Cherrypicking Kidneys and Patients: Incentives in Transplant Centers

Mazhar Arikan, University of Kansas, 931 Drum Dr, Lawrence, KS, 66049, United States, mazhar@ku.edu, Baris Ata, Rodney P.Parker

The Centers for Medicare and Medicaid Services' (CMS) Conditions of Participation requirements evaluate transplant centers based on one-year risk-adjusted patient and organ survival rates post transplantation. Using actual transplant data, we empirically analyze some potential unintended consequences of these regulations such that more risk averse centers choose healthier patients and higher quality organs to transplant.

4 - Personalized Health Care Outcome Analysis of Cardiovascular Surgical Procedures

Guihua Wang, Ross School of Business, University of Michigan, 1209 McIntyre Drive, Ann Arbor, MI, 48105, United States, guihuaw@umich.edu, Jun Li, Wallace J. Hopp

Using patient-level data from thirty-five hospitals for six cardiovascular surgeries in New York state, we identify patient groups that exhibit significant differences in outcomes with a recently developed instrumental variable tree approach. We find that outcome differences between hospitals are heterogenous across patients. By quantifying these differences, we demonstrate that a large majority of patients can achieve better expected outcomes by selecting providers based on personalized outcome information. We also show how personalized outcome information can help providers to improve their processes and payers to design effective pay-for-performance programs.

Operations Research and Analytics for Healthcare

Sponsored: Health Applications

Sponsored Session

Chair: Sharan Srinivas, Penn State University, State College, PA, 16803, United States, sus412@psu.edu

1 - Smart Appointment Scheduling Rules for Outpatient Clinics

Sharan Srinivas, Penn State University, 265 Blue Course Dr, Apt 3E, State College, PA, 16803, United States, sus412@psu.edu, Arunachalam Ravindran

In this research, a new framework that uses a combination of predictive analytics and simulation is proposed for scheduling patients dynamically. Further, new appointment scheduling rules that leverage patient specific no-show values are proposed to improve patient satisfaction and resource utilization of outpatient clinics. A case study with real data from a Family Medicine Clinic is used to compare the effectiveness of the proposed rules with current scheduling practices. The results indicate that the proposed scheduling rules significantly outperform the current practice for all the clinic settings tested.

2 - Guided Undersampling Classification for Automated Radiation Therapy Quality Assurance of Prostate Cancer Treatment

William Eric Brown, Texas A&M.University, 3131 TAMU, College Station, TX, 77843-3131, United States, webrown@tamu.edu, Kisuk Sung, Dionne Aleman, Erick Moreno-Centeno, Thomas Purdie, Chris J. McIntosh

Review of radiation therapy (RT) treatment plans requires ample care and human capital; failure to identify errors can cause sizable patient harm. We cast this issue as imbalanced-data classification and address it with a novel modularized guided undersampling method. A sequence of accepted and erroneous RT plans for low to intermediate risk prostate cancer patients was used for testing. While upholding clinically acceptable false-positive rates (FPR), we identify 100% of flawed plans. Remarkably, our framework correctly identifies error types it was not trained on with an FPR of only 18%.

3 - Optimizing the Emergency Call Taking Process with Machine Learning Methods.

Nikiah Nudell, Dakota State University, 2800 7th St N, St. Cloud, MN, 56303, United States, nnudell@paramedicfoundation.org

Over 7 billion emergency calls are made worldwide to emergency numbers such as 911 each year. For cardiac arrest cases, delays cost lives and the currently used decision tools only achieve about 85% accuracy. This study proposes the first work to optimize the emergency call taking process based on patient outcomes using an adaptive hybrid machine learning method. Our method could be implemented in emergency call centers to improve the accuracy and speed of incident detection for up to 50% improvement in survival benefit. These self-optimizing methods could be deployed across many industries from military to retail, to manufacturing, to customer service upstream of decision support systems.

4 - A Hybridized Machine Learning Framework for Health Risk Ranking

Doug Popken, Senior Vice President, NextHealth Technologies, Denver, CO, United States, doug.popken@nexthealthtechnologies.com, Jeremy Schendel

We have deployed a hybrid predictive modeling system in a production environment to predict different forms of medical utilization. Predictions are used for risk stratification and subsequent targeting of behavior changing interventions. Challenges and ongoing research directions are presented.

Online Advertising Markets

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Gabriel Weintraub, Stanford Graduate School of Business, Stanford, CA, 94304, United States, gweintra@stanford.edu

1 - Budget Management Strategies in Repeated Auctions

Anthony Kim, Stanford University, 39 Angell Court Apt. 106, Stanford, CA, 94305, United States, tonyekim@stanford.edu, Santiago Balseiro, Mohammad Mahdian, Vahab Mirrokni

One of the most important features advertising platforms often provide is budget management, which allows advertisers to control their cumulative expenditures. We study the "system equilibria" of a range of budget management strategies in terms of the seller's profit, buyers' utility and overall welfare. We show these methods admit a system equilibrium in a rather general asymmetric setting and prove dominance relations between them when buyers are symmetric. We also empirically compare the system equilibria of these strategies using real ad auction data.

2 - Price Discrimination with Ex-post Participation Constraints

Francisco Castro, Columbia University, New York, NY, United States, fcastro19@gsb.columbia.edu, Dirk Bergemann, Gabriel Weintraub

In online display advertising markets, publishers typically use a series of second-price auctions to "waterfall" a given impression, implicitly imposing different priorities and reserve prices over buyers. In addition, business constraints do not allow sellers to charge up-front fees. Thus motivated, we study a sequential screening problem with ex-post participation constraints. Our results shed light on the effectiveness of the series of waterfall auctions as a price discrimination device and on what type of improvements could be implemented in practice.

3 - Boosted Second-price Auctions, Simple Mechanisms to Capture Heterogeneity

Negin Golrezaei, University of Southern California, 812 S Marengo Avenue, Unit 6, Pasadena, CA, 91106, United States, golrezae@usc.edu, Max Lin, Vahab Mirrokni, Hamid Nazerzadeh

We propose a new auction format called boosted second-price auctions that can yield more revenue than widely used second-price auctions. In boosted second-price auctions, for each advertiser, a boosted bid is calculated, where the boosted bid is a linear function of submitted bids. Then, an advertiser with the highest boosted bid wins. We provide theoretical justification as to how new boosted second-price auctions increase revenue over second-price auctions when advertisers are heterogeneous. We further provide practical guidelines to determine boosts. We validate our guidelines theoretically and empirically using Google Ad Exchange data.

4 - Multiplicative Pacing Equilibria in Auction Markets

Christian Kroer, Carnegie Mellon University, Computer Science Department, 5000 Forbes Avenue, Pittsburgh, PA, 15213, United States, ckroer@cs.cmu.edu, Vincent Conitzer, Eric Sodomka, Nicolas Stier-Moses

Budgets play a significant role in auction markets implemented by Internet companies. To maximize the value provided to auction participants, spending is smoothed across auctions so budgets are used for the best opportunities. We consider a smoothing procedure that relies on pacing multipliers: for each bidder, the platform applies a factor between 0 and 1 that uniformly scales the bids across all auctions. We introduce the notion of pacing equilibrium, and prove that one or more equilibria always exist. Although computing a social welfare or revenue maximizing pacing equilibrium is NP-hard, we develop an integer program that can be used to characterize pacing equilibria and optimize among them.

Data and Information in Operations

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Fuqiang Zhang, Washington University in St. Louis, St. Louis, MO, 63130, United States, zhang@olin.wustl.edu

1 - Trade-off Between Flexibility and Productivity: An Empirical Analysis of Manufacturing Networks

Vivek Choudhary, INSEAD, Singapore, Singapore, Vivek.Choudhary@insead.edu, Sameer Hasija, Serguei Netessine

Manufacturing flexibility has been studied in many contexts and the celebrated "chaining" principle dictates how manufacturing networks should be structured. However, empirical analysis of this principle are non-existent. We analyze the impact of manufacturing network structure on productivity.

2 - Consumer Equilibrium, Pricing, and Efficiency in Group Buying: Theory and Evidence

Tunay Tunca, Unversity of Maryland, 8803 Courts Way, College Park, MD, 20742, United States, ttunca@rhsmith.umd.edu, Liu Ming

We study consumer equilibrium and network effects in group buying mechanisms. We theoretically model dynamic consumer behavior in group buying and derive the continuous time stochastic recursive equilibrium. Utilizing data from a major retail platform, we structurally estimate the model and predict the efficiency gains created by employing the mechanism.

3 - Demand Information Sharing for a Platform

Zekun Liu, Washington University in St. Louis, One Brookings Drive, Campus Box 1156, St. Louis, MO, 63130, United States, liu.zekun@wustl.edu, Fuqiang Zhang, Dennis Zhang

We study the information sharing strategy for a platform on which independent sellers engage in Cournot competitions. The platform possesses superior information than the sellers and may choose to share the information with the sellers. We characterize the optimal sharing strategy for the platform.

4 - Corporate Social Responsibility with Asymmetric Information

Xiaomeng Guo, Hong Kong Polytechnic University, Hong Kong, Hong Kong, xiaomeng.guo@polyu.edu.hk, Guang Xiao, Fuqiang Zhang

We develop a game-theoretic model to analyse the impact of consumers' social-responsibility concerns on a firm's pricing decision and profit. The firm can be either socially responsible or non-responsible, and consumers do not have perfect information about the firm's type. We find that the existence of information asymmetry may have interesting implications for the firm regarding corporate social responsibility.

Sponsored Session

Chair: Pnina Feldman, University of California-Berkeley, University of California-Berkeley, Berkeley, CA, 94720, United States, feldman@haas.berkeley.edu

1 - Welfare Implications of Congestion Pricing: Evidence from SF Park

Hsin-Tien Tsai, University of California, Berkeley, CA, 94703, United States, hsintien@berkeley.edu

Congestion pricing offers an appealing solution to urban parking congestion. We find that SFpark increases consumer and social welfare in congested regions but may hurt welfare in uncongested regions. Interestingly, congestion pricing may not surely reduce search traffic, because dispersed prices induce consumers to search for affordable spaces. In such cases, a simpler pricing policy may achieve higher welfare than a complex one. Lastly, congestion pricing increases social welfare compared to capacity rationing. The insights offer important implications for local governments considering regulation vs. market-based approaches for managing parking.

2 - Listen to the Crowd: Network Effects and Online Reviews in Restaurant Sales Forecasting

Shawn Mankad, Cornell University, Ithaca, NY, United States, spm263@cornell.edu, Qiuping Yu, Masha Shunko

Using a comprehensive dataset from a major restaurant franchise, we forecast weekly store sales using classical measures of service quality from internal surveys at focal and neighboring stores, in addition to online ratings. Our results show that higher quality at the neighboring stores leads to higher sales at the focal store. We also find that the accumulation of online reviews reduces the importance of internal quality surveys at focal and neighboring stores as predictors.

3 - The Customer May Not Always be Right: Customer Compatibility and Service Performance

Ryan Buell, Harvard Business School, Morgan Hall 429, Boston, MA, 02163, United States, rbuell@hbs.edu, Dennis Campbell, Frances X. Frei

Leveraging data from a nationwide retail bank, we investigate the extent to which customer satisfaction is explained by differences between customers (versus differences among factors more directly controlled by the firm). We find that differences among customers account for more than 90% of the explainable variation in customer satisfaction, and that although individual customers tend to experience the operation consistently, there are surprisingly large differences in experiences among customers. The presentation will also preview ongoing research that highlights how operational design choices can shape customer selection, and in turn, customer compatibility.

4 - Ratings and Version Updates in the Mobile App Market

Gad Allon, University of Pennsylvania, gadallon@wharton.upenn.edu, Yorgos Askalidis, Randall Berry, Nicole Immorlica, Ken Moon, Amandeep Singh

Mobile apps have become an economy with a projected market size of $77 Billion in 2017. One of the key features that distinguishes mobile apps from other types of digital goods (such as movies, songs or books) is that they have versions. A developer can release an app into a mobile app store, and can then keep adding, removing, or editing features of the app with subsequent version updates. We characterize the optimal strategy for timing such updates and structurally estimate the extent to which developers respond to demand-side incentives in a ratings-sensitive environment. We discuss implications for platforms and developers.

Game Theory

Contributed Session

Chair: Jian Yang, Rutgers University, Newark, NJ, United States, jyang@business.rutgers.edu

1 - Multi-strategy Trust Evolution Dynamics in the Venture Capital Syndicate Network

Heyin Hou, Southeast University, School of Economics and Management, Southeast University, Nanjing, 211189, China, heyinhou@hotmail.com, Jun Yin, Weida Chen

Venture Capital Syndicate Network (VCSN) derives from syndicate investments and relies on trust between venture capitalists (VCs). Based on a Wright-Fisher process, we introduce a general game model of trust evolution dynamics with multi-strategy and protection mechanism in the VCSN. Then, we explore influences of the protection mechanism on evolutionary stability conditions for the two-strategy and the four-strategy game models. Finally, we construct the global profit function for the VCs and adopt simulation experiments to verify the trust evolution dynamics for the two-strategy and the four-strategy game models.

2 - Augmented Probability Simulation Methods for Non-cooperative Games

Tahir Ekin, Assistant Professor of Quantitative Methods, Texas State University, 601 University Dr. Mccoy 451, San Marcos, TX, 78666, United States, t_e18@txstate.edu

We provide an augmented probability simulation framework to solve non-cooperative games, focusing on sequential problems. We include approaches to approximate Nash equilibria under common knowledge conditions, assess such solutions under a robust approach and, finally, approximate adversarial risk analysis solutions when lacking common knowledge. A security example serves as illustration.

3 - Competition for Blood Donations: A Nash Equilibrium Network Framework

Pritha Dutta, Doctoral Candidate, University of Massachusetts-Amherst, 6 H.Brandywine Drive, Amherst, MA, 01002, United States, pdutta@umass.edu, Anna B. Nagurney

In this paper, we develop a game theory model where blood service organizations compete for blood donations at collection sites in different regions based on the quality of their service and seek to maximize their transaction utilities. The governing equilibrium concept is that of Nash Equilibrium. The equilibrium is formulated as a variational inequality problem. An algorithm with nice features for computations is proposed and applied to a case study consisting of examples of increasing complexity. The results demonstrate that enhanced competition can improve the quality service level and that blood service organizations can also benefit from having collection sites in multiple regions.

4 - Column Generation Approach for Patrolling Games

Abdolmajid Yolmeh, Rutgers University, Dept of Industrial & System Engineering, 96 Frelinghuysen Road, Piscataway, NJ, 08854, United States, majid_yolmeh@yahoo.com, Melike Baykal-Gursoy

Most of the studies in the patrolling games area assume that all of the nodes have the same value or their values are fixed throughout time. However, in reality different nodes may have different values and these values may change over time. In this study we consider a patrolling game model on a general graph with different and dynamically changing node values and different attack times. We develop an efficient column generation approach to solve this problem. We also present a lower bound for the value of the game which can be used to terminate the column generation algorithm when a desired solution quality is reached. Computational experiments show the efficiency of the proposed column generation method.

5 - The Cooperative Game with Non-deterministic Payoffs

Jian Yang, Rutgers University, 1 Washington Park Rm 1084, Newark, NJ, 07102, United States, jyang@business.rutgers.edu

We study a non-traditional cooperative game where payoffs from coalitions are non-deterministic. Under various conditions, we show how the game's core can be related to that of a traditionally defined auxiliary. When individuals both contribute to coalitions in additive fashions and share a common mean-deviation utility, we show that increased risk aversion will promote the formation of the grand coalition. Core members can also be identified by solving nonlinear or even linear programs.

Operations Research for Health Systems in Emerging Countries

Sponsored: Manufacturing & Service Oper Mgmt, Healthcare Operations

Sponsored Session

Chair: Jorge Vera, Pontificia Universidad Catolica de Chile, Santiago, 7820436, Chile, jvera@ing.puc.cl

1 - A Proactive Policy to Manage Critical Inpatient Flow in Hospitals

Juan-Carlos Ferrer, Pontificia Universidad Catolica de Chile, Casilla 306 Correo 22 Stgo, Santiago, Chile, jferrer@ing.puc.cl, Jaime Gonzalez

Critical beds scarcity in Chilean hospitals produce overcrowding in emergency rooms, generating patients being hospitalized in urgency beds leading to large delays in emergency care. A Markov decision process was formulated to study the relation between bed availability and critical patient demand. This model shows a policy to proactively discharge patients from a unit, leaving space for an expected critical patient. The policy was tested in a simulation of a hospital in Santiago. The results show that, with the same amount of resources, both emergency patient waiting time and patient renege were reduced, increasing real capacity of the emergency room.

2 - Age Dependent Optimal Policies for Hepatitis C Treatment

Susana Mondschein, Universidad Adolfo Ibanez, 2640 Diagonal las Torres, Penalolen, Santiago, 7550000, Chile, susana.mondschein@uai.cl, Natalia Yankovic

Highly effective drugs for hep C virus have become available. However, their high prices require a cost effectiveness evaluation, due to the economic constraints most health care systems face. We developed a dynamic programming model with age dependent transitions, to determine optimal timing for the drug. The optimal solution is of a threshold-box type (no-yes-no, as function of the fibrosis stage). Using an age-dependent cohort, we achieved similar performance for the number of transplants, HCV deaths, and QALYs, with less overall expenditure, compared to the current Spanish policy. We also evaluated 3 heuristics, to improve both, life expectancy and expected QALYs, while containing the costs.

3 - Scheduling Operating Rooms under the Uncertainty of Surgery Duration and the Early Cancellation Decision

Guillermo Latorre-Núñez, Pontificia Universidad Católica de Chile, Santiago, Chile, golatorre@uc.cl, Vladimir Marianov, Armin Lüer-Villagra, Jorge Vera, Germán Paredes-Belmar

Operating Rooms (ORs) are among the most expensive resources in a hospital. Poor scheduling of the ORs can generate delays in the schedules, excess of overtime, even cancellation of some surgeries. This directly affects the hospital costs, as well as patient and medical team satisfaction. We solve the daily OR programming problem. It consists on assigning and sequencing the surgeries to the ORs, considering uncertainty in the surgeries' duration and a priori cancellation of surgeries. The objective is to minimize total costs. We use a robust type of approach.

4 - Admission Planning in Real Time for Emergency Services

Jorge Vera, Dept. Industrial and System Engineering, Universidad Catolica de Chile, Santiago, 7820436, Chile, jvera@ing.puc.cl Jorge Vera, Pontifical Catholic University of Chile, Santiago, Chile, jvera@ing.puc.cl, Ana Celeste Batista

Admission Planning Problem (APP) is concerned with deciding which patient to admit. The problem is complex due to service capacity, patient priorities and uncertainty in health care processes, such as patient length of stay. Off-line approaches have been proposed but they assume knowledge of the (uncertain) arrival rate of patients and these models would not be helpful for real-time bed allocation. We study an advance APP to control real-time bed allocation decisions for emergency patients considering on-line optimization. We derive mathematical insights to compare with the existing APP methodologies. We present computational results for a set of benchmarks in a public hospital from Chile.

Topics in Supply Chain Management

Sponsored: Manufacturing & Service Oper Mgmt, Supply Chain

Sponsored Session

Chair: Nikolay Osadchiy, Emory University, Atlanta, GA, 30322, United States, nikolay.osadchiy@emory.edu

1 - The Structure of Grocery Retail Markets and Food Waste

Elena Belavina, University of Chicago Booth School of Business, 5807 S.Woodlawn Ave, Chicago, IL, 60637, United States, elena.belavina@chicagobooth.edu

This paper examines the impact of grocery-store density on food waste using a stylized two-echelon perishable-inventory model. We find that the effects on household and store food waste are opposite, yet household waste dominate. We find that increasing store density reduces household and total food waste, typically achieving around 6% waste reduction for a 10% reduction in the distance between stores, while making groceries more affordable—- policy makers should promote laws that encourage new store openings. Finally, popular store targeted interventions must carefully weigh the intervention's impact on household food waste; otherwise, they might result in overall higher food waste.

2 - The Implications of Visibility on the use of Strategic Inventory in a Supply Chain

Abhishek Roy, Doctoral Student, University of Texas-Austin, 2110 Speedway Stop B6500, Austin, TX, 78712-1277, United States, abhishek.roy@utexas.edu, Stephen M.Gilbert, Guoming Lai

It is now widely accepted that, by holding strategic inventory, a retailer can influence the wholesale price offered by an upstream manufacturer and improve the efficiency of the supply chain. Yet, although it is typically assumed that the manufacturer can observe the retailer's inventory, this is often not the case in practice. We recognize that this inability to observe downstream inventory creates a form of hidden action and investigate the implications upon the use of strategic inventory under both linear and non-linear contracts.

3 - Operational Transparency with Investors

William Schmidt, Cornell University, 314 Sage Hall, Ithaca, NY, 14850, United States, wschmidt@cornell.edu

We use two complementary approaches to tie the impact of operational disruptions to changes in the firm's systematic risk in the aftermath of a disruption. First we show that compared to firms that comply with new transparency requirements, firms that do not comply experience a materially larger decrease in their market value after an operational disruption, even after controlling for the earnings impact of the disruption. Second, we use the change in the volatility of the firm's share price return as a proxy for the change in the firm's systematic risk to show that firms that do not comply experience a materially larger increase in risk after an operational disruption compared to firms that do comply.

4 - Evolution of Supply Networks
Nikolay Osadchiy, Emory University, 1300 Clifton Rd NE, Atlanta, GA, 30322, United States, nikolay.osadchiy@emory.edu, Vishal Gaur, Maximiliano Udenio

Using a large panel of firm-level buyer-supplier relationships, we study evolution of supply networks over time and implications for idiosyncratic and systematic risk.

Operations Management

Contributed Session

Chair: Katsunobu Sasanuma, Stony Brook University, Stony Brook, NY, United States, katsunobu.sasanuma@stonybrook.edu

1 - New Heuristics for the Lost Sales Inventory Problem
Peter L. Berling, Associate Professor, Lund University, Box 118, Lund, SE-22100, Sweden, peter.berling@iml.lth.se, Víctor Martínez-de-Abénis

We develop two heuristics based on the ideas of the "Single-unit decomposition approach" that originates from Axsäter (1990) and have been further developed by Muharremoglu and Tsitsiklis (2008) among others. Both heuristics use the expected cost per demanded unit inked to the next unit to be ordered but there is a difference in how this cost is defined. The best myopic decision, i.e. the one that minimizes the expected cost per demanded unit, can then be determined and implemented in respective heuristic. The resulting policy is a simple state-dependent base-stock policy and the numerical test show an improvement of the performance compared to traditional base-stock or time-phased policies.

2 - The Optimization Model of Inventory Control of Spare Components when Inventory Fails
Liying Cai, Mechanical Technology Institution, Shijiazhuang, China, cailiyingsharon@sina.cn

Properly control of spare components is the core element in optimization of inventory control of spare components. This paper established an optimization model of inventory control of spare components when inventory fails. Firstly, we established a single component system with its spare components' type being irreparable; then analyzed its system lifetime and cost; finally, a case study is carried out, which proved the effectiveness of the proposed optimal model made in this article.

3 - Stochastic Setup Cost Inventory Model with Backorders and Quasiconvex Cost Functions
Yan Liang, Stony Brook University, Department of Applied Mathematics and Statistics, Stony Brook, NY, 11794, United States, yan.liang@stonybrook.edu, Eugene A. Feinberg

This talk is concerned with a periodic-review setup-cost inventory model with backorders and holding/backlog costs satisfying quasiconvexity assumptions. We show that this model satisfies assumptions that imply the validity of optimality equations for discounted and average cost criteria and the family of discounted relative value functions is equicontinuous. We establish two groups of results: (i) optimality of (s,S) policies for infinite-horizon problems under discounted and average cost criteria, and (ii) convergence of optimal discounted lower thresholds s and discounted relative value functions to their average-cost counterparts as the discount factor converges to 1.

4 - Finding Repair Shop Priorities
Ece Zeliha Demirci, Postdoc Researcher, Eindhoven University of Technology, Eindhoven, 5600 MB, Netherlands, e.z.demirci@tue.nl, Joachim Jacob Arts, Geert-Jan van Houtum

We investigate the dynamic scheduling problem of a repair shop with a single server. The problem is to allocate the capacity of the repair shop between spare parts and decide on which part to repair first. Using the MDP formulation of the problem, we show that longest queue policy is optimal if the parts have identical characteristics and controlled with the same or different levels of base stock.

5 - Analysis of Perishable Inventory with Substitution under a Base Stock Policy
Katsunobu Sasanuma, Assistant Professor, Stony Brook University, Harriman Hall, Stony Brook University, Stony Brook, NY, 11794, United States, katsunobu.sasanuma@stonybrook.edu, Mohammad Delasay, Christine Pitocco, Thomas Raymond Sexton, Alan Scheller-Wolf

We study heuristic control policies for perishable inventory systems with substitution. We derive a simple state-dependent base stock policy by approximating the exact optimality condition. We demonstrate its validity by comparing with simulation results.

Robust Optimization and Applied Probability

Sponsored: Applied Probability

Sponsored Session

Chair: Chaithanya Bandi, Northwestern University, Evanston, IL, 60208, United States, c-bandi@kellogg.northwestern.edu

1 - Beyond Worst-case: A Probabilistic Analysis of Affine Policies in Dynamic Optimization
Omar El Housni, Columbia University, 110 Morningside Drive, Apt 64, New York, NY, 10027, United States, oe2148@columbia.edu, Vineet Goyal

Affine policies are widely used in dynamic optimization where computing an optimal adjustable solution is usually intractable. While the worst case performance of affine policies can be significantly bad, the empirical performance is observed to be near-optimal for a large class of problem instances. In this paper, we aim to address this stark-contrast. In particular, we consider a two-stage dynamic robust optimization problem with linear covering constraints and uncertain right hand side and show that affine policies give a good approximation on random instances generated from a large class of distributions including the commonly used distributions such as uniform and Gaussian.

2 - Learning-based Robust Optimization: Procedures an d Statistical Guarantees
Henry Lam, University of Michigan, 1205 Beal Avenue, Industrial & Operations Engineering, Ann Arbor, MI, 48109, United States, khlam@umich.edu, Jeff Hong, Zhiyuan Huang

We discuss a statistical framework to integrate data into robust optimization (RO) based on prediction set learning and a simple data-splitting validation scheme that achieves finite-sample statistical guarantees on the feasibility of the underlying uncertain constraints. We demonstrate how the framework satisfies a dimension-free sample size requirement on feasibility guarantees and how it provides a platform to integrate machine learning tools into RO driven by convoluted or high-dimensional data.

3 - Distributionally Robust Inventory Control when Demand is a Martingale
Linwei Xin, University of Chicago, Booth School of Business, Chicago, IL, 60637, United States, linwei.xin@chicagobooth.edu, David Goldberg

Independence of random demands across different periods is typically assumed in multi-period inventory models. In this talk, we consider a distributionally robust model in which the sequence of demands must take the form of a martingale with given mean and support. We explicitly compute the optimal policy and worst-case distribution in closed form. We prove that at optimality the worst-case distribution corresponds to the setting in which inventory may become obsolete at a random time, a scenario of practical interest. We also compare to the analogous setting in which demand is independent across periods, and identify interesting differences between these two models.

4 - Tractable Distributionally Robust Optimization with Data
Zhi Chen, National University of Singapore, NUS Business School, PhD B1-02 Biz2 Building, Singapore, 117592, Singapore, chenzhi@u.nus.edu, Melvyn Sim

We present a unified and tractable framework for distributionally robust optimization then encompasses a variety of statistical information including, among others things, expectation constraints, uncertain probabilities of regions and Wasserstein distance. We also introduce a new region based linear decision rule that provides better approximations of adaptive distributionally robust optimization problems and this can also be applied in situations when the recourse variables are discrete.The framework can be incorporated in an algebraic model tool box to facilitate modeling of robust optimization problems.

A/B Testing and Experimentation

Sponsored: Applied Probability

Sponsored Session

Chair: Ramesh Johari, Stanford University, Stanford, CA, 94305-4121, United States, ramesh.johari@stanford.edu

Co-Chair: David Walsh, Stanford University, San Francisco, CA, 94117, United States, dwalsh@stanford.edu

1 - Should A/B Testers Just be Bayesian?
David Walsh, Stanford University, 876 Shotwell Street, San Francisco, CA, 94110, United States, dwalsh@stanford.edu

Any large internet company runs thousands of A/B tests each week, because they provide objective feedback on which ideas work. Progress is incremental, so there are usually strong connections between new experiments and those run before. However, the default Frequentist approaches analyze each A/B test in isolation. A Bayesian framework can easily leverage such prior data, enabling more accurate results with shorter experiments. But we examine how it can also be vulnerable to strategic behavior by the experimenter. This undermines the objective feedback loop and enables the A/B tester simply to get the answer they want.

2 - Improving the Expected Improvement Algorithm
Russo Dan, dan.joseph.russo@gmail.com

The expected improvement (EI) algorithm is a popular strategy for information collection in optimization under uncertainty. To provide rigorous insight into EI, we study its properties in a simple setting where the goal is to choose the best among a finite set of options based on noisy measurements of their quality. In this framework, one can show formally that EI is far from optimal. To overcome this shortcoming, we introduce a simple modification of the expected improvement algorithm. Surprisingly, this simple change results in an algorithm that is asymptotically optimal for problems with Gaussian observation noise, and provably outperforms standard EI by an order of magnitude.

3 - Experimentation and Interference in a Marketplace
Nicholas Chamandy, Lyft, San Francisco, CA, United States, nickchamandy@gmail.com

Simple "random-user" experiment designs fall short in the face of complex dependence structures. These come in the form of large-scale social graphs or, more recently, spatio-temporal network interactions in a two-sided transportation marketplace. Naive designs are susceptible to statistical interference, which can lead to biased estimates of the treatment effect of interest. We consider the implications of interference for the design and analysis of experiments at Lyft. The literature on causal inference for infectious diseases offers some insights; these are briefly discussed. We motivate the use of large-scale simulation to both filter candidate tests and validate design methodology.

4 - A Personalized BDM Mechanism for Efficient Market Intervention Experiments
Imanol Arrieta, Stanford University, Stanford, CA, United States, imanol@stanford.edu

The BDM mechanism employs a second-price auction against a random bidder to elicit a consumer's willingness to pay. It has been recently utilized as a treatment assignment mechanism to evaluate policy interventions while simultaneously measuring the demand for the interventions. We develop a personalized extension of this mechanism using modern machine learning algorithms to predict an individual's willingness to pay and personalize the "random bidder". We show through simulations and a mock experiment on Amazon Mechanical Turk that our personalized BDM mechanism results in lower costs and provides better balance over covariates.

Operations/Innovative Financing Interaction

Sponsored: Manufacturing & Service Oper Mgmt, iFORM

Sponsored Session

Chair: S. Alex Yang, London Business School, London, NW1 4SA, United Kingdom, sayang@london.edu

1 - The Impact of Demand Uncertainty on Business Interruption Insurance
Yuan-Mao Kao, Duke University, Durham, NC, United States, yuan.mao.kao@duke.edu, Kevin Shang, N. Bora Keskin

We consider a firm that faces uncertainty about demand and possible business interruptions in advance of a selling season. In this setting, we formulate an optimal insurance design problem and study how different types of uncertainty affect the insurance offering as well as the firm's operational decisions.

2 - The Benefit of Scale: Crowdfunding Risks and Returns
Mabel Chou, National University of Singapore, 3 60 Pasir Panjang Rd, #01-11, Singapore, 118699, Singapore, mabelchou@nus.edu.sg, Guodong Lyu, Chung-Piaw Teo, Zhichao Zheng, Yuanguang Zhong

With the internet becoming more accessible than ever, entrepreneurs nowadays do not need to ask a few people for big sums of money. Instead, they can use the internet to talk to thousands or even more potential funders that each contribute a small amount. A natural question any potential funder would want to ask is: what are the risks and returns for this investment? To attract more funders, this is a question an entrepreneur needs to address properly. In this talk, we will help the entrepreneurs who are looking for crowdfunding to address this important question based on the new insights obtained from an application of Blackwell's Approachability Theorem.

3 - Signaling to the Crowd: Private Quality Information and Rewards-based Crowdfunding
Soudipta Chakraborty, Duke University, 100 Fuqua Drive, Durham, NC, 27708, United States, sc390@duke.edu, Robert Swinney

We consider the problem faced by a seller designing a rewards-based crowdfunding campaign via a platform like Kickstarter. The seller solicits donations from contributors, and if total contributions exceed a pre-determined threshold the campaign is a success, the seller receives all donations and each contributor receives a reward; otherwise, contributors are refunded their donations and the campaign is a failure. We determine how the seller should design her crowdfunding campaign when contributors know less than the seller about the value of the reward.

4 - Financing through Advance Selling: the Role of Social Ties
S. Alex Yang, London Business School, Regent's Park, London, NW1 4SA, United Kingdom, sayang@london.edu, Shuang Xiao, Yiangos Papanastasiou

Advance selling (the practice of selling a product in advance of its consumption date) has received significant attention in the recent operations literature, and has shown to be beneficial in a variety of industries as a tool for implementing price discrimination, reducing demand uncertainty, and managing capacity more effectively. More recently, start-up companies have been exploring the use of advance selling as a mechanism to help capital-constrained firms secure bank financing. This paper conducts a theoretical investigation into the efficacy of this alternative financing approach.

Topics on Service Design

Sponsored: Technology, Innovation Management & Entrepreneurship

Sponsored Session

Chair: Ioannis Bellos, George Mason University, Fairfax, VA, 22030, United States, ibellos@gmu.edu

1 - First Ranked First to Serve: Strategic Agents in Service Contest
Konstantinos Stouras, University of Virginia, Charlottesville, VA, United States, StourasK@darden.virginia.edu, Serguei Netessine, Karan Girotra

Work-from-home contact centers crowdsource demand to a pool of freelance agents, who are ranked in a predetermined number of priority classes based on their sales performance. The agents endogenously decide whether to participate and provide service on-demand. Agents' idle time is not compensated and higher ranked agents are utilized more and earn more. In a markovian queueing model with ex ante random capacity, we show that a coarse partition with two priority classes provide better incentives for agents to participate, maximize firm's profit and asymptotically maximize social welfare.

2 - Balancing Advisory and Service Delivery Efforts in a Nonprofit Organization
Priyank Arora, Georgia Institute of Technology, Atlanta, GA, United States, Priyank.Arora@scheller.gatech.edu, Morvarid Rahmani, Karthik Ramachandran

This paper studies how a nonprofit organization (NPO), which aims to maximize overall utility delivered to its clients, should balance levels of effort between advisory and service delivery stages.

3 - Consumption Decisions in Queues
Sezer Ulku, Georgetown University McDonough School of Business, 594 Rafik B. Hariri Building, Washington, DC, 20057, United States, su8@georgetown.edu, Christopher Hydock, Shiliang Cui

We study how the time spent waiting in line influences consumption decisions. We conduct a series of lab experiments and field studies in a variety of contexts, and observe that people deviate from rational behavior; we find that the longer people wait in line, the larger is their purchase quantity. In our final experiment, we show that two strategies that are used to improve consumer experience in queues can in fact result in lower purchase quantities.

4 - When Should Customers Control Service Delivery? Implications for Service Design
Ioannis Bellos, George Mason University, Enterprise Hall, 4400 University Dr., MS.5F4, Fairfax, VA, 22030, United States, ibellos@gmu.edu, Stylianos Kavadias

What do a Mongolian stir-fry restaurant, a discount broker, and a lab specializing in home-test kits have in common? They are examples of innovative services that base their success on customers' participation in the service delivery. Motivated by these practices we develop an analytical model to determine which parts of a service process should be performed by the service provider and which parts should be delegated to the customers.

Supply Chain Risk and Disruptions

Invited: InvitedNatural Hazard Planning

Invited Session

Chair: Eghbal Rashidi, Clemson University, erashid@clemson.edu

1 - Supply Chain Risk Analysis using Dynamic Fault Tree
Xue Lei, Iowa State University, Ames, IA, 50011, United States, xlei@iastate.edu

Supply chain risk analysis can help supply chain managers assess the risk in their supply chain and identify mitigation strategies. This research applies dynamic fault trees to assess the risk in manufacturing supply chains. Dynamic fault trees were developed to measure the reliability of systems in which the timing of failure for different components impacts total system failure. Applying dynamic fault trees to quantify the risk in a supply chain allows us to analyze how the time at which a primary supplier fails impacts the ability of a backup supplier to meet the delivery schedule. A new dynamic gate is proposed to consider the situation in which a firm relies on two primary suppliers.

2 - Risk Mitigation Models for Low Volume High Value (LVHV) Supply Chains
Michael Daniel Sherwin, Mississippi State University, 1767 Independence Way, Valencia, PA, 16059, United States, mdsherwin@gmail.com, Hugh Medal

Firms that produce low volume high value (LVHV) goods are more susceptible in many ways to delays within their respective supply chains than higher volume, higher value manufacturers. Due to the scarcity of capable suppliers to produce large, complex, highly precise items combined with the cost to develop a new supplier, a large number of LVHV firms have many single or sole source suppliers within their supply chains. We define supplier unreliability as the probability that a given product or service is not delivered on-time and develop a multinomial logistic regression model based on the variables that affect the unreliability of a LVHV supplier.

3 - Simulating Severe Supply Chain Disruptions with Multiple Suppliers and Firms
Cameron MacKenzie, Iowa State University, 3029 Black Engineering, Industrial and Manufacturing Systems Eng, Ames, IA, 50011, United States, camacken@iastate.edu

This presentation discusses a model and simulation of a severe supply chain disruption in which several suppliers suffer from disabled production facilities and firms that purchase goods from those suppliers may suffer a supply shortage. The simulation is applied to a case inspired by the Japanese tsunami.

5 - A Multi Stage Stochastic Programming Model for Semiconductor Supply Chain Risk Management
Eghbal Rashidi, Clemson University, Clemson, SC, United States, erashid@clemson.edu

We propose a three-stage stochastic programming model for a multi-product semiconductor supply chain risk management problem with uncertainty in process yield and product demand. The production processes are considered to follow a push policy in the Front-End, and a pull policy in the Back-End; with the die bank being the decoupling point. Outsourcing of production and process is considered for each process step in this study, at fabrication, sort, assembly and test. Computational results on test case problems show that our proposed stochastic programming model produces solutions that are significantly better than those produced by a deterministic expected value approach.

4 - Effectiveness of Resilience Strategies Against Supply Chain Disruptions: An Empirical Study
Milad Baghersad, Virginia Polytechnic Institute and State, Pamplin Hall, Room 1007, Blacksburg, VA, 24061, United States, mbaghers@vt.edu, Christopher Zobel

In this study, we empirically evaluate the effectiveness of three specific resilience strategies- operational slack, business diversification, and geographical diversification- in reducing the negative impacts of supply chain disruptions on firms' financial performance. Borrowing from the systems resilience literature, we develop four complementary metrics to quantify the negative impacts of supply chain disruptions on firms' performance. By adopting a more comprehensive view of firms' performance, we are able to develop new and expanded inferences about the types of impacts that the different strategies have on firms' performance after supply chain disruptions.

Multi-product Assortment, Pricing and Inventory Control

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Anran Li, Columbia University, New York, NY, United States, al2942@columbia.edu

1 - Complementarity Analysis for Optimal Multi Item Inventory and Partial Price Management
Sang Jo Kim, The Hong Kong University of Science and Technology, Clear Water Bay, Hong Kong, sangjo@ust.hk, Youyi Feng, Jianjun Xu

We study a multi-product joint inventory replenishment and pricing problem, where some pairs of products are economic complements but other pairs are substitutes. The seller periodically replenishes the products and controls the selling price of one of them while the other prices are exogenously determined. We show that there always exists an economic relationship between products that the seller should reflect in the optimal operations, and moreover, such a relationship may not be identical to that from the customers' viewpoint. Further, the optimal decisions should follow a base-stock list-price policy in which there exist a set of ideal values of the inventory levels and the price.

2 - Dynamic Pricing under Consumer's Sequential Search
Sajjad Najafi, University of Michigan, Ann Arbor, MI, United States, snajafi@umich.edu, Sami Najafi Asadolahi, Chi-Guhn Lee, Steven Nahmias

We study a firm offering a line of perishable products with fixed initial inventory over a finite horizon. Consumers arrive randomly and inspect products sequentially until they find a product to purchase (if any). Each consumer incurs a positive cost to inspect a product and hence may stop the sequential search without inspecting all the available items. The firm aims at offering the best sequence of products, as well as the best price for each product at each time. We show that, under some circumstances, (i) it is optimal to present products in a descending order of quality; (ii) surprisingly, the optimal price can increase over time.

3 - Approximation Algorithms for Product Framing and Pricing
Anran Li, Columbia University, Mudd 345, Columbia University, New York, NY, 10027, United States, al2942@columbia.edu, Guillermo Gallego, Van-Anh Truong, Xinshang Wang

We propose one of the first models of "product framing" and pricing. Product framing refers to the way consumer choice is influenced by how the products are framed, or displayed. We present a model where a set of products are displayed into a set of virtual web pages. We assume that consumers consider only products in the top pages, with different consumers willing to see different numbers of pages. Consumers select a product, if any, from these pages following a general choice model. We show that the product framing problem is NP-hard. We derive algorithms with guaranteed performance relative to an optimal algorithm under reasonable assumptions. We also present structural results for the pricing problem under framing effects.

4 - Incentive Issues in the Implementation of Urban Consolidation Centers

Xin Fang, Singapore Management University, 50 Stamford Road, #05-01, Singapore, 178899, Singapore, xfang@smu.edu.sg, Yun Fong Lim

The growth of e-commerce worsens the traffic congestion in cities. An urban consolidation center (UCC) is a potential solution, but many UCC projects have failed due to the reluctance of carriers to cooperate. In this paper, we develop a game-theoretical model that captures carriers' incentives. We find that the price that carriers are willing to pay for UCC's service is too low for UCC to make a profit. We propose that UCC can work as information intermediary among carriers for capacity sharing. In this case, UCC can always make a profit from commissions, and carriers have stronger incentives to cooperate.

Revenue Management in Fashion Retailing

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Kris Johnson Ferreira, Harvard Business School, Boston, MA, 02163, United States, kferreira@hbs.edu

1 - Pass-through Constrained Vendor Funds for Promotion Planning

Lennart Baardman, Massachusetts Institute of Technology, Operations Research Center, 77 Mass Ave, Bldg E40-130, Cambridge, MA, 02139-4307, United States, baardman@mit.edu, Georgia Perakis, Kiran Venkata Panchamgam

Pass-through constrained vendor funds are trade deals in which suppliers offer discounts to retailers, encouraging them to promote their products, while demanding pass-through to the customers. First, we analyze the supplier's strategic model about what vendor fund to offer. We show that pass-through constrained vendor funds eliminate forward-buying behavior and coordinate supply chains. Additionally, we model the retailer's operational problem about which vendor funds to select. To solve this model we propose a fast Lagrangian relaxation approach with analytical performance guarantees.

2 - Using Clickstream Data to Improve Flash Sales Effectiveness

Victor Martinez de Albeniz, IESE Business School, Av Pearson 21, Barcelona, 08034, Spain, valbeniz@iese.edu, Arnau Planas, Stefano Nasini

Flash sales retailers organize online campaigns where products are sold for a short period of time at a deep discount. The demand in these events is very uncertain, but clickstream data provides very detailed information about the shopping process. We build a model for shoppers' sequential decisions about visiting a campaign, obtaining product information and placing a purchase, which we validate using a large data set from a leading flash sales firm. Our forecasting model allows flash sales retailers to learn about the performance of new products in a few hours. We use this information to update prices so as to better match supply and demand forecast, and increase profits, on average by 20%.

3 - Assortment Rotation and the Value of Concealment

Kris Johnson Ferreira, Harvard Business School, Morgan Hall 492, Boston, MA, 02163, United States, kferreira@hbs.edu

We study one reason why frequent assortment rotations can be valuable. Namely, by distributing its seasonal catalog of products over many assortments, the retailer conceals a portion of its product catalog from consumers, injecting uncertainty into the consumer's relative product valuations. Rationally acting consumers may respond to this uncertainty by purchasing more products, generating additional sales for the retailer. We refer to this phenomenon as the value of concealment. We develop a consumer choice model and stochastic dynamic program to study the value of concealment.

Topics in Revenue Management & Pricing

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: N. Bora Keskin, Duke University, Durham, NC, 27708-0120, United States, bora.keskin@duke.edu

1 - Strategic Experimentation on Networks

Ramandeep Randhawa, University of Southern California, Bri 401p, 3670 Trousdale Pkwy, Los Angeles, CA, 90089, United States, ramandeep.randhawa@marshall.usc.edu, Kimon Drakopoulos

We study a dynamic game with multiple agents who are working to discover the quality (type) of an unknown project. An example is multiple R&D teams experimenting with new technology. At any time, an agent must decide whether to exert costly effort to "experiment" with the unknown project, or to wait in hope to see the outcome from other agents. We study this game in a networked setting, in which agents only have access to information from their neighbors. We find that agents with access to more information free-ride in optimistic scenaria, but work more in pessimistic scenaria.

2 - Learning Customer Preferences through Crowdvoting

Yifan Feng, The University of Chicago, 5807 S.Woodlawn Avenue, Chicago, IL, 60637, United States, yfeng4@chicagobooth.edu, Rene A. Caldentey, Christopher T. Ryan

A firm is launching a new product with multiple potential designs. To pick the design most preferred by customers, the firm invites potential customers to vote for their favorite designs. We study how to dynamically customize each voter's choice set, in order to most efficiently learn overall customer preferences.

3 - Dynamic Pricing for Batch Jobs in the Cloud

Hossein Jahandideh, 3777 Mentone Avenue, Apt 405, Los Angeles, CA, 90034-6473, United States, hs.jahan@gmail.com

A growing model for selling cloud computing services is for the cloud provider to accept batch jobs such as machine learning, classification, large-scale optimization, etc. and commit to finishing the job by a certain deadline. The provider receives service requests and quotes a menu of prices for different completion times, based on the job type and resources required to fulfill the job. This amounts to a dynamic network revenue management problem, for which we propose a dynamic pricing mechanism and demonstrate its effectiveness.

4 - Discontinuous Demand Functions: Estimation and Pricing

N. Bora Keskin, Duke University, Fuqua School of Business, 100 Fuqua Drive, Durham, NC, 27708-0120, United States, bora.keskin@duke.edu, Arnoud Victor den Boer

Motivated by online price-rankings that create discontinuities in demand functions, we consider a dynamic pricing-and-estimation problem with an unknown and discontinuous demand function. We show that ignoring such discontinuities results in substantial loss of revenues, and construct near-optimal policies that can handle demand discontinuities.

Recent Development in Electricity Markets

Invited: Energy Systems Management

Invited Session

Chair: Feng Qiu, Argonne National Laboratory, Lemont, IL, 60439, United States, fqiu@anl.gov

1 - Development of MISO Market to Embrace Current and Future Challenges

Yonghong Chen, Midwest ISO, 720 City Center Drive, Carmel, IN, 46032, United States, ychen@misoenergy.org

This presentation will first give an overview of recent developments at MISO to improve market clearing and market pricing efficiency. It will then discuss new initiatives to embrace future challenges.

2 - Multi-market Settlements and Computational Efficiency in Power System Planning Studies

Clayton Barrows, NREL, Denver, CO, United States, Clayton.Barrows@nrel.gov

The pathway towards modernized grids will consider enhanced coordination between markets and interconnected systems. However, traditional models of power systems represent one of two extremes: centrally-planned and operated models of an entire interconnection, or mostly-isolated market footprint models with little trade between neighboring systems. Neither of these approaches accurately reflects present or future power system operations. This research develops techniques to simulate decentralized coordination of operations and trade between entities while enhancing the computational efficiency of power system planning studies.

3 - A Market for Transactive and Deliverable Flexibility Based on Uncertainty Marginal Price

Hongxing Ye, Cleveland State University, Cleveland, OH, United States, hye9@hawk.iit.edu

The demand of flexibility increases dramatically with rapid growth of variable energy resource. We propose a new concept of transactive flexibility that can be bought and sold at the uncertainty marginal price (UMP). The proposed model positions deliverable flexibility cost-effectively, and its cost is allocated to flexibility consumers respecting a cost-causation principle. With a proposed solution approach, it provides an option to address emerging questions: 1) how to determine the flexibility amount while keeping ISO independent; 2) how to allocate deliverable flexibility to demander cost-effectively; 3) how to handle the high flexibility demand when the flexible resource is scarce.

4 - An Aggragator Business Model for Distribution Level Electricity Market

Shmuel S. Oren, Professor, University of California at Berkeley, 57 Hill Rd, Berkeley, CA, 94720, United States, oren@ieor.berkeley.edu, Clay Campaigne

The Californa ISO has introduced a tariff that recognizes aggragators of distributed resources at the distribution level as wholesale market participants. In this talk I will describe an end to end business model in which aggragators bundle demand response at the distribution level with intermitten renewable energy resources so as to create a firm energy product that is offered into the wholesale market. We describe the contract structure and incentive mechanism offered to customers and the deployment and bidding strategy of the bundled wholesale product.

5 - Modeling of Operating Reserve Demand Curve in ERCOT Electricity Market

Hailong Hui, ERCOT, Taylor, TX, United States, hhui@ercot.com

ERCOT has implemented the Operating Reserve Demand Curve (ORDC) in its Real-Time market since June 1, 2014. The Real-Time prices determined by Security Constraint Economic Dispatch (SCED) would be increased by the Real-Time Reserve Price which is determined based on remaining reserves in the system and a predefined ORDC to reflect the incremental value of scarce operating reserves. This presentation will discuss the current implementation of ORDC and the impact since it went live. Future possible improvement for ORDC in ERCOT market will also be discussed.

Clustering and Social Network Analysis

Sponsored: Telecommunications

Sponsored Session

Chair: Eli Olinick, Southern Methodist University, Dallas, TX, 75275-0123, United States, olinick@lyle.smu.edu

1 - The One Time Period Least Cost Influence Maximization Problem on Social Networks

Rui Zhang, University of Colorado, Boulder, CO, United States, Rui.Zhang@Colorado.edu, S. Raghavan

We consider an influence maximization problem where there is requirement that the diffusion of influence takes place within one time period, which is referred to as the one time period least cost influence problem (1TPLCIP). First, we propose a linear-time algorithm for the 1TPLCIP on trees. More importantly, we present a tight and compact extended formulation for the 1TPLCIP on trees. Then, we project the extended formulation onto the space of the original payment and node selection variables. Finally, we observe that the good formulation for trees is also a valid formulation on general graphs resulting in a stronger formulation for the 1TPLCIP on general graphs and discuss our experiment results.

2 - Finding the Hierarchy of Dense Subgraphs

Ahmet Sariyuce, Sandia National Laboratories, Livermore, CA, United States, asariyu@sandia.gov

Finding dense substructures in a network is a fundamental operation, with applications in social networks, visualization, and cyber-security, to name a few. Current dense subgraph finding algorithms usually optimize some objective, and only find a few such subgraphs without providing any structural relations or distribution over the graph. We define the nucleus decomposition of a graph, which represents the graph as a tree of subgraphs, called nuclei, where smaller cliques are present in many larger cliques. The tree of nuclei consistently gives a global, hierarchical snapshot of dense subgraphs which are higher quality than the state-of-the-art.

3 - Analysis and Comparison of Node Centrality Measures

Eli Olinick, Southern Methodist University, Dept Eng Mgmt Info and Systems, P.O. Box 750123, Dallas, TX, 75275-0123, United States, olinick@lyle.smu.edu

We propose a new clustering algorithm based on hierarchical maximum concurrent flow (HMCF) and its duality relation to the sequence of sparsest cuts, and discuss theoretical properties which make it more accurate and often more robust than many popular algorithms in the literature. We present a new measure of node centrality, determined from the HMCF, called flowthrough centrality, and empirical results comparing its improved stability relative to currently used centrality measurements employed in social network analysis when knowledge of the network topology is incomplete or in transition.

Psychology Neural Cognitive Computing

Invited: Social Media Analytics

Invited Session

Chair: Jiayin Qi, Shanghai University of International Business and Economics, Room 338, Bocui building, 1900th Wenxiang Road, Songjiang District, Shanghai, China, Shanghai, 201620, China, qijiayin@139.com

1 - Braking and Snowballing: The Moderating Roles of Adaptive and Maladaptive Cognitive Emotion Regulation Strategies between Job Stressor and General Health

Charles Deng, PhD, Shanghai University of International Business and Economics, Shanghai, 201620, China, dengsc@live.com

The present study investigated the moderating role of cognitive emotion regulation strategies between job stressor and general health. With the survey data from 495 employees, we found that job stressor was significantly and negatively associated with general health in both males and females with demographics being controlled.

2 - Recognition, Retrieval and Content Analysis for Massive Speech Data

Ji Wu, PhD, Associate Professor, Tsinghua University, Beijing, 100084, China, wuji_ee@tsinghua.edu.cn, Xiangling Fu

In this talk, I will talk about a speech content analysis platform developed at the Multimedia Signal and Intelligence Information Processing Lab at Tsinghua University and iFlytek for call centers in China that integrates ASR, audio indexing and spoken language understanding techniques. Quality inspection of custom service can be automatically achieved through this platform and its analysis results will be of a great help to strategy design and initiative marketing. The platform has been widely used in call centers in twenty provinces in China.

3 - Experimental Techniques for a Novel Neural-network-like System for Image Classification

Lai Xue, Shanghai Xiayun Culture Communication Co., Ltd, Shanghai, China, sheley1998@gmail.com

Artificial neural networks are extremely robust in areas such as image classification and speech recognition due to the fact that they could be trained instead of having to be explicitly programmed. This research presents several experimental non-biologically-inspired techniques for a neural-network-like system. An open-source web based implementation of this system is constructed to evaluate the efficiency of these techniques, provide realtime visualizations, as well as provide an interface for user interaction in order to further experiment with the capability of said system.

4 - Diffusion of Collective Action through Social Media Networks

Rostyslav Korolov, Doctoral Student, Rensselaer Polytechnic Institute, Troy, NY, 12210, United States, korolr@rpi.edu, Molly Renaud, David Mendonca, William A. Wallace

Previous work has shown that social media communications can be used to predict collective responses to certain events in the real world. However, the actual processes that enable this prediction remain unexplained. Considering collective behavior as a diffusion process, we expect the dynamic structural properties of the social network to play a role in the diffusion of collective behavior. We explore the possibility of using structure and dynamics of networks found in social media to predict collective action and identify events that may trigger it.

Algorithmic Game Theory and Data Science

Invited: Auctions

Invited Session

Chair: Vasilis Syrgkanis, Microsoft Research, Cambridge, MA, 02139, United States, vasy@microsoft.com

1 - Oracle-efficient Online Learning and Applications to Auction Design

Nika Haghtalab, Carnegie Mellon University, 5000 Forbes Avenue, CS Department, Pittsburgh, PA, 15213, United States, nhaghtal@cs.cmu.edu, Miroslav Dudik, Haipeng Luo, Robert Schapire, Vasilis Syrgkanis, Jennifer Wortman Vaughan

We consider the fundamental problem of no-regret learning from experts and its applications to auction design. We consider designing computationally efficient no-regret algorithms given access to an oracle that finds the historically best-performing expert. We apply these results to an online auction framework, where the seller's goal is to maximize its revenue by adaptively choosing the auction that is run on an online series of bid profiles. Our algorithms are general-purpose and, by design, can use little overhead to tap into existing tools that optimize auctions over historical data, thereby achieving online no-regret results without the need for building new specialized tools from scratch.

2 - Fairness Incentives for Myopic Agents

Jamie Morgenstern, University of Pennsylvania, Philadelphia, PA, United States, jamiemmt.cs@gmail.com

We consider schemes to incentivize myopic agents (such as Airbnb landlords, who may emphasize short-term profits and property safety) to treat arriving clients fairly, in order to prevent overall discrimination against individuals or groups. Our notion of fairness asks that more qualified individuals are never (probabilistically) preferred over less qualified ones [Joseph et al]. We investigate whether it is possible to design inexpensive (subsidy) or payment schemes for a principal to motivate myopic agents to play fairly in all or almost all rounds. We show both positive and negative results in the classic and linear bandit settings by upper and lower bounding the cost of fair subsidy schemes.

3 - Deep Learning for Predicting Human Strategic Behavior

James R. Wright, Microsoft Research, New York, NY, United States, jrwright@microsoft.com, Jason Hartford, Kevin Leyton-Brown

Predicting the behavior of humans in strategic settings is an important problem in many domains. Most existing work either assumes that participants are perfectly rational, or attempts to directly model each participant's cognitive processes based on insights from cognitive psychology and experimental economics. We present an alternative, a deep learning approach that automatically performs cognitive modeling without relying on such expert knowledge. We introduce a novel architecture that allows a single network to generalize across different input and output dimensions, and show that it significantly outperforms the previous state of the art, which relies on expert-constructed features.

Sponsored Session

Chair: Sagar Samtani, sagars@email.arizona.edu

1 - Aspect Extraction and Polarity Classification of Reviews Based on Deep Neural Network

Czang Yeob Kim, Korea University, Seoul, Korea, Republic of, czangyeob@korea.ac.kr, Pilsung Kang

Consumers buy products and leave opinions online. Companies need to analyze the voice of consumers online to understand the response of the market. Consumer reviews can be analyzed with sentimental analysis at the aspect-level to gain insights for new products by reflecting the consumer's response to current products' functionality. We propose a deep neural network-based aspect extraction and polarity classification model. The aspect extraction model identifies the product feature the review is referring to, whereas polarity classification determines the review is whether positive or negative to the identified feature. The proposed model is verified based on Amazon's review data.

2 - Semantics in Hacker Forums

Sandeep Suntwal, University of Arizona, Tucson, AZ, United States, sandeepsuntwal@email.arizona.edu

Cyberattacks are a high impact technological risk. Cyber threat intelligence (CTI) is the process of understanding the threats to an organization based on available data points focusing on understanding key threat actors and relevant threat vectors. In this talk, we discuss a framework to model online hacker forums into Heterogeneous Information Networks (HIN) and identify semantically similar hackers. Identifying similar hackers can aid in proactive CTI by providing actionable intelligence.

Social Media Analytics I

Invited: Social Media Analytics

Invited Session

Chair: Shu He, University of Connecticut, Storrs, CT, 06268, United States, shuhe@utexas.edu

1 - Online to Offline: Impact of Social Advertising on Pro-social Behavior

Cenying Yang, ycy_tracy@utexas.edu, Shun-Yang Lee, Andrew B. Whinston

We attempt to link the social advertising to offline pro-social behavior. We launch advertising campaign on Facebook and test its effectiveness on actual pro-social behavior in real world. We run field experiments under the context of political voting, blood donation and HPV vaccine shot. Psychological mechanisms that could potentially drive people to behave pro-socially are explored.

2 - Unraveling the "Social" in Social Norms: the Conditioning Effect of User Connectivity

Che-Wei Liu, University of Maryland, Robert H. Smith School of Business,, College Park, MD, 20742, United States, cwliu@rhsmith.umd.edu, Guodong Gao, Ritu Agarwal

We studied the effect of social norms on users' goal setting and goal attainment behavior. We find that while social influence increases the rate of goal setting, strikingly, we also observe an undesirable effect in that such influence leads to lower rates of goal attainment. Our examination of heterogeneous treatment effects shows that individuals with higher levels of social connectivity are the most susceptible. Further analysis suggests that social norms motivate these runners with high social connectivity to set up a goal beyond their own capabilities, resulting in low goal attainment. Our findings have important implications for the design of interventions in mobile health technologies.

3 - Impacts of Online Diaries on Sales of Credence Goods: Evidence from a Cosmetic Surgery Platform

Hongfei Li, University of Connecticut, School of Business, 2100 Hillside Road, Storrs, CT, 06269, United States, hongfei.li@uconn.edu, Gang Wang, Jing Peng, Xue Bai

Credence goods are defined as products whose quality is difficult to evaluate. While online reviews have found to be effective in driving sales of search and experience goods, little is known about its effectiveness on credence goods. Using data from a cosmetic surgery platform, we investigate the impact of a novel form of online reviews, i.e. diaries, on the sales of credence goods. We also examine how the effects are moderated by the risk of surgeries. We focus on two diary features: number of images and post duration. We find the number of images has a positive impact on sales and the effects are stronger for more risky surgeries. These findings shed some light on the online marketing of credence goods.

Financial Engineering

Contributed Session

Chair: Mingying Song, The University of Hong Kong, Hong Kong, mysong@hku.hk

1 - An Efficient Simulation Method for Normal Stochastic Volatility Model

Jaehyuk Choi, Peking University HSBC Business School, Shenzhen, China, jaehyuk@phbs.pku.edu.cn, Byoung Ki Seo

Normal, as opposed to lognormal, distribution is often suitable for modeling some financial observables which allow negative values. This study concerns a class of normal stochastic volatility model which includes the zero beta case of the popular Stochastic-Alpha-Beta-Rho (SABR) model. We provide an exact one-step simulation method and an efficient integration method for vanilla option pricing. A special case of the class admits a closed-form distribution, which can be used for modeling and simulating leptokurtic distributions.

2 - Structural Pricing of Cocos and Deposit Insurance with Regime Switching and Jumps

Olivier Le Courtois, Professor, EM Lyon Business School, Lyon, 69134, France, lecourtois@em-lyon.com, Xiaoshan Su, Xiaoshan Su

This article constructs a structural model with jumps and regime switching features that is specifically dedicated to the pricing of CoCos and deposit insurance. This model assumes that the assets of a bank evolve as a geometric regime switching double exponential jump diffusion and that debt profiles are of exponential type. The definition of an Esscher transform and the definition and implementation of a related matrix Wiener-Hopf factorization are developed. Then, valuation formulas for the bank equity, debt, deposits, CoCos and deposit insurance are obtained. An illustration concludes the paper and addresses the respective impacts of jumps and regime switching on the viability of a bank.

4 - A New Framework for Pairs Trading without Spread Functions

B. Ross Barmish, Professor, University of Wisconsin, 1415 Engineering Drive, ECE Department, Madison, WI, 53706, United States, barmish@engr.wisc.edu, Atul Deshpande

Pairs-trading methods in the literature largely rely on mean-reverting spread functions defined on the two stock prices under consideration. In this paper, we present a new framework for trading pairs which only requires a weak assumption involving correlation of the returns; i.e., no spread function is used. Within this idealized framework, our main result is a trading algorithm which is proven to guarantee a positive expected profit for the generic case when the expected returns are non-zero. Whereas traditional pairs trading relies on a widening spread function to obtain such a result, in our framework, we obtain such results for new situations.

5 - Investigate the Most Suitable Distance Measurement for Evaluation of Portfolio Composition

HeonBae Jeon, Yonsei University, Yonsei-ro 50, Bld#212, Seoul, 03722, Korea, Republic of, kimsm@yonsei.ac.kr, Hongseon Kim, Seongmoon Kim

This study suggests the portfolio composition evaluation in terms of the distance. Various vector distance measurements are compared to select a method to evaluate the portfolio composition. Through the regression analysis and the symmetry analysis of the distribution, we confirmed that Euclidean distance measurement is suitable to evaluate the portfolio composition. In addition, by comparing the portfolio performance, such as Sharpe ratio and return, with Euclidean distance, we checked the relationship between the portfolio performance and the composition. Therefore, we confirmed that Euclidean distance measurement can be used as a new analysis method for portfolio optimization models.

6 - Resilience Measurement of the Financial System Considering Recovery Solutions

Mingying Song, The University of Hong Kong, Haking Wong Room 824, Hong Kong, 999077, Hong Kong, mysong@hku.hk, Junwei Wang

Resilience is a property of the system, which focuses on the recovery ability of the system after a shock. Financial system plays a key role in our society. Therefore, resilience is especially important for the financial system. In this paper, we present a modified novel model for the risk contagion process of the financial system considering both network effects and market liquidity effects. In addition, we put forward several some recovery solutions. Based on these recovery solutions, we present a measure for resilience in the context of the financial system. A case study considering shocks of different levels is given to illustrate the whole risk contagion and resilience measurement process.

Operations/Finance Interface

Contributed Session

Chair: Philippe Chevalier, UCL, Louvain La Neuve, Belgium, philippe.chevalier@uclouvain.be

1 - Welfare Implication of Reforming Energy Subsidies

Hossein Mirzapour, University of Montreal (HEC School of Business), 920-6275 Northcrest, Montreal, QC, H3S.2N3, Canada, hossein.mirzapour@hec.ca, Michèle Breton

Reforming energy consumption subsidies has been frequently referred to as a quick-win policy to enhance environmental mitigation. One of the most recognized challenges of such reform is "selling" the new energy prices to citizens, particularly those with a more fragile purchasing power. Several studies have prescribed that a direct compensation mechanism may ensure the feasibility of reform. That practice was successful at the beginning in cases like Iran but did not proceed as expected. In this paper, we develop a stylized model to study the feasibility range of a subsidy reform where direct compensation is the instrument proposed to restore consumers' utility against increased energy prices.

2 - Managing Product Innovation in Sourcing

Yunke Mai, Duke University, 4225 Larchmont Road, Durham, NC, 27707, United States, yunke.mai@duke.edu, Sasa Pekec, Bin Hu

We study strategic decisions of an innovator and a competitor-supplier in the presence of spillover risk. The value of innovation is uncertain, and depends on the market acceptance of new product features or the innovative concept. We characterize equilibrium decisions for both firms and show that the innovator's optimal sourcing decision involves making tradeoffs between managing innovation spillover risk and (not-) securing market leadership position. The exact nature of this tradeoff depends on the structure of uncertainty in the product value that the innovation brings.

3 - Pricing and Prioritization in a Duopoly with Self Selecting Heterogeneous Time Sensitive Customers

Arvind Sainathan, Nanyang Business School, S3-B2a-03, Nanyang Business School, 50 Nanyang Avenue, Ntu, Singapore, 639798, Singapore, Asainathan@ntu.edu.sg

Time is often used as a differentiating factor in several service operations contexts by service providers (SPs) who prioritize their customers. We investigate the competition between two SPs involving a three-stage game. In the first stage, the SPs decide whether single service, in which customers are not prioritized, or differentiated service, with two service classes, should be offered. In the second stage, they set their prices. In the third stage, customers self-select and decide which option they should purchase. We consider impatient and patient customers. We use a novel approach to model customer self-selection. We characterize key equilibria and derive insights on when they occur.

4 - Optimal Forecast Disclosure in Ride-sharing Platforms

Hao Sun, Tsinghua University, School of Economics and Management, Tsinghua, Beijing, China, sunh3.13@sem.tsinghua.edu.cn, Peng Shi

We study how much forecast information on future demand should a ride-sharing platform disclose to drivers. We show that there is an interplay between the wage structure and the optimal disclosure policy. We show that when the wage is fixed, or when it is optimized but does not depend on the forecast, there are cases in which the platform should hide the forecast; we solve for the optimal disclosure policy in this case. However, when the wage is optimized and can depend on the forecast, then the platform should share as much forecast information as possible. We support our analytical findings with numerical experiments.

5 - Enterprise Optimal Selling Strategy when Considering Product Quality and Response Time

Guoqing Gao, Student, HUST, Room 328, School of Management, HUST, Wuhan, 430074, China, 1414902387@qq.com

Researching on a company's selling strategy under different conditions. Establishing the revenue function based on customer utility, and solve the problem to get the optimal strategy. The result suggests that firms should increase the product price and product quality, or decrease the response time when the production cost raises, or price sensitivity declines.

6 - Joint Dynamic Pricing and Lot-sizing under Competition

Philippe Chevalier, Professor, UCL, Louvain School of Management - CORE, L1.03.01, Louvain La Neuve, B1348, Belgium, philippe.chevalier@uclouvain.be, Alejandro Lamas

We study the joint dynamic pricing and lot-sizing problem when firms operate in a competitive environment. The pricing strategies of the firms should reach a Nash equilibrium. In order to compute the equilibrium efficiently, we propose a framework to bound solutions a priori. For this we use the fact that, under some conditions, pricing and inventory planning remain stable to marginal variations in competitors' prices. Our approach reduces the computation times by more than an order of magnitude, and we show that dynamic pricing can give significant profit improvements.

Aviation Forecasting

Sponsored: Aviation Applications

Sponsored Session

Chair: Reed Harder, Dartmouth, 14 Engineering Drive, Hanover, NH, 03755, United States, reed.haseltine.harder.TH@dartmouth.edu

1 - Airline Entry and Exit Predictive Modeling: A Structural Econometric Approach Versus Machine Learning

Chia-Mei (Mei) Liu, Federal Aviation Administration, Washington, DC, United States, Chia-Mei.Liu@faa.gov, Peng Wei, Xufang Zheng, Lei Kang

Airline passenger route choice forecast modeling has not been a widely explored area in the airline forecasting community even though it is studied quite often in the airline empirical papers. This paper takes the initiative to build a model to forecast passenger choice between direct and connecting flights. Individual itineraries from 2000 to 2016 are aggregated to the airport-pair level to form our target variable, the percent of passengers flying direct. We compare forecast performance between statistical modeling and machine learning. Our preliminary findings show great promise with machine leaning techniques.

2 - Predicting Performance of Traffic Management Initiatives

Alexander Estes, University of Maryland-College Park, College Park, MD, United States, aestes@math.umd.edu, Michael O. Ball, David J.Lovell

The Federal Aviation Administration uses traffic management initiatives to manage excess demand for resources in the national airspace system. We present methods for estimating the performance that a given traffic management initiative will produce under a given set of weather and traffic conditions. These methods combine a weighting scheme from Geographic Weighted Regression with forest-based regression methods. Estimates of the conditional density can be produced along with standard regression estimates.

3 - Airline Entry and Exiting Predictive Modeling: A Structural Econometric Approach

Kang Hua Cao, Hong Kong Baptist University, WLB 517, 34 Renfrew Road, Kowloon Tong, Hong Kong, kanghuacao@hkbu.edu.hk, Chia-Mei Liu, Vikrant Vaze

Airlines' decisions on entering or exiting a market are interrelated with other airlines' choices of entry and exit. Ignoring such strategic effects in forecasting can lead bias results. In this paper, we develop a discrete game and estimate the structural parameters of the payoff function. Thus, we recover valuable information about how airline makes entry/exit decisions and predict its future outcomes. We apply the structural econometric approach on a rich airline dataset, which features variables signaling the health of the economy such as employment and housing starts, network variables such as the connectivity at the airports, and competition variables such as Herfindahl-Hirschman Index.

4 - Combining Empirical and Game Theoretic Approaches to Airline Frequency Decision Modeling

Reed Harder, Dartmouth, 14 Engineering Drive, Hanover, NH, 03755, United States, reed.haseltine.harder.TH@dartmouth.edu, Vikrant Vaze

Forecasts of air traffic are leveraged by the Federal Aviation Administration in planning and policy making. In practice, airlines allocate capacity across their networks in the face of competition from other airlines on service frequency and price. We present approaches to combining empirical data on airline operations and game theoretic models of airline competition for the purpose of modeling and forecasting airline frequency decisions, and show the potential of behavioral models of airline decision making to augment air traffic forecasts.

Military Decision Making Under Uncertainty

Sponsored: Military Applications

Sponsored Session

Chair: Brian J. Lunday, Air Force Institute of Technology, Air Force Institute of Technology, WPAFB, OH, 45433, United States, brian.lunday@afit.edu

1 - A Military Variant of the Stochastic Inventory Routing Problem

Ethan Salgado, Air Force Institute of Technology, Dayton, OH, United States, ethan.salgado@afit.edu, Matthew J.D. Robbins, Darryl Ahner

Military commanders resupply forward operating bases from a central location within the area of operations mainly via convoys. Commanders must decide when and how much inventory to distribute throughout the area of operations while minimizing soldier risk; we call this problem class the military inventory routing problem (MILIRP). We examine the unique structure of the MILIRP by considering a small problem instance and prove that the optimal policy is monotone when a sufficient penalty is applied. Moreover we show how the unique structure can be exploited by utilizing monotone approximate dynamic programming algorithms.

2 - Analysis of Personnel Policy via Discrete Event Simulation

Lee Evans, University of Louisville, lee.evans@louisville.edu

An effective performance appraisal system is critical in identifying officers with the knowledge, skills, and abilities to lead the future force. This study uses discrete event simulation to analyze the effect of system structure, system dynamics, and human behavior on the performance of the United States Army's officer evaluation system. We demonstrate the efficacy of simulation optimization throughout the model development process, from model validation to model implementation.

3 - Using Markov Decision Processes with Heterogeneous Queueing Systems to Examine Military MEDEVAC Dispatching Policies

Phillip R.Jenkins, Air Force Institute of Technology, WPAFB, OH, 45433, United States, phillip.jenkins@afit.edu, Matthew J.D. Robbins, Brian J. Lunday

The goal of this research is to identify how to dispatch military medical evacuation (MEDEVAC) units to optimize system performance. A Markov decision process (MDP) model is developed to examine the MEDEVAC dispatching problem. A notional planning scenario is utilized to investigate differences between the optimal policy and three practitioner-friendly policies. Results indicate that dispatching the closest available unit is not always optimal. Moreover, an analysis of solution approaches for the MEDEVAC dispatching problem reveals that the policy iteration algorithm substantially outperforms the linear programming algorithms executed by CPLEX 12.6 in regards to computational effort.

Supply Chain Management, Green

Contributed Session

Chair: Samar K Mukhopadhyay, GSB SKK University, 53 Myeongnyung-dong 3-ga, Jongno-gu, Seoul, 110-745, Korezca, Republic of, samar@skku.edu

1 - Severity Assessment of Food Security Impediments in Food Supply Chain

Rachita Gupta, Research Scholar, Indian Institute of Technology Delhi, New Delhi, 110016, India, rachitagupta1987@gmail.com, Ravi Shankar

One of the major challenges worldwide is food security. The study proposes integrated Evidential Reasoning Algorithm to prioritize various food security impediments during logistics and distribution phases of Food Supply Chain. This would enable regulatory authorities to identify the most severe impediment and ensure affordable food security to the masses.

3 - Selection of Online Pickup Facility Networks using Fuzzy AHP

Choonki Min, YonginSongdam College, Yoingin, Korea, zcRepublic of, ckmin@ysc.ac.kr, Byeong-Yun Chang

Online pickup has become one of the most popular omnichannel services. In this study, we categorized the types of online pickup service facilities and analyzed the characteristics of each facility type. Using the fuzzy AHP method, the relative importance of online pickup service selection factors for each type of facility was derived from related experts.

4 - Managing Used Products: Who Should Refurbish?

Narendra Singh, Indian School of Business, Knowledge City, Sector 81, SAS.Nagar, Mohali, 140 306, India, narendra_singh@isb.edu, Ahmed Timoumi

We study a supply chain where a manufacturer sells new products through a retailer and decides whether to refurbish used products itself or to let the retailer refurbish them. We examine whether and when should a manufacturer allow the retailer to refurbish the used products.

5 - Brand Selection in a Supply Chain with Customer Returns

Jing Chen, Professor, Dalhousie University, 6100 University Avenue, Halifax, NS, B3 H.4R2, Canada, JChen@dal.ca, Bintong Chen

A retailer can sell a retailer can sell either or both of two brands, a well-known brand and a new brand, in a market supplied by two manufacturers in a manufacturer Stackelberg supply chain. We identify the conditions under which the retailer should choose one or both of the two manufacturers. We also show that an MBG enhances the profit of the manufacturer with low satisfaction rate, resulting in an increase in both the wholesale price and demand, but it has an opposite impact on the manufacturer with high satisfaction rate. In addition, an MBG enhances the retailer's profit and expands the overall market.

6 - Effect of CSR on Product Differentiation in the Presence of Cost Advantage

Samar K. Mukhopadhyay, Professor, University of Wisconsin-Milwaukee, 3200 N.Maryland Ave., Milwaukee, WI, 53211, United States, samar@uwm.edu, Guangliang Ye, Lu Xu

This paper links a firm's CSR strategy with its product differentiation strategy when it competes within another firm in a Hotelling type product differentiation line. The CSR firm maximizes a convex combination of its profit and a form of utility function, while the non-CSR firm maximizes its profit only. The CSR firm is also assumed to have a technological advantage that reduces its production cost. The interaction of the effects of both the extent of CSR is considered along with a scenario of asymmetric information. Our main results show that the degree of product differentiation is reduced when CSR is practiced. On the other hand, product differentiation increases with production cost advantage.

Diversification

Invited: INFORMS Special Sessions

Invited Session

Chair: Michael P Johnson, University of Massachusetts-Boston, Department of Public Policy & Public Aff, 100 Morrissey Boulevard, Boston, MA, 02125-3393, United States, michael.johnson@umb.edu

Co-Chair: Ruben Proano, Rochester Institute of Technology, Gleason College of Engineering, 81 Lomb Memorial Drive, Rochester, NY, 14623, United States, rpmeie@rit.edu

1 - Strengthening the Profession Through Diversity, Inclusion and Equity: Best Practices and Distinguished Practitioners

Michael P.Johnson, University of Massachusetts-Boston, Department of Public Policy & Public Aff, 100 Morrissey Boulevard, Boston, MA, 02125-3393, United States, michael.johnson@umb.edu

This session will introduce INFORMS conference participants to the mission and goals of the diversity, inclusion and equity committee. Panelists will describe the state of diversity and inclusion at INFORMS and other professional societies; at organizations whose employees and members participate in INFORMS and other professional societies; and the community of practice associated with operations research, management science and analytics, other STEM fields and related disciplines. Speakers and audience members will explore values, strategies and tactics that may enable INFORMS members of diverse backgrounds and experiences to achieve professional success, and that may enable organizations to produce greater social impact through best practices in diversity and inclusion.

MCDM Challenges in Highly-Constrained Problems

Sponsored: Multiple Criteria Decision Making

Sponsored Session

Chair: Stephen Henry, Sandia National Labs, Albuquerque, NM, 87109, United States, smhenry@sandia.gov

1 - Increasing Stakeholder Confidence in Multi-criteria Decision Analysis

Lucas Waddell, Sandia National Laboratories, 6401 Santa Monica Avenue NE, Apt 2085, Albuquerque, NM, 87109-4166, United States, lucas.waddell44@gmail.com

Optimization techniques are increasingly being used to inform high-consequence, national-scale decision making. These problems are typically multi-objective, nonlinear, and highly constrained, necessitating heuristic solution methods. Lack of optimality conditions, simplifying modeling assumptions, and imperfect data often leave stakeholders asking the gut-wrenching question, "How can I be confident that the analysis is leading to well-informed decisions?" This talk will explore practical ways that we have increased analyst and customer confidence in our modeling and optimization techniques.

2 - Addressing Inconsistent Trade-Space Exploration in Constrained Genetic Algorithms

Marissa Ballantine, Sandia National Labs, Albuquerque, NM, United States, mdballa@sandia.gov

The Whole System Trades Analysis Tool (WSTAT) employs a multi-objective genetic algorithm to identify Pareto optimal system designs that also adhere to the physical and operational constraints of the system. Systems with complex constraints can yield solutions that fall into one of several "system architectures" (defined by the manner the constraints are satisfied). Unfortunately, genetic operators can have difficulty jumping from one architecture to another, resulting in solution sets that are inconsistent from run to run. The talk presents research for automatically identifying multiple system architectures and ensuring the genetic algorithm represents each one fairly and consistently.

3 - Integrating System Design and Portfolio Optimization: A Computational Study

Matthew Hoffman, Sandia National Laboratories, 1624 Singletary Dr. NE, Albuquerque, NM, 87112, United States, mjhoffm@sandia.gov, Stephen Henry, Lucas Waddell, Frank Muldoon

Optimal system design should consider the portfolio into which the system will be integrated, but representing portfolio constraints in a multi-objective metaheuristic is typically intractable. We will review previous work that described a method for incorporating multiobjective system design tradeoff information into a mixed-integer portfolio optimization, using a convex hull representation of the system design Pareto set. We will discuss refinements to the method and provide computational results comparing this method versus a typical approach of including all system design Pareto solutions in the portfolio optimization and limiting to a choice of one design via SOS1 constraints.

4- Multi-objective Optimization for Task Mode Selection and Scheduling Utilizing a Genetic Algorithm

Alexander Dessanti, Sandia National Laboratories, P.O. Box 5800, MS.1188, Albuquerque, NM, 87185-1188, United States, adessan@sandia.gov

Schedule Management Optimization (SMO) is a new analytic capability that utilizes a multi-objective genetic algorithm to identify optimal combinations of activities to complete a set of tasks for a project as well as the optimal schedule for each set of selected activities. SMO is flexible and can account for various constraints such as precedence relationships between activities, resource availability, and fixed dates for certain activities. Focus will be on introducing the SMO capability, pros and cons of using a genetic algorithm for this type of problem, and how constraints are handled.

Health Care, Modeling and Optimization

Contributed Session

Chair: Haolin Feng, Sun Yat-sen University, Guangzhou, China, FengHaoL@mail.sysu.edu.cn

1 - Robust Nurse Scheduling

Kjartan Kastet Klyve, PhD Student, Norwegian University of Science and Technology, Prinsens gate 61, Trondheim, 7011, Norway, kjartan.klyve@ntnu.no, Henrik Andersson, Marielle Christiansen, Anders Nordby Gullhav

We present a tactical staff-scheduling problem at the neonatal intensive care unit at a Norwegian hospital, with a planning horizon of 6 months. We expand the scope of the typical tactical scheduling problem by formulating a scheduling model that produces schedules that are robust, i.e. well prepared for operational disruption. A simulation model, simulating staff absence and requirement at the ward, is also developed. We can thus test different strategies for robust scheduling in the scheduling model and evaluate the robustness of them using extensive historical data and the simulation model.

2 - Optimal Elective Surgery Scheduling Subject to Disruptions of Emergent Cases

Xiaoqiang Cai, Chinese University of Hong Kong, Dept of Systems Eng & Eng Management, Shatin NT, Hong Kong, xqcai@se.cuhk.edu.hk, Xianyi Wu, Xian Zhou

We consider the scheduling of elective surgeries in an operation theater that has to treat emergent patients with priority when they arrive (randomly). The problem is to find the optimal policy to determine the sequence of all operations in waiting. Optimal policies are derived based on the theory and techniques of stochastic scheduling and open bandit processes.

3 - Nursing Skill-mix Optimization in Inpatient Care Units using a Queueing Theory Approach

Parisa Eimanzadeh, Wichita State University, 1845 N.Fairmount,, Wichita, KS, 67260-0035, United States, p.eimanzadeh@gmail.com, Ehsan Salari

Hospitals often use nursing staff with different skill levels in inpatient units for cost-saving purposes. Highly trained nurses can perform all types of tasks while lower-skilled staff can only perform limited tasks. Additionally, the care intensity for each patient involves uncertainty and varies depending on their acuity. This research aims at finding optimal skill-mix configurations that minimize staffing costs while ensuring timely delivery of nursing care. A finite-source queueing model with multiple patient classes and server types is developed to analyze the nursing care delivery.

4 - Float Nursing Strategy: An Alternative Short Term Strategy in Hospitals to Minimize Nurse Shortage and Decrease Total Labor Cost

Kamil Ciftci, PhD Candidate, Lehigh University, 200 West Packer Avenue, Bethlehem, PA, 18015, United States, kac208@lehigh.edu

Float nursing strategy has been discussed in literature to reduce labor cost and provide more scheduling flexibility. However, float nursing strategy may decrease service quality because of changing work environment and location and no direct responsibility to assigned department. In this study, we investigate the effects of float nursing strategy using different regular nurse levels. While we find optimal number of nurses need to be hired as a float nurses, we determine how much more than based salary health Network should offer to them in order to decrease total labor cost. A case study with real data from a local hospital is used to prove efficiency of proposed approach.

5 - Adaptive Appointment Scheduling for Patient Centered Medical Homes

Ali Kemal Dogru, University of Alabama, Box 870226, Tuscaloosa, AL, 35487, United States, akdogru@crimson.ua.edu, Sharif Melouk

Incorporating patient centered medical home (PCMH) principles, we develop an adaptive appointment scheduling model for a primary care setting. We propose a simulation optimization approach to sequentially schedule appointments to provide desirable schedules from the perspective of both patients and the medical practice. Our data-driven algorithm is efficient and takes patient preferences into account. We benchmark against myopic and optimal algorithms. Computational results show that the adaptive scheduling approach provides significant value.
Key Words: Appointment Scheduling, Simulation, Patient Centered Medical Home

6 - Sequential Clinical Scheduling with Patient Re-entrant and No-show: the Case with MOHS Micrographic Surgery for Skin Cancer

Haolin Feng, Sun Yat-sen University, Lingnan College, Guangzhou, 510275, China, FengHaoL@mail.sysu.edu.cn, Mark Alan Lawley, Stephen Steidle

Mohs Micrographic Surgery (MMS) is a surgical method for the excision of skin cancers. It repetitively removes one skin layer at a time, with each removed layer sent for pathology examination until a cancer free layer is found. This results in same-day patient re-entrants. Currently patients often experience long in-clinic waiting due to the stochastic nature of layer removals and pathology. To improve patient experience and clinic revenues, we develop a model for MMS clinic scheduling. The model captures the key characteristics of the surgery-pathology and stochastic re-entrants. Theoretical results and numerical study demonstrating the improvement are provided.

Precision Manufacturing

Invited: Invited OR and Advanced Manufacturing

Invited Session

Chair: Prahalad Rao, University of Nebraska-Lincoln, University of Nebraska-Lincoln, Liconoln, NE, 68506, United States, prahalad.k.rao@gmail.com

1 - Quantifying Geometric Accuracy with Unsupervised Machine Learning: using Self-Organizing Map on Fused Filament Fabrication Additive Manufacturing Parts

Mojtaba Khanzadeh, Mississippi State University, Industrial and Systems Engineering Department, P.O. Box 9542, Mississippi State University, MS, 39762, United States, mk1349@msstate.edu, Linkan Bian

Complex geometries are attainable with additive manufacturing (AM), a major barrier preventing its use in mission-critical applications is the lack of geometric accuracy of AM parts. The objective of this work is to quantify the geometric deviations of additively manufactured parts from a large data set of laser-scanned coordinates using an unsupervised machine learning approach called the self-organizing map. The outcomes of this research are: (1) visualizing and quantifying the link between process conditions and geometric accuracy in FFF; and (2) significantly reducing the amount of point cloud data required for characterizing of geometric accuracy.

2 - Data Analytics and Optimization for Efficient E-warehousing
Ugur Yildiz, University of Waterloo, Waterloo, ON, Canada, uyildiz@uwaterloo.ca, Fatma Gzara, Samir Elhedhli

We analyze data from an e-commerce warehouse, characterized by high product variety and small order sizes, to model the order fulfillment process and identify areas of improvement. We focus on the order consolidation process and pose a problem that we call the Wave Sorting Problem. We provide models and solution methodologies based on column generation where the subproblem is solved using dynamic programming.

3 - A Novel, Dynamic Sparse Classification Approach for Online Monitoring of the Functional Properties of Printed Electronics in Aerosol Jet Printing Process
Roozbeh Salary, Ph.D. Candidate and Graduate Research Assistant, State University of New York (SUNY) at Binghamton, 25 Tracy Street, Binghamton, NY, 13905-1841, United States, rsalary1@binghamton.edu, Jack P. Lombardi, Mohammad Samie Tootooni, Darshana L. Weerawarne, Prahalad K. Rao, Mark D. Poliks

The goal of this work is online monitoring (and ultimately, closed-loop control) of the functional properties of aerosol jet-printed electronic devices. In pursuit of this goal, the objective is to develop a multiple-input, single-output (MISO) machine learning model to predict the device functional properties in a real-time fashion as a function of process parameters as well as 2D/3D morphology characteristics. The aim is to use the MISO model for in situ classification and thus, monitoring of line/device resistance in aerosol jet printing (AJP) process. The core hypothesis of the work is that line resistance is predicted (and as a result, monitored) online within 10% of offline measurements.

Matching in Two-Sided Markets with Social Impact

Sponsored: Public Sector OR

Sponsored Session

Chair: Ozlem Ergun, Northeastern University, Boston, MA, 02115, United States, o.ergun@neu.edu

Co-Chair: Tina Rezvanian, Northeastern University, Boston, MA, 02115-4420, United States, rezvanian.t@husky.neu.edu

1 - KUDU: A Mobile Market for Agricultural Trade in Uganda
Neil Newman, University of British Columbia, Vancouver, BC, Canada, newmanne@cs.ubc.ca, Nicole Immorlica, Kevin Leyton-Brown, Brendan Lucier, Richard Ssekibuule, John Quinn

In developing countries such as Uganda, agricultural markets exhibit inefficiencies as rural farmers have poor access to pricing information. Kudu is a two sided market for agricultural produce in Uganda seeking to address this problem using AI. Farmers and traders each submit bids to a centralized system using SMS and USSD (technologies available on non-internet-enabled phones) and a matching algorithm periodically proposes trades. This talk will discuss the challenges we have faced designing a market in this unique setting over the past four seasons of operation.

2 - Effect of Selfish Choices in Deferred Acceptance with Short Lists
Hedyeh Beyhaghi, Cornell University, Ithaca, NY, United States, hedyeh@cs.cornell.edu, Daniela Saban, Eva Tardos

We study the outcome of deferred acceptance when prospective medical residents can only apply to a limited set of hospitals. This limitation requires residents to make a strategic choice about the quality of hospitals they apply to. We study the effect of this strategic choice on the preferences submitted by participants, as well as overall welfare. We find that residents' choices in our model mimic the behavior observed in real systems where individuals apply to a mix of positions consisting mostly of places where they are reasonably likely to get accepted, as well as a few "reach" applications to hospitals of very high quality, and a few "safe" applications to hospitals of lower than their expected level.

3 - Optimal Trading and Shipping of Agricultural Commodities
Nicolas Stier-Moses, Universidad Torcuato Di Tella, Buenos Aires, Argentina, nstier@utdt.edu, Nicolas Merener, Ramiro Moyano, Pablo Watfi

We develop a model for a profit-maximizing firm that provides an intermediation service between commodity producers and end-users. We are motivated by the grain intermediation business at Los Grobo, one of the largest commodity-trading firms in South America. Producers and end-users are distributed over a realistic spatial network, and trade with the firm through contracts for delivery of grain during the marketing season. Under realistic capacities, network structure and shipping costs, we identify the optimal trading, storing and shipping policy for the firm as the solution of a minimum cost flow problem in a time-expanded network that captures both geography and time.

4 - Two-sided Stable Matching with Negotiations in Markets with Multiple Periods
Tina Rezvanian, PhD, Northeastern University, Boston, MA, 02115, United States, rezvanian.t@husky.neu.edu, Ozlem Ergun

It is a well-known fact that the core of match stays the same under any stable algorithms. Stable algorithms in multi-period two-sided markets come at the cost of continuous dissatisfaction for same group of agents, resulting in high turn overs, low overall welfare and ultimately, unsustainability over multiple periods. Many industries demand mechanisms that guarantee sustainability and perfect assignments over all periods. We use labor marker auction models to offer contract-like negotiations to agents, identified through a novel centrality measure that we introduce for two-sided markets. Proposed heuristic relaxes stability only to guarantee sustainability over multiple periods.

1 - A Method of Exploration of the Solution Space for Decision Support in Design of a Green Supply Chain
Lin Guo, University of Oklahoma, Norman, OK, United States, lin.guo@ou.edu, Warren Smith, Janet Katherine Allen, Farrokh Mistree

Multi-objective optimization models have been proposed to improve supply chain design, considering social and environmental goals as well as financial goals. However, optimization models search for single optimal solution that is sensitive to variations. In this paper, we propose a multi-goal model built on the construct of compromise Decision Support Problems (cDSP) to output solution space that is relatively insensitive to variations. A method of exploration of the solution space is used to provide us the insight on how to improve the feasibility robustness of the supply chain with multiple conflict goals.

2 - Modoalgos.jl: Computing Approximate and Exact Efficient Frontiers of Multiobjective Mixed Integer Linear Programs in Julia
Aritra Pal, Doctoral Candidate, University of South Florida, 4202 E. Fowler Avenue, Tampa, FL, 33620, United States, aritra1@mail.usf.edu

We introduce Modoalgos.jl (and 2 other related packages), a Julia package capable of computing the exact and approximate frontiers of both Biobjective and Multiobjective Mixed Integer Linear Programs using state of the art algorithms.

3 - B-pop: A Multi-parametric Programming Based Toolbox for the Global Solution of Bi-level Mixed-integer Linear and Quadratic Programming
Efstratios N. Pistikopoulos, Texas A&M.University, College Station, TX, United States, stratos@tamu.edu
Efstratios N. Pistikopoulos, Texas A&M.Energy Institute, College Station, TX, United States, stratos@tamu.edu, Styliani Avraamidou, Styliani Avraamidou, Nikolaos A. Diangelakis

We present a prototype toolbox, B-POP, a MATLAB toolbox for bi-level programming, for the exact, global and parametric solution of different classes of bi-level programming problems. The toolbox features i) bi-level programming solvers for linear and quadratic programming problems and their mixed-integer counter-parts, ii) a versatile problem generator capable of creating random bi-level problems of arbitrary size, and iii) a library of bi-level programming test problems. The toolbox is based on multi-parametric theory and our developed algorithms and software tools. A set of test problems was solved illustrating the computational performance and scalability of the toolbox.

Revenue Management, Pricing

Contributed Session

Chair: Alejandro Lamas, NEOMA Business School, Rouen, France, alejandro.lamas@neoma-bs.fr

1 - Spatial Distribution of Surge Prices under Incentive Compatible Driver Assignment

Shuangyu Wang, Columbia University, Rm 323 SW. Mudd Building, 500W. 120th Street, New York, NY, 10027, United States, sw2756@columbia.edu, Garud N.Iyengar, Vineet Goyal

In our work, we propose a fluid model for computing the optimal spatial distribution of surge prices on ride-sharing platforms in the presence of temporal demand shocks, to manage the mismatch in supply and demand of rides. The goal of surge is to maximize total revenue or throughput over the traffic network and the platform can assign drivers to riders but is constrained to respect driver incentives with respect to assignment deviations. Our main contribution is to show the structural properties of optimal surge prices with an efficient computation of surge prices.

2 - Dynamic Pricing when Customers Learn the Quality of the Product

Ruizhi Shi, University of Minnesota, 2600 University Avenue SE, Apt 413, Minneapolis, MN, 55414, United States, shixx588@umn.edu

In this talk, we consider a revenue management problem when customers give review ratings of the products and take that into account when making purchase decisions. In particular, we consider a seller selling a single product to a sequence of customers. Customers' utilities are based on both the price and other customers' rating. Each time, one customer comes and gives a rating which is drawn from a certain distribution, and the rating of the product will be updated after each customer's purchase. We derive optimal policy on how the seller should change its prices during the time horizon to maximize his revenue. We also derive lower bounds on the best performance of any policy.

3 - Competitive Revenue Management with Sequential Bargaining

Yuanchen Li, Purdue University, 2192 Tortuga Lane, West Lafayette, IN, 47906, United States, li1820@purdue.edu, Qi Feng, J. George Shanthikumar

We study the role of bargaining in competitive revenue management. The seller firms each have some fixed initial stocks and compete to sell to a random arrive stream of potential buyers who are heterogeneous in product valuation. We fully characterize the equilibrium outcome, which depends on the length of the selling season and the initial stock levels. When the selling season is up to three periods, the seller with a lower stock level is weakly preferred by an incoming buyer. When the selling season is longer than three periods, the seller with a higher stock level may win the competition.

4 - Dynamic Pricing for Multi-period Home Delivery

Alejandro Lamas, Assistant Professor, NEOMA Business School, Rouen, 76130, France, alejandro.lamas@neoma-bs.fr

We consider a firm that delivers goods (or provides service) to a set customers. When a customer requests a delivery, the firm charges a price based on the geographical location, the available capacity and the lead-time of the delivery. Since customers and firms agree on the lead-time of the delivery, the problem for the firm consists of setting prices for deliveries in a rolling-horizon. The problem suffers from the "curse of dimensionality", thus we propose heuristic approaches for obtaining efficient solutions.

5 - Optimal Pricing for Selling to a Static Multi-period Newsvendor

Xiao Alison Chen, University of Minnesota, 111 Church Street SE, ME 1101, Minneapolis, MN, 55455, United States, chen2847@umn.edu, Zizhuo Wang, Hongsong Yuan

This paper considers a multi-period supply chain model in which a supplier sells to a multi-period newsvendor. Such a problem is relevant in industries with long production lead times. We study the optimal pricing problem for the supplier. We derive procedures for solving the optimal prices and show that the optimal pricing sequence is decreasing in time. We also show that the optimal prices are increasing in the backorder cost when the cumulative demand functions have increasing generalized failure rates.

6 - Airline Switching Revenue with Price-guarantees

Fouad H. Mirzaei, Santa Clara University, Unit 3, 559 Alviso St, Santa Clara, CA, 95050, United States, fhmirzaei@scu.edu

Many airlines permit passengers to change the time of their flight by paying a switching fee. In this study, we model a firm which delivers two sequential homogeneous services and generates ancillary revenue from customers switching between two services. Without imposing any distributional assumptions, we analyze the firm's revenue function and derive the optimal switching fee. We also investigate the impact of the uncertainty in switching behavior of customers on the ideal switching policy.

Scheduling in Project Environment

Invited: Project Management and Scheduling

Invited Session

1 - Resource-Constrained Dynamic Programming with"Hot-Starting" for the Elementary Shortest Path Problem

Luis Novoa de Oro, The George Washington University, Washington, DC, United States, ljnovoa@gwu.edu, Ahmad I. Jarrah, Jonathan F. Bard, Daniel Chudnov

New hot-starting procedures to significantly improve the efficiency of a dynamic program (DP) for solving the Resource Constrained Elementary Shortest Path Problem are implemented and tested. The DP is integrated with bidirectional extensions, decremental state-space relaxation, 2-cycle elimination and a sharpest-to-date restricted set of unreachable nodes.

2 - Scheduling Public Requests for Proposals

Janne Kettunen, The George Washington University, Department of Decision Sciences, 2201 G.Street NW, Washington, DC, 20052, United States, jkettune@gwu.edu, Young Hoon Kwak

We show that the schedule for contracting public procurements can impact the number of proposals and thereby the cost of procured services or products. We formalize this previously unexplored problem of scheduling procurement contracting and develop an optimization framework to solve it. Furthermore, we develop heuristics that do not require solving optimization problems, such as (i) equal number with mixed cost scheduling heuristic and (ii) equal cost scheduling heuristic. We apply our optimization framework to the Florida Department of Transportation's procurement contracts scheduling problems and show that it yield significant cost savings over the actual schedules employed in practice.

3 - Establishing Actionable Visibility in Project Scheduling under Optimism, Heuristics, and Algorithmic Biases

Byung-Cheol Kim, Penn State, Erie, PA, United States, buk70@psu.edu

Establishing an actionable visibility into the future in terms of effective scheduling is a crucial challenge for successful management of a project. This session presents analytical approaches to establish the actionable visibility required for the project manager to make informed decisions under optimism, heuristics, and algorithmic biases. The presentation starts with illustrative examples of the situations where the project visibility is less actionable with incomplete and often biased information. Then a set of analysis tools is formulated based on best practices and proven techniques in project scheduling, risk analysis, and systematic error controls.

Economics of Online Platforms

Sponsored: EBusiness

Sponsored Session

Chair: Hossein Ghasemkhani, Purdue University, 425 W State Street, West Lafayette, IN, 47907, United States, hossein@purdue.edu

1 - The Advertising Big Picture: Analyzing the Cross Platform Synergies Between TV and Online Advertising

Mohammed S. Alyakoob, Purdue University, 2165 Cushing Drive, West Lafayette, IN, 47906, United States, malyakoo@purdue.edu

The advent of the internet naturally gave rise to digital advertising, which provides a unique and insightful avenue for researchers and practitioners to monitor customers' responses to a multitude of different types of advertisements. This research seeks to utilize this potential in combination with a detailed television advertising data set to gain insights regarding the synergies that exist between television and online advertising platforms and the way these interactions affect customer behavior. We study the relationships between the online and television advertising platforms and the impact these synergies have on a customer's propensity to purchase (convert) in an online setting.

2 - Level Up: Leveraging Skill and Engagement to Maximize Player Retention in Online Video Games

Yan Huang, University of Michigan, 701 Tappan Street, Ann Arbor, MI, 48109, United States, yphuang@umich.edu, Stefanus Jasin, Puneet Manchanda

We propose a novel two-stage data analytic modeling approach, combining statistical methods with optimization techniques to maximize customer retention via matching in the online video game industry. In Stage 1, we build a Hidden Markov Model (HMM) to capture the evolution of gamers' latent engagement state and calibrate the HMM using a longitudinal dataset obtained from a major video game company. We find high-, medium- and low-engagement-state gamers respond differentially to motivations such as achievement and challenge. In Stage 2, we develop a matching algorithm that learns a gamer's current engagement state and exploits that learning to match the gamer to a round to maximize retention.

3 - The Impact of an Augmented Reality Game on Local Businesses: A Study of Pokemon Go on Restaurants

Vandith Pamuru Subramanya Rama, Purdue University, West Lafayette, IN, United States, vandith@purdue.edu, Warut Khern-am-nuai, Karthik Kannan

Pokemon Go, an augmented reality technology based game incentivizes it's user to move in the physical world. Such incentives can have potential externalities to businesses associated with them. Using online reviews of restaurants as a proxy for sales and quality, we study the impact of Pokemon Go on local restaurants. We treat the release of Pokemon Go as a natural experiment and study the post-release impact for the associated restaurants. We find that restaurants that are located near PokeStops indeed observe a higher number of customers compared to restaurants that do not have PokeStops nearby. However, the online quality perception isnt affected due to this effect.

4 - Platform Control and Complementor Performance: Evidence from Mobile Apps

Anparasan Mahalingam, Purdue University, 403 W. State Street, Krannert Building, West Lafayette, IN, 47906, United States, anparasan@purdue.edu

We study how changes in platform control affect the performance of complementors. Leveraging the jailbreak of iOS 10 as a natural experiment, we examine how an exogenous deciency in iOS's gatekeeping policy affects the performance of mobile apps on iOS compared with apps on Android. We also show several boundary conditions shaping the effect of the jailbreak on apps' performance

1 - BOM Working Paper Competition Finalists

Michael Becker-Peth, University of Cologne, Albertus-Magnus-Platz, Supply Chain Management & Man. Sci., Cologne, 50923, Germany, michael.becker-peth@uni-koeln.de

Finalists in the BOM Best working paper competition will present.

2 - Discrimination with Incomplete Information in the Sharing Economy: Evidence from Field Experiments on Airbnb

Ruomeng Cui, Emory University, 1300 Clifton Rd, Atlanta, GA 30322, Atlanta, GA, 30322, United States, ruomeng.cui@gmail.com, Jun Li,, Dennis J Zhang

Recent research has found widespread discrimination by hosts against guests of certain races in online marketplaces, which endangers the very basis of a sharing economy â€" building trust in the communities. In this paper, we explore the root cause of discrimination and how to reduce discrimination. We conducted two randomized field experiments among 1,256 hosts on Airbnb by creating fictitious guest accounts and sending accommodation requests to them. We find that requests from guests with distinctively African American names are 19 percentage points less likely to be accepted than those with distinctively White names. However, a public review posted on a guestâ€™s page mitigates discrimination: when guest accounts receive a positive review, the acceptance rates of guest accounts with distinctively White and African American names are statistically indistinguishable. We further demonstrate that a negative review also significantly reduces discrimination. Our finding is consistent with statistical discrimination: when lacking perfect information, hosts infer the quality of a guest by race and make rental decisions based on the average predicted quality of each racial group when enough information is shared, hosts do not need to infer guestsâ€™ quality from their race, and discrimination is eliminated. Our results offer direct and clear guidance for sharing-economy platforms on how to reduce discrimination. Platform owners should motivate users to write reviews of one another and design a better mechanism to facilitate information sharing â€" especially information that signals guest quality.

3 - Modeling Newsvendor Behavior: A Prospect Theory Approach

Bhavani Shanker Uppari, INSEAD, 1 Ayer Rajah Avenue, Singapore, 138676, Singapore, BhavaniShanker.Uppari@insead.edu, Sameer Hasija

Problem definition: Studies have shown that the behavior of subjects in newsvendor experiments is not consistent with expected profit maximization as an assumption that is often made in inventory and supply chain management literature. Although prospect theory has been established as a popular model of behavioral decision making under uncertainty, it was considered to be inconsistent with observed newsvendor behavior (in particular, the pull-to-center effect) until a recent study proposed a prospect theory model that is consistent with the pull-to-center effect however, this model's ability in representing newsvendor behavior compared to other plausible prospect theory models is unexplored in the literature. This paper takes a more comprehensive approach in building several prospect theory-based newsvendor models, and evaluates their competence in representing the observed newsvendor behavior. An important feature of these models is that they are not only consistent with the pull-to-center effect, but they also can accommodate individual level heterogeneity in order quantities. This is in accordance with the findings from recent research that there is remarkable heterogeneity in the order quantities in newsvendor experiments, and that the behavior of a significant proportion of individuals is inconsistent with the pull-to-center effect.

Practice/eBusiness II

Contributed Session

Chair: Xinyi Ren, University of Maryland-College Park, College Park, MD, United States, xinyi.ren@rhsmith.umd.edu

1 - Measuring Consumer Surplus in the On-demand Economy: The Case of Ride Sharing

Meng Liu, Massachusetts Institute of Technology, 100 Main Street, Sloan Room 412, Cambridge, MA, 02142, United States, mengliu@mit.edu

To understand the consumer welfare impact of ride-sharing platforms, we estimate a demand model for rides. Leveraging on the unusually rich taxi, Uber, and Lyft trip records from NYC as well as Uber and Lyft dynamic pricing and wait time, we find substitution patterns that vary by location, time, and demographics. We further provide strong evidence that consumers value time and dislike waiting. The consumer welfare gain mainly comes from two channels: first, the tech-aided ride-sharing platforms represent a more efficient "meeting" technology, causing an overall reduction in wait time; second, the platforms "fill in" the previously under-served communities by taxi.

2 - Neighborhood Selection Methods to Improve Recommendation Diversity

Pelin Atahan, Assistant Professor, Ozyegin University, Nisantepe Mah Orman Sok Cekmekoy, Istanbul, 34794, Turkey, pelin.atahan@ozyegin.edu.tr

Recommendation systems help match users with products in order to ease information overload of users. Recommendation systems are being utilized in many domains such as e-commerce, social networks, entertainment, and apps. While majority of the literature has focused on improving recommendation accuracy, recent studies have focused on other aspects of recommendation quality, such as diversity. However, there is typically a trade-off between recommendation accuracy and diversity. We propose a method that carefully selects neighbors in a way that will help learn the unique tastes of the users in order to improve recommendation diversity, while not compromising recommendation accuracy.

3 - Customer Differentiation with Shipping as an Ancillary Service: Free Service, Prioritization, and Strategic Delay

Arvind Sainathan, Nanyang Business School, S3-B2a-03, Nanyang Business School, 50 Nanyang Avenue, Ntu, Singapore, 639798, Singapore, Asainathan@ntu.edu.sg

A service provider/retailer offers ancillary service (e.g. shipping by an online retailer) to impatient and patient customers, who may be heterogeneous both in their delay sensitivities and service valuations. She can use prioritization and/or strategic delay to differentiate them. We characterize the optimal solutions under both exogenous and endogenous capacities, and find conditions in which these key service delivery features are present: (i) free service, (ii) single/differentiated service, (iii) split of customers, and (iv) strategic delay.

4 - Pricing in the ERA FF Omni-channel Retailing
Nevin Mutlu, Assistant Professor, Eindhoven University of Technology, Eindhoven University of Technology, P.O. Box 513, Eindhoven, 5600 MB, Netherlands, n.r.mutlu@tue.nl

In this research, we develop an analytical model to study an omni-channel retailer's pricing policy across store and online channels, considering that different channels exhibit different cost structures, yet an inconsistent pricing scheme across channels may lead to consumer confusion, resulting in important long-term effects.

5 - It is Hard to Please the Consumers. the Impact of Omnichannel Operation on Firm Performance
Xinyi Ren, PhD Student, University of Maryland-College Park, College Park, MD, 20742, United States, xinyi.ren@rhsmith.umd.edu, Philip Evers

In this paper, we analyze the impact of omnichannel operation on firm performance. In particular, we predict that after a retailer launches the mobile app, it will not only affect the sales from the online platform, but also exert spillover effects to the Brick and Mortar (B&M) channel. In addition, because of the differences in regard to the information delivery mechanism, we propose that there exist distinguished return rate as well as cart abandonment decisions between the PC customers and mobile customers. By adopting econometric models, we empirically investigate the hypotheses using company level data.

Activity-based Modeling and Emerging Mobility Patterns

Sponsored: TSL, Urban Transportation

Sponsored Session

Chair: Feixiong Liao, f.liao@tue.nl

1 - A Comprehensive Scenario Analysis of Household use of Autonomous Vehicles and On-demand Ride Sharing
Yashar Khayati, State University of New York at Buffalo, Buffalo, NY, United States, yasharkh@buffalo.edu
Yashar Khayati, State University of New York at Buffalo, Buffalo, NY, United States, yasharkh@buffalo.edu, Jee Eun Kang, Mark Karwan, Chase Murray

We define a framework to model and evaluate potential household-level use of Autonomous Vehicles (AVs) and on-demand ridesharing (ODR) systems. We introduce a new formulation, the Household Activity Pattern Problem for AV and ODR, to simulate the travel patterns of people. A comprehensive scenario analysis is designed to assess the impact of various parameters such as parking availability in different urban areas, parking cost, ODR cost, value of travel time, AV operational cost, etc. on travel behavior changes. We define and measure new metrics to suggest new policies on parking locations, AV ownership, ODR coverage.

2 - Representing Carsharing Operators Competition in an Agent-based Simulation of Transport
Milos Balac, ETHZ, Zurich, Switzerland, milos.balac@ivt.baug.ethz.ch, Francesco Ciari

In the past, almost all carsharing services were local monopolies of a sort. However, as carsharing is gaining momentum, competition among different operators in the same area is becoming a reality and research on this issue is required. Therefore, the goal of our ongoing work is twofold: 1) to implement a carsharing framework suitable to incorporate both land use information and socio demographic characteristics of people in the study area and 2) to model the competition of different free-floating carsharing operators. The simulations and analysis conducted will give us an opportunity to draw conclusions on the impacts on all involved parties of having a competing carsharing environment.

3 - Modeling Mode Choice and Parking Service for Commuting Trips in a Corridor: An Inclusion of Self-driving Cars
Cong Zhao, Key Laboratory of Road and Traffic Engineering of the Ministry of Education, Tongji University, 4800 Cao'an Road, Shanghai, China, Shanghai, 201804, China, zhc_tongji@163.com, Feixiong Liao, Yuchuan Du, Xinghua Li

This paper studies multimodal travel patterns in a corridor with the presence of self-driving cars. We focus on the commuting trips along a corridor connecting two CBDs, where commuters are distributed and allowed to use public transit (PT), park-and-ride, and pick-up and drop-off services.. The proposed model integrate choice of mode, paring location and departure time within a dynamic traffic assignment (DTA) simulation system. Computational experiments are conducted to demonstrate the proposed formulations and potential applications for the evaluation of transport and land pricing policies.

4 - Incorporating Free-floating Car Sharing into an Activity-based Dynamic User Equilibrium Model in Multi-state Super Network
Qing Li, Nanjing University of Information Science & Technology, 219 Ningliu Road, Nanjing, 210044, China, liqing_321@hotmail.com, Feixiong Liao, Harry J.P. Timmermans, Haijun Huang, Jing Zhou

Free-floating carsharing (FFC) has recently received increasing attention. Existing studies related to FFC have been rare to model the dynamic choice of free-floating shared cars (SC) in daily multi-modal multi-activity trip chains. This study proposes a tolerance-based multi-class dynamic activity-travel assignment model in an extended multi-state supernetwork representation. Dynamic traffic flows and supply-demand interactions of SC are formulated endogenously. Three numerical examples demonstrate that fleet size, distribution, rental and parking prices of SC significantly influence the choice of activity-travel patterns.

Chair: Rakesh Reddy Mallipeddi, Texas A&M University, College Station, TX, 77843-4217, United States, rmallipeddi@mays.tamu.edu

1 - The Effects of Social Media Sentiment on Engagement
Rakesh Reddy Mallipeddi, Texas A&M.University, 320 Wehner - 4217, Mays Business School, Dept of Info&Operations, College Station, TX, 77843-4217, United States, rmallipeddi@mays.tamu.edu

Individual celebrities or "human brands" from different fields ranging from sports to art to politics use various social media platforms to connect and communicate with their target audience. We empirically analyze the effects of content generated by human brands on the popular social media platform, Twitter, on audience engagement.

2 - How Information Sharing Helps Firms Fight Return Abuse: A Network Perspective
Serkan M. Akturk, Texas A&M.University, 4217 TAMU, Wehner 320 M, College Station, TX, 77843-4217, United States, makturk@mays.tamu.edu

We study a setting where a service provider offers return information exchange (RIE) services, which exhibit network externalities for participating retailers and manufacturers. Firms can participate in the network by paying a subscription fee and benefit from shared databases. The RIE provider can offer customer proling, product tracking, and joint networks. Under different conditions of the network service, we derive the equilibrium subscription fees and the sizes of the customer profiling, product tracking, and joint networks. Our results provide strong managerial insights for retailers, manufacturers, and the RIE provider.

3 - Impact of Online Retail on Movement of Long Tail Products: An Empirical Study
Samayita Guha, sguha@mays.tamu.edu, Rakesh Reddy Mallipeddi, Subodha Kumar

Retailers have now started to pay attention to long tail products that individually have low demand but in aggregate can combine to create higher demand than few best-selling products. In this study, we propose an econometric model to examine the movement products in and out of long tail using data from a large retailer.

4 - How Much to Invest and How Much Information to Share for Information Security
Yueran Zhuo, University of Massachusetts, 121 Presidents Drive, Amherst, MA, 01003, United States, yzhuo@som.umass.edu, Senay Solak

In this study, we model the interplay between information sharing and technology investments for information security. As part of our findings, we identify policies defining optimal technology investments and information sharing levels for firms in different industries. We also present results on the value of sharing security information in different information security environments.

5 - How Information Sharing Helps Firms Fight Return Abuse: A Network Perspective
Serkan M. Akturk, Texas A&M.University, 4217 TAMU, Wehner 320 M, College Station, TX, 77843-4217, United States, makturk@mays.tamu.edu

In this paper, we study a setting where a service provider offers return information exchange (RIE) services that exhibit network externalities for participating retailers and manufacturers. Under different conditions of the network service, we derive equilibrium subscription fees and the sizes of the customer profiling, product tracking, and joint networks.

1 - Modeling Frequency Regulation in Isolated Power Systems

Miguel Carrion, Universidad de Castilla-La Mancha, Avda Carlos II I.s/n, Toledo, Spain, miguel.carrion@uclm.es, Rafael Zarate-Miñano, Miguel Cañas, Ruth Domínguez

Isolated power systems are particularly vulnerable to power plant failures. In order to guarantee the supply security in these systems, electrical energy is provided by a large number of small-sized generating units. Because of the low inertia of these units, frequency fluctuations in isolated systems are much higher than in interconnected systems. Considering this framework, we propose a stochastic unit commitment with frequency regulation constraints to model the operation of a renewable-dominated isolated power system. Uncertain renewable units and demand side management actions are explicitly considered. The proposed formulation is tested in a realistic case study.

2 - Arbitrage Pricing in Revenue Cap Regulation of Electricity Distribution

Timo Kuosmanen, Aalto University, Runeberginkatu 22-24, Helsinki, Finland, timo.kuosmanen@aalto.fi, Tuan Nguyen

Revenue cap is a widely used instrument in the regulation of local monopolies such as electricity and gas distribution firms. Due to its simplicity, most regulators apply Capital Asset Pricing Model (CAPM) to set the rate of return for the capital invested. However, the expected return and associated risks dependent on several latent factors besides the single market factor used in CAPM. Arbitrage Pricing Theory (APT) provides a more general and flexible approach to assess the risk and return. This paper explores the practical aspects of applying APT in regulation. We examine the real world example of revenue cap regulation of electricity distribution firms in Finland.

3 - An Energy Infrastructure Adaptation Framework for Changing Climatic Conditions

Site Wang, Clemson University, 100 Freeman Hall, Clemson University, Clemson, SC, 29634, United States, sitew@clemson.edu Site Wang, Los Alamos National Labotoary, TA-03, Building 1690, Room 101C, Los Alamos, NM, 87545, United States, sitew@clemson.edu, Russell Bent, Carleton Coffrin, Donatella Pasqualini, Nathan Urban, Sandra D.Eksioglu, Scott J. Mason

In recent years, global climate change has highlighted potential issues for coastal area energy infrastructure reliability. Changing climate increases uncertainty in predicting extreme weather such as tidal incursion and stronger, more frequent hurricanes. As it is critical to adapt energy infrastructures to these potential risks, we present a stochastic optimization framework for infrastructure adaptation to uncertain weather events using state-of-the-art climate simulation models for stochastic quantification. Our framework can provide decision makers with forward-thinking plans that consider adaptation costs and risks under exogenous stochastic hurricane events.

Design of Transportation Infrastructure and Services

Sponsored: TSL, Intelligent Transportation Systems (ITS)

Sponsored Session

Chair: Yu Zhang, University of South Florida, 4202 E. Fowler Ave., ENB118, Tampa, FL, 33620, United States, yuzhang@usf.edu

1 - A New Resilience Measure for Infrastructure Restoration Plan Optimization Considering Unmet Demand in Transportation System after Disruptive Event

Tingting Zhao, Research Scholar, University of South Florida, 4202 E Fowler Avenue, Tampa, FL, 33620, United States, tingtingzhao@mail.usf.edu, Yu Zhang

A bi-level optimization problem is formulated for restoration plan optimization of transportation infrastructure system after a disruption, e.g. flood, hurricane or other natural disasters. The upper-level problem is to maximize the system resilience index, combining mobility and accessibility, with limited resources. The lower-level one is a network flow assignment problem considering unmet demand in the system after the disruption. We propose an efficient heuristic algorithm for solving this problem and examine its performance with a typical road network (Sioux-Falls network). With multiple random disruptions in the experiment system, enormous combinations of damaged links are generated. The restoration plan optimization method proposed in this work could effectively identify the links to be restored with resource constrains. Furthermore, we vary the number of damaged links to examine its impact on system resilience performance. All these numerical analysis results show that the proposed method could be of great help for decision makers not only for restoration stage but also for identifying critical road section sets that need more attention for maintenance.

2 - Scheduling Models in Multimodal Transportation Networks with Commuter Preferences

Julia Y. Yan, Massachusetts Institute of Technology, Cambridge, MA, 02143, United States, jyyan@mit.edu, Dimitris Bertsimas, Yeesian Ng

Modern transportation systems in urban settings are increasingly complex. Public transportation services are often operated at large scale and under tight budget constraints. Furthermore, passengers are able to make choices between a variety of commuting options. We develop novel formulations for minimizing system backlog in multi-modal networks, while accounting for operator budget concerns and commuter preferences. Our formulations can solve within minutes, and we show improvement over heuristics through simulations on real data from the Boston MBTA network.

3 - A Stochastic Programming Approach for Electric Vehicle Charging Network Design

Sina Faridimehr, Wayne State University, 4815 Fourth Street, Manufacturing Engineering Building, Detroit, MI, 48202, United States, sina.faridimehr@wayne.edu, Saravanan Venkatachalam, Ratna Babu Chinnam

Advantages of electric vehicles (EV) include reduction of greenhouse gas and other emissions, energy security, and fuel economy. The societal benefits of large-scale adoption of EVs cannot be realized without adequate deployment of publicly accessible charging stations. We propose a two-stage stochastic programming model to determine the optimal network of charging stations for a community. We conducted computational experiments using various publicly available data sources, and benefits of the solutions are evaluated both quantitatively and qualitatively for a given community.

4 - Revenue Management in Urban Parking Systems with Learning and Competition

Yuguang Wu, University of Wisconsin, Madison, WI, United States, wu376@wisc.edu, Qiao-Chu He, Xin Wang

We consider decentralized garages who maximizes their revenue when the parking demand is uncertain but spatially correlated. A "smart parking" company provides demand forecast to increase system efficiency. At an individual garage level, we analyze the optimal operational strategy to leverage its limited capacity. At a system level, we investigate the optimal parking data sharing policy for the society. We aim to provide guidelines for the "smart parking" company concerning the design of information system towards more efficient utilization of urban parking resources.

5 - Optimal Snow Removal Facility Locations for Stochastic Snowfall

Yufeng Zhang, University of Minnesota, 500 Pillsbury Drive S.E., Room 175, Minneapolis, MN, 55455, United States, zhan4879@umn.edu, Avinash Unnikrishnan, Alireza Khani

A MIP formulation is proposed for the optimal locations of snow truck stations to minimize the capital and operating cost of snow removal operations. Uncertainties of snowfalls are modeled by a chance constraint, which takes the correlation of snowfalls into consideration. The stochastic problem is reformulated to a MICQP to make it practically applicable for realistic problems. Several variations of the problem are solved based on the real case of the state of Minnesota.

R&D Issues in Agribusiness

Invited: Agricultural Analytics

Invited Session

Chair: Saurabh Bansal, Penn State University, Penn State University, State College, PA, 16801, United States, sub32@psu.edu

1 - Optimizing the Classification of Soybean Varities as Elite Varities in a Three Stage Experimentation

Durai Sundaramoorthi, Washington University in Saint Louis, 10352 Conway Road, Saint Louis, MO, 63131, United States, dsundaramoorthi@gmail.com, Yujin Lee

As world population grows, the, need for more food is increasing. On the other hand, land available for farming is reducing. Agribusinesses use a multi-year testing strategy to narrow down the choice of new varieties introduced by breeders. Syngenta -an agribusiness - uses a three stage experimentation to choose a handful of elite soybean varieties at the end of stage three by starting with thousands of varieties in stage one. We use machine learning and optimization to identify elite varieties at the end of stage three.

3 - Design of Internet of Things (IoT) Framework for Agricultural Sector (IoT-Agro)

Pachayappan Murugaiyan, Pondicherry University, Tamilthai Nagar, Puducherry, 605001, India, pachayappanvn@gmail.com

In this paper an Internet of Things (IoT) framework for agricultural sector (IoT-Agro) in particular for sugar cane industry is proposed. IoT-Agro can best control and monitor the growth environment of sugar cane, achieve high and stable yield of sugar cane, monitor the pesticide level in crop, water level and soil moisture and also control the cultivation wastages. Based on proposed IoT-Agro framework a new collaboration model between the farmer (producer), mills (production) and government is designed. The proposed collaboration model will create a live communication platform and instant decision making flexibility between the decision maker's viz. farmers, mills and governments agencies

4 - Supplier Opportunistic Behavior in Post-disaster Agriculture Supply Chain

Hsin-Tsz Kuo, Doctoral Student, National Taiwan University, Taipei, 10617, Taiwan, d01741003@ntu.edu.tw, Jiuh-Biing Sheu

This paper address the causal relationships among supplier opportunistic intention, supplier power asymmetry, magnitude of disaster, and its antecedents in a post-disaster agriculture supply chain. We proposed a research model that supplier power asymmetry can moderate the relationships between supplier opportunistic intention and supplier attitude of competitor influence.

Finance Methods

Sponsored: Financial Services

Sponsored Session

Chair: Christoph Frei, University of Alberta, Edmonton, AB, T6G 2G1, Canada, cfrei@ualberta.ca

Co-Chair: Abel Cadenillas, University of Alberta, Edmonton, AB, T6G 2G1, Canada, abel@ualberta.ca

1 - Bail-ins and Bailouts: Incentives, Connectivity and Systemic Stability

Benjamin Bernard, UCLA, Los Angeles, CA, United States, benbernard@ucla.edu, Agostino Capponi, Joseph E. Stiglitz

We analyze the stability of an interbank network, in which subsidized bail-ins or public bailouts can be coordinated to stop financial contagion. Banks are willing to contribute to a subsidized bail-in only if the social planner's threat to not bail out insolvent banks is credible. We characterize the optimal bail-in plan and show that the socially preferable network structure shifts from densely connected networks for small shocks to sparsely connected networks for large shocks. The presence of this resolution plan affects interbank trading decisions and we show that banks aim to arrive at a network structure that is "too interconnected to fail," thereby forcing the government to a public bailout.

2 - Optimal Contracting and Consumption/Portfolio Selection with Limited Commitment

Hyeng Keun Koo, PhD, Ajou University, Suwon, Korea, Republic of, koo_h@msn.com

Recently there has been a steady growth of literature on optimal contracting/equilibrium with limited commitment. In particular, there is now a newly emerging literature on contracting theory with limited commitment in continuous-time. There has also been a literature on consumption/portfolio selection with liquidity(or borrowing constraints). I will explain the connection between the two strands of literature and discuss new results relevant to the two strands of literature.

3 - The Optimal Band of Government Stabilization Fund

Abel Cadenillas, University of Alberta, Department of Mathematical Sciences, Edmonton, AB, T6G 2G1, Canada, abel@ualberta.ca, Ricardo Huaman-Aguilar

To mitigate the negative consequences of a crisis, an instrument of fiscal policy is the stabilization fund, which is a mechanism to save money in the good economic times to be used in the bad economic times. We present a model to study the optimal management of a stabilization fund.

4 - Managing Counter Party Risk in Over-the-counter Markets

Christoph Frei, University of Alberta, Mathematical and Statistical Sciences, CAB 621, Edmonton, AB, T6G 2G1, Canada, cfrei@ualberta.ca, Agostino Capponi, Celso Brunetti

We study how counterparty risk affects trading decisions in over-the-counter markets. Banks first manage their default risk, and then decide on credit default swap (CDS) trading volumes to hedge against an aggregate risk factor. Our model predicts that perfect risk sharing is only done between safe banks, while riskier banks maintain diverse post-trade exposures. The costly actions exerted by banks to reduce their default risk are not socially optimal. Banks may choose to reduce their default probabilities below the socially optimal level, depending on trade size limits and costs of risk management. The model produces new empirical predictions which are borne out by data from the CDS market.

Recent Advances on Facility Location and Network Design Problems II

Sponsored: Location Analysis

Sponsored Session

Chair: Takamori Ukai, Keio University, Yokohama, 2238522, Japan, ukai@ae.keio.ac.jp

1 - Optimal Management Model for Road Maintenance by City Government

Mondo Sugiyama, The University of Tokyo, Ce408. 4-6-1, Komaba, Meguroku, Tokyo, 1538505, Japan, mondo@iis.u-tokyo.ac.jp, Yudai Honma

For the local government, the road maintenance and management is one of the important duties. The works of road maintenance lasts for many divergences including the identification of the repair points and the real repair, and the road total distance is also enormous. Therefore, effective scheduling planning of road maintenance is essential. In this study, the possibility to apply the scheduling model in the field of operations research to the road maintenance and management is examined. Based on the real road repair data in Japan, more effective repair scheduling plan will be proposed.

2 - Reliability Network Design for an Aircraft Door Management System

Lukas Schaefer, University of Edinburgh, JCMB, Room 6324, The King's Buildings, Edinburgh, EH9 2DG, United Kingdom, lukas.schaefer@ed.ac.uk

The door management system (DMS) is a safety system in an aircraft to check if all doors are properly closed and the cabin is correctly pressurized. As for every critical system in an aircraft, it has to meet safety regulations (redundancy, reliability) and should be designed optimally in terms of weight, costs, power consumption or reliability. This talk will introduce a new MILP formulation of the optimal redundancy and reliable design for a DMS. Furthermore, it will present an exact solving method for the redundancy problem and a heuristic for the reliability/redundancy problem.

3 - Big Data Location Analytics – Predicting Purchase Location with Mobile Location Data

Karthik Babu Nattamai Kannan, PhD Candidate, IT Management, Scheller College of Business, Georgia Tech, 800 West Peachtree NW, Atlanta, GA, 30308, United States, karthikbabu.nk@scheller.gatech.edu, Sridhar Narasimhan

We work with a leading national mobile carrier in the USA to explore how its customers choose the location of brick-and-mortar store to purchase or upgrade wireless service. We explore how understanding people's travel patterns is helpful in choosing the optimal number of stores in a given market based on maximum coverage model. We explore literature on firm expansion and franchising to develop a machine learning based heuristic solution procedure (work in progress).

4 - Ratio of Visible Green Associated with Pedestrian Location and Visual Line

Takamori Ukai, Keio University, 3-14-1, Hiyoshi, Kouhoku-ku, Yokohama, 2238522, Japan, ukai@ae.keio.ac.jp, Osamu Kurita, Yuki Hirasawa

Green gives people relaxing, comfortable and some positive effects. Ratio of visible green is an index that represents the ratio of greenery part to the entire vision field. Although some municipalities in Japan have employed this index to their policies, there are some differences between measuring methods that municipalities have employed. Furthermore, it is time consuming to measure it by taking photographs, because one have to go to the site.Therefore, it is meaningful to propose new convenient method for estimation. In this talk, we define ratio of visible green as the ratio of solid angle of trees to unit semi-sphere and propose estimation method regarding trees as spheres.

Statistical and Optimal Learning

Sponsored: Simulation

Sponsored Session

Chair: Ilya O. Ryzhov, University of Maryland, 4322 Van Munching Hall, University of Maryland, College Park, MD, 20742, United States, iryzhov@rhsmith.umd.edu

1 - Optimization of Tree Ensembles

Velibor Misic, University of California Los Angeles, Los Angeles, CA, United States, velibor.misic@anderson.ucla.edu

Decision trees and tree ensemble models such as random forests are often used to predict the effect of different decisions. While such models are widely used for predictive purposes, little is known about how to use them for effective decisions. In this talk, we consider the problem of finding a decision that is optimal with respect to a tree ensemble model. We formulate this problem as a mixed-integer optimization model and present theoretical results on the structure of this model. We demonstrate the value of our methodology on real datasets and present two detailed applications to drug design and multiproduct pricing.

2 - Markov Decision Processes with Exogenous Variables

Robert Louis Bray, 830 Hinman Ave., 2s, Evanston, IL, 60202, United States, robertlbray@gmail.com

I present two new dynamic program solution methods: endogenous value iteration and endogenous policy iteration. I define the exogenous space of a Markov decision process as the vector space comprising the set of value function deviations that never influence the policy function. My algorithms iteratively apply Bellman contractions, projecting the portion of the value function that lies in the exogenous space to zero at each step. When the exogenous space is one-dimensional, my algorithms are equivalent to relative value iteration and relative policy iteration; but when the exogenous space is multi-dimensional, my algorithms can be faster.

3 - Derivative-based and Derivative-free Adaptive Sampling Trust Region Optimization

Raghu Pasupathy, Purdue University, West Lafayette, IN, United States, pasupath@purdue.edu, Susan R.Hunter, Sara Shashaani, Fatemeh S. Hashemi

We will present an adaptive sampling trust region method for solving unconstrained stochastic optimization problems where the objective function can only be estimated using an inexact oracle, e.g., Monte Carlo or quasi-Monte Carlo simulation. We will discuss both derivative-based and derivative-free versions of the algorithm, along with convergence calculations. We will also briefly demonstrate a global complexity result in a specific deterministic inexact oracle setting.

4 - Rate-optimality of the Complete Expected Improvement Criterion

Ye Chen, University of Maryland, 1305 Mathematics Building, University of Maryland, College Park, MD, United States, yechen@math.umd.edu, Ilya O.Ryzhov

Expected improvement (EI) is a leading algorithmic approach to simulation-based optimization. However,it was recently proved that, in the context of ranking and selection, some of the most well-known EI-type methods cause the probability of incorrect selection to converge at suboptimal rates. We investigate a more recent variant of EI (known as "complete EI") that was proposed by Salemi, Nelson, and Staum (2014), and summarize results showing that, with some minor modifications, complete EI can be made to achieve the optimal convergence rate in ranking and selection with independent Gaussian noise. This is the strongest theoretical guarantee available for any EI-type method.

Applications of Facility Logistics - I

Sponsored: TSL, Facility Logistics

Sponsored Session

Chair: Amir Gharehgozli, Texas A & M University, Galveston, TX, 77553, United States, gharehga@tamug.edu

1 - Emission Control Strategies in the Maritime Transport: LUG vs. Scrubber Debate

Okan Duru, Nanyang Technological University, 50 Nanyang, N1-01C-95, Singapore, 638798, Singapore, duruokan@yahoo.com

This paper investigates the trade-off between three major strategies for controlling Sulphur emissions from ships due to the new international regulations. According to the recent international regulation, shipping firms will need to change their fuel type or implement an emission control device to comply with the sulphur emission limits. Each of these choices will eventually have advantages and disadvantages in terms of cost and efficiency. This paper evaluates the selection of relevant control strategy for various kinds of ships.

2 - Berth Allocation – Do we have it all Wrong?

Stefan Voss, University of Hamburg, Von-Melle-Park 5, Hamburg, 20146, Germany, stefan.voss@uni-hamburg.de

The Berth Allocation Problem (BAP) aims at assigning and scheduling incoming vessels to berthing positions along the quay of a container terminal. During the last decades many terminal operators and academics have developed algorithms and decision support systems for optimizing berth planning including the BAP. Despite a wealth of existing systems as well as academic surveys there are still quite a few issues that seem to be neglected including the consideration of berth error as well as disturbances in the daily operation. Here, we set up a research agenda pointing out that we need to consider and model disturbances and stochastic influences to make the problem more realistic.

3 - Geometric Partitioning Algorithms for Facility Location Problems

Mehdi Behroozi, Assistant Professor, Northeastern University, Boston, MA, 02115, United States, m.behroozi@neu.edu, Reyhaneh Mohammadi

We present fast approximation algorithms for the continuous facility location problems such as k-centers problem and k-medians problem over a convex polygon. The objective here is to find the location of k facilities so as to minimize a distance-based cost function. Our strategy is to use a geometric partitioning scheme to partition the convex polygon into k sub-regions and allocate one facility to each sub-region.

4 - Synchronized Scheduling of Yard Cranes and Vehicles in Container Yards

Chenhao Zhou, National University of Singapore, 1 Engineering Drive 2, E1A-05-21, Singapore, 117576, Singapore, a0096340@u.nus.edu, Haobin Li, Byung Kwon Lee, Loo Hay Lee, Ek Peng Chew

In the container block, the handshake between a yard crane and a vehicle when handling over a container can lead to unproductive waiting time, and consequently low block throughput. This study aims to discuss the synchronized scheduling to reduce the waiting time and to improve the handling efficiency between yard cranes and vehicles. The decision elements are the handshake positions for handshaking, and the operations sequence of activities, under the Chebyshev metric of yard crane movement. The scheduling algorithm is proposed and examined its effectiveness on a simulation testbed.

5 - Modeling MIAPP NALT in Order Picking Applications with a Class Based Storage Policy

Jingming Liu, Research Assistant, University of Arkansas, 920 N Leverett, Apt 811, Fayetteville, AR, 72701, United States, liujingming1215@gmail.com, Haitao Liao, John A. White

A multiple-in-the-aisle pick positions (MIAPP) case picking operation is modeled as an M|Ek|1 queueing problem. In the queueing formulation, the narrow aisle lift truck (NALT) serves two types of customers: single-command storage, single-command retrieval. The travel time probability distributions are derived under a rectilinear travel and class-based storage policy, and an Erlang distribution is used to approximate the distribution of service times.

Joint session RAS/Practice: Intermodal Transportation

Sponsored: Railway Applications

Sponsored Session

Chair: Nathaniel Richmond, University of Iowa, The Colony, TX, 75056, United States, nathaniel-richmond@uiowa.edu

Co-Chair: Mike D. Prince, BNSF Railway, BNSF Railway, Fort Worth, TX, 76244, United States, mike.prince@bnsf.com

1 - Breaking Deadlocks in Widespan Crane Planning

Steven Tyber, Operations Researcher, GE Transportation, 500 W. Monroe St, Chicago, IL, 60613, United States, tyber@ge.com

We explore the problem deadlocks in planning wide span crane operations. Like many scheduling problems, wide span crane tasks have precedence relations that need to be observed to produce a feasible plan. When a set of tasks are mutually dependent, they are said to be deadlocked and prevent any plan from being feasible. In this talk, we show how such deadlocks arise in wide span crane operations and how standard practices for arranging and loading units give rise to an easily executed solution to this challenging problem.

2 - Intermodal Hub Simulation
Mike D.Prince, BNSF Railway, 4853 Grinstein Drive, Fort Worth, TX, 76244, United States, mike.prince@bnsf.com

Intermodal hubs are the facilities at which BNSF Railway's intermodal trains interface with customers. This presentation will discuss an AnyLogic simulation model that was developed for the purpose of assisting in the capital expansion planning process for these facilities.

3 - Investigating General Intermodal Terminal Capacity Relationships with AnyLogic Simulations
Darkhan Mussanov, University of Illinois at Urbana-Champaign, RailTEC, 205 N.Mathews Avenue, Urbana, IL, 61801, United States, mussano2@illinois.edu, Tyler Dick

Currently, intermodal terminal capacity is largely evaluated on the basis of practitioner planning experience. The industry is in need of a more thorough understanding of the interaction between fundamental factors that influence intermodal terminal capacity. As a first step to create a tool for investigating the factors affecting intermodal terminal capacity, this research develops a simulation model of the intermodal terminal operation.

4 - Managing Intermodal Equipment under Supply and Demand Uncertainties – An Implementation of an Operations Research Tool in a North American Railway
Yudi Pranoto, Norfolk Southern Corporation, 1200 Peachtree Street Ne, Box 12-117, Atlanta, GA, 30309, United States, yudi.pranoto@nscorp.com, Clark Cheng

Intermodal units such as containers and trailers are transported by train using intermodal flatcars. The demand of intermodal flatcar is varies by location and by day of the week. In this presentation, we will discuss implementation of a forecasting tool to assist intermodal equipment manager to better plan for the availability of intermodal flatcars. Key concepts of prediction interval, network optimization, intermodal yard capacities, and equipment loading rules will also be discussed.

Integrating Scholarship with the Teaching of OR/MS/Analytics

Sponsored: INFORMEd

Sponsored Session

Chair: Neil Desnoyers, Saint Joseph's University, Upper Darby, PA, 19082, United States, ndesnoye@sju.edu

1 - An Experiential Learning Activity for Integrating Optimization and Group Work in the ORMS Classroom
Mihai Banciu, PhD, Bucknell University, Lewisburg, PA, United States, mmb018@bucknell.edu

Traditionally, topics like linear and integer optimization in a spreadsheet-based modeling course are taught based on a "follow the instructor approach". We present a web-based interactive activity whereby students can work in small groups in the classroom, while the instructor aggregates the intermediate results into a master problem and provides instant feedback.

2 - Instructional Guidance for Client-Based ORMS Education
Susan E. Martonosi, Harvey Mudd College, Department of Mathematics, 301 Platt Boulevard, Claremont, CA, 91711, United States, martonosi@hmc.edu

How do we move beyond the theory of ORMS in our classrooms and give students the skills to be practitioners? Many ORMS programs have begun instituting field-based projects serving real clients as part of their curricula. This talk will offer the audience a set of design principles drawn from the myriad approaches described in ORMS educational literature.

3 - An Advance in Web-Based Spreadsheet Modeling Resulting from Classroom Use
Neil Desnoyers, Saint Joseph's University, 133 Green Valley Rd, Upper Darby, PA, 19082, United States, ndesnoye@sju.edu

Spreadsheets are moving online. Introduction of an OR/MS case in an MBA classroom helped uncover an issue modeling using Google Sheets and the OpenSolver tool. We apply lessons learned to the feedback loop between teaching and scholarship.

4 - Designing Educational Assessment via Network Optimization
Camilo Gómez, Universidad de los Andes, Cra 1 E.No 19 A.- 40, Bogata, Colombia, gomez.ch@uniandes.edu.co, Jorge Huertas, Jorge A. Leal

Network models are useful abstractions for a variety of systems. This work explores the application of network flows models in the organizational realm, approaching an education problem in an industrial engineering department, following ABET guidelines and standards. We propose different network optimization models at different scales of abstraction to promote the interactions between, and within, the courses towards the continuous improvement of the program. While there are challenges in the quantification of non-tangible aspects, the proposed approach proves useful to engage stakeholders in meaningful interactions and convey otherwise abstract features of complex systems.

Sports Analytics II

Sponsored: SpORts

Sponsored Session

Chair: Stephen Hill, UNC, Wilmington, NC, United States, hills@uncw.edu

1 - Late Game Decision Making in the NFL
Stephen Hill, UNC Wilmington, NC, United States, hills@uncw.edu

Late-game decision-making in the National Football League (NFL) has drawn considerable scrutiny in recent years. In this presentation, an analysis of late-game decision-making is presented. In particular, the analysis focuses on field goal versus "going for it" decisions late in close games.

2 - Optimal Defensive Allocation in Baseball
Jim Ostrowski, University of Tennessee, 11421 Old Colony Pkwy, Knoxville, TN, 37934, United States, jostrows@utk.edu

We will discuss the problem of optimal allocation defensive baseball positions. By integrating open-source collected data into our integer formulation, we are able to of identify an optimal defensive allocation for MLB hitters that can have a significant impact on their batting average.

3 - A Playbook for Teaching Sports Analytics to Undergraduate Business and MBA Students
Scott Nestler, University of Notre Dame, 383 Mendoza College of Business, Notre Dame, IN, 46556, United States, snestler@nd.edu

The presenter teaches a half-semester length course in Sports Analytics to undergraduates and MBAs at the University of Notre Dame. Offensive plays — reaching out to faculty members at other schools who teach similar courses; allowing students freedom to use familiar tools or coding languages. Defensive plays — selecting Excel as a common language for class examples (may revisit in future with a more pro-style scheme that incorporates R); using a known but somewhat dated text (Winston's "Mathletics"). Please come listen and share your experiences in teaching quantitative techniques using a subject matter that students are truly excited about.

4 - An Approximate Dynamic Programming Approach to Determine the Optimal Substitution Strategy for Basketball
David Hughes, George Mason University, Fairfax, VA, United States, dhughe12@masonlive.gmu.edu

Coaches currently use a variety of substitution strategies (such as player rotations and playing the "next best" player). However, such strategies may not be optimal in terms of distributing rest over the course of a whole game. In part, this is because live monitoring of physiological factors is not authorized by the NCAA. Even with such data, it may not be obvious when to rest a skilled player in order to ensure that player is fresh throughout the game. This research develops an approximate dynamic programming (ADP) model of a coach's lineup decisions accounting for changing players' endurance levels and the uncertainty of the defensive intensity played against them.

5 - An Interactive Optimization Web App for the NHL Expansion Draft
Benjamin Potter, University of Toronto, Mechanical and Industrial Engineering, 5 Kings College Road, Toronto, ON, M5S.3G8, Canada, ben.potter@mail.utoronto.ca, Timothy Chan

The Vegas Golden Knights are the newest team to enter the NHL. The league laid out rules for an Expansion Draft where the existing teams protect some of their players from being drafted and Vegas fills its roster by selecting from the remaining players. We developed a web app based on integer programs that model the existing 30 teams' protection decisions and Vegas's draft decisions. The app allows fans to optimize the draft using one of a number of performance based metrics. Users can also plan for the future by balancing on-ice performance with financial flexibility objectives.

Spatio-Temporal Models for Forecasting

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Yu Ding, Texas A&M University, College Station, TX, 77843-3131, United States, yuding@tamu.edu

Co-Chair: Ahmed Aziz Ezzat, Texas A&M University, College Station, TX, United States, aa.ezzat@tamu.edu

1 - Smart Energy: A Modern Data-Driven Perspective

Andrew Kusiak, The University of Iowa, Iowa City, IA, 52242, United States, andrew-kusiak@uiowa.edu

The world of energy is transforming towards renewable energy generation with wind energy experiencing the fastest growth. Renewable energy has introduced a shift from centralized to distributed generation. The cost to operate and maintain renewable energy plants is a major determinant of energy prices. Autonomy of renewable energy generators and plants offers a viable path to competitive prices of clean energy. Using wind industry as an example, problems awaiting research attention and solution approaches are outlined. A strategy to democratization of energy research aiming at accelerated response to meeting wind energy needs is presented.

2 - Distributed Ensemble Solar Power Forecasting through the Generalized Dynamic Factor Model

Duehee Lee, Assistant Professor, KonKuk University, Kwangjin Gu, Seoul, Korea, Republic of, hello.keanu@konkuk.ac.kr, Ross Baldick, Jaehyung Roh

Total daily solar irradiance for the next day is forecasted through an ensemble of multiple machine learning algorithms using forecasted weather scenarios from numerical weather prediction models. We also forecast the distributed solar power through the generalized dynamic factor model. Six interpolation functions are used to interpolate weather scenarios at non-integer grid points and performances are compared. The forecasting models are verified using data from the American Meteorological Society 2014 Solar Energy Prediction competition by observing the post-competition rankings. We achieved 16th place out of 160 in this competition, and our best post-competition ranking is 5th place.

3 - A Markov Switching Vector Autoregressive Stochastic Wind Generator for Multiple Spatial and Temporal Scales

Amanda Hering, Baylor University, Waco, TX, United States, Mandy_Hering@baylor.edu

Stochastic realizations of wind are important for wind energy grid integration and reliability studies. Here, we introduce a Markov-Switching Vector Autoregressive model (MSVAR) model and demonstrate its flexibility in simulating wind vectors for various temporal and spatial scales. In addition, we demonstrate how the model can be used to simulate wind vectors at multiple locations simultaneously. The parameter estimation and simulation algorithm is presented along with a validation of important statistical properties of each simulation scenario. The MSVAR is very flexible in characterizing a wide range of properties in the wind vector.

4 - Short-term Wind Forecasting using Spatio-temporal Asymmetric Models

Ahmed Aziz Ezzat, Texas A&M.University, aa.ezzat@tamu.edu

Despite the growing recognition for non-separable spatio-temporal models, a significant reliance on separable, fully symmetric models is still the norm in today's renewable industry. We explore the reasons behind the disregard of these models in wind farm analytics and devise a special pair of spatio-temporal lens that unearths the fine-scale spatio-temporal variations and interactions, at which the merits of the highly-statistically capable models are perceived. Given this lens, we investigate the potential benefits, in terms of inference and forecasting, achieved through extending non separable asymmetric spatio-temporal models for wind energy applications.

Spatio-Temporal Conservation Models for Controlling Biological Invasions

Sponsored: Energy, Natural Res & the Environment Environment & Sustainability

Sponsored Session

Chair: Esra Buyuktahtakin, New Jersey Institute of Technology, Newark, NJ, United States, esratoy@njit.edu

1 - Valuing Monitoring Networks for New Agricultural Pathogens

Tiesta Thakur, University of Minnesota, St. Paul, MN, 55108, United States, thaku035@umn.edu, Terry Hurley, Frances Homans, Robert Haight

US soybean production, a $30 billion industry, is threatened by soybean rust, a new agricultural pathogen that entered the U.S. in 2004. To monitor rust occurrence, a public-private partnership funds a sentinel plot network, which reached a peak of 900 plots in 2008. Soybean producers use sentinel plot information to assess annual risk of infection and make fungicide application decisions. To value the network, we first develop a dynamic, farm-level decision model and estimate producers' willingness to pay for sentinel plot information. Then, we use an assignment model to locate sentinel plots in the eastern U.S. to maximize net benefits. Results are compared with current plot locations.

2 - Optimal Survey Strategies in Early Detection Programs of Bio-invasions: Detect or Delimit?

Denys Yemshanov, Natural Resources Canada, 1219 Queen Street East, Sault Ste. Marie, ON, p6a2e5, Canada, Denys.Yemshanov@canada.ca, Robert G.Haight, Frank H.Koch, Robert Venette, Tom Swystun, Ronald Fournier, Yongguang Chen, Mireille Marcotte, Jean J.Turgeon

We present a scenario-based model that incorporates uncertainty about the arrival of an invasive species and damage from an outbreak and optimizes the deployment of surveys for early detection of the outbreak. The model minimizes time to first detection and overall damage from an outbreak in a landscape and accounts for decision-making aspirations towards worst-case outcomes. We apply the model to allocate early detection surveys of Asian longhorned beetle in the Greater Toronto Area, Canada. Our approach is focused to support early detection programs for novel invasive pests and pathogens

3 - A Multi-stage Stochastic Optimization Approach to Cost-effective Surveillance and Control of Biological Invasions

Eyyub Kibis, The College of Saint Rose, Albany, NY, United States, eyyubyunus@gmail.com, Esra Buyuktahtakin, Robert G. Haight, Kathleen S. Knight, Charlie Flower

In this study, we develop a new multistage stochastic programming model, which considers all possible scenarios for surveillance, treatment, and removal decisions over a planning horizon to control the emerald ash borer invasion in North America. Our objective is to maximize the net benefits of the ash trees on a given landscape by applying surveillance to the ash population, followed by treatment or removal of trees based on their infestation level. Due to the model's complexity, we develop new cutting planes to facilitate the solution process. Results provide insights into surveillance and control policies, and provide an optimal strategy to minimize EAB infestation with scarce resources.

Retail Analytics

Sponsored: Data Mining

Sponsored Session

Chair: Matthew A. Lanham, Purdue University, 403 W. State St., KRAN 466, West Lafayette, IN, 47907, United States, lanhamm@purdue.edu

1 - Assortment Optimization with Big Data: Weather, Social, Halo and Cannibalization

Victor Pereira, IBM, Columbus, OH, United States, vpereira@vt.edu

This talk showcases a complex and time-constrained data science project to optimize deodorant assortments at dozens of demographics-grounded store clusters. The project was sponsored by a CPG manufacturer on behalf of two major retailers and leveraged the effect of hyperlocal weather, changes in consumer sentiment towards product attributes, cluster-level halo and cannibalization, and minimum inventory for high-velocity SKUs. Over a billion rows of data occupying nearly 5TB were analyzed during this 8-week proof of concept. Model outputs matched the opinions of CPG experts at the product attribute level.

2 - Examining Multi-classification Methods for Consumer Choice
Matthew A. Lanham, Purdue University, West Lafayette, IN, United States, lanhamm@purdue.edu

This study examines multi-classification methodologies that a retailer might employ to gauge the propensity a product might sell when purchase substitution is inevitable. This study is important because retailers are routinely reevaluating the mix of products they offer consumers and often use predictive models that enable them to estimate the substitutability of their products. We model the substitution propensity for a set of products using a national retailer's data using common and less-common multi-classification methodologies and compare the results. We highlight where certain models perform better than others and discuss our future extensions of this study.

3 - A Two-stage Learning Approach to Improve New Item Forecasts in Retail
Inderjeet Singh, Infor Inc., Atlanta, GA, 30309, United States, Inderjeet.Singh@infor.com, Ronald P. Menich, Ashwin Mishra

Forecasting new items for planning, vendor ordering, pricing, allocation and replenishment functions is a challenging problem in retail. To forecast new items, legacy forecasting solutions require users to manually set up one or more clone item(s), leading to a tedious process. At Infor, we use an in-house implementation of Factorization Machines to generate more accurate forecasts. Our attribute-based demand forecasting solution offers clone free forecasts for new items. We recently implemented a simple two-stage learning approach to further improve our new item forecasts. We present real-life examples to elaborate the approach and talk about an implementation experience.

4 - Estimating Demand for Substitutable Products when Inventory Records are Unreliable
Daniel Waymouth Steeneck, Air Force Institute of Technology, WPAFB, OH, United States, steeneck@mit.edu, Fredrik Eng-Larsson, Francisco J. Jauffred

We present a procedure for estimating demand for subsitutable products when the inventory record is unreliable and only validated infrequently and irregularly. The procedure uses a structural model of demand and inventory progression, which is estimated using a modified version of the EM algorithm.

Same-Day Delivery Logistics

Sponsored: TSL, Freight Transportation & Logistics

Sponsored Session

Chair: Ozlem Ergun, o.ergun@northeastern.edu

Co-Chair: Necati Duman, duman.n@husky.neu.edu

1 - A Robust Optimization Approach for Crowdsourcing Last-mile Deliveries
Soraya Fatehi, University of Washington, 5215 15th Avenue, Apt 15, Seattle, WA, 98105, United States, sfatehi@uw.edu, Michael R.Wagner

We study a robust optimization model of last-mile deliveries motivated by the Amazon Flex and Uber Eats programs. In these applications, the crowd is utilized for last-mile deliveries. We derive the optimal usage of the crowd to supplement traditional delivery options, to minimize the delivery cost per package, under delivery window constraints.

2 - Peer-to-Peer Transshipment in On-demand Same Day Delivery
Jane Lin, University of Illinois-Chicago, 842 W. Taylor Street (M/C 246), Chicago, IL, 60607, United States, janelin@uic.edu

In light of the emerging on-demand, same-day (ODSD) delivery service market, this study proposes, formulates, and evaluates a new ODSD delivery strategy using direct peer-to-peer transshipment (P2PT). P2PT involves direct en-route package relays among multiple couriers to extend beyond the normal service range of a single courier in order to reach the package's final destination. Our results show that P2PT improves initially with the economy of scale, and then flattens out in the static demand scenario or worsen in the real-time demand scenario. Compared with direct shipping, P2PT is shown a low cost strategy for the ODSD service with the economy of scale.

3 - Order Acceptance Mechanisms for Same-Day Delivery
Mathias A. Klapp, Pontificia Universidad Catolica de Chile, Santiago, 7820436, Chile, maklapp@ing.puc.cl, Alan Erera, Alejandro Toriello

We study same-day delivery by formulating the Dynamic Dispatch Waves Problem with Immediate Acceptance that models integrated request management and order distribution decision-making where delivery requests arise dynamically throughout the day. When a request arises, a decision is made immediately to accept (offer service) or reject (with a penalty). All accepted requests are included in dynamically-updated dispatch plans that serve each request by the end of the day. We provide computational experiments that estimate a cost increase of 4.4% when imposing immediate order acceptance.

4 - A Study to Improve Routing Precision in Same Day Delivery
Necati Oguz Duman, Northeastern University, Boston, MA, United States, duman.n@husky.neu.edu, Mehmet Talha Dulman, Ozlem Ergun

Most of the studies on vehicle routing problems assume that distances between nodes are given as parameters and they are accurate. However, in most real world applications, the nodes are given and distances between each pair must be acquired either from a map provider or with an approximation method. In this study, we analyze the relationship between driving distance and straight line distance and provide a regression model to predict the driving distance. To test the efficiency of our model, we use a simple routing algorithm with clustering and insertion methods in construction and several local search methods in improvement phases.

1 - Tutorial: Analytics Applications for Additive Manufacturing
Linkan Bian, Mississippi State University, Industrial and Systems Engineering Department, P.O. Box 9542, Mississippi State University, MS, 39762, United States, bian@ise.msstate.edu, Alaa Elwany

Data analytics is playing a key role in advancing numerous research and application areas. Additive manufacturing is a particular area that can benefit greatly from data-driven analytics and predictive modeling, especially when properly integrated with relevant physics-based models and experimental methods. This tutorial will take a deep dive into how tools of data analytics can be applied in the modeling, analysis, and control of Additive Manufacturing processes. Topics in process planning and optimization, materials informatics, process monitoring, and quality control will be the focus of the tutorial.

1 - Characterization of Lithium-ion Battery Model Uncertainty for Effective Battery SOC Estimation

Zhimin Xi, University of Tennessee-Knoxville, 851 Neyland Dr, 517 JDT, Knoxville, TN, 37996, United States, zxi1@utk.edu

Equivalent circuit models (ECMs) are major models employed in current battery management systems (BMS) for battery SOC estimation due to its high computational efficiency. However, fidelity of the ECMs varies for different battery operating conditions, thus often resulting in inaccurate battery SOC estimation. In this paper, approaches are developed to characterize the model uncertainty of an ECM under various battery operating conditions. Fidelity of the ECM is hence further improved without giving up the high efficiency of the model for onboard battery SOC estimation. Comparison study is conducted for the SOC estimation using the proposed approach and conventional method.

2 - Optimal Personnel Deployment Strategy for Self-perform Maintenance on Wind Farms

Jason Kriel Lawley, Texas A&M.University-College Station, 3780 Copperfield Drive, Apt 325, Bryan, TX, 77802, United States, jsnlawley@tamu.edu

Turbine maintenance is a major cost and key determinant of wind farm productivity. Many companies outsource critical maintenance while others perform these tasks in-house, referred to as self-perform maintenance. While expected to reduce time to profit on asset investment, self-perform requires an efficient personnel deployment strategy, proposed as the following: a balanced scorecard aligning data driven performance indicators to O&M deliverables, an optimization package delivering daily maintenance tasks paired with ideal teams of technicians, and a simulation model demonstrating implementation benefits. Development, features, and results of this strategy will be discussed.

3 - Adaptive Importance Sampling for Extreme Load Estimation in Wind Turbines

Qiyun Pan, University of Michigan, 1205 Beal Avenue, Department of IOE, Ann Arbor, MI, 48109-2117, United States, qiyun@umich.edu, Eunshin Byon, Henry Lam

To help wind turbine reliability analysis in a design stage, aeroelastic simulators have been developed to generate stochastic load responses imposed on a wind turbine. However, crude Monte Carlo sampling to simulate the extreme load associated with a small load exceeding probability is computationally prohibitive, and the estimation results are highly uncertain. We develop an adaptive importance sampling algorithm to iteratively refines the importance sampling density to efficiently estimate the extreme load.

4 - Game Theory Based Distributed Control Algorithm for Energy Storage Systems

Jinkyoo Park, Korea Advanced Institute of Science and Technology, Daejeon, Korea, Republic of, jinkyoo.park@kaist.ac.kr, Heechang Ryu

We construct a game theoretic framework that can model the strategic interactions between the grid operator and energy users. The grid operator seeks to maximize their profit and reduce the peak load by applying demand response strategies, such as changing energy price. On the other side, the users aim to minimize their energy consumption costs by optimally operating ESSs that can charge the energy when the price is low and discharge the energy when the demand and price are high. With the constructed game model, we derive the equilibrium strategy for both grid operator and users that can lead the minimize energy consumption cost for the users and the reduced peak load for the grid operator.

Chair: M'Hallah Rym, Kuwait University, P.O. Box 5969, Kuwait, 13060, Kuwait, rymmha@yahoo.com

1 - Research and Optimization of Facility Layout in Passenger Transfer Hall of Shapingba Transport Hub Based on Legion Simulation

Anjun Li, National United Engineering Laboratory of Integrated and Intelligent Transportation, Chengdu, China, siyu.tao@okstate.edu, Qiyuan Peng, Qiyuan Peng, Siyu Tao, Siyu Tao, Siyu Tao

Transfer hall plays a significant role in transport hub, determining the hub's operating and evacuation efficient. Legion software is used to create the model and simulate pedestrians' movement in transfer hall of Shapingba transport hub. According to the simulation result, the existing layout scheme of various facilities in the hall is evaluated, and some possible congestion points are identified. Ultimately, some optimization suggestions, from the view of convenient transfer, are proposed.

2 - Generating Delivery Plans in Real Time by Dynamically Evaluating Multiple Scenarios

Yihuan Yang, The Hong Kong University of Science and Technology, Clear Water Bay, Kowloon, Hong Kong, Kowloon, Hong Kong, yyangax@connect.ust.hk, Xiangtong Qi

Many Internet sellers now commit a very short lead-time for delivery upon the confirmation of orders. This requires to generate a delivery routing plan in real time. This paper presents a solution framework that dynamically traces the buyers' ordering process. The core is a genetic algorithm designed to consider multiple possible delivery scenarios at the same time. It generates a pool containing situations which are more likely to happen and adjusts the pool according to current customers' purchasing progress. With consideration of possible scenarios in advance, a delivery route with low cost can be obtained immediately after the cutoff time.

3 - Branch-cut-price Algorithm for the Traveling Salesperson Problem with Hotel Selection

Luiz Henrique Barbosa, UFF, Niteroi, Brazil, luizhsb@gmail.com, Eduardo Uchoa

The Traveling Salesperson Problem with Hotel Selection (TSPHS), a natural extension of the classic Traveling Salesperson Problem, has only recently been introduced to the literature. Current approaches focus mainly in metaheuristic techniques. The lack of a robust a exact algorithm limits the extent to which this problem can be studied. This work proposes a sophisticated branch-cut-and-price algorithms, including recent techniques like ng-route pricing and limited memory subset row cuts. Computational results show that medium-sized instances can be solved.

4 - A Matheuristic Approach to the Orienteering Problem with Service Time Dependent Profits

Qinxiao Yu, Tianjin University, 92# Weijin Road Nankai District, Tianjin, China, yuqinxiao@tju.edu.cn

This paper addresses the orienteering problem with service time dependent profits (OPSTP), in which the profit collected at each vertex is characterized by a nonlinear function of service time, and the objective is to maximize the total profit by determining a subset of the vertices to be visited and assigning appropriate service time to each of them respecting to time budget. To solve this problem, we formulate a mixed integer nonlinear programming model and propose a two-phase matheuristic algorithm. Extensive numerical experiments are conducted for small and large scale instances. The results show that our proposed algorithm can be quite effective in finding good-quality solutions.

5 - A Hybrid Constraint Programming Very Large Neighborhood Search for Vehicle Routing Problems with Multiple Time Windows

M'Hallah Rym, Professor, Kuwait University, P.O. Box 5969, Safat, Kuwait, 13060, Kuwait, rymmha@yahoo.com

This paper models the vehicle routing problem with multiple time windows as a constraint program, and solves easy instances exactly. It approximately solves difficult instances using a hybrid iterated very large neighborhood search and a constraint programming heuristic. It obtains near-optimal feasible solutions that respect the time windows of the clients and depot as well as the capacity and load constraints of the vehicles. The computational investigation highlights the benefits of the hybridization as well as the cost saving it induces.

1 - Deep Causal Inference

Yuanyuan Shen, Stanford Graduate School of Business, 10 Comstock Circle, Apt 325, Stanford, CA, 94305, United States, yyshen@stanford.edu

Kiva is an online non-profit microfinance platform that raises funds for the poor. To raise funds as fast as possible, borrowers have the option to form groups and post loan requests in the name of groups. While group loans pose less risk for investors than individual loans do, we study whether this is the case in a philanthropic online marketplace. We measure the effect of group loans on funding time and control for the loan sizes and other factors. Because loan descriptions play an important role in lenders' decision process on Kiva, we make use of this information through deep learning in natural language processing. We find that on average, forming group loans speeds up the funding time by at least two days.

2 - Uber Demand Modeling

Amir Mousavi, George Washington University, 475 K.St NW, Apt 419, Washington, DC, 20001, United States, ahmn00@gmail.com

Undoubtedly, UBER has become one of the most significant startups of the 21st century. Despite the simple and user-friendly interface, UBER runs complex processes behind the scenes. it is crucial to understand the demand; more specifically, the demand distribution in order to calculate the optimal price. This project uses historical data to determine the demand distribution at given times and locations.

3 - Analysis of Feature Extraction and Feature Selection Impact on Angiographic Disease Diagnosis Accuracy

Amirhossein Koneshloo, Texas Tech University, Lubbock, TX, United States, amir.koneshloo@ttu.edu

This study investigates the importance of appropriate Feature Extraction (FE) and Feature Selection (FS) to improve Angiographic disease diagnosis accuracy with multivariate statistical analysis such as kernel PCA. The data for this analysis comes from the Cleveland Clinic Foundation. Widely-used techniques, i.e. Support Vector Machine and Cross Validation, are applied for data classification and performance evaluation, respectively.

4 - Frequent Temporal Pattern Mining with Extended Lists

Anton Kocheturov, Research Assistant, Department of Industrial and Systems Engineering, UF, 2600 SW. Williston Road, Apt 707, Gainesville, FL, 32608-3949, United States, antrubler@gmail.com

In this paper we consider Temporal Pattern Mining (TPM) for extracting predictive class-specific patterns from multivariate time series. We suggest a new approach that extends usage of the apriori property which requires a more complex pattern to appear only at places where all its subpatterns appear as well. It is based on tracking positions of a pattern inside records in a greedy manner. We demonstrate that it outperforms the previous version of the TMP on several real-live data sets independent of the way how the temporal pattern is defined.

5 - Incremental Feature Importance Ranking for Mixed Classification Tasks

Alaleh Razmjoo, PhD Student, University of Central Florida, 4000 Central Florida Blvd, Orlando, FL, 32816, United States, Orlando, FL, 32816, United States, alaleh.razmjoo@knights.ucf.edu

Online data mining methods are normally adaptations of classical data mining techniques for learning in an incremental fashion. In this paper, we present a method for online feature importance ranking in online classification tasks. In this method, the merit of features is based on their impact on the classification outcome. Unlike available algorithms, our method could be applied for both continues and categorical features, without a need to discretization of the input. To evaluate the merits of the proposed method, we performed experiments on benchmark datasets. Primary experiments show promising results compared with available methods.

6 - Clustering-conditional-importance Variable Selection with Random Forests

Gianluca Gazzola, Rutgers University, 100 Rockafeller Road, 5th floor, Piscataway, NJ, 08854, United States, ggazzola@rutgers.edu

We present a variable selection algorithm that employs a novel variant of random-forest conditional-permutation-importance measure. This measure permutes observations within groups obtained by clustering, via a criterion defined by the structure of dependencies existing among variables, in order to eliminate unimportant and/or redundant predictors. The algorithm outperforms several other permutation-importance variable selection algorithms on both artificial and real-world data sets.

Black-box or Simulation Optimization

Sponsored: Optimization, Global Optimization

Sponsored Session

Chair: Zelda B Zabinsky, University of Washington, Seattle, WA, 98195-2650, United States, zelda@u.washington.edu

1 - A Two-time-scale Random Search Algorithm for Global Optimization

Qi Zhang, Stony Brook University, SUNY, Stony Brook, NY, 11794, United States, qi.zhang.1@stonybrook.edu, Jiaqiao Hu

We propose a random search algorithm for solving black-box optimization problems. The algorithm iteratively finds improved solutions by modifying and sampling from a probability distribution over the solution space. In contrast to existing algorithms in the class, which are mostly population-based, our approach employs a two-time-scale stochastic approximation idea and uses only a single candidate solution per iteration. We establish global convergence of the algorithm and present numerical results to illustrate its performance.

2 - An Epsilon-constraint Method for Integer-ordered Bi-objective Simulation Optimization

Kalyani S. Nagaraj, Oklahoma State University, 322 Engineering North, Industrial Engineering & Mgmt, Stillwater, OK, 74078, United States, kalyani.nagaraj@okstate.edu, Kyle Cooper, Susan R.Hunter

Consider the context of integer-ordered bi-objective simulation optimization, in which the feasible region is a finite subset of the integer lattice. We propose a retrospective approximation (RA) framework to identify a local Pareto set that involves solving a sequence of sample-path bi-objective optimization problems at increasing sample sizes. We apply the epsilon-constraint method to each sample-path bi-objective optimization problem, thus solving a sequence of constrained single-objective problems in each RA iteration. Our algorithm displays promising numerical performance.

3 - Parallel Simultaneous Perturbation Optimization

Atiye Alaeddini, Institute for Disease Modeling, 3150 139th Ave SE, Bellevue, WA, 98005, United States, aalaeddini@idmod.org, Atiye Alaeddini

Optimization is a common problem in stochastic simulations. The objective function, however, is time-intensive to evaluate, and cannot be directly measured. Individual realizations of the model are corrupted by noise. We consider the problem of optimizing the expected value of an expensive black-box function, from which observations are corrupted by Gaussian noise. We present Parallel Simultaneous Perturbation Optimization (PSPO), which takes advantage of parallel computing resources, like high-performance cloud computing. PSPO algorithm takes fewer time-consuming iterations to converge, automatically chooses the step size, and can vary the error tolerance by step.

4 - Sampling within Adaptive Level Set Approximations for Black-box Global Optimization

David Desmond Linz, University of Washington, 5246 NE 15th Avenue, Apt 101, Seattle, WA, 98105, United States, ddlinz@gmail.com, Zelda B.Zabinsky

Several random search approaches (e.g., pure adaptive search) have been shown to be effective for global optimization with expected performance that increases linearly with dimension. We explore a practical implementation that uses models in order to sample from a series of nested level set approximations. The paper describes a method for adjusting quantile levels and parameters to achieve a probability of successfully sampling within each level set. We explore the application of this framework to various model-based sampling methods. We discuss theoretical bounds for convergence and pair the results with numerical examples.

1 - A Traveling Repairman Problem with Job Dependencies

Feng Qiu, fqiu@anl.gov, Bahar Cavdar

Electricity service in power distribution network is often disrupted by various events (such as accidents and extreme weather). Many of the service disruptions are a result of physical damages of electrical components and require repair. We consider a power distribution network restoration problem with repair crew routing. We first present the description of the problem and its variations, and give a formulation in a general form. Then, we discuss the computational complexity of the problem. We present solution approaches and computational results.

2 - A Network-level Lane-based Mesoscopic Traffic State Estimation and Prediction Framework

Kerem Demirtas, Arizona State University, 699 S. Mill Ave. Tempe, Brickyard Engineering 553, Tempe, AZ, 85281, United States, kdemirta@asu.edu

Microscopic traffic models consider the interaction of individual vehicles with nearby vehicles as well as the transportation infrastructure in a very detailed resolution for a short-term horizon. On the other hand, in mesoscopic models, vehicles are considered either individually or in platoons, and how they move through the links of the network are governed by macroscopic traffic conditions. In this research, we propose a mesoscopic simulation framework that can enable traffic state estimation in a lane-level resolution for a network of connected links with multiple lanes. Preliminary results based on synthetic ground truth data generated by VISSIM are presented.

3 - Multiple Scenario Planning Approach for Two-stage Stochastic Team Orienteering Problems

Yongjia Song, Virginia Commonwealth University, 1015 Floyd Avenue, P.O. Box 843083, Richmond, VA, 23284, United States, ysong3@vcu.edu, Marlin Wolf Ulmer, Barrett Thomas, Stein W. Wallace

In this talk, we discuss study the multiple scenario planning approach in dynamic vehicle routing problems, from a stochastic programming perspective. In particular, we illustrate our preliminary findings using two-stage stochastic orienteering problems as test instances.

4 - A Tabu Search Heuristic for the Vehicle Routing Problem with Soft Time Windows under Fairness and Customer Service Perception Considerations

Bahar Cavdar, Middle East Technical Univeristy, Ankara, Turkey, bcavdar@metu.edu.tr, Joel Sokol

For vehicle routing problems with time windows, soft time window assumptions provide more opportunity to study the tradeoff between the efficiency-based objectives such as number of vehicles, travel distance and the objectives reflecting the customers' satisfaction such as total time window violation, number of violations. In this study, we develop a new tabu search heuristic for the vehicle routing problem with soft time windows. In addition to the traditional objectives, we also consider fairness and resulting service quality perception assuming that customers share information through word of mouth communication.

A Short Introduction to Quantum Computing for the OR Community

Invited: Operations Research and the Future of Computing

Invited Session

Chair: Lior Horesh, IBM TJ Watson, Ossining, NY, 10562, United States, lhoresh@us.ibm.com

Co-Chair: Giacomo Nannicini, IBM T.J. Watson, Yorktown Heights, NY, 10598, United States, giacomo.n@gmail.com

1 - A Short Introduction to Quantum Computing for the OR Community

Giacomo Nannicini, IBM.T.J. Watson, 1101 Kitchawan Road, Yorktown Heights, NY, 10598, United States, giacomo.n@gmail.com

Quantum computers have usually been considered unattainable devices, but quantum computing has come a long way since its inception in the 1980s. Indeed, universal quantum computers of small size are now available for general use - in the case of IBM's Quantum Experience, even for free. So what is a quantum computer, and what can it do differently from classical computers? In this tutorial we will describe the paradigm underpinning the behavior of quantum computers, treating quantum computers as purely mathematical objects. We will use a simple gate model and show the basic ideas underlying quantum algorithms more closely related to operations research. This introduction does not require any prior knowledge of physics, and will, in fact, not discuss any quantum physics at all. However, it requires some familiarity with linear algebra on complex vector spaces

1 - Embedded Code in GAMS - using Python as an Example

Michael R. Bussieck, GAMS, Washington, DC, United States, MBussieck@gams.com, Lutz Westermann

This talk is about a recent extension of the General Algebraic Modeling System (GAMS): The "Embedded Code" facility. With the data model used by GAMS, code for parallel assignment and equation definition is compact, elegant, and efficient. However, traditional data structures (arrays, lists, ...) are not natively available. Though it is possible to represent such data structures, the GAMS code can become unwieldy or inefficient. To overcome this and other issues, the Embedded Code facility was introduced recently. It allows the use of external code (e.g. Python) to access GAMS symbols in memory, so that the user can concentrate on the task at hand and not the mechanics of moving data in and out of GAMS.

2 - Integrating Optimization Modeling with General-purpose Programming for Efficient and Reliable Application Deployment

Robert Fourer, AMPL.Optimization Inc., 2521 Asbury Ave, Evanston, IL, 60201, United States, 4er@ampl.com, Filipe Brandao, Christian Valente

We describe a new framework that combines the advantages of modeling in a specialized optimization environment and of coding in a general-purpose programming language. Models are formulated concisely and naturally in AMPL, promoting ease of development, reliability of maintenance, and experimentation with solvers and data sources. APIs for a variety of full-featured programming languages permit AMPL models and scripts to be embedded into complex applications, gaining access to extensive libraries for data management and interface development. We illustrate the possibilities with two roll-cutting examples using Python, and a collaborative optimization environment built in Java.

3 - Optimizing in the Cloud – Deploying Optimization Models on the Cloud with Web Services REST API's

Bjarni Kristjansson, Maximal Software Inc., 2111 Wilson Boulevard, Suite 700, Arlington, VA, 22201, United States, bjarni@maximalsoftware.com

Over the past decade the IT has been moving steadfastly towards utilizing software on clouds using Web Services REST API's. The old traditional way of deploying software on standalone computers is slowly but surely going away. In this presentation we will demonstrate the MPL REST Server, which allows optimization models to be easily deployed on the cloud. By delivering optimization through a standard REST API, which accepts data in JSON format, the optimization becomes purely data-driven. Client applications can now be implemented relatively easily on different client platforms such as mobile/tablets or web sites, using just standard HTML/CSS with JavaScript, or any other preferred programming language.

4 - Min Cost Optimization for an Epic Major League Baseball Road Trip

Christopher Santos, United States Navy, OPNAV. N81 Assessment Division, 2000 Navy Pentagon, Rm 4D453, Washington DC, DC, 20350-2000, United States, christopher.p.santos@navy.mil

Baseball is America's Pastime and is the inspiration for many a childhood dream. What better way to be a fan of the game than to get a group of good friends together for an epic road trip to watch a game at all 30 Major League Baseball ballparks? While there exist online tools to minimize the number of days to accomplish such a trip, we wanted to optimize cost, but with our own custom constraints and requirements (read: make the trip fun and not grueling).The initial implementation of our optimization routine was performed using Python and GAMS with the CPLEX solver. We are currently porting over our model to Python and Pyomo with an open-source CBC solver.

Nonlinear Optimization Algorithms

Sponsored: Optimization, Nonlinear Programming

Sponsored Session

Chair: Frank Edward Curtis, Bethlehem, PA, 18015, United States, frank.e.curtis@gmail.com

Co-Chair: Andreas Waechter, Northwestern University, Evanston, IL, 60208, United States, waechter@iems.northwestern.edu

1 - Failure of the Gradient Method on Nonsmooth Convex Functions

Azam Asl, NYU, 251 Mercer St., New York, NY, 10012, United States, aa2821@nyu.edu, Michael L.Overton

Motivated by the success of the BFGS method on nonsmooth functions, along with the difficulty of analyzing this phenomenon, we consider the behavior of the simpler gradient method on nonsmooth problems. We give an analysis of the gradient method with an Armijo-Wolfe inexact line search on the function $f(u,v)=alul+v$ where $a > 0$. We show that if a certain constant C, depending only on a and the Armijo parameter, is positive then the method converges to a point $(0, \bar v)$, although f is unbounded below. In contrast if $C \le -0.5$ then the points generated are unbounded below. Experimental results demonstrate that our analysis is reasonably tight.

2 - Logical Benders Decomposition for Quadratic Programs with Complementarity Constraints

Francisco Jara-Moroni, Northwestern University, 2145 Sheridan Road, Evanston, IL, 60208, United States, franciscojaramoroni2013@u.northwestern.edu, Andreas Waechter, John E. Mitchell, Jong-Shi Pang

We study a logical Benders decomposition approach to solving binary-constrained quadratic programs with linear complementarity constraints. It is based on a satisfiability master problem to which feasibility cuts are added that are computed from primal and dual subproblems for chosen complementarity pieces and binary variables. Interpreting the logical Benders decomposition approach from a branch-and-bound point of view, we propose several new methods for strengthening the feasibility cuts and guiding the master problem solution. Their efficiency is assessed by numerical experiments.

3 - An Algorithm for Optimization Problems with Joint Chance Constraints using a Nonlinear Value-at-risk Formulation

Alejandra Pena-Ordieres, Northwestern University, Evanston, IL, United States, alejandra.pena@u.northwestern.edu, Andreas Waechter

In this work, we are presenting a nonparametric reformulation of an optimization problem with chance constraints. The probabilistic constraints will be redefined as the Value-at-Risk (VaR) and a smoothing technique will be applied on the historical empirical quantile via a Kernel. This method results in an approximation of the quantile function that reduces the nonconvexity of the feasible region derived from the empirical quantile approximation. Some computational results are included.

4 - A Trust Funnel Algorithm for Equality Constrained Nonconvex Optimization

Mohammadreza Samadi, PhD Candidate, Lehigh University, Bethlehem, PA, 18015, United States, mos213@lehigh.edu, Frank E. Curtis, Daniel Robinson

A method is proposed for solving equality constrained nonlinear optimization problems. The method employs a trust funnel approach consisting of two phases: a first phase to locate an ϵ-feasible point and a second phase to seek optimality while maintaining ϵ-feasibility. A two-phase approach of this kind based on a cubic regularization methodology was recently proposed, which completely ignores the objective function in the first phase. Our method achieves the same worst-case iteration complexity, but with a first phase that also accounts for improvements in the objective function. As such, the method requires fewer iterations, as the numerical experiments demonstrate.

10:30 - 11:15 Responsive Learning Technologies/11:15- 12:00 FICO

Invited: Vendor Tutorial

Invited Session

1 - Online Games to Teach Operations and Supply Chain Management

Samuel C.Wood, Responsive Learning Techologies, 4546 El Camino Real, #243, Los Altos, CA, 94022, United States, wood@responsive.net

Littlefield Technologies, the Supply Chain Game, and the Sourcing Game are online competitive assignments used to teach topics including process analysis, inventory control, supply chain management, and sourcing and purchasing. We will describe the games' learning objectives, typical assignments, and actual game results.

2 - How to Deploy Your Analytic Models to Empower Non-Technical Business Users

James Williams, FICO, Roseville, MN, United States, JWilliams@fico.com

You have a team with great analytics background. They have developed advanced analytical tools using Python, R, or with your current traditional optimization solver. They have derived crucial insights from your data, and figured out how your decisions shape your customers' behaviors. Now it's time to put these critical analytical insights in the hands of your non-technical business users. In this tutorial, we will cover how FICO's Optimization Suite (including Xpress-Mosel, Xpress-Workbench, and Xpress-Insight) make it possible to embed your analytic models in user-friendly business-user facing applications. Learn how you can supercharge your analytic models with simulation, optimization, reporting, what-if analysis and agile extensibility.

New Results for Coordinate Descent and Related Methods for Convex Optimization

Sponsored: Optimization, Linear and Conic Optimization

Sponsored Session

Chair: Robert Michael Freund, MIT, Cambridge, MA, 02139, United States, rfreund@mit.edu

Co-Chair: Haihao Lu, MIT, Cambridge, MA, 02142, United States, haihao@mit.edu

1 - Pathwise Coordinate Optimization for Nonconvex Sparse Learning

Tuo Zhao, Georgia Tech, Atlanta, GA, United States, tourzhao@gatech.edu

Nonconvex optimization arises in many machine learning problems. Although classical optimization theory has shown that nonconvex optimization is computationally intractable, practitioners have proposed numerous heuristic algorithms, which achieve outstanding performance in real-world applications. To bridge this gap between practice and theory, we propose a new generation of model-based optimization algorithms and theory, which incorporate the statistical thinking into modern optimization. We exploit hidden geometric structures behind nonconvex optimization problems, and obtain global optima with desired statistics properties in polynomial time with high probability.

2 - Relatively-continuous Convex Optimization via Mirror Descent Algorithm

Haihao Lu, MIT, 60 Wadsworth St, Apt.14E, Cambridge, MA, 02142, United States, haihao@mit.edu

The usual approach to developing and analyzing first-order methods for non-smooth convex optimization assumes that the objective function is uniformly Lipschitz continuous. However, in many settings the non-differentiable convex function is not uniformly Lipschitz continuous. Herein we develop a notion of "relative continuity" that is determined relative to a user-specified "reference function" (that should be computationally tractable for algorithms), and we show that many non-differentiable convex functions are relatively continuous with respect to a correspondingly fairly-simple reference function. We use mirror descent algorithm for solving problems in this setting.

Leveraging OR to Assess and Enhance Power Systems Resilience

Sponsored: Energy, Natural Res & the Environment Electricity

Sponsored Session

Chair: Roshi Nateghi, rnateghi@purdue.edu

1 - Assessing Changes in Residential Electric Power Consumption Due to Emerging Changes in Climate and Technology

Hua Cai, Purdue University, West Lafayette, IN, 47907, United States, huacai@purdue.edu, Roshanak Nateghi, Ruoxi Wen, Benjamin Rachunok

The electricity sector - particularly the residential sector - is undergoing significant transformations due to the emerging changes in technology (e.g., distributed generation, electric vehicles), policy, and climate. However, the existing energy systems models (e.g., NEMS, MARKAL) are highly deterministic and do not adequately account for the uncertainties associated with future climate or technology adoption scenarios. Using agent-based models, we aim to estimate the residential electricity use over the next 30 years, considering not only the energy demand for space conditioning with different housing characteristics, but also the adoption and use of EV and PV at the household level.

2 - Assessing Residential Power Inadequacy Risks in the U.S.

Roshanak Nateghi, Purdue University, West Lafayette, IN, 47907, United States, rnateghi@purdue.edu

The US power system is increasingly vulnerable to adverse impacts of extreme weather and climate events. Supply inadequacies can result from unanticipated climate-induced shifts in demand. This talk is primarily focused on the risks associated with deviated residential demand patterns due to climate variability and change. A data-driven approach is leveraged to identify and assess the risk factors that render the residential electricity sector vulnerable in face of future climate variability and change. The proposed method, can be used by the energy professionals and regulators to design effective mechanisms to minimize supply inadequacy in face of climate variability and change.

3 - Enhancing Resilience of the Electric Power Sector after Hurricane Sandy

Cameron MacKenzie, Iowa State University, 3029 Black Engineering, Industrial and Manufacturing Systems Eng, Ames, IA, 50011, United States, camacken@iastate.edu, Christopher Zobel

This talk presents a framework to help a decision maker allocate resources to increase his or her organization's resilience to a system disruption, where resilience is measured as a function of the average loss per unit time and the time needed to recover full functionality. Enhancing resilience prior to a disruption involves allocating resources from a fixed budget to reduce the value of one or both of these characteristics. The optimization model is applied to an example of increasing the resilience of an electric power network following Superstorm Sandy.

4 - Parallel Computing of Stochastic Programs with Application to Energy System Capacity Expansion

Run Chen, Purdue University, 1399 Neil Armstrong Drive, Apt 7, West Lafayette, IN, 47906, United States, chen885@purdue.edu, Andrew Lu Liu

Power grids' planning and operations exhibit extreme multiscale, ranging from hourly operation to decades of planning. The linkage such decisions can be treated in a primal-dual fashion to produce multiple independent subproblems. We propose to use a primal-dual-based proximal method to design a parallel algorithm to solve such multiscale problems. Convergence can be shown for both convex and non-convex problems. We use the algorithm to demonstrate the importance to consider ramping constraints in finer time-scale in long-term capacity planning with large-scale renewable resources.

5 - Possible Improvements for Generation Reserves to Back-up Wind in the Dutch Electricity Market

Robin Broder Hytowitz, Johns Hopkins University, 3400 North Charles Street, Ames 313, Baltimore, MD, 21218, United States, hytowitz@jhu.edu, Ozge Ozdemir, Paul Koutstaal, Benjamin Field Hobbs

Reserve capacity is needed in an electric system in case of a contingency. With the increased penetration of renewable energy in the Netherlands, a new type of renewable contingency can require additional reserve on the system. The Netherlands currently procures reserve months in advance through long time contracts with little coordination with its neighbors. This project suggests improvements that can be made to the process of procuring, allocating, and activating reserve. A nodal model of Europe is used to analyze the improvements, employing a future scenario with high wind penetration. Comparison of different improvements will elucidate which have the most benefits to the system as a whole.

Automotive

Contributed Session

Chair: Mark Colosimo, Urban Science Applications, Inc., Detroit, MI, United States, macolosimo@urbanscience.com

1 - Location Optimization Solution in Car Auction Industry

Wennian Li, Data Scientist, Cox Automotive, 18th Floor, 1001 Summit Blvd, Atlanta, GA, 30319, United States, li_wennian@hotmail.com

Cox Automotive is a leading provider of products and services for automotive dealers and car buyers. The company unites 30+ brands, including AutoTrader.com, Kelley Blue Book, Manheim, NextGear Capital, and vAuto, to help transform the way people buy and sell cars. The Location Optimization project helps the sellers to determine where to sell their inventory and gain more profit/ROI without lower the sale through rate and velocity at both wholesale and retail market. We provide a package solution for the seller not only just the suggested solution to locate their inventory, but also interactive interface for the current inventory, market status and suggested solutions.

2 - Using Leading Economic Indicators to Predict Changes in Monthly Car and Light Truck Sales in the United States Market

Karl Majeske, Associate Professor, Oakland Unverisity, School of Business Administration, Rochester, MI, 48309, United States, majeske2@oakland.edu

This research uses economic indicators (e.g., unemployment rates, gas price, consumer confidence, ect.) as independent variables to predict changes in car and light truck sales. Each economic indicator is evaluated in a variety of ways (actual values, monthly change and annual change) to determine the best measure to relate with sales. In addition, the economic indicators are lagged over a collection of time periods to identify the time lag that best correlates it's change to a related change in car and light truck sales. Establishing representations and time lags for a collection of economic indicators will allow determining how to identify an economic signal that future sales will change.

3 - Automobile Logistics Optimization Between Mexico and the United States

Ahad Ali, Associate Professor, Lawrence Technological University, 21000 West Ten Mile Road, 21000 West Ten Mile Road, Southfield, MI, 48075, United States, aali@ltu.edu

The goal of this project is to optimize the logistics of an automobile company between Mexico and the U.S. The logistics involved are the ones between the manufacturing plants of one of these companies in Mexico, how they interact between each other, and how they transport the products from one country to another. The methods that are going to be used are optimization methods and simulation. The possible outcome of this research is to optimize the logistics method one of these companies use in order to reduce costs and time. Optimization techniques and simulation will be done in order to reduce the costs and time of transferring the car parts between plants and countries.

4 - The Future of Autonomous Carsharing - A Delphi Study

Katrin Merfeld, EBS.Universitaet fuer Wirtschaft und Recht, Gustav-Stresemann-Ring 3, Wiesbaden, 65189, Germany, katrin.merfeld@ebs.edu, Mark-Philipp Wilhelms, Karin Kreutzer, Sven Henkel

Autonomous driving is set to disrupt the mobility landscape in the coming years. Academia predominantly examines individual aspects of this novel technology, such as enhanced traffic safety or ethical issues. As individual adoption may be hindered by financial hurdles, autonomous cars will be especially relevant for carsharing practices. We conducted a four-stage Delphi study with 40 international experts from various sectors to elicit drivers, barriers and future developments of carsharing with autonomous vehicles. We discuss our findings and draw implications for managers and further academic research.

5 - Time to Recall Decision Making

Chelsey Helena Hill, Drexel University, Gerri C. LeBow Hall Room #730, 3220 Market Street, Philadelphia, PA, 19104, United States, chh35@drexel.edu, Chaojiang Wu

This paper investigates the impact of the time-to-recall decision on marketing and operations performances in the automobile industry. While we find that the consumer market seems to have little response to the delay of recalls, recall effectiveness deteriorates. This motivates the creation of an analytical model to quantify the impact of this delaying effect on recall costs. Using the estimated relationship between time and effectiveness from our empirical model, we present an analytical model minimizing total recalls costs. The findings reveal that an early recall decision is primarily driven by higher liability costs, and later recall decisions are driven by the cost of sales disruption.

6 - Evaluating the Qualitative Aspects of Automotive Dealerships Alongside Traditional Quantitative Metrics

Mark Colosimo, Urban Science Applications, Inc., 400 Renaissance Center, Suite #2900, Detroit, MI, 48315, United States, macolosimo@urbanscience.com

Quantitative metrics to evaluate automotive dealerships is a practice that has existed and grown over many decades. Now, even more data is available and the number of metrics of Key Performance Indicators is overwhelming to those trying to operate a dealership business. Additionally, these indicators do not tell the whole story. There are many other activities within a dealership that are not measured or require additional research in order to determine their impact on desired outcomes. This study begins to simply what a dealership operator must regularly review to obtain a complete perspective on their operation, while incorporating new analysis via survey results of actual dealership operators.

1 - Inspecting Railways for Defects: A Game Theoretic Approach

Pedro Cesar Lopes Gerum, Rutgers University, New Brunswick, NJ, pedro.gerum@gmail.com, Melike Baykal-Gursoy

Train track inspections are important to repair defects that could cause delays or accidents. Even though most train companies have inspection guidelines, there is little research done on optimal track inspection scheduling policies. Our research addresses this issue by using game theoretic concepts to determine the optimal strategy for inspection crews. We define a number of zero-sum hider and searcher games, each with increased complexity. The higher the complexity, the more accurate the strategy represents the true optimal strategy for the problem; however, the more complex the game is, the more data is needed. Additionally, we provide data analysis on train track defects, exemplifying how the parameters for the games can be defined.

2 - Evolution and Development of Railway Passenger Hub

Liwen Wang, Southwest jiaotong University, chengdu, China, siyu.tao@okstate.edu
Liwen Wang, National United Engineering Laboratory of Integrated and Intelligent Transportation, Chengdu, China, siyu.tao@okstate.edu, Qiyuan Peng, Qiyuan Peng, Siyu Tao, Siyu Tao, Siyu Tao

This article studies optimization method of railway passenger hub in the big city of contemporary in China. It reviews evolution stages and its inner dynamic on railway passenger hub in China and abroad, comparatively analyzes the different cases in order to sum up the valuable experience. It shows that railway station in urban centers of China should be both transport nodes and urban places, Urban-Station Complex is its development trend only in necessary given conditions.

3 - Exact and Heuristic Algorithms for the Real-time Train Scheduling and Routing Problem

Marcella Sama, Post-Doc, Roma Tre University, 79 via della Vasca Navale, Roma, 00146, Italy, sama@ing.uniroma3.it, Andrea D'Ariano, Marco Pranzo, Dario Pacciarelli

This talk deals with the real-time train scheduling and routing problem. The problem is NP-hard and finding a good quality solution in a short computation time for practical size instances is a challenging task. We propose a solution approach based on the relaxation of train routing constraints in the formulation. Working in the relaxed problem allows to quickly compute good quality lower bounds, and represents the first step toward the development of a branch-and-bound algorithm for the overall problem. Computational experiments are performed on several networks and disturbed traffic situations.

4 - Railroad Crew Balancing Model

Jaydeep Kumar Chanduka, Masters' Student, University of Illinois, Urbana-Champaign, 1618 Melrose Park Court, Urbana, IL, 61801, United States, jkc2@illinois.edu

In this paper, we are trying to minimize the operational cost of crew balancing in a railroad network by optimizing crew deadhead, crew assignment, and train delay decisions. We assume that there is not always sufficient crew at each terminal for all the trains. Some of the crew must be deadheaded to different terminals while others have to be detained at other terminals to match all the trains. All the major constraints of the railway industry are considered in this paper. Some of them being: mandatory minimum rest, crew ordering, and detention rules. Crew pairing and assignment is a very intensively studied problem in the airline industry but railroad industry has evaded this problem so far. In this paper, the problem is formulated by applying the concept of "virtual crew" and a multi-day time period is studied. The effect of single day model and multi-day model is analysed with one home terminal and a number of away terminals. The results show that multi-day model gives a better performance in terms of objective values and computational time.

5 - Scheduling Trains to Minimize Peak Power and Maximize Regenerative Braking Power Utilization

S. Viswanathan, Professor of Operations Management, Nanyang Technological University, Nanyang Business School, Nanyang Avenue, Singapore, 639798, Singapore, asviswa@ntu.edu.sg, Mahendra Birhade, Rohit Bhatnagar

We address energy-efficient train scheduling for urban Mass Rapid Rail Systems. We formulate and solve an IP model that aims to minimize both peak power and total energy consumption. Test results on real problem instances obtained from the Mumbai Suburban System show that on average our model reduces the peak power demand by 28% and increase the regenerative braking energy utilization by 7.5 % while limiting the average trip time increases to only 2%.

Planning and Operation of Energy and Chemical Hubs with Renewables and Storage

Sponsored: Energy, Natural Res & the Environment, Energy

Sponsored Session

Chair: Kaveh Rajab Khalilpour, Monash University, Melbourne, Australia, kr.khalilpour@monash.edu

1 - Expansion Planning under Long-term Uncertainty for Hydrothermal Systems with Volatile Resources

Álvaro Lorca, Pontificia Universidad Católica de Chile, Departamento de Ingeniería Eléctrica, Av Vicuna Mackenna 4860, Santiago, 7820436, Chile, alvarolorca@uc.cl, Benjamín Maluenda, Matias Negrete-Pincetic, Daniel Olivares

The significant integration of volatile energy sources in power systems stimulates the use of greater operational details in power system expansion planning models. Motivated by this, we will present a stochastic expansion planning model for hydrothermal power systems, including uncertainty in water inflows and using representative days to capture inter-hourly phenomena such as renewable power production profiles and energy storage. Computational experiments showing the advantages of the proposed model for an actual power system will also be presented.

2 - Enhanced Representative Days and System States Modeling for Energy Storage Investment

Diego Alejandro Tejada Arango, Universidad Pontificia Comillas, 23 Alberto Aguilera, Madrid, 28015, Spain, dtejada@comillas.edu, Sonja Wogrin, Efraim Centeno

In this work, we analyze the impact of different options to represent the operation decisions in the study of energy storage (ES) investment for long-term planning models. We compare the representative days and the system-states approaches for the representation of these operation decisions. We proposed enhanced versions of these approaches to improve the ES investment approximation. An Spanish case study isevaluated and the results are used to identify the potential profits that energy storage investment can obtain.

3 - A Risk-averse Approach for the Planning of a Hybrid Renewable Energy System

Ozlem Yilmaz, Bilkent University, Universiteler Mah, Bilkent/Cankay, Ankara, 06800, Turkey, ozlem.yilmaz@bilkent.edu.tr, Ozlem Cavus, Ayse Selin Kocaman

We consider a risk-averse approach to a two stage stochastic programming problem that aims to design a hybrid renewable energy system consisting of solar panels and hydropower stations in a most cost effective way in order to satisfy the demand for energy. We use Conditional Value at Risk (CVaR) as the measure of risk and propose a scenario-wise decomposition algorithm to solve this model. The main source of the randomness is water inflow to the reservoirs. We therefore generate scenarios for inflow using a modified K-NN method developed by Prairie et.al (2006).

Distributionally Robust Optimization: Theory and Applications

Sponsored: Optimization, Optimization Under Uncertainty

Sponsored Session

Chair: Ruiwei Jiang, University of Michigan, University of Michigan, Ann Arbor, MI, 48109, United States, ruiwei@umich.edu

1 - Distributionally Robust Optimization with Principal Component Analysis

Jianqiang Cheng, University of Arizona, jqcheng@email.arizona.edu, Richard Li-Yang Chen, Habib Najm, Ali Pinar, Cosmin Safta, Jean-Paul Watson

In this talk, we propose a new approximation method to solve distributionally robust optimization problems with moment-based ambiguity sets. Our approximation method relies on principal component analysis (PCA) for optimal lower dimensional representation of variability in random samples. We show that the PCA approximation yields a relaxation of the original problem and derive theoretical bounds on the gap between the original problem and its PCA approximation. Furthermore, an extensive numerical study shows the strength of the proposed approximation method in terms of solution quality and runtime.

2 - Optimized Bonferroni Approximations of Distributionally Robust Joint Chance Constraints

Weijun Xie, Georgia Institute of Technology, 4301 Lakeshore Xing NE, Atlanta, GA, 30324, United States, wxie33@gatech.edu, Shabbir Ahmed, Ruiwei Jiang

In this paper, we study a conservative approximation - referred to as a Bonferroni approximation - of a joint chance constraint, i.e. a chance constraint involving a system of multiple uncertain constraints. We show that such a Bonferroni approximation is exact when the uncertainties are separable across the individual constraints, i.e., each uncertain constraint involves a different set of uncertain parameters and corresponding distribution families. We show that, while in general the optimization over the Bonferroni approximation is NP-hard, there are various sufficient conditions under which it is convex and tractable.

3 - Distributionally Robust Contingency-Constrained Unit Commitment

Chaoyue Zhao, Oklahoma State University, 4599 North Washington Street APT.32J, Stillwater, OK, 74075, United States, cherryzhao09@gmail.com

In this work, we propose a distributionally robust optimization approach for the contingency-constrained UC problem. We consider a case where the true probability distribution of contingencies is difficult to accurately estimate. Instead of assigning a probability estimate for each contingency scenario, we consider a set of contingency probability distributions based on the N - k security criterion and moment information. Our approach considers all possible distributions in the ambiguity set, and is hence distributionally robust. Meanwhile, as this approach utilizes moment information, it can benefit from available data and become less conservative than robust optimization approaches.

4 - Ambiguous Risk Constraints with Moment and Unimodality Information

Ruiwei Jiang, University of Michigan, 1205 Beal Ave., Ann Arbor, MI, 48109, United States, ruiwei@umich.edu, Bowen Li, Johanna Mathieu

We study risk constraints based on probabilistic guarantee and conditional value-at-risk under distributional ambiguity. We find that these risk constraints can be recast as a set of second-order conic constraints if we characterize the ambiguity based on moment and unimodality information. We demonstrate the theoretical results via a computational case study on power system operations.

Parallelization and Evaluation of Stochastic Programming Algorithms

Sponsored: Optimization, Optimization Under Uncertainty

Sponsored Session

Chair: Jean-Paul Watson, Sandia National Laboratories, Albuquerque, NM, 87113-2065, United States, jwatson@sandia.gov

1 - Parallel Decomposition and Analysis of Contingency-Constrained AC Optimal Power Flow Problems

Jean-Paul Watson, Distinguished Member of Technical Staff, Sandia National Laboratories, 7305 Blue Cypress Avenue NE, Albuquerque, NM, 87113-2065, United States, jwatson@sandia.gov, Carl Laird, Anya Castillo

We present a nonlinear stochastic programming formulation for the contingency-constrained optimal power flow problem. Using a non-linear AC power flow model, we construct a nonlinear, multi-scenario optimization formulation where each scenario considers nominal operation followed by a failure an individual transmission element. Given the number of potential failures in the network, these problems are large, yet must be solved rapidly. We demonstrate that this multi-scenario problem can be solved quickly using a parallel decomposition approach based on progressive hedging and nonlinear interior-point methods. Parallel and serial timing results are shown using Matpower test cases.

2 - Evaluation of Decision Systems in the Presence of Uncertainty

David L. Woodruff, University of California-Davis, Graduate School of Management, One Shields Avenue, Davis, CA, 95616, United States, dlwoodruff@ucdavis.edu

When inputs are uncertain, the performance of a decision system requires consideration both of the way stochastic processes are modelled as well as the optimization models and methods. In this talk we will describe ongoing work to provide software to support this sort of validation.

3 - Internal Decomposition Approaches for Nonlinear Programming Problems in Power Systems

Carl Laird, R&D Software and Engineering, Sandia National Laboratories, Albuquerque, NM, United States, cdlaird@sandia.gov

Stocahstic programming is an important tool for advanced design and operation of power transmission systems. To ensure optimal solutions are feasible for the real system, there is a need to include rigorous nonlinear models of AC transmission within the multi-scenario problem. In this presentation, we discuss key applications of nonlinear stochastic programming in power systems and compare different decomposition strategies for these large-scale nonlinear optimization problems.

4 - A Framework for Modeling and Optimizing Dynamic Systems under Uncertainty

Bethany Nicholson, Sandia National Laboratories, 11600 Academy Rd NE, Apt 3924, Albuquerque, NM, 87111, United States, blnicho@sandia.gov, John Siirola

There are many classes of optimization problems that are not easily represented in most Algebraic modeling languages (AMLs). These problems are typically reformulated before implementation, requiring significant effort from the modeler and obscuring the original problem structure or context. In this talk we show how the Pyomo AML can be used to represent complex models using high-level constructs. We describe the model transformations available in Pyomo for transforming high-level constructs to solvable forms, we demonstrate the combination of Pyomo extensions for stochastic programming and dynamic optimization, and we show the scalability of this framework on large-scale models.

Optimization, Robust

Contributed Session

Chair: Jagdish Ramakrishnan, Walmart Labs, 1000 National Ave, Unit 214, San Bruno, CA, 94066, United States, jagdish.ram@gmail.com

1 - Stochastic Variance Reduction Method with Low Memory and Operation Cost for Smooth Finite Sum Optimization

Jourdain Lamperski, Massachusetts Institute of Technology, 540 Memorial Drive, Cambridge, MA, 02139, United States, jourdain@mit.edu

We propose a stochastic variance reduction method for the minimization of a smooth finite sum of convex functions. Current stochastic variance reduction methods enjoy a faster convergence rate than "vanilla" methods like stochastic gradient descent, but incur either a higher operation or memory cost. We show in the context of logistic regression that our method preserves the operation and memory complexity of stochastic gradient descent while enjoying the faster sublinear rate of convergence. Various aspects of the convergence analysis generalize to the setting of smooth finite sum optimization. We present several numerical results that support our theoretical analysis.

2 - Topology Optimization using Conditional Value at Risk

Geoffrey Oxberry, Member of the Technical Staff, Lawrence Livermore National Laboratory, 2934 Worthing Common, Livermore, CA, 94550, United States, oxberry1@llnl.gov

Traditional approaches to formulating stochastic topology optimization problems for additive manufacturing tend to use linear combinations of the mean and standard deviation of a design figure of merit (e.g., compliance). However, this choice of objective/constraint underweights tail events for non-normal random variables. We propose replacing these mean-plus-standard-deviation expressions with the conditional value-at-risk (CVaR), and argue that it better compensates for worst-case tail events.

3 - An Inexact Bundle Method for Risk-averse Two-stage Stochastic Optimization

Ricardo A. Collado, Assistant Professor, Stevens Institute of Technology, 1 Castle Point Terrace, Hoboken, NJ, 07030, United States, ricardo.collado@stevens.edu, Somayeh Moazeni

We consider multistage stochastic optimization problems with elements of risk aversion obtained via dynamic coherent risk measures. For these problems we develop inexact and sampled bundle methods that require only a fraction of cut and subgradient generating problems to be solved. We demonstrate our methods with an application to network interdiction.

4 - Optimization of a Portfolio of American Options with Continuous Strikes

Dmitry Chernikov, University of Arizona, Tucson, AZ, 85705, United States, dchernikov@email.arizona.edu, Pavlo A. Krokhmal

In this work we consider an options portfolio optimization problem where strikes of options are included as continuous control variables. Such a setting can be interesting from the perspective of the asset liability management, the sell side, or from the point of view of a person who has an opportunity to buy and sell an option with any strike they choose. We present different ways to formulate and solve such a problem including MIP and biconvex maximization. In case of biconvex formulation, by employing problem's special structure we derive an algorithm that is guaranteed to converge to a KKT point. Numerical results are demonstrated.

5 - Dual Approximate Dynamic Programming for Multi-stage Stochastic Unit Commitment

Jagdish Ramakrishnan, Data Scientist, Walmart Labs, 1000 National Ave, Unit 214, San Bruno, CA, 94066, United States, jagdish.ram@gmail.com, James Luedtke

We study the multi-stage stochastic unit commitment problem in which commitment and generation decisions can be made and adjusted in each time period. We formulate this problem as a Markov decision process, which is "loosely coupled" in the sense that if the demand constraint is relaxed, the problem decomposes into a separate, low-dimensional, Markov decision process for each generator. We demonstrate how the dual approximate dynamic programming method of Barty, Carpentier, and Girardeau (2010) can be applied to obtain bounds and a policy for this problem, and present numerical results.

Meet the Editors

Sponsored: Decision Analysis

Sponsored Session

Chair: L Robin Keller, University of California, Irvine, University of California, Irvine, Irvine, CA, 92697-3125, United States, LRKeller@uci.edu

1 - Meet the Editors

L.Robin Keller, University of California, Irvine, Paul Merage School of Business, Irvine, CA, 92697-3125, United States, LRKeller@uci.edu

Editors at major outlets for Decision Analysis research will discuss their experiences in evaluating decision analysis research, followed by a Q&A session.

2 - Panelist, Editor, Decision Analysis

Rakesh Kumar Sarin, University of California-Los Angeles, Anderson School, Suite B519, 110 Westwood Plaza Box 95148, Los Angeles, CA, 90095-1481, United States, rakesh.sarin@anderson.ucla.edu

3 - Panelist, Department Editor for Decision Analysis, Management Science

Manel Baucells, University of Virginia, Darden School of Business, 100 Darden Boulevard, Charlottesville, VA, 22903, United States, mbaucells@gmail.com

4 - Panelist, Area Editor for Decision Analysis, Operations Research

Kevin F.McCardle, UCLA, Anderson School at UCLA, 110 Westwood Plaza Box 951481, Los Angeles, CA, 90095-1481, United States, kevin.mccardle@anderson.ucla.edu

5 - Panelist, Department Editor for Decision Analysis, IISE Trans. (Oper. Engr. & Anal. focus)

Ali E.Abbas, University of Southern California, Center for Interdisciplinary Decisions and Et, Industrial and Systems Engineering and Public, Los Angeles, CA, 90015, United States, aliabbas@usc.edu

Decisional Conflicts and Incentives in Healthcare

Sponsored: Decision Analysis

Sponsored Session

Chair: Mehmet U.S. Ayvaci, University of Texas at Dallas, Richardson, TX, 75080-3021, United States, mehmet.ayvaci@utdallas.edu

Co-Chair: YeongIn Kim, University of Texas-Dallas, Richardson, TX, 75080, United States, yxk130930@utdallas.edu

1 - Strategic Flexibility in Health Practice Guidelines under Litigation Concerns

YeongIn Kim, University of Texas-Dallas, 800 W. Renner Road, Apt 711, Richardson, TX, 75080, United States, yxk130930@utdallas.edu, Mehmet U. Ayvaci, Srinivasan Raghunathan, Turgay Ayer

We examine the optimal formulation of guidelines in a generic health screening with consideration for the physician's increased liability risk under ubiquitous health information and information technologies. We find that under the litigation concern, the social planner strategically provides guidelines with flexible recommendations regarding which patients should undergo the test while providing rigid guidelines regarding the physician's decisions based on test results. Strategic flexibility in guidelines may lead to lower utilization of health care services, depending on the benefit and cost of the test considered.

2 - Clinical Ambiguity and Conflicts of Interest in Interventional Cardiology Decision-making

Tinglong Dai, Johns Hopkins University, 100 International Dr, Baltimore, MD, 21202, United States, dai@jhu.edu, Xiaofang Wang, Chao-Wei Hwang

Conventional wisdom suggests that more-precise diagnostic testing will help to reduce overtreatment. However, the literature rarely recognizes that the decision about whether to administer these tests is itself endogenous. In this paper, we examine inappropriate usage of percutaneous coronary intervention (PCI) procedures for stable coronary artery disease patients. Advanced intracoronary tests such as fractional flow reserve provide more precise and objective measures of the physiologic severity of coronary stenosis. We model both clinical ambiguity and conflicts of interest in an interventional cardiologist's decision to administer advanced tests.

3 - Design of Two-tiered Payment Model for Maternity Care

Cheng Zhu, McGill University, 701-801 Sherbrooke Est, Montreal, QC, H2L.0B7, Canada, cheng.zhu@mail.mcgill.ca, Beste Kucukyazici

The amount of unnecessary C-Sections, which expose proven higher postpartum complications of mothers and newborns as well as heavy economic burden, has been increasing constantly and this growth raises great concerns for the policy makers. This research proposes a two-tiered payment mechanisms to reimburse obstetricians, in order to reduce unnecessary C-sections while retain it for those who need it, resulting in enhanced birth quality with alleviated economic burden for overall health care system. The optimal reimbursement schemes are further verified empirically with large data sets.

Environmental Policy and Decision Analysis

Invited: Tutorial

Invited Session

1 - Environmental Policy and Decision Analysis

Max Henrion, Lumina Decision Systems, Inc, Los Gatos, CA, United States, henrion@lumina.com

Climate change and other environmental crises create a growing need for analysts who can design and evaluate policies that reconcile environmental and economic sustainability. I'll explain the practical value of decision analysis, influence diagrams, treating uncertainty, multi-attribute tools, creative option design, and model-driven stakeholder conversations. I'll illustrate the use of these methods in the successful "rigs to reefs" analysis of how to decommission California's offshore oil platforms, which achieved policy consensus.

Co-Chair: Xuewei Yang, Nanjing University, Nanjing, 210093, China, xwyang@nju.edu.cn

1 - Stochastic Game of Finite Fuel Problem

Renyuan Xu, University of California-Berkeley, 4141 Etcheverry Hall, OR.Department, Berkeley, CA, 94720, United States, dorisxu1026@gmail.com, Xin Guo

In general, finding a Nash equilibrium or proving Pareto optimality for continuous-time stochastic game with multiple players is hard, even when there are only two players in the game. Mean Field Game (MFG) provides a powerful tool and analytically feasible framework to approximate the Nash equilibrium of the N-player stochastic games. In this talk, we will first present the stochastic game for the classical finite fuel follower problem in the seminal paper by Benes, Shepp, and Witsenhausen (1980). We will then solve and compare with explicit solutions for the Nash equilibrium and the Pareto optimality for the two-player game, and the corresponding MFG when the number of players goes to infinity.

2 - An Optimal Stopping Problem under General Levy Model

Wei Zhang, Hong Kong University of Science and Technology, Hong Kong, Hong Kong, wzhangas@ust.hk

We consider a pricing problem of one financial instrument, which is essentially an optimal stopping problem, under the general L\'{e} model. We give both the probabilistic and the algebraic characterization of the continuation region. Finally, we give some examples under some specific L\'{e}vy models.

3 - Credit Ratings as Regimes: Evidence from the Sovereign Credit Default Swaps Market

Xuewe I. Yang, Nanjing University, Hankou Road 22, Gulou District, Nanjing, 210093, China, xwyang@nju.edu.cn

We study sovereign credit risk through a rating-based regime switching model. Each country's default intensity consists of a rating-modulated systematic factor and an idiosyncratic factor. The rating-dependence enables the model to conduct cross-sectional predictions, generate model-implied ratings, and jointly capture CDS spreads of multiple countries. Consequently, a 17-parameter version of the model fits CDS spreads of 68 countries equally well with the classical country-by-country model with hundreds of parameters. The systematic factor along with the observed (model-implied) ratings can explain more than 60% (80%) of the variations of sovereign CDS spreads of all countries.

4 - Mean-variance-Skewness Portfolio Selection

Jingnan Chen, Singapore University of Technology and Design, 20 Dover Drive, Singapore, 138682, Singapore, jingnan_chen@sutd.edu.sg, Fang Zhen

We introduce a mean-variance-skewness portfolio selection model to account for the asymmetry in portfolio returns. Assuming a multivariate skew-normal distribution for asset returns, we obtain a mean-variance-skewness efficient frontier and derive a closed-form optimal portfolio strategy. In addition, we propose a three-moment capital asset pricing model incorporating skewness for asset valuation. The superiority of our mean-variance-skewness portfolio strategy over the classical mean-variance strategy is demonstrated through empirical tests.

Advances in E-commerce

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Van-Anh Truong, Columbia University, Mudd Hall, New York, NY, 10027, United States, vt2196@columbia.edu

1 - Online Resource Allocation under Arbitrary Arrivals: Optimal Algorithms and Tight Competitive Ratios

Will Ma, MIT, willma353@gmail.com, David Simchi-Levi

We consider the problem of allocating fixed resources to heterogeous customers arriving sequentially, under the framework of competitive analysis, which does not assume any predictability in the sequence of customer arrivals. We derive the first optimally-competitive algorithms when there are both multiple resources, and different rewards for allocating resources to different customers. Our algorithms are simple, intuitive, and robust, and broadly expand the applicability of competitive analysis, in areas such as online advertising, matching markets, and personalized e-commerce. We test our methodology extensively on the publicly-accessible hotel data set of Bodea et al.

2 - Approximation Algorithms for Dynamic Assortment Optimization Models

Ali Aouad, Massachusetts Institute of Technology, Cambridge, MA, United States, aaouad@mit.edu, Retsef Levi, Danny Segev

Motivated by retailing in highly-differentiated markets, we study joint assortment optimization and inventory management. Here, customers show a dynamic substitution behavior elicited by stock-out events. We devise the first provably-good algorithms by revealing hidden submodular-like structure. Our approximation factor is best-possible under a general rank-based model, while we obtain constant-factor guarantees under popular specialized structures, such as Multinomial Logit. Our approach is an order of magnitude faster than existing heuristics and increases revenue by 6% to 12% in the experiments.

3 - Peak-end Demand Models and their Impact on Promotion Planning

Tamar Cohen, Massachusetts Institute of Technology, Cambridge, MA, United States, tcohen@mit.edu, Georgia Perakis

We consider the problem of promotion planning for a single product. We propose a new demand model that predicts actual sales more accurately than current methods. By utilizing the structure of this proposed demand model, we suggest a tractable Dynamic Programming approach and provide conditions under which it solves the promotion planning problem exactly. In the cases where these conditions do not hold, we provide an analytical guarantee. Finally, we test our approach on sales data and demonstrate improvement in the precision of the demand prediction as well as an increase in revenue.

4 - Dynamic Optimization of Mobile Push Advertising Campaigns

Xinshang Wang, Columbia University, New York, NY, United States, xw2230@columbia.edu, Van-Anh Truong, Shenghuo Zhu, Qiong Zhang

We study a novel resource-allocation problem where mobile push messages must be sent to hundreds of millions of users. Each message yields a reward when it generates a clickthrough, subject to a budget constraint. The problem aims to maximize total reward without overwhelming each user with too many messages. We propose an algorithm that sends push messages in two cycles and makes use of information observed in the first cycle to adapt decisions in the second cycle. The algorithm has a provable regret that is asymptotically smaller than the regret of simple LP-base algorithms. Numerical experiments on real data sets show that the former improves the regret of the latter by at least 10%-50%.

Economic Models in OM

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Manu Goyal, University of Utah, Salt Lake City, UT, 84112, United States, manu.goyal@eccles.utah.edu

1 - Price and Customization of a Conspicuous Good in Monopolies and Duopolies

Cheryl Druehl, Associate Professor, George Mason University, Fairfax, VA, 22030, United States, cdruehl@gmu.edu, Jesse Bockstedt

Consumers increasingly desire uniqueness, but within recognizable status-oriented brands. The model investigates the customization and pricing decisions of conspicuous goods in monopoly and duopoly settings. The firm trades-off the cost vs the demand-enhancing impact of customization, which allows better matching of customers' tastes. We find that the monopolist always benefits from offering horizontal product customization. In a duopoly market, however, a prisoner's dilemma scenario results. The dominant strategy is for both firms to offer a customizable good, but this outcome is not Pareto optimal.

2 - RFQ, Sequencing, and the Most Favorable Bargaining Outcome

Leon Zhu, University of Southern California, University Park Campus, Bridge Hall 401T, Los Angeles, CA, 90089, United States, leonyzhu@usc.edu, Ying Rong, Huan Zheng

We study quantity-dependent pricing contracts with exclusion clauses in a dual-sourcing setting when the suppliers are imperfect substitutes. We analyze the negotiations between a buyer and two suppliers both with and without a request for quotation (RFQ) stage that precedes the negotiation. We show that the buyer can leverage the RFQ stage even under a full information setting when the negotiation sequence is endogenously determined by the final quotations of the RFQ process. Specifically, the buyer's equilibrium payoff with RFQ dominates the most favorable equilibrium under bargaining without RFQ.

3 - Buyback Pricing of Durable Goods in Dual Distribution Channels
Gokce Esenduran, Ohio State University, 2100 Neil Avenue, 656 Fisher Hall, Columbus, OH, 43210, United States, esenduran@gmail.com, Lauren Xiaoyuan Lu, Jayashankar M. Swaminathan

In the U.S. automobile industry, manufacturers distribute cars through dealers and rental agencies. Rental agencies can compete against dealers by selling slightly used rental cars in the sales market. To mediate this conflict between the two intermediaries, manufacturers launched buyback programs to repurchase used rental cars from rental agencies and redistribute them through dealers. Manufacturers can precommit a buyback price to rental agencies at the time of initial sales or postpone the pricing to the time of repurchase. Using a two-period model with and without competition, we aim to understand how to manage buyback pricing to maximize manufacturer profits in dual distribution channels.

4 - Ethics, Bounded Rationality and the Hold Up Problem
Manu Goyal, University of Utah, 1655 E Campus Center Drive, 7235 Sfebb, Salt Lake City, UT, 84112, United States, manu.goyal@eccles.utah.edu, Krishnan S. Anand

In our study of the hold up problem, in addition to the classical profit-maximizing firm unconstrained by ethics, we model an ethically-constrained firm that honors its contractual obligations irrespective of legal restraints. We prove that under bounded rationality, the ethically-constrained firm can obtain strictly greater profits than the unconstrained profit-maximizing firm, even when (i) the unconstrained firm has access to a superset of the ethical firm's strategies, and (ii) the ethical firm is unable to reveal its ethical commitment to its contracting partner. Thus, we show that a commitment to ethics, while of course being morally desirable, can be a superior business strategy.

Teaching Innovations in Operations/Sustainability

Sponsored: Manufacturing & Service Oper Mgmt, Sustainable Operations

Sponsored Session

Chair: Erica Plambeck, Stanford University, Stanford, CA, 94305-5015, United States, elp@stanford.edu

1 - Sustainability in a Core OM Class
Erica Plambeck, Stanford University, Stanford, CA, 94305-5015, United States, elp@stanford.edu

I will speak about a new case and teaching materials for introducing climate science, life cycle analysis, and product-process innovation for net zero emission buildings, used in the base course in operations management for Stanford MBA students. I may also speak briefly about teaching for Stanford's joint MBA - MS Environment and Resources degree program.

2 - Business Sustainability as Extreme Operations
Andre Du Pin Calmon, INSEAD, Boulevard de Constance, Fontainebleau, 77300, France, andre.calmon@insead.edu

We present an overview of the new case studies and material developed for the course "Business Sustainability," an MBA elective at INSEAD. This course reframes sustainable operations as "extreme operations" and connects operations management and business model innovation to topics such as circular economy, industry self-regulation, and climate change. The course has attracted a wide range of students and has become one of the most popular MBA electives at INSEAD.

3 - Combining Curricular and Co-Curricular Approaches to Teaching Business Sustainability
Beril Toktay, Georgia Institute of Technology, Atlanta, GA, United States, beril.toktay@scheller.gatech.edu

In the presentation, I will share my experience teaching sustainability in our operations management program as well as promoting sustainability infusion at Scheller College and Georgia Institute of Technology.

4 - Share YOUR Teaching Innovations and Ideas
Erica Plambeck, Stanford University, Graduate School of Business, Knight Management Center, Stanford, CA, 94305-7298, United States, elp@stanford.edu

The final 15 minutes of session are reserved for discussion. Please share your innovations, needs and opportunities in teaching for environmental sustainability.

Computational Modeling for Public Health Decision Making

Sponsored: Health Applications

Sponsored Session

Chair: Ozgur M Araz, PhD, University of Nebraska-Lincoln, Lincoln, NE, 68588-0491, United States, oaraz2@unl.edu

1 - Modeling the National, State, and Individual-level Impact and Cost-effectiveness of HPV Vaccination
David Durham, PhD, Yale University, New Haven, CT, United States, david.durham@yale.edu, Martial Ndeffo-Mbah, Laura Skrip, Forrest Jones, Chris Bauch, Alison Galvani

Vaccines provide strong protection against cancer-causing HPV. However, coverage remains below targets and varies greatly across the US. We modeled HPV transmission, vaccination, and cervical cancer at the national, state, and individual levels. At the national level, the nonavalent vaccine, which covers more serotypes but at a greater cost, was cost-effective compared with older HPV vaccines. At the state level, the benefit gained per vaccine was greatest in states with the lowest coverage, due to decreasing marginal returns. At the individual level, the lifetime cancer risk was greatly reduced among vaccinated women, while herd immunity slightly reduced risk among unvaccinated women.

2 - Our Walk to the End of Cancer? Understanding Long-term Trends in Medical Screening
Ozge Karanfil, Harvard T.H. Chan School of Public Health, 651 Huntington Avenue, FXB Building, 643E, Boston, MA, 02115, United States, karanfil@hsph.harvard.edu, John D. Sterman

We develop a broad boundary feedback theory and formal model to explain dynamics of screening. The theory includes a decision-theoretic core, and feedbacks conditioning formal guidelines and actual practice. The model is generic but to provide context we use PSA screening as a motivating example to present a behaviorally realistic model that creates oscillations in policy recommendation thresholds. This core model, entailing only the evidence generation and translation processes, demonstrates how oscillations are natural to this category of problems due to inherent delays in evidence-based screening. These fluctuations lead to long periods during which guidelines are suboptimal.

3 - The Potential Impact of the Affordable Care Act and Medicaid Expansion in North Carolina on Reducing Colorectal Cancer Screening Disparities Among African American Males
Leah Frerichs, PhD, University of North Carolina Chapel Hill, NC, United States, leahf@email.unc.edu, Wizdom Powell, Rachel M. Townsley, Maria Esther Mayorga, Giselle Corbie-Smith, Stephanie B. Wheeler, Kristen Hassmiller

We used an individual based simulation model to estimate the impact of ACA and Medicaid expansion in NC on colorectal cancer (CRC) screening, incidence and death among African American (AA) and White males. Using a synthetic population of NC males, we simulated the natural progression of CRC, CRC screening compliance (by demographic characteristics and insurance status), and CRC incidence, survival, and death. ACA and Medicaid Expansion policy scenarios reduced disparities in CRC screening between AA and white males. Due to savings in treatment costs, Medicaid Expansion has potential to result in $9.6 million in cumulative cost savings for White males and $5.1 million for African American males.

4 - Assessing Jail Based Sexually Transmitted Disease Screening Programs for Optimized Public Health Benefit
Ozgur M.Araz, P.O. Box 880491, CBA 260, Lincoln, NE, 68588-0491, United States, oaraz2@unl.edu, Maytee Cruz-Aponte

We present a mathematical model of Chlamydia trachomatis (CT) transmission dynamics with two interacting populations and analyze the impact of both screen-treat operations and behavioral interventions. Analytical assessment of the public health interventions are presented in support of extracting the value of the screening and treatment operations using the jail systems and theoretical and practical insights are provided for various scenarios of controlling the epidemic for general cases. Numerical simulation results are then analyzed and presented for a predefined specific population in a case study in order to evaluate the effectiveness of the public health programs.

Improving Access and Outcomes in Healthcare

Sponsored: Health Applications

Sponsored Session

Chair: Maria Esther Mayorga, North Carolina State University, Raleigh, NC, 27695, United States, memayorg@ncsu.edu

1 - Resource Allocation Strategies under Dynamically Changing Patient Health Conditions

Siddhartha Nambiar, North Carolina State University, 1120 Clarion Heights Lane, Apt 303, Raleigh, NC, 27606, United States, snambia@ncsu.edu, Maria Esther Mayorga

Consider a group of patients being treated for a disease (such as Sepsis), whose condition may change over time. Resources allocated to a patient (e.g. bedside lactate) influence their disease progression and outcomes. In this study, our goal is to allocate limited number of resources to patients, depending on their health states, in order to maximize outcomes. We formulate two models; an MDP model with resources allocated dynamically, and a jackson queueing network, where the number of resources is assigned in advance. The performance of these policies is then tested against existing practices and heuristics.

2 - Evaluating Hospital Readmission Decisions

Gabriel Zayas-Caban, University of Wisconsin, Madison, WI, United States, zayascaban@wisc.edu, Amy Cochran, Keith Kocher

The Hospital Readmissions Reduction Program penalizes hospitals with excess re-admissions. Re-evaluating admissions decisions, providers have considered delays or increases in decisions. To understand the impact of these changes on patient outcomes, we analyzed over 150,000 encounters in the Emergency Department from the University of Michigan from 2012 through 2015. A Hidden Markov model is fit to the data to capture the interplay between confounding latent variables (e.g. patient severity) and admission decision process. This allowed us to gain insight into how decisions are made and how changes in decisions impact patient outcomes.

3 - Strategies for Improving Specialty Care Appointment Scheduling

Ashley N. Anhalt, University of Pittsburgh, 525 S. Aiken Avenue, APT.3, Pittsburgh, PA, 15232, United States, ana88@pitt.edu, Arnab Bhattacharya, Jeffrey P. Kharoufeh

In resource-constrained environments, patients are often unable to schedule specialty care appointments within a reasonable time. We first present a stochastic optimization model that aims to maximize the proportion of patients who are scheduled within a prescribed time threshold, subject to provider availability. However, due to intractability of the model, we subsequently devise and analyze a set of computationally-efficient strategies that significantly reduce appointment scheduling delays. Our strategies are illustrated for a major healthcare provider's cardiology unit.

4 - Microsimulation Model using Christiana Care Early Warning System (CEWS) to Evaluate Physiological Deterioration

Shengfan Zhang, University of Arkansas, Fayetteville, AR, United States, na, Bin Li, Muge Capan

Patients often exhibit signs of physiologic deterioration in the hours before harm events occur. Christiana and Wilmington Hospitals are adapting the Christiana Care Early Warning System (CEWS) to detect all-cause acute clinical deterioration impacting inpatients and support clinical decision making. We used a microsimulation model to simulate the inpatients cohort's CEWS value and to explore the possible intervention policies on mortality, length of stay, average percent time over critical CEWS thresholds with the change of policies.

Operations Research for Critical Care

Sponsored: Health Applications

Sponsored Session

Chair: Vedat Verter, McGill University, Montreal, QC, H3A 1G5, Canada, vedat.verter@mcgill.ca

1 - Dynamic Patient Location in the ICU

Hamidreza Eslami, McGill University, Montreal, QC, Canada, hamidreza.eslami@mail.mcgill.ca

Healthcare location studies at patient level usually target the groups of patients and not the individual ones. Due to the critical status of the ICU patients, their location on the ICU may have significant impacts on the unit operations and costs. We develop a model to optimally locate the incoming ICU patients on the floor so that the overall nurse costs and patient relocation costs are minimized by considering the evolvement of patients' health status. Therefore, the patients who are prone to get better at the same time and thus share a nurse, will be located in adjacent rooms.

2 - Evaluating the Performance of Emergency Department Physicians

Raha Imanirad, Harvard University, Boston, MA, United States, rimanirad@hbs.edu

Given the vital role of emergency department (ED) physicians in the timely and effective delivery of care, it appears pertinent to have a measure of physician performance in place. Despite recent advances, however, a standard metric for evaluating ED physicians has yet to emerge. In this study, we use data envelopment analysis (DEA) to evaluate the performance of ED physicians based on two measures of quality and speed. In addition to identifying which physicians demonstrate best practices, we conduct various statistical analyses to examine which variables are associated with higher levels of physician performance.

3 - Measuring Emergency Care Networks with Location Allocation Models and GIS

Peter Vanberkel, Dahousie University, P.O. Box 1000, Halifax, NS, B3 H.4R2, Canada, peter.vanberkel@dal.ca

The objective of this study is to measure how the Nova Scotian Emergency Medical System (EMS), consisting of Emergency Departments (EDs) and ambulance services, covers the population. This study uses location-allocation models including the P-median problem (PMP) and P-centre problem (PCP). We analyze the existing network by computing the weighted travel distance of the population to each facility, the maximum distance any person must travel, and the number of people within a specified distance from a facility. We also consider several proposed changes to the network and compute the degree of improvement expected using these metrics.

Disaster and Emergency Management

Contributed Session

Chair: Zeina Bousaid, Lamar University, Beaumont, TX, United States, zbousaid@lamar.edu

2 - An Emergency Logistics Distribution Approach for Real-time Response to Relief Demand in Uncertain Environment

Yajie Liu, Associate Professor, National University of Defense Technology, NUDT, Changsha, 410073, China, liuyajie@nudt.edu.cn, Zhiyong Wu, Yue Wang, Jianmai Shi

When making emergency distribution plans in response to disasters, we should not only consider uncertain and dynamic input data but also the real-time adjustment requirements of the existing plans. A multi-commodity, multi-period distribution model is presented to minimize the total weighted unmet demands. Moreover, a rolling horizon-based framework that is based on the robust optimization and model predictive control approaches is proposed to obtain robust relief distribution plans and adjust them in accordance with updated real-time information. A numerical example based on the Great Sichuan Earthquake is utilized to investigate the application of our proposed model and approaches.

3 - Integrated Logistics Decisions and Representative Objectives of Preparedness and Response Phases of Disaster Operations

Syed Tariq, Lahore University of Management Sciences (LUMS), Shah House, A-10, Block 2, Chapal Sun City, Lahore, 75280, Pakistan, 14080009@lums.edu.pk, Muhammad Naiman Jalil

Disaster response operations are linked to preparedness. The response stage consists of three sub-stages: 1) Emergency response, 2) Continuum response, and 3) Initial recovery response (Sheu and Pan, 2016). In this paper, we present a model which utilizes objective functions which better represent the objectives of Humanitarian actors at each stage. The stages are modeled in conjunction with each other to see the impact of decisions made at each stage on overall performance.

4 - Determining Inventories of Relief Supplies During Disaster Response Operations by Predicting Non Linear Human Behavior with a System Dynamics Model

Zeina Bousaid, Lamar University, 4400 SMLK Jr. Pkwy, P.O. Box 10643, Beaumont, TX, 77710, United States, zbousaid@lamar.edu, Alberto Marquez

Forecasting relief supplies is a challenge due to uncertainties, limited resources, delays, disruptions, and complex human factors. We propose system dynamics to model people's behavior during evacuation, and to forecast the relief inventory needed during disaster response operations. Our model consists of four compartments communicating through feedback loops and generating complex nonlinearities. FEMA Hurricane Evacuation reports are used for numerical validation, along with regression analysis, and Monte Carlo simulation. Risk is quantified, and policies are suggested for better response.

Big Data and Innovation

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Serguei Netessine, University of Pennsylvania, Wharton School, Philadelphia, PA, 138676, United States, serguei.netessine@insead.edu

1 - When to Innovate and When to Grow? Empirical Analysis of Startup Operation

Christophe Pennetier, INSEAD, 6 Marina Boulevard, # 27-15, Singapore, 018985, Singapore, christophe.pennetier@insead.edu, Serguei Netessine, Karan Girotra

We conduct a thorough examination of the effects of business model innovation on startups' performance (probability to raise funding, exit) and we empirically evaluate them. We by that offer a new perspective to the pivoting approach that has captured practitioners' attention in the past few years since the Lean Startup framework became widely adopted.

2 - Impact of Telematics: An Empirical Study of Drivers' Behavior

Vivek Choudhary, INSEAD Business School, 1 Ayer Rajah Avenue, Singapore, 138676, Singapore, Vivek.Choudhary@insead.edu, Serguei Netessine

Telematics is one of the hottest developments in the automobile insurance industry. Adoption of this innovation suggests that this is going to be the future of motor insurance. We study a novel private dataset from a start-up company operating in this space. Using this dataset, which consists of trip level details; we study the effect of providing feedback of drivers' behaviour on driving performance.

3 - Impact of Mobile Channel on Demand Concentration

Fangyun Tan, Southern Methodist University, 6212 Bishop Blvd, Dallas, TX, 75275, United States, ttan@cox.smu.edu, Nitish Jain

We analyze a large transactional data from an Indian online apparel to understand the impact of mobile channel on demand concentration. Utilizing the natural experiment where the company shut down its PC channel and kept only their mobile channel, we find that the mobile channel reduces the demand concentration because its search costs are higher than those in the PC channel. We show evidence of the mechanisms and discuss the implications for operational decisions.

4 - Reading Between the Stars: Understanding the Effect of Online Customer Reviews on Product Demand

Hallie Cho, INSEAD, Singapore, 138676, Singapore, hallie.cho@insead.edu, Sameer Hasija, Manuel Sosa

Many studies have examined star ratings in customer reviews and established that they are a relevant source of quality information. We examine the sentiments of text reviews and study the interplay between sentiments and star ratings and how this relates to product demand. To fully exploit the abundance of online reviews, we implemented a novel algorithm that reads the text portion of customer reviews and assesses its sentiment. We find that sentiments and star ratings both have a decreasingly positive effect on product demand and that their interaction effect on demand suggest they act as complements, not substitutes.

1 - Price Competition in Customer Inertia Markets with Capacity Uncertainty

Junhyun Bae, Cornell University, Ithaca, NY, United States, jb2258@cornell.edu, Li Chen, Yao Cui

In this paper, we investigate price competition under capacity uncertainty in which consumers have costs of switching between two firms. While previous literature has examined the effect of switching costs on prices, our paper addresses the effect of capacity uncertainty on prices. Using a two-period duopoly setting, we show that capacity uncertainty increases price in both periods and it diminishes price discount in the first period.

2 - Resolving Supplier Information Asymmetry: Reliability or Improvement Cost?

Yutian Li, PhD Candidate, University of Miami, Coral Gables, FL, 33146, United States, ytli@umiami.edu, Sammi Tang

We consider a manufacturer who sources from an unreliable supplier. The supplier can take costly effort to improve its reliability, but has private information about both its initial reliability level and improvement cost. We examine which type of supplier information is more valuable to the manufacturer. For that, we study two models with different asymmetric information, and compare how each type of information affects manufacturer's profit, information rent and channel loss differently.

3 - Analytical Solution to a Partially Observable Machine-maintenance Problem

Weihua Zhang, University of British Columbia, Sauder School of Business, University of British Columbia, Vancouver, BC, V6T.1Z2, Canada, weihua.zhang@sauder.ubc.ca, Hao Zhang

We examine a classic machine-maintenance problem in which the state of the system evolves as a hidden Markov process under production. The state can be observed upon inspection and reset by replacement. The goal is to find a production-inspection-replacement policy to minimize the expected discounted cost over an infinite horizon. We adopt a new framework to derive an exact, analytical solution to this problem and uncover an elegant cyclic structure in the optimal solution, which are unavailable through the Bayesian framework. We find that the well-known and puzzling non-monotone optimal policy results from the transient behavior under optimal control.

4 - Position Ranking and Auctions for Online Marketplaces

Heng Zhang, University of Southern California, Los Angeles, CA, 91776, United States, hengz@usc.edu, Leon Yang Chu, Hamid Nazerzadeh

E-commerce platforms connect thousands of sellers and consumers every day. We study how such platforms should rank products displayed, and utilize the top slots with auction design. We present a model that considers consumers' search costs and seller externalities. This model allows us to study a multi-objective optimization, whose objective includes consumer and seller surplus, and sales revenue, and derive the optimal ranking. Motivated in part by the sponsored search program, we propose a so-called surplus-ordered ranking mechanism for selling top slots, which is near-optimal. When the platform sells all slots, we show that our mechanism can be implemented as a NE in a modified GSP auction.

1 - Do Mandatory Overtime Laws Improve Quality? Staffing Decisions and Operational Flexibility of Nursing Homes

Lauren Xiaoyuan Lu, University of North Carolina at Chapel Hill, Kenan-Flagler Business School, CB #3490, Mccoll Building, Chapel Hill, NC, 27599, United States, lauren_lu@unc.edu, Susan F.Lu

During the 2000s, over a dozen U.S. states passed laws that prohibit health care employers from mandating overtime for nurses. Using a nationwide panel dataset from 2004 to 2012, we find that these mandatory overtime laws reduced the service quality of nursing homes, as measured by an increase in deficiency citations. This outcome can be explained by two undesirable changes in the staffing hours of registered nurses: decreased hours of permanent nurses and increased hours of contract nurses per resident day. These observations are consistent with the predictions of a stochastic staffing model that incorporates demand uncertainty and operational flexibility.

2 - Transitional Care Appointment Scheduling

Benjamin Grant, Kellogg School of Management, 1881 Oak Avenue, # 1307W, Evanston, IL, 60201, United States, b-grant@kellogg.northwestern.edu, Itai Gurvich, R. Kannan Mutharasan, Jan A. Van Mieghem

In this paper we develop a framework modeling transitional-care appointment scheduling from the perspective of the hospital or social planner who takes into account the total cost of transitional-care under a value-based compensation model. We employ a stochastic dynamic programming model rich enough to capture many of the complexities that exist in practice, while enabling interesting insights and evaluation of a variety of simple scheduling policies compared to theoretical optimal policies.

3 - Optimal Workload Management During a Physician's Shift in Emergency Departments

Zhankun Sun, City University of Hong Kong, 7-242, 7/F, Academic 3, Tat Chee Avenue, Kowloon Tong, Hong Kong, zhanksun@cityu.edu.hk, Nan Liu

ED physicians can dynamically adjust their workload to reduce patient handovers which raise safety concerns due to the discontinuation of care. We present a dynamic programming model to inform patient flow management during a single ED physician's work shift. Our results can help understand physician's strategic choice of idling at the end of the shift and provide decision support.

4 - Managing EMS Systems with User Abandonment in Emerging Economies

Lavanya Marla, The University of Illinois, lavanyam@illinois.edu, Kaushik Krishnan Sarang Deo (sarang_Deo@isb.edu)

Abstract: We introduce, and consider an issue specifically seen in Emergency medical Services in emerging economies, called in-service abandonment. Due to resource constraints in the system, patients have a limited willingness to wait for ambulances. Because actual wait times are censored in the data, we build a maximum likelihood estimation to estimate the waiting times based on the Proportional Hazards Model. We employ a simulation-based greedy optimization approach to find good allocations to match the demand waiting time estimates, and demonstrate that policy changes that simply re-arrange ambulances at the current bases, increase fleet size or dispatch policy are unlikely to cause significant gains. Instead, we posit, and demonstrate using the data, that re-designing the base set using a huge optimization model that considers each street corner as a base, allows us to identify better base locations for ambulances. We demonstrate that the new system design matches the demand profiles better, decreasing inefficiencies in the system due to abandonment.

Inventory Control with Additive Manufacturing

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Rob Basten, Eindhoven University of Technology, Eindhoven, 5600 MB, Netherlands, R.J.I.Basten@tue.nl

Chair: Jing-Sheng Jeannette Song, Duke University, Durham, NC, 27708-0120, United States, jssong@duke.edu

1 - Improving Effectiveness of Spare Parts Supply by Additive Manufacturing as Dual Sourcing Option

Nils Knofius, University of Twente, Enschede, Netherlands, n.knofius@utwente.nl, Matthieu van der Heijden, Andrei Sleptchenko, Henk Zijm

We discuss the value of sourcing spare parts with a combination of additive manufacturing (AM) and conventional manufacturing (CM) methods. In the dual sourcing literature, costs are higher and lead times are lower for the fast supply option. In our case, we also need to consider that AM parts show a different failure behavior than CM parts. As a consequence, the sourcing decision may impact future demand. Numerical experiments and a case study show that dual sourcing reinforces the value of AM methods in the low-volume, downtime-critical spare part business.

2 - Assessing the Impact of Additive Manufacturing on Spare Parts: An Inventory Management Perspective

Jakob Heinen, Kuehne Logistics University, Grosser Grasbrook 17, Hamburg, 20457, Germany, johannes.jakob.heinen@the-klu.org, Kai Hoberg

Spare parts are often identified as a relevant application area for additive manufacturing. Characterized by relatively low demand over long periods, additive manufacturing has the potential to reduce inventory costs and offset higher unit production costs. We develop an approach for selecting the manufacturing technology for spare parts based on supply chain related costs and derive optimal inventory policy parameters. Using a data set for 53,457 spare parts over 9 years, we assess additive manufacturing's potential for a leading intralogistics manufacturer. Based on an analysis by part category, a significant share of spare parts can be economically produced using additive manufacturing.

3 - Temporary Replacements of Spare Parts through Additive Manufacturing

Rob Basten, Eindhoven University of Technology, Eindhoven, 5600MB, Netherlands, r.j.i.basten@tue.nl, Bram Westerweel, Geert-Jan Van Houtum

When spare parts have long supply lead times, equipment may experience high downtime costs during stockouts. We propose to use additive manufacturing, i.e., 3D printing, to supply temporary replacements. Analyzing the resulting model and using empirical data leads to interesting insights.

4 - Impact of Additive Manufacturing on After-sales Service Supply Chains

Brian Tomlin, Tuck School of Business, Dartmouth College, 100 Tuck Hall, Hanover, NH, 03755-9000, United States, brian.tomlin@tuck.dartmouth.edu, Sang Kim

In this preliminary research we study how additive manufacturing (3D printing) technology changes the incentive dynamics between a manufacturer and a supplier in after-sales service supply chains. Because spare parts needed for repairs and maintenance can be 3D printed on the fly, the importance of parts inventory management and related service offerings can be diminished. At the same time, an issue arises as to how component design licensing should be arranged between the buyer and the supplier. We investigate new challenges introduced by additive manufacturing technology through the lens of contracting and game-theoretic analysis.

Game Theory

Contributed Session

Chair: Nabeel Hamoud, University of Milwaukee, Milwaukee, WI, United States, nmhamoud@uwm.edu

1 - Disease Dynamics on a Network Game: A Little Empathy Goes a Long Way

Ceyhun Eksin, Georgia Tech, 310 Ferst Drive, Cherry Emerson Building, Atlanta, GA, 30332, United States, ceyhuneksin@gatech.edu, Jeff S. Shamma, Joshua S. Weitz

Individuals change their behavior during an epidemic in response to whether they and those they interact with are healthy or sick. Healthy individuals may utilize protective measures while sick individuals may adopt preemptive measures to stop disease spread to their contacts. Yet, in practice both protective and preemptive behavior come with costs. We propose a stochastic network disease game that captures the self-interests of individuals during disease spread on a network. We show that there is a critical level of concern, i.e., empathy, by the sick individuals that eradicates the disease fast while the protective measures cannot eradicate the disease without the preemptive measures.

2 - A New Incomplete Information Approach to Modeling Payment and Concession Period Bargaining in Public Private Partnership Agreements

Ahmadreza Talebian, Postdoctoral Fellow, University of Memphis, 302 Eng Admin Bldg, 3795 Central Ave, Memphis, TN, 38152, United States, ataleb2@uic.edu, Sabyasachee Mishra

In this study, we first propose a complete information bargaining game to understand the interactions between agents negotiating to form a P3 agreement for a smart transportation infrastructure system. Then we extent the model to an incomplete information setting, in which the public agency does not have full information about the cost information of the private agency. This is a plausible setting in the real-world as private companies often consider their financial information sensitive to profitability and thus maintain it confidential. In addition to analytically solving the problem, we perform numerical analysis and offers policy-relevant insights into the state-of-the-practice.

3 - The Role of Third Part Retailer at Designing Online Return Policies: Analytical Approach

Maryam Mahdikhani, Rutgers University, 1 Washington Park, Room 442, Newark, NJ, 07102, United States, m.mahdikhani@rutgers.edu, Yao Zhao

Nowadays, online retailers are competing to increase their market share, and marginal profit rate by offering more services, specifically with focusing on the return policy. Although a generous return policy will be welcome by the customers, and therefore will enhance demand in the long term, this will increase cost due to increased likelihood of return. This paper develops a cost-minimization model by considering the risk mitigation from online retailers to the third part retailers in order to obtain optimal policies. We extend the model by considering the win-win-win strategy for the online retailers, customers, and third part retailers.

4 - Network Interactions and the Social Value of Information

Gowtham Tangirala, Columbia Business School, 3022 Broadway, 4th Floor West, New York, NY, 10027, United States, gtangirala18@gsb.columbia.edu, Alireza Tahbaz-Salehi

In this paper, we study the social value of information in a standard finite-agent beauty contest setting, but allowing the agents to have asymmetric coordination motives. We show that the extent of agents' overreaction/under-reaction to public information relative to the team-efficient benchmark depends on the details of their coordination motives. We also show that even though economies that are efficient under complete information have the same equilibrium welfare when the fundamental is common knowledge, that statement may no longer hold in the presence of incomplete information.

5 - An Election Game Based on Discretization of the Hotelling - Downs Model

Timothy Murray, Graduate Student, University of Illinois, Urbana-Champaign, Urbana, IL, 61801, United States, tsmurra2@illinois.edu

We present a discretized version of the Hotelling-Downs election game based on centroidal clustering of opinion polls. We show that it can be modeled as a congestion game, addressing the common issues of non-independent voter opinions and non-existence of a pure Nash equilibrium (PNE) when there are more than two candidates. Furthermore, we show that a PNE still exists when a non-shared penalty is added to each edge in the congestion game which can be used to model the cost of running a campaign. Finally, we provide a quadratic time algorithm for computing a PNE.

6 - Game Theoretic Modeling of Water Energy Nexus in the Presence of Competition Between Interdependent Firms

Nabeel Hamoud, PhD Student, University of Wisconsin-Milwaukee, P.O. Box 413, Milwaukee, WI, 53201, United States, nmhamoud@uwm.edu, Jaejin Jang

A game theoretic model of the Water-Energy Nexus is introduced to find the equilibrium of the water and electricity markets, when some of the output of a firm in one market (e.g. water market) is an input of another firm in a different market (e.g. electricity market) and vice versa. The firms make their decisions of the quantity to produce simultaneously. The result shows that market power is practiced and output is withheld when less players exists. It also shows that technology efficiency allows a player to capture more market share. It also increases the output of the firm, the total output of the industry and the output of the cross industry; hence reducing the market prices of the two goods.

Robust and Stochastic Optimization in Healthcare

Sponsored: Manufacturing & Service Oper Mgmt, Healthcare Operations

Sponsored Session

Chair: Chaithanya Bandi, Northwestern University, Evanston, IL, 60208, United States, c-bandi@kellogg.northwestern.edu

1 - Design of Patient Flows via Robust Analysis of Fork-join Queues

Chaithanya Bandi, 2001 Sheridan Road, Suite 566, Evanston, IL, 60208, United States, chaitu1287@gmail.com

We consider the patient flow design in hospitals and model them using fork-join queues. Using robust queueing theory approaches, we provide tractable solutions.

2 - Ambulance Emergency Response Optimization in Developing Urban Centres

Justin James Boutilier, University of Toronto, 532 Palmerston Boulevard, Apartment 6, Toronto, ON, M6G 2P5, Canada, j.boutilier@mail.utoronto.ca, Timothy Chan

Time sensitive medical emergencies are a major health concern comprising one third of all deaths in low and middle income countries (LMICs). Despite evidence that ambulance services can save lives, poor access and availability of emergency medical care in LMICs continues to be a widespread problem. In this paper, we develop a novel ambulance location-routing model, tailored to address the challenges faced by urban areas in LMICs. We use extensive field data from Dhaka, the capital of Bangladesh and one of the most densely populated cities on earth, to apply our modelling framework.

3 - Robust Multi-period Regional Capacity, Location, and Access of Rural Cardiovascular Service under Uncertainty

Dominic Johannes Breuer, Healthcare Systems Engineering Institute, Boston, MA, 02119, United States, dbreuer@coe.neu.edu, Nadia Lahrichi, Mohit Shukla, James C. Benneyan

Timely access to cardiovascular services in rural areas is difficult to ensure due to long wait times, travel distance, and practice capacity restrictions. A robust multi-period model is developed to determine long-term locations, staffing, and assignment of patients with heterogeneous care needs under uncertainty. The objective is to improve access by minimizing patients' travel distance, out-of-network referrals, and costs. The models are tested with a large health system in Maine. The model has important implications on existing and rapidly expanding health systems to aid their decisions related to care allocation.

1 - On the Real-time Procurement of Impressions by Mobile-promotion Platforms

Manmohan Aseri, University of Texas-Dallas, 2200 Waterview Parkway, Apt 1738, Richardson, TX, 75080, United States, mxa113030@utdallas.edu, Milind Dawande, Ganesh Janakiraman, Vijay S.Mookerjee

A mobile-promotion platform enables advertisers to launch their personalized mobile advertising campaigns. The platform bids on behalf of dynamically-arriving campaigns to procure impressions at an ad exchange. We offer an effective rolling-horizon procedure, with an attractive guarantee, in which the platform periodically re-computes its policy for the procurement of impressions.

2 - Sustaining a Good Impression: Mechanisms for Selling Impressions at Ad Exchanges

Sameer Mehta, sameer.mehta@utdallas.edu, Milind Dawande, Ganesh Janakiraman, Vijay S.Mookerjee

At mobile ad exchanges, impressions are sold to advertisers through an auction mechanism. The status quo mechanism selects a single ad for display over the lifetime of an impression. We argue that such a mechanism leads to allocative inefficiency. To address this efficiency loss, we consider mechanisms in which multiple ads can be displayed sequentially over the lifetime of an impression. We obtain an optimal mechanism for this setting. Our analysis reveals that on an aggregate level, the optimal mechanism is a win-win for the ad exchange and the advertisers. We also obtain a "socially-responsible" optimal mechanism that guarantees a higher surplus to the ad exchange and the advertisers in the long run.

3 - The Effect of Supply Flexibility on Price-only Contracts for Fixed-price Newsvendors

Mehdi Hosseinabadi Farahani, PhD Student, The University of Texas at Dallas, 800 W. Campbell Road, Richardson, TX, 75080-3021, United States, mxh143930@utdallas.edu, Milind Dawande, Haresh B. Gurnani, Ganesh Janakiraman

We analyze a contract in which a supplier, who is exposed to disruption risks, presents a wholesale price and a supply-flexibility parameter to a buyer facing the newsvendor problem. The supplier is allowed to deviate from the order quantity by at most the flexibility parameter. We find the optimal contract when the demand distribution has an increasing generalized failure rate and show that the order quantity under the supply-flexibility contract is higher than that under the price-only contract. Furthermore, the supply-flexibility contract improves the supply chain efficiency. More interestingly, profits of the supplier and the buyer both increase by introducing flexibility into the contract.

4 - Sourcing under Multiple Attributes: Cost-sharing Mechanisms

Shivam Gupta, Texas State University, 601 University Drive, San Marcos, TX, 78666, United States, s_g515@txstate.edu, Milind Dawande, Ganesh Janakiraman, Shouqiang Wang

We propose a simple cost-sharing mechanism for a principal procuring a product (or service for a project) under multidimensional information asymmetry on the agent's cost and non-cost attributes. We establish its optimality/near-optimality under several special cases, and provide valuable insights into the nature of cost-sharing for its use in practice.

1 - Recurrent Neural Networks with Long Term Dependencies in Machine Tool Wear Diagnosis and Prognosis

Jianlei Zhang, Research Assistant, North Carolina State University, Raleigh, NC, United States, jzhang45@ncsu.edu, Binil Starly

Automated real-time tool condition monitoring is critical to improving productivity and part quality in manufacturing processes. This paper proposes a Recurrent Neural Network (RNN) approach for online diagnosis and prognosis of the tool wear. It avoids an analytic model for specific tool wear model, and aims to capture the long term dependencies. Without increasing the complexity of the Neural Networks, our approach can realize multi-step ahead tool wear prediction and Remaining Useful Life forecast. This is realized by applying real time indirect measurements obtained from vibration signals and power signals during the machining process.

2 - Comparing Multiple Linear Profiles for Determining Alternative Processes

Chen-ju Lin, Associate Professor, Yuan Ze University, No. 135 Yuan Tung Rd., Taoyuan, 320, Taiwan, chenju.lin@saturn.yzu.edu.tw, Yuan-Chung Chuang

A product can be manufactured by using alternative processes to reach a predefined product specification. Having several alternative processes can have flexible production scheduling, increase capacity utilization, or reduce lead time. To maintain consistent product performance, this research aims at identifying the alternative processes having similar quality performance to the current production process. Linear profile data for quality characteristic is investigated. A step-up procedure is developed to distinguish profiles from a controlled profile. The simulation results show that the proposed method is more powerful in differentiating profiles than using Bonferroni adjustment.

3 - A Comprehensive Learning Model for Determining Optimal Investments in a Dyadic Chain

Didun Peng, Purdue University, Krannert Graduate School of Management, west lafayette, IN, 47906, United States, peng67@purdue.edu, Robert Plante, Jen Tang

We explore the optimal investment in quality improvement efforts within a centralized dyadic supply chain, in which a manufacture outsources product components to several suppliers. The end product's quality depends on several performance measures, each of which is affected by the interaction of the various supplier sourced components. Manufacturer and suppliers both incur quality-related cost, encouraging both parties to invest in quality-improvement efforts for each component. We attribute quality improvement and concurrent degradation to suppliers' comprehensive learning curve, which considers autonomous and induced learning, and their respective knowledge depreciation.

4 - Product Branding in the International Context a Case of Norwegian Fashion Apparel Manufacturing Industry

Rhythm Wadhwa, NTNU, Teknologiveien 22, Gjoevik, 2821, Norway, rhythmwadhwa@hotmail.com

The paper investigates the product branding and supply chain issues of Norwegian fashion brands and their positioning in the international apparel retail industry. The research questions explored include current state challenges, knowledge and perception of brands, regional differences regarding fashion and consumer behavior. Qualitative semi structured interviews and survey research methodology was used for investigation.

5 - The Myths and Clarification for the Theory of Constraints

Kan Wu, Nanyang Technological University, School of MAE, 50 Nanyang Ave, Singapore, 639798, Singapore, kan626@gmail.com

The theory of constraints was proposed in the mid-1980s and has had a significant impact on the productivity improvements in many manufacturing systems. While it is intuitive and easy to understand, its conclusions are mainly derived from deterministic settings or based on the first moment results. Since production systems are stochastic in general, some of its conclusions are not rigorous and have to be modified. In this study, we show that the process of ongoing improvement may lead to unfavorable outcomes and a throughput bottleneck should be planned for certain types of machines. Specifically, if a system has no bottleneck, every station will be a bottleneck.

6 - Market Anomalies of Open Innovation

Yen-Ju Chiang, Student, National Cheng Kung University, No.1, University Road, Tainan, 701, Taiwan, r48031016@mail.ncku.edu.tw, Shuang-Shi Chuang

Sponsored Session

Chair: Mor Harchol-Balter, Carnegie Mellon University, Pittsburgh, PA, 15213, United States, harchol@cs.cmu.edu

1 - Scheduling on Queues under Imperfect Information: Stability and Robustness

Zheng-Yuan Zhou, Stanford University, Stanford, CA, 94305, United States, zyzhou@stanford.edu, Mehdian Saied, Nicholas Bambos

Scaling up schedulers in computing systems (e.g., data centers) and communication networks may require sampling queue depths at random times and/or communicating the information with substantial random delays over relatively large distances to the schedulers. Imperfect state information (noisy, delayed, partial) can severely affect system performance in terms of backlog congestion and even queue stability. We discuss canonical scheduling examples and examine their stability and performance under increasingly "looser" state information in the interest of evaluating their robustness.

2 - Optimally Scheduling Jobs with Multiple Tasks of Unknown Duration

Ziv Scully, Carnegie Mellon University, Pittsburgh, PA, 15213, United States, zscully@cs.cmu.edu, Guy Blelloch, Mor Harchol-Balter, Alan Scheller-Wolf

We consider optimal job scheduling where each job consists of multiple tasks, each of unknown duration, with precedence constraints between tasks. A job is not considered complete until all of its tasks are complete. Traditional heuristics, such as favoring the job of shortest expected remaining processing time, are suboptimal in this setting. Furthermore, even if we know which job to run, it is not obvious which task within that job to serve. In this talk, we characterize the optimal policy for a class of such scheduling problems. We show the policy is simple to compute in many practical cases.

3 - Near Optimal Performance via Fixed-width Parallelization

Benjamin Berg, Carnegie Mellon University, Pittsburgh, PA, 15213, United States, bsberg@cs.cmu.edu

Running jobs in parallel is an excellent way to reduce their mean response time. In applications such as jobs running on multiple cores, the user chooses the level of parallelization for her jobs. We propose instead that the system should choose the level of parallelization so as to minimize mean response time across jobs. Interestingly, we find that a fixed level of parallelization suffices. While one might imagine that a system should dynamically change a job's level of parallelization based on the current system state, our work shows that the right static level of parallelization yields near-optimal performance. 1 - The Effectiveness of Supplier Buy Back Finance: Evidence from the Chinese Automobile Industry

Weiming Zhu, IESE Business School, Avenida Pearson 21, Barcelona, 08034, Spain, zhuwm923@gmail.com, Tunay Tunca

Facing a budget-constrained buyer, a novel approach for large suppliers is adopting buy-back financing schemes to relieve their downstream partners and reduce channel costs. Through counterfactual analysis, we analyze the efficiency of these financing schemes. We find that such contract agreements can improve channel efficiency over traditional financing methods.

2 - Default Risk Premia and a Non Linear Asset Pricing Model

Yi Zhang, Illinois Institute of Technology and Accenture Management Consulting, Chicago, IL, United States, marco.y.zhang@chicagobooth.edu, John R. Birge

The value of an equity investment can be framed as an embedded call option on a firm's assets. The embedded call option creates a non-linear relationship between stock returns and underlying risk factors. In addition, losses given default create discontinuities in the value of these options that are differentially determined for firms with distinct characteristics, such as size and value. We introduce a non-linear equity pricing model that includes these aspects of potential default consequences and seems to explain and predict individual stock returns.

3 - Merchant Energy Trading in a Network

Selvaprabu Nadarajah, College of Business, University of Illinois at Chicago, 601 South Morgan Street, UH 2406, Chicago, IL, 60607, United States, selvan@uic.edu, Nicola Secomandi

Motivated by practice, we formulate a merchant trading energy in a network of storage and transport assets as a Markov decision process with uncertain energy prices. We develop tractable approximate dynamic programming methods to obtain operating policies and bounds, also highlighting the importance of joint storage and transport optimization.

4 - Operational Risk Management: Preventative v.s. Corrective Controls

Yuqian Xu, University of Illinois at Urbana-Champaign, Champaign, IL, United States, yxu@stern.nyu.edu, Lingjiong Zhu, Mike Pinedo

In this paper, we consider a stochastic control framework with a jump process to analyze the impact of large shocks caused by operational risk events on a financial firm's value process. We study capital investments in the infrastructure of a financial firm that aims at mitigating the impact of operational risk events. We characterize the analytical solutions of optimal investment strategies as a function of the rm's growth rate, the jump process parameters, and a loss reduction function. Our modeling framework, combining a typical operational risk process with stochastic control, suggests a future research direction in operations management and operational risk management.

5 - Sourcing from Suppliers with Financial Constraints and Performance Risk

Jing Wu, City University of Hong Kong, Department of Management Sciences, Rm 7-233, Lau Ming Wai Academic Building, Hong Kong, Hong Kong, jingwu49@cityu.edu.hk, Christopher S.Tang, S. Alex Yang

Two innovative financing schemes have emerged in recent years that were intended to enable suppliers to obtain financing for production, Purchase Order Financing (POF) and Buyer Direct Financing (BDF). In this talk, we use a game-theoretical model to examine the relative efficiency of these two schemes. We find that both POF and BDF yield the same payoff under symmetric information, and However, information asymmetry only lowers the efficiency of POF when the supplier's asset level is sufficiently low.

1 - Local Search Methods for Link Scheduling Problem of Wireless Mesh Networks

Kagan Gokbayrak, Professor, Bilkent University, Ankara, 06800, Turkey, kgokbayr@bilkent.edu.tr, Yucel Naz Yetimoglu

We aim to increase the average connection speed of a wireless mesh communication network, whose transmissions are scheduled to occur at different time slots, by decreasing the average queueing delay. Under steady state conditions, the average queueing delay is linearly proportional to the average queue size, so we search for the link schedule that minimizes the time-average of the sum of queue lengths over all nodes. We formulate a Mixed Integer Linear Programming problem and solve this NP-hard problem by the Simulated Annealing and the k-change local search methods. We also conduct computational experiments on several example networks to demonstrate the performances of these methods.

2 - A Branch and Cut Algorithm to Design LDPC Codes with out Small Cycles in Communication Systems

Banu Kabakulak, PhD, Bogazici University, Industrial Engineering, Department, Istanbul, 34342, Turkey, banu.kabakulak@boun.edu.tr, Z. Caner Ta kın, Ali Emre Pusane

In a digital communication system, information is sent from one place to another over a noisy communication channel using binary symbols (bits). Original information is encoded by adding redundant bits, which are then used by low-density parity-check (LDPC) codes to detect and correct the errors. Error correction capability of an LDPC code is severely degraded due to small cycles in its bipartite graph representation (Tanner graph). We introduce an integer programming formulation for generating Tanner graphs which do not include cycles smaller than a given size. We propose a branch-and-cut algorithm for its solution.

3 - Device Caching in Mobile Networks: Modeling and Optimization

D I.YUAN, Professor, Uppsala University, Department of Information Tech, Uppsala, 751 05, Sweden, di.yuan@it.uu.se, Tao Deng, Ghafour Ahani, Pingzhi Fan

Caching files at user devices in mobile networks is gaining research interest in the field of telecommunications. We consider a cost-optimal caching problem for device-to-device communications. In this presentation, we provide recent results on modeling and optimization of the cost-optimal caching problem. Specifically, we discuss a bounding approach using integer programming, to approximate the cost function that models mobility using stochastic distribution, and derive a low-complexity algorithm. Performance evaluation of the proposed schemes are presented and discussed.

1 - The Information Collecting Vehicle Routing Problem: Stochastic Optimization for Emergency Storm Response

Lina Al-Kanj, Princeton University, Olden Street, Sherrerd Hall, Office 115, Princeton, NJ, 08542, United States, lina.kanj@gmail.com

In this talk, a new policy is presented that routes a utility truck to restore outages in the power grid using trouble calls and the truck's route as mechanisms for collecting information to create beliefs about outages. This means that routing decisions change our belief about the network, creating the first stochastic vehicle routing problem that explicitly models information collection. First, the problem is formulated as a sequential stochastic optimization. Then, a stochastic lookahead policy is presented that uses Monte Carlo tree search to produce a practical policy that is asymptotically optimal. Simulation results show that the developed policy has a close-to-optimal performance.

2 - Restoration of Services in Disrupted Infrastructure Systems: A Network Science Approach
Aybike Ulusan, Northeastern University, 409 Huntington Avenue, Apt #17, Boston, MA, 02115, United States, ulusan.a@husky.neu.edu, Ozlem Ergun

The goal in this study is to establish the functionality of the disrupted service networks operating on infrastructure systems in a timely manner by prioritizing the restoration operations. As an illustrative case study, we consider a road network blocked by debris in the aftermath of a natural disaster, where the services correspond to the emergency relief efforts flowing from relief providers to disaster sites. We propose a heuristic that prioritizes the restoration activities based on a novel centrality measure that captures the service related operational characteristics of the infrastructures.

3 - Integrating Location and Network Restoration Decisions in Relief Networks under Repair Time Uncertainty
Ece Sanci, University of Michigan, 3552 Greenbrier Blvd, Apt 463C, Ann Arbor, MI, 48105, United States, ecesanci@umich.edu, Mark Stephen Daskin

We propose a two-stage stochastic programming model to locate emergency response facilities prior to a disaster. These facilities are used to distribute emergency relief items to disaster victims using the road network after the disaster. We integrate location and network restoration decisions so that the unmet demand at inaccessible demand points can be met as paths between these demand points and facilities become available. We capture uncertainty in the network availability by incorporating the repair times required to restore the damaged roads. Our computational results show significant improvement in unmet demand and cost measures compared to the model omitting repair decisions.

Co-Chair: Shengqi Ye, Shengqi.Ye@utdallas.edu

1 - Real-time Spatial Dynamic Pricing for Balancing Supply and Demand in a Network
George Chen, University of Texas at Dallas, Richardson, TX, United States, georgeqc@umich.edu, Yanzhe Lei, Stefanus Jasin

Motivated by recent expansion of mobile ride-hailing apps in the taxi industry in big cities, we study a real-time spatial dynamic pricing problem where a firm who uses many units of reusable resources (e.g., taxis) in a network to serve price-sensitive customers who arrive over a finite selling season (e.g., one day) in a stochastic and nonstationary fashion. For any origin-destination pair, the quoted price equals a nominal price times an origin-specific price multiplier. The firm can dynamically change quoted prices by adaptively adjusting the price multipliers over time. We develop a Network Balancing Control that has asymptotically optimal performance and discuss some extensions.

2 - Price, Wage and Fixed Commission in On-Demand Matching
Yun Zhou, Rotman School of Management, Toronto, ON, Canada, Yun.Zhou13@Rotman.Utoronto.Ca, Ming Hu

Motivated by the emerging sharing economy, we study an on-demand matching platform which crowdsources a service from independent suppliers and sells it to customers. The platform offers a wage to the supply side and charges a price to the demand side. Under market uncertainty, we study the performance of the widely practiced, flat, across-the-board commission contracts, under which the platform takes a fixed cut and the wage is equal to a preset fraction of the price, regardless of what price is charged.

3 - Optimal Spending for a Search Funnel
Shengqi Ye, The University of Texas at Dallas, 800 West Campbell Road, Richardson, TX, 75080, United States, shengqi.ye@utdallas.edu, Goker Aydin, Shanshan Hu

Sponsored search marketing has been a major advertising channel for online retailers. Recent observation indicates that not all customers finalize their purchase decision after their first search query. Instead, customers might take a path of keywords and clicks - a search funnel - to complete a conversion. Noting this behavior, we investigate a retailer's optimal advertising budget allocation across keywords in the search funnel.

Topics in Revenue Management and Pricing I

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Stefanus Jasin, University of Michigan, Ann Arbor, MI, 48105, United States, sjasin@umich.edu

1 - Dynamic Inventory Control with Stockout Substitution and Demand Learning
Boxiao (Beryl) Chen, University of Illinois at Chicago, Chicago, IL, United States, bbchen@uic.edu, Xiuli Chao

Stock-out substitution is the phenomenon that if the first-choice product of a customer is out of stock, besides leaving the market immediately, the customer may also substitute for other products. In this paper, we study a data-driven inventory management problem and infer the customer substitution behavior from historical sales data.

2 - Assortment Optimization with Small Consideration Sets
Jacob Feldman, jbfeldman@wustl.edu, Alice J. Paul, Huseyin Topaloglu

We study a customer choice model that captures purchasing behavior when customers substitute a limited number of times. Under this model, we assume each customer is characterized by a ranked preference list of products and that upon arrival, they will purchase the highest ranking product in her list that is offered. We assume that these rankings contain at most k products. This paper focuses on the assortment optimization problem under this choice model. First, we show that this problem is NP-hard even for k=2. Motivated by this result, we then develop a novel linear programming based rounding algorithm for the assortment optimization problem for general k.

3 - Design of Futures Contracts for Risk Averse Internet Advertisers
Antoine Desir, Columbia IEOR.Department, 601 W. 113th Street, Apt 3J, New York, NY, 10025, United States, ad2918@columbia.edu, Maxime Cohen, Nitish Korula, Balasubramanian Sivan

We consider the problem of selling ad impressions to risk-averse advertisers via Internet display advertising platforms. Advertisers' buying choices typically include two options: Either they commit to a reservation contract in advance, or they buy programatically in real time via an exchange. In this paper, we formally study how risk aversion affects the desire for guarantees, and their pricing. We propose an additional programmatic purchase option (called Market Maker) which acts like an automated reservation. We show that adding the Market-Maker contract results in a Pareto improvement in the seller revenue and in the sum of advertiser utilities.

4 - Joint Dynamic Pricing and Order Fulfillment for E-commerce Retailers
Yanzhe (Murray) Lei, University of Michigan, Ann Arbor, MI, United States, leiyz@umich.edu, Stefanus Jasin, Amitabh Sinha

We consider a joint dynamic pricing and order fulfillment optimization problem in the context of e-commerce retail, where a retailer sells multiple products to customers from different locations and fulfills orders through multiple fulfillment centers. The objective is to maximize the total expected profits, defined as the revenue minus the shipping cost. We propose two heuristics that are easily implementable and show both theoretically and numerically their good performances compared to reasonable benchmarks.

Strong and Extended Formulations for Unit Commitment Problems

Invited: Energy Systems Management

Invited Session

Chair: Yongpei Guan, University of Florida, 303 Weil Hall, P.O. Box 116595, Gainesville, FL, 32611, United States, guan@ise.ufl.edu

1 - Polynomial Time Algorithms and Extended Formulations for Unit Commitment Problems
Kezhuo Zhou, University of Florida, 411 Weil Hall, Gainesville, FL, 32611, United States, zhoukezhuo@ufl.edu, Kai Pan, Yongpei Guan

In this talk, we develop polynomial time dynamic programming algorithms for unit commitment(UC) problems with general convex or piecewise linear cost functions. The algorithms are also extended to stochastic UC with piecewise linear cost. Extended formulations and physical insights are explored based on these dynamic programming algorithms.

2 - A Computational Study for the Unit Commitment Model
Jianqiu Huang, University of Florida, 411 Weil Hall, Dept of Industrial and System Engineering, Gainesville, FL, 32608, United States, jianqiuhuang@ufl.edu, Kai Pan, Yongpei Guan

In this talk, we present the recent progress on the polyhedral study of the power system operation problems. The computational studies verify the effectiveness of our proposed approach.

3 - Unified Formulations for Combined-Cycle Units
Yongpei Guan, University of Florida, 303 Weil Hall, P.O. Box 116595, Gainesville, FL, 32611, United States, guan@ise.ufl.edu, Lei Fan, Yanan Yu

In this talk, we describe and develop edge-based and node-based formulations for combined-cycle units (CCUs) with different levels of accuracy in respecting physical restrictions of each turbine, from no restriction requirement of each turbine, to include min-up/-down time restrictions of each turbine, to finally include most restrictions such as min-up/-down time, capacity, and ramping restrictions of each turbine. We develop corresponding models for Independent System Operators (ISOs) and Vertically Integrated Utilities (VIUs), respectively. These models demonstrate the complexity in terms of the size of decision variables and show the tradeoff between accuracy and computational complexity. In general, to the best of our knowledge, this letter provides one of the first models that can capture both configuration-based model needs and all physical restrictions for each turbine within CCUs.

4 - Improving International Oil and Gas Supply Projections
Tuncay Alparslan, Operations Research Analyst, U.S. Department of Energy, Washington, DC, United States, Tuncay.Alparslan@eia.gov

While there are many models of energy production, no existing model adequately estimates worldwide oil and gas production, conversion, and logistics in a single integrated decision framework that also reflects coproduction of oil and gas resources. To better capture the interplay between shared resources and markets, U.S. Energy Information Administration is developing the Global Hydrocarbon Supply Module (GHySMo). GHySMo provides flexible geographic resolution, endogenous modeling of other fuels, and resource trade-offs that will advance current models. We will present model structure, core innovations, and early results with a focus on logistics and integration.

1 - A Dynamic Flocking Algorithm for Topology Control in Mobile Ad HOC Networks
Abdullah Konak, Penn State Berks, Tulpehocken Road, PO.7009, Reading, PA, 19610, United States, konak@psu.edu

Mobile Ad Hoc Networks (MANETs) has many application areas, including sensor networks, vehicular networks, robot swarms, and disaster emergency networks. On the other hand, MANETs have dynamic topologies which could be disconnected because of mobility of nodes. This paper presents an improved flocking algorithm to maintain the connectivity of a MANET using autonomous and intelligent agents. In the proposed flocking algorithm, agents modify their behavior parameters dynamically based on the size of their neighborhoods. A simulation study is conducted to investigate the performance of the new algorithm. Simulation results show that the algorithm outperforms earlier approaches.

2 - Cooperative Human-centric Sensing (HCS) Communications
Albena Mihovska, Aalborg University, Center for TeleInfrastruktur, Fredrik Bajers Vej 7C1, Aalborg, 9000, Denmark, amihovska@btech.au.dk

Human-Centric Sensing (HCS) is a newly emerged concept in the context of the Internet of Things (IoT) and the active and assisted living (AAL) scenario. HCS connectivity, also referred to as "smart connectivity" enables applications that are highly personalized and often time-critical. In a typical HCS scenario, there may be many hundreds of sensor streams connections; centered around the human, who would be the determining factor for the number, the purpose, the direction and the frequency of the sensor streams. This conribution investigates the delivery of a personalized assistive applications for a scenario of several users within the same HCS environment.

3 - A Distributed Server Provisioning Algorithm for Data Centers with Nonstationary User Requests
Yongkyu Cho, POSTECH, 77 Cheongam-ro, Pohang-si, Korea, Republic of, yongkyu.cho@lstlab.org, Young Myoung Ko

In the era of growing information communication technology, large-scale data centers are inevitable solutions for processing and storing huge amount of incoming data. Large-scale data centers, however, consume tremendous amount of energy. Achieving energy-efficiency is one of the key problems in data center operations. In the previous research study, we proposed a distributed speed scaling and load balancing algorithm for reducing energy consumption while attaining a desired quality of service when the user requests are stationary stochastic processes. In this research study, we seek how to extend the previous algorithm when the user requests are arriving in nonstationary fashion.

Social Media Analysis: Marketing and Management Applications

Invited: Social Media Analytics

Invited Session

Chair: Soo Jeong Hong, Michigan State University, East Lansing, MI, 48824, United States, hongsoo3@msu.edu

1 - The Effect of Social Media Information on Financial Analysts
Kwangjin Lee, Michigan State University, East Lansing, MI, 48824, United States, leekwan6@msu.edu

The news media is an important information intermediary in financial markets. Social media encourage participation, collaboration, and information sharing and has transformed the disclosure landscape. While social media allow investors to become more informed and thereby contribute to a reduction in information asymmetry, there is limited evidence on how social media messages affect financial analysts. Using a sample of S&P 500 firms over the period 2012 - 2014, I examine whether and how social media information influences financial analysts.

2 - Effect of Social Media Messages on Stock Price Behavior During Firm Crises
Soo Jeong Hong, Michigan State University, 404 Wilson Rd, Room 309, East Lansing, MI, 48824, United States, hongsoo3@msu.edu

This study examines whether and how social media messages influence on stock price behavior under firm crises situations. Regression analyses on a sample of S&P 500 firms from 2004 to 2015 show the effect of volume and valence of social media messages on abnormal returns. Results suggest theoretical and practical implications.

Auctions and Economics

Invited: Auctions

Invited Session

Chair: Benjamin Brooks, University of Chicago, Chicago, IL, United States, babrooks@uchicago.edu

1 - An Ascending Auction with Multidimensional Signals
Tibor Heumann, tahe@princeton.edu

A single-unit ascending auction in which agents observe multidimensional Gaussian signals about their valuation of the good is studied. A class of equilibria is constructed in two steps: (i) the private signals of each agent are projected into a one-dimensional equilibrium statistic, and (ii) the equilibrium strategies are constructed "as if" each agent observed only his equilibrium statistic. Novel predictions of ascending auctions that arise only when agents observe multidimensional signals are provided.

2 - Selling to Intermediaries: Optimal Auction Design in a Common Value Model
Benjamin Brooks, University of Chicago, Chicago, IL, United States, Dirk P.Bergemann, Stephen Morris

We characterize revenue maximizing auctions when the bidders are intermediaries who wish to resell the good. The bidders have differential information about their common resale opportunities: each bidder privately observes an independent draw of a resale opportunity, and the highest signal is a sufficient statistic for the value of winning the good. If the good must be sold, then the optimal mechanism is simply a posted price at which all bidders are willing to purchase the good, and all bidders are equally likely to be allocated the good, irrespective of their signals. If the seller can keep the good, then under the optimal mechanism, all bidders make the same expected payment and have the same expected probability of receiving the good, independent of the signal. Conditional on the good being sold, the allocation discriminates in favor of bidders with lower signals. In some cases, the optimal mechanism again reduces to a posted price. The model provides a foundation for posted prices in multi-agent screening problems.

3 - Collusion in Markets with Syndication

John Hatfield, McCombs School of Business, 2110 Speedway, Stop B6600, Austin, TX, 78172, United States, john.hatfield@gmail.com, Scott Kominers, Richard Lowery

Markets for IPOs and debt issuances are syndicated, in the sense that a bidder who wins a contract may invite losing bidders to join a syndicate to fulfill the contract. We show that in such markets, standard intuitions from industrial organization can be reversed: Collusion may become easier as market concentration falls, and market entry may facilitate collusion. In particular, price collusion can be sustained by a strategy in which firms refuse to join the syndicate of any firm that deviates from the collusive price. Our results thus can rationalize the apparently contradictory facts that the market for IPOs exhibits seemingly collusive pricing despite its low level of market concentration.

4 - Signal Design and Costly Entry

Vitor Farinha-Luz, ancouver School of Economics, 6000 Iona Drive, Vancouver, QC, Canada, vitor.farinhaluz@ubc.ca

A buyer observes a noisy signal about his own value for a good before making a costly entry decision. The signal structure can be designed by the seller, who cannot commit to a posted price post-entry. Following entry, the buyer perfectly observes his valuation and the seller makes him an offer. I show that, if entry occurs with interior probability, the optimal information structure provides partial information and solves a trade-off between efficient entry and guaranteeing positive rents to the buyer.

1 - Binary Matrix Completion Methods for Reciprocal Recommendation with Applications in Online Dating

Qihang Lin, University of Iowa, 21 East Market Street, S380, Pappajohn Business Building, Iowa City, IA, 52245, United States, qihang-lin@uiowa.edu, Kang Zhao, Xi Wang

The success of an online dating site depends on its effectiveness in recommending potential partners to each other. Compared to the traditional recommendation systems, the recommendation systems used by online dating sites must predict the mutual interests of a male and a female users in each other, which is a reciprocal recommendation system. In this paper, we study various binary matrix completion methods that can integrate the different behavior information of male and female users to improve the overall prediction accuracy for reciprocal recommendation. The proposed method is based on solving non-convex matrix optimization problems by alternating proximal gradient methods.

2 - Understanding the Impact of Individual User's Rating Patterns on Predictive Accuracy of Recommender Systems

Jingjing Zhang, Indiana University, 1309 E.10th St, HH4143, Bloomington, IN, 47405, United States, jjzhang@indiana.edu, Xiaoye Cheng, Lu Yan

This paper investigates how the rating patterns of individual users affect the performance of recommendation algorithms. We measure each individual user's rating patterns from three different perspectives: rating value, rating structure and neighborhood network embeddedness. We study how these three groups of rating measures influence the recommender systems' predictive accuracy performance for each user. Our experiments use five real-word datasets with varying characteristics. Our experimental results show consistent and significant effects of several rating measures on recommendation accuracy.

3 - Analyzing Firms' Performance -A Supply Chain Network Perspective

John Rios, University of Iowa, Iowa City, IA, 52242, United States, john-riosrodriguez@uiowa.edu, Kang Zhao, Jennifer Blackhurst

This research explores the relationship between the performance of a firm and the structure of its supply chain and competition networks. The analysis starts with building the supply chain network and the competition network among 4.7k firms. Incorporating baseline features of firms' individual characteristics, we show that firms' structural features based on its supply chain network and competition network (e.g., diversity or coordination) contribute to the analysis of firms' performance.

4 - Multi-label Annotation Aggregation in Crowdsourcing

Xuan Wei, University of Arizona, Tucson, AZ, United States, weix@email.arizona.edu, Dajun Daniel Zeng, Junming Yin

As a means of human-based computation, crowdsourcing has been widely used to annotate large-scale unlabeled datasets. One of the obvious challenges is how to aggregate these possibly noisy labels provided by a set of heterogeneous annotators. When each instance is associated with many possible labels simultaneously, the problem becomes even harder because of its combinatorial nature. In this paper, we present new flexible Bayesian models and efficient inference algorithms by taking both annotator reliability and label dependency into account. Extensive experiments on real-world datasets reveal that the proposed methods outperform other competitive alternatives.

1 - Mental Health Monitoring using Dynamic Vocal Biomarkers

Ying Lin, University of Houston, Houston, TX, 77030, United States, ylin58@uh.edu, Shuai Huang

Modes disorder is inherently related to emotion. With recent progresses in linking the acoustic and linguistic features to emotion, automatic analysis of audio data could provide a powerful tool to assist in detection and monitoring of mode disorder. The audio data contains a rich array of features, such as the pitch, energy and linguistic content, that can inform or indicate signify emotion changes in the communication. This study employed a variety of signal processing techniques to convert the audio signals into dynamic vocal biomarkers that capture the acoustic and linguistic features in speech. We further monitored the underlying emotion based on the identified dynamic vocal biomarkers.

2 - Graph Theoretic Compressive Sensing Approach for Classification of Global Neurophysiological States from Electroencephalography Signals

Prahalada Rao, University of Nebraska-Lincoln, Lincoln, NE, United States, rao@unl.edu
Prahalada Rao, University of Nebraska-Lincoln, Lincoln, NE, 68588, United States, rao@unl.edu, Samie Tootooni, Chun-An Chou, Vladimir Miskovic

We present a data-fusion framework integrating graph theoretic and compressive sensing (CS) techniques to detect global neurophysiological functions states using high-resolution electroencephalography (EEG) recordings. Acute stress experiments were induction (and control procedures) were used to elicit distinct states of neurophysiological arousal. Our experimental results revealed that the proposed graph theoretic compressive sensing approach yielded better classification performance (~90% F-score) compared to SVM use with statistical features (~50% F-Score).

Risk Analysis

Contributed Session

Chair: Sadegh Kazemi Zarkouei, Washington State University, Pullman, WA, United States, m.kazemi@wsu.edu

1 - Pricing Decisions when Consumers Have Access to Quality Reviews and a Secondary Market

Sadegh Kazemi Zarkouei, Washington State University, Todd Hall Addition 470, Pullman, WA, 99164, United States, m.kazemi@wsu.edu, Michelle Wu

We are studying the effect of strategic consumers' behavior on a firm's profit when consumers socially interact among each other in the primary and secondary market in two periods. When the firm introduces a new product to the primary market, it may face a group of strategic consumers in the first period who postpone their purchases with the hope of a discounted price in the second period. These forward-looking behaviors are exacerbated when consumers have the opportunity to socially interact with each other through quality reviews. The presence of social learning and the secondary market significantly influence the consumers' purchasing decision and the firms optimal profit.

2 - A Multi-level Demand System for Differentiated Fare Products in Airline Industry

Hunkar Toyoglu, Senior Director, Sabre Airline Solutions, Southlake, TX, 76092, United States, hunkar.toyoglu@sabre.com, Yuhui Shi, Evrim Dener, Mu Liu, Joakim Kalvenes

We discuss econometric and theoretical considerations in specifying a demand system and suggest a flexible model to understand the competition between differentiated fare products in airline industry. We develop a multi-level hierarchical demand system and provide formulas and derivations in estimating own and cross price elasticity of demand in an unrestricted manner. Using transaction data, we estimate expenditure elasticity, own-price and asymmetric cross-price elasticity of demand for airlines and their competitors. We then identify which fare products are equivalent in the eyes of consumers, conduct competitive analysis and draw inference on the competitive structure in a market.

3 - Improving Overbooking Decisions using Customers Past Behaviour

Vinaysingh Chawan, Indian Institute of Management Indore, IIM.Indore Campus, Fac. Block B, Indore, 453556, India, vinaysingh@iimidr.ac.in

Overbooking models depend upon predictions of last moment cancellations and no-shows. A model is proposed to use CRM data to build predictive models that classify customers and assign a probability of cancellation/no-show to each customer/class. This predictive model is augmented with a revenue management model that considers the trade-offs associated with the overbooking decisions. The potential for revenue enhancement with this method is estimated using simulated data.

4 - A Choice Based Optimization Approach in Flexible Mobility on Demand

Shadi Sharif Azadeh, Assistant Professor, Erasmus University Rotterdam, Burgemeester Oudlaan 50, Rotterdam, 3062 PA, Netherlands, sharifazadeh@ese.eur.nl, Michel Bierlaire, Bilge Atasoy, Moshe E.Ben-Akiva, Yousef Maknoon

One of the main challenges of operation managers is to decide about how to o er a mix of products to the customers at a given time with the objective of maximizing the expected revenue as well as maximizing the customers' satisfaction. The expected revenue from an o er set is defined by the price and the demand of each of the o ered products. Smart phones have revolutionized urban transportation and mobility. We introduce an integrated choice-based optimization model that takes into account the cost of routing for taxis and shared taxis while accounting for customer choice behavior.

5 - Drivers of Degree of Hotel Revenue Management System Sophistication

Lizao Zhang, Washington State University, 1630 NE Valley Rd Apt V303, Pullman, WA, 99163, United States, lizao.zhang@wsu.edu, Timothy K.Baker, Xun Xu

We aim to develop a measure of hotel revenue management system sophistication. We revise a general taxonomy for the hotel settings and use it as a dependent variable to test the drivers of the need for revenue management system sophistication. We generate the drivers by delving into the literature of management, organizational behavior, and marketing; and test the drivers using hotels from North America.

6 - Cognitive Pricing for Personalized Bundle of Products and Services

Shuyu Chu, Virginia Institute of Technology, 1880 Pratt Drive, XV, Suite 1100-1, Blacksburg, VA, 24060, United States, cshuyu@vt.edu, Zhengliang Xue, Huijing Jiang, Xinwei Deng

We integrate classification, regression and optimization models to provide pricing solutions for bundles of product and service businesses, in which the services are highly customized projects, possibly associated with hardware and software orders. The services have distinguished features such as the band of labor force involved, service contents (travel expense, setup, maintenance, etc.), the duration of service, risk of project, and service category. The model considers the risk and cost involved during the project, and increase the expected profit by comparing optimal prices with actual prices in a business case study.

Chair: Tao Lu, Rotterdam School of Management, Erasmus University, Rotterdam, Netherlands, lu@rsm.nl

1 - Contracting for Product Support under Information Asymmetry

Nishant Mishra, Faculty of Business and Economics, KU. Leuven, Naamsestraat 69, Leuven, 3000, Belgium, nishant.mishra@kuleuven.be, Dong Li, Serguei Netessine

Despite advantages of Performance-based contracts (PBC) that have been highlighted in many previous studies, the more traditional Transaction-based Contracts (TBC) are still widely adopted in the product support industry. In this paper, we build a stylized adverse selection model to explore the hidden superiorities of TBC in screening products with different failure rates when the information about product reliability is privately owned by the customer. We find that TBC can achieve separation of product reliability without losing efficiency in setting service capacity, whereas, PBC requires interactions of pricing and capacity decision, resulting in over-investment in repair capacity.

2 - A Scenario Generation Approach for Integrated Supply Chain Network Design with Risk Considerations

Minghe Sun, Professor, The University of Texas at San Antonio, One UTSA Circle, San Antonio, TX, 78249, United States, minghe.sun@utsa.edu, Zhimin Guan, Jin Tao, Hao Wu

An optimization approach is developed for integrated design and operations for resilient supply chain networks with disruption risks. A mixed binary integer programming model is formulated. Scenarios are used to describe disruption events. Uncertainties in supplies, demands and prices are also considered. A region-wide dual-sourcing strategy, strategic emergency inventories and alternative sourcing facilities are used to increase network resilience. The Sample Average Approximation method is used to solve the proposed model with disruption risks. An illustrative example demonstrates the validity of the model and sensitivity analysis results provide important references.

3 - Deployment of Online Pickup Facility Networks for Omnichannel Supply Chain Management with GIS

Byeong-Yun Chang, Ajou University, San5 Woncheon-dong, Yeongtong-gu, Suwon, 443-749, Korea, Republic of, bychang@ajou.ac.kr, Choonki Min

Omni-channel supply chain management is one of the most challenging research fields in operations management arena. In this study we propose a method combining GIS and multi-criteria decision models to allow retailers providing online pickup service for omnichannel operation to determine locations for pickup sites and the type of the facilities.

4 - The Impact of Service Oriented Manufacturing on Core Enterprise in Supply Chain

Ruihan Zhang, Harbin Engineering University, No. 145, Nantong Avenue, Nangang District, Ha, Harbin, 150000, China, zhangruihan0826@163.com, Bing Sun

Based on the mediating role of core enterprise cost, the effect of Service-Oriented Manufacturing on core enterprise performance is explored. The result indicates that (1) Service-Oriented Manufacturing has a positive effect on the core enterprise performance; (2) Core enterprise cost in supply chain has a negative effect on the core enterprise performance; (3) Core enterprise cost plays a partial mediated role in the relationship between Service-Oriented Manufacturing and the core enterprise performance. This paper is funded by the International Exchange Program of Harbin Engineering University for Innovation-oriented Talents Cultivation.

5 - Path Based Versus Lane Based Formulation of Network Design Problems

Gokhan Memisoglu, LLamasoft Inc, 2813 Barclay Way, Ann Arbor, MI, 48105, United States, Gokhan.memisoglu@llamasoft.com, Ali Taghavi, Nejat Karabakal, Zheng Ouyang

Path-based formulation and lane-based formulation are usually the alternative approaches used in designing a supply chain network. In this study we review the main use cases for either of these formulations along with their pros and cons. Later, we present how we integrate these formulations for solving network design problems and show a number of related business problems solved by Llamasoft's network optimization tool (Supply Chain Guru).

6 - Shipping to Heterogeneous Customers with Competing Carriers

Tao Lu, Assistant Professor, Rotterdam School of Management, Erasmus University, Mandeville Building T09-03, P.O. Box 1738, Rotterdam, 3062 PA, Netherlands, lu@rsm.nl, Ying-Ju Chen, Jan C. Fransoo, Chung-Yee Lee

We consider a shipper selling a perishable product to heterogeneous customers in a destination market. The product can be shipped via two competing carriers with distinct speeds. Our analysis reveals a trade-off between the benefits from differentiation and competition. Dual-mode shipping can therefore be inferior to restricting to a single mode.

1 - The Impact of Airline Market Competition Structure on Fares

Susan Hotle, Assistant Professor, Virginia Tech, 200 Patton Hall, 750 Drillfield Drive, Blacksburg, VA, 24061, United States, shotle3@vt.edu, Stephanie Atallah

In recent years, changing economic conditions have led airlines to realign service to the most profitable routes and reduce operating costs. This presentation evaluates how non-stop airline markets have evolved with an emphasis on the continuity of service and the relationships between competition structure, market airport sizes, and fares. This analysis is performed using DB1B, OAG airline schedules, and the FAA's Airport Classification on size for years 2005-2015.

2 - A Nonparametric Approach to Estimating Air Travel Demand Structures from Panel Data

Johannes Jörg, RWTH Aachen University, Aachen, 52072, Germany, johannes.ferdinand.joerg@ada.rwth-aachen.de, Catherine Cleophas

Analyzing historical sales data to draw conclusions on the underlying demand structure is a central theme of revenue management. This contribution focuses on the estimation of demand segments present in a market using nonparametric methods on panel data. We employ finite mixtures to model purchase events over time frames and obtain estimators for purchase probabilities and market share. The approach shows promising performance when applied to simulated panel data sets with a MNL customer choice model.

3 - Using Online Surveys to Develop Choice Set Generation Models

Laurie A.Garrow, Georgia Institute of Technology, School of Civil & Environmental Engr, 790 Atlantic Drive, Atlanta, GA, 30332-0355, United States, laurie.garrow@ce.gatech.edu, Ziran Chen, Mohammad Ilbeigi

We designed an online experiment to capture how individuals filter and screen alternatives for discrete choice modeling applications. We ran this experiment on Amazon Mechanical Turk (AMT) and Qualtrics. We present preliminary results comparing responses obtained from AMT (a crowdsourcing Internet marketplace), Qualtrics (a traditional marketing survey panel), and an online survey conducted by the Resource Systems Group that recruited participants from airlines' frequent flyer databases. Based on these results, we offer a conceptual framework for how online surveys can be used to develop a choice set generation model for airline itinerary choice applications.

Operations Research and Intelligence

Sponsored: Military Applications

Sponsored Session

Chair: Andrew Oscar Hall, United States Military Academy, West Point, NY, 10996, United States, andrew.hall@usma.edu

1 - Hazardous Materials (hazmat) Transport Risk Assessment Considering Terrorist Assaults

Zafer Yilmaz, McGill University, Montreal, QC, Canada, zyilmaz1996@gmail.com, Vedat Verter

Terrorist attacks against military convoys including hazmat trucks have increased during the past decade. We developed a methodology that incorporates the risk of such attacks as well as the accident risks. A case study focusing on the eastern part of Turkey suffering from terrorist attacks will be presented. Based on data from the past five years, the proposed risk assessment method is incorporated in a GIS framework so as to identify the best paths among the common origin-destination pairs.

2 - Second-order Extensions to Nearly Orthogonal-and-balanced Mixed-factor Experimental Designs

Zachary C.Little, Air Force Institute of Technology, Wright-Patterson AFB, OH, United States, zach.c.little@gmail.com Zachary C.Little, The Perduco Group, Beavercreek, OH, United States, zach.c.little@gmail.com, Jeffery D. Weir, Raymond R. Hill, Brian B.Stone, Jason K.Freels

Many simulation studies can involve a large number of both quantitative (how many?) and qualitative (which type?) decisions with different numbers of choices for each. Second-order extensions are developed for the nearly orthogonal-and-balanced (NOAB) design that accounts for such varied decisions, allowing analysts to better examine possible two-way interactions and quadratic effects. A case study is presented for evaluation and comparison of NOAB design construction approaches for a design space involving notional Intelligence, Surveillance, and Reconnaissance (ISR) decisions.

3 - Data Science Application for Medical Intelligence"

Russell Walter, U.S. Army, Washington, DC, 22207, United States, walt@mail.mil

We examined machine learning and natural language processing to detect articles containing relevant warnings of disease outbreak. For years, medical intelligence analysts have categorized articles based on relevant information they contained, yielding an extensively labelled dataset to train a machine learning classifier. Differences between classes are subtle. Applying several machine learning algorithms, the biggest sensitivity resulted from the preparation of the training corpus and not the models' parameters. Lessons learned regarding data having large class imbalances are also shared.

Supply Chain Management, Green

Contributed Session

Chair: Elif Elcin Gunay, Iowa State University, Ames, IA, United States, eekabeloglu@gmail.com

1 - Optimality of Rule-based Allocation Planning in Customer Hierarchies with Stochastic Demand wnd Heterogeneous Service-level Targets

Konstantin Kloos, Research Assistant, University of Wuerzburg, Stephanstraße 1, Wuerzburg, 97070, Germany, konstantin.kloos@uni-wuerzburg.de, Benedikt Schulte, Richard Pibernik

To account for the multi-level hierarchical structure of sales organizations companies often times refrain from centralized optimization-based approaches but use simple allocation rules (i.e. per commit, rank based,...) better suited for decentralized, top-down planning regimes. Using the global optimum as a benchmark, we show analytically that these simple rules are optimal only under very restrictive conditions. Based on our analytical insights we develop two new rules resulting in optimal allocations under less restrictive conditions. In a numerical experiment we show that these new approaches consistently out perform conventional simple rules and lead to close-to-optimal results.

2 - Optimal Product Architecture and Supply Chain Configuration Designs under Labor Cost Fluctuation

Elif Elcin Gunay, Iowa State University, Ames, IA, United States, eekabeloglu@gmail.com, Kijung Park, Gul Kremer

Many companies utilize globally distributed supply chains in order to take advantage of lower labor costs in different countries. Changes in both the value and the volatility of labor costs can affect the production costs unexpectedly. At the same time, the product architecture i.e. the way product is assembled, and the quality and cost of components can be major factors affecting the production cost. This study proposes a stochastic optimization model for deciding the optimal product architecture and the supply chain configuration simultaneously, considering randomness in labor costs. Simultaneous consideration of these decisions enables improvements in product design as well as supply chain.

3 - The Impact of the Supply Chain on the Success of Product Pre-announcements

Laharish Guntuka, Doctoral Student, University of Maryland College Park, 3346 Van Munching Hall, College Park, MD, 20742, United States, lguntuka@rhsmith.umd.edu, Curt Grimm, David E. Cantor

We explore factors that influence a consumer's willingness to purchase a competitor's pre-announced product. Using competitive dynamics and relational view theories, we investigate how issues in the supply chain moderate these relationships. Example of factors explored include competitive aggressiveness, geographic and reputational concerns. We designed a behavioral experiment to test our research questions.

4 - Healthcare Supply Chain vs. Traditional Supply Chains: A Comparative Analysis

Balaraman Rajan, Assistant Professor, California State University East Bay, 25800 Carlos Bee Blvd, Hayward, CA, 94542, United States, balaraman.rajan@csueastbay.edu, Vishwanath Hegde

We compare and contrast the healthcare supply chain structure with that of traditional supply chains using publicly available financial data and analyzing financial ratios. We find that companies that operate in different stages of the healthcare supply chain do exhibit different characteristics and develop a framework to analyze the healthcare supply chain stages. We then draw inferences about the structural difference from traditional supply chains based on the performance of companies in comparable stages.

5 - How do Supply Chains Benefit from Supply Chain Finance? A Large Scale Empirical Investigation

David Wuttke, EBS.Universität, Burgstr. 5, Oestrich-Winkel, 65375, Germany, david.wuttke@ebs.edu

Supply chain finance gains increasing popularity among buyers and suppliers. In this study, we test a series of hypotheses on decisions and strategies related to the use supply chain finance in practice. Based on secondary data from a leading supply chain finance provider this study reveals substantial impact of supply chain finance on payment terms.

6 - Do Social Ties along the Supply Chain Foster Corporate Innovation?

Audrey Mathews, Illinois Institute of Technology, 3300 South Federal Street, Chicago, IL, 60616, United States, amathew2@hawk.iit.edu, Jiong Sun, Yiwei Fang

This paper investigates whether, and to what extent, managers' social ties between suppliers and major customers foster alternative information channels which ultimately lead to innovation by the supplier. We find that with more social connections, supplier firms invest more in R&D, and in turn, generate more supplier patents and patent citations. We also find that these additional patents and citations are associated with greater firm value for the supplier, as well as for customer firms.

12:05 - 12:50 Provalis Research/ 12:50 - 1:35 Frontline Systems, Inc.

Invited: Vendor Tutorial

Invited Session

1 - Provalis Research

Adam Alami, Provalis, Montreal, QC, Canada, adam@provalisresearch.com

Operations Research and Management Sciences involves researching incident reports, corporate reports, news articles, press releases, social media and much more. The volume of available text has exploded in the digital age. It is extremely time consuming, expensive and in many cases impossible to read each and every document related to one's research. Automated content analysis makes it possible to systematically import and analyze very large volumes of text documents without spending vast sums on hiring coders. This presentation will showcase the different content analysis approaches such as computer assisted qualitative coding; text mining; content analysis dictionaries or taxonomies and supervised machine learning. We will discuss when one technique may be more appropriate than another and how they can work together to analyze text data.

2 - AnalyticSolver.com: Data Mining, Simulation and Optimization in Your Web Browser

Daniel H.Fylstra, Frontline Systems, Inc., P.O. Box 4288, Incline Village, NV, 89450-4288, United States, daniel@solver.com

AnalyticSolver.com is the new, simple, point-and-click way to create and run analytic models using only your web browser - that also works interchangeably with your spreadsheet. Whether you need forecasting, data mining and text mining, Monte Carlo simulation and risk analysis, and conventional and stochastic optimization, you can "do it all" in the cloud. We'll show how you can upload and download Excel workbooks, pull data from SQL Server databases and Apache Spark Big Data clusters, solve large-scale models, and visualize results - without leaving your browser. If you're more comfortable working on your own laptop or server, we'll show how you can do that, too.

Managing Customer Contact

Sponsored: Service Science

Sponsored Session

Chair: Moein Khanlari, University of New Hampshire, 10 Garrison Avenue, Room 313, Durham, NH, 03824, United States, moein.khanlari@unh.edu

1 - Feature Selection for Voice Self-Service Transfer Rate in Insurance Call Centers

Rodrigo Andrade, Stevens Institute of Technology, 1 Castle Point Terrace, Hoboken, NJ, 07030, United States, rcaporal@stevens.edu, Somayeh Moazeni

We study effective features for the transfer outcome of a call arriving at the self-service voice response system based on customers' information from massive data of an insurance company. Our findings indicate that the call duration, distinct channels of contact, average temperature, customer types, and specific intents are relevant features to determine whether the call is transferred. Although customers' location is essential to select the active set of features we found no correlation between the country's region and the selected features. Managerial insights into policyholders' behavior are discussed. The algorithm is scalable and applicable to other business analytics applications.

2 - Impact of Extended Warranty Information Availability Strategies on Consumers' Product and Warranty Purchase Decisions

Moein Khanlari, University of New Hampshire, 10 Garrison Avenue, Room 313, Durham, NH, 03824, United States, moein.khanlari@unh.edu, Paul Messinger

In this paper, we ask whether and how the availability of Extended Warranty(EW) information during product choice might affect buyers' product and EW purchase decisions. Our results from a series of choice experiments show a combination of effects in this scenario that are attributable to two distinctive groups of customers. We observe lower sensitivity to EW prices combined with buying EWs for higher quality products (i.e. a reparative EW-focused mindset) attributable to risk-averse consumers, as well as a lower EW purchase likelihood associated with lower sensitivity to product prices (i.e. a preventative product-focused mindset) attributable to consumers with low risk aversion.

3 - Issues in Public Sector Service

Paul R.Messinger, University of Alberta, Faculty of Business, 3-20e Faculty of Business Bldg, Edmonton, AB, T6G 2R6, Canada, paul.messinger@ualberta.ca

We study problems for public consultation arising out of the long lifecycles of major municipal projects. We propose a framework that breaks the practice of public-involvement processes into Planning, Engagement, Impact, and Assessment/organizational learning. Conduct (or practice) is preceded by Commitment and followed by Outcomes. Using interview, survey, and field data, we consider the applicability of the framework and discuss the differences in public involvement processes of several U.S. and Canadian cities.

Multiple Criteria Optimization and Issues in Choice Behavior

Sponsored: Multiple Criteria Decision Making

Sponsored Session

Chair: Hannele Elina Wallenius, Aalto University, Espoo, Finland, hannele.wallenius@aalto.fi

1 - Considerations of Choices with Decreasing Marginal Values

Jyrki Wallenius, Aalto University School of Business, Runeberginkatu 22-24, Helsinki, Finland, jyrki.wallenius@aalto.fi, Tolga Genc, Pekka J.Korhonen, Xu Peng

Our problem is to "fill" a basket with multiple goods using win-win and tradeoff strategies, assuming decreasing marginal value functions. Our ultimate goal is to increase knowledge of a Decision Maker's (DM) behavior in such stepwise choice situations. A key question is how to find the Most Preferred Final Basket and how to recognize it. The basket can be filled either with identical or different (various) goods. Some empirical experiments are used to illustrate the considerations.

2 - Predicting Choice Quality with Decision Style, Cognitive Reflection and Decision Environment

Tommi Juhani Pajala, Aalto University, Melkonkatu 19 A.29, Helsinki, 00210, Finland, tommi.pajala@aalto.fi

Psychological measures of decision style are rarely used in economic decision research. However, they could have value in explaining individual differences in a Multiple Criteria Decision Making task. I investigate whether decision style and cognitive measures together with the decision environment can explain choice quality. 159 participants answered the psychological measures and made 26 choices in a setting with six alternatives and six criteria. Low Cognitive Reflection and high Alternative Search were related to higher choice quality. Other decision style variables showed no effects. Conclusions are robust to a variety of model specifications, software packages, and priors.

3 - Approximated Set-valued Mapping Approach for Handling Multi-objective Bilevel Problems

Pekka Malo, Aalto University School of Business, Runeberginkatu 22-24, Helsinki, 00100, Finland, pekka.malo@aalto.fi, Ankur Sinha, Kalyanmoy Deb

A significant amount of research has been done on bilevel optimization problems both in the realm of classical and evolutionary optimization. However, the multiobjective extensions of bilevel programming have received relatively little attention from researchers in both the domains. In this paper, we develop insights into multiobjective bilevel optimization through theoretical progress made in the direction of parametric multiobjective programming. We introduce an approximated set-valued mapping procedure that would be helpful in the development of efficient evolutionary approaches for solving these problems.

4 - Multi-criterion Optimization using Evolutionary Algorithms

Kalyanmoy Deb, Michigan State University, Electrical & Computer Engineering, 428 S. Shaw Lane, East Lansing, MI, 48824, United States, kdeb@egr.msu.edu

In this talk, we shall present a 25 years of research and application of multi-criterion optimization and decision-making using evolutionary algorithms. The so-called EMO field, started in early nineties, have become a mainstream research area within evolutionary computation, with 500+ PhD theses, commercial softwares, and high impacting (one having 24000 citations) journal papers.

1 - Informs Prize Winner Showcase – the Walt Disney Company

Dayana Cope, The Walt Disney Company, P.O. Box 10000, Lake Buena Vista, FL, 32830, United States, dayana.cope@disney.com, Peter Buczkowski, Haining Yu

This presentation will include a summary of the Prize winning application submitted by The Walt Disney Company.

2 - Analysis in the United State Air Force: 2017 Informs Prize Presentation

Mark Gallagher, Doctorate, United States Air Force, Arlington, VA, United States, mark.a.gallagher16.civ@mail.mil

The Secretary of the Air Force signed our winning nomination for the INFORMS Prize. We highlighted 3 exemplar topics of aircraft repair, nuclear deterrence, and testing. We had 17 additional topics in operation effectiveness, logistics, manpower, acquisitions, and cost analysis. Leaders from Congress, US and allied defense forces, industry, professional societies, and academia endorsed the Air Force. We summarized recent Air Force research, publications, and awards. We discussed the history of operations research in the Air Force along with contributions to the foundations of operations research. We conclude with how the Air Force develops, trains, and organizes analysts.

Contributed Session

Chair: Xin Ding, University of Houston, Houston, TX, United States, xding@uh.edu

1 - Holistic Data Analytics and Lean in Architectural Healthcare Pre-design

Sung Nam Hwang, Data Analytics and Senior Modeling Specialist, CallisonRTKL, 1717 Pacific Ave, Dallas, TX, 75201, United States, shwang@rtkl.com, Cortney Asberry

As healthcare systems implement EMR to store key information, exploring this data becomes crucial to strongly support process improvement initiatives seamlessly aligned with the schematic design process prior to any construction. Building new ORs adjacent to existing ORs adds more complexities during design phases since considering multiple transitional phases without deteriorating quality of service. Therefore, applying holistic data analytics, along with process analysis techniques, enables all members to understand pros and cons with respect to KPIs. Consequently, the schematic design process is better coordinated with all known and potential needs from clients.

2 - On Reducing Waiting Time for Specialists in Emergency Department

Cheng Zhu, McGill University, 701-801 Sherbrooke Est, Montreal, QC, H2L.0B7, Canada, cheng.zhu@mail.mcgill.ca, Beste Kucukyazici

From Emergency Department (ED) decision makers' perspective, we first decide the optimal specialist response policies for time-dependent patient arrivals, and then propose the optimal patient prioritization policies accordingly, in order to reduce the total LOS. Parameters are derived from 40,000 annual ED visits in a local hospital, and verified with ARENA simulation.

3 - Process Innovation in the Pharmaceutical Industry

Ivan Lugovoi, HEC Paris, 1 Square Theodore Judlin, Paris, 75015, France, ivan.lugovoi@hec.edu

Using a unique dataset of process - patent expert evaluations, we explore the benefits from process innovation. Combining our data with the sales of eighty generic pharmaceutical products over a ten-year period we find that process-patent activation is associated with a significant increase in a company's market share. To explain what drives this effect we evaluate process innovation across three dimensions: novelty, strength and depth. We find that two of these dimensions are mainly responsible for explaining the effect: i) the strength of a firm's process-patent portfolio for a given product and ii) the depth of a firm's process-patent portfolio for a given product.

4 - Does Hospital Operational Data Contain Signals of Resiliency and Safety Risk?

Dana Womack, PhD Candidate, Oregon Health & Science University, 48230 NW. Narup Road, Portland, OR, 97106, United States, womacda@ohsu.edu, Michelle Rose Hribar, Nancy Vuckovic, Paul Gorman

Acute care nurses enhance resiliency and enable patient care units to function under varying conditions by adjusting their work to meet ever changing patient needs. Adaptive strategies such as early task initiation, task deferral and delegation vary by workload state. We identify strategies frequently employed by nurses in normal, high and extreme workload states. We then explore whether "echoes" of these adaptive behaviors can be identified in ambient data generated by medication dispensing, nurse call and other systems used in care delivery. Analysis of ambient data may inform patient safety and improve the work experience of nurses by providing early signals of workload state transitions.

5 - The Impact of Focus Strategy and Market Competition on Cost Efficiency

Xin Ding, University of Houston, T2-230C, Technology I I.Building, Houston, TX, 77204, United States, xding@uh.edu, Xiaosong David Peng, Gregory R. Heim

In this study, we examine the longitudinal impact of focus strategy on cost efficiency in U.S. hospitals. We hypothesize that as the level of focus increases, hospital cost efficiency increases at a decreasing rate. In addition, we also hypothesize that focus helps improve cost efficiency in a competitive market when specialty hospitals are not present. Lastly, we propose that focus strategy has the strongest effect on cost efficiency for proprietary hospitals in highly competitive markets.

Models and Algorithms for Radiation Treatment Planning

Sponsored: Public Sector OR

Sponsored Session

Chair: Gino J Lim, University of Houston, Houston, TX, 77204, United States, ginolim@uh.edu

Co-Chair: Azin Khabazian, University of Houston, 5465 Braesvalley Dr. Apt 566, Houston, TX, 77096, United States, akhabazian@uh.edu

1 - A New Model and Algorithm for Planning Tomotherapy Delivery

Wilmer Henao, University of Michigan, 555 E. William Street, Apt 16C, Ann Arbor, MI, 48104, United States, wilmer@umich.edu

Current tomotherapy treatments for cancer tumors are developed assuming instantaneous opening and closing of gantry leaf apertures. Hence, conventional treatment planning spurs an excessive number of leaf events, leading to inaccuracies in dose delivery, and machine attrition. We propose a treatment model that explicitly controls the number of leaf events. The result is a treatment plan that represents dose effects more realistically, but which is modeled by a large-scale combinatorial problem. We therefore implement a fast iterative heuristic algorithm that achieves high-quality results.

2 - Incorporating Linear Energy Transfer in the Optimization of Intensity Modulated Proton Therapy

Azin Khabazian, University of Houston, Houston, TX, 77096, United States, akhabazian@uh.edu, Wenhua Cao, Gino Lim, Pablo Yepes, David Grosshans, Radhe Mohan

We developed a new optimization approach for incorporating linear energy transfer (LET) in intensity modulated proton therapy (IMPT) treatment planning. We hypothesize that the modified objective function will produce IMPT plans that not only satisfy clinical dose criteria but also achieve reduced LET distributions (thus lower biologically effective dose distributions) in critical structures and increased LET in target volumes compared to plans created based on conventional objectives. The resulting plan is compared with the conventional dose optimization regarding dose, LET and the product of dose and LET distributions

3 - Impact of Robust Optimization on Variable Relative Biological Effectiveness in IMPT Dose Distributions

Xuemin Bai, University of Houston, Houston, TX, 77054, United States, baid8432@gmail.com, Wenhua Cao, Hans-Peter Wieser, Gino J. Lim, Radhe Mohan

Robust optimization has been adopted to ensure robustness of intensity modulated proton therapy (IMPT) treatment plans in face of physical uncertainties such as range and setup errors. However, it has been established using a simplified constant value of relative biological effectiveness (RBE) for protons instead of using more complex and accurate variable RBE models. In this work, we investigate the impact of robust optimization on biologically effective IMPT dose distributions using a recently published RBE model for one phantom case and two head and neck cancer patient cases.

Operations Management/Marketing Interface

Contributed Session

Chair: Refik Gullu, Bogazici University, Istanbul, Turkey, refik.gullu@boun.edu.tr

1 - Optimizing Revenue of Share-private Parking System

Shuo-Yan Chou, The National Taiwan University of Science and Technology, Office: MA217, No. 43, Section 4, Keelung Rd, Taipei City, 106, Taiwan, sychou@mail.ntust.edu.tw

This study proposes a share-private parking system to increase the availability of parking spaces by optimizing the utilization rate of the existing parking spaces. Through this system, parking spaces owners share their parking spaces when they do not use it and generate revenue. On the other hand, drivers can easily find the available parking space and make a reservation. The main objective of this system is optimizing the revenue from sharing without disturbing the parking owner needs. Before releasing the private parking space to public, the proposed system analyzes the usage pattern of parking owner to find optimal acceptance rate for incoming reservation.

2 - Multiproduct Price Optimization under the Multilevel Nested Logit Model

Hai Jiang, Associate Professor, Tsinghua University, Dept of Industrial Engineering, Tsinghua University, Beijing, 100084, China, haijiang@tsinghua.edu.cn, Rui Chen

We study the multiproduct price optimization problem under the multilevel nested logit model. When the price sensitivities are identical within each primary nest, that is, within each nest at level 1, we prove that the profit function is concave with respect to the market share variables. We proceed to show that the markup is constant across products within each primary nest, and that the adjusted markup is constant across primary nests at optimality. This allows us to reduce this problem to an equivalent single-variable maximization problem involving a unimodal function. We also investigate the oligopolistic game and characterize the Nash equilibrium.

3 - On the Dependence of Customer Valuation and Service Requirement

Chenguang Allen Wu, Northwestern University, 2145 Sheridan Road, Room C229, Evanston, IL, 60208, United States, allenwu@u.northwestern.edu, Achal Bassamboo, Ohad Perry

In many services, the value of service may depend on each customer's individual service requirement. We therefore consider a queueing model in the presence of a stochastic dependence between customers' valuation and service requirement. We employ a bivariate dependence order to rank the strength of dependence and show that the provider's revenue is strictly decreasing in the strength of dependence. We demonstrate via numerical examples that the revenue loss caused by a positive dependence can be substantial. Moreover, we show that a positive dependence can also lead to a violation to a known result in the literature that the provider always prefers a large market size when there is no dependence.

4 - Capacitated Assortment and Price Optimization under the Nested Logit Model

Rui Chen, Tsinghua University, Shunde Building of Tsinghua University, Beijing, China, chenr15@mails.tsinghua.edu.cn, Hai Jiang

We study the capacitated assortment and price optimization problem, where a retailer sells categories of substitutable products subject to a capacity constraint. The goal of the retailer is to determine the subset of products as well as their selling prices so as to maximize the expected revenue. We model the customer purchase behavior using the nested logit model and formulate this problem as a non-linear binary integer program. We then propose an efficient algorithm to obtain its ϵ-approximate solution based on solving a series of multiple-choice parametric knapsack problems.

5 - Modeling Correlation in Competitive Revenue Management

Refik Gullu, Professor, Bogazici University, Bogazici University, Industrial Engineering Department, Istanbul, 34342, Turkey, refik.gullu@boun.edu.tr, Engin Yildiz, Taner Bilgic

We model a competitive revenue management game where two firms choose their prices to maximize their revenues. Respective valuation of the firms by consumers (consumers' willingness-to-pay) are correlated random variables. A consumer who is willing to pay a higher than average price to a product or service may be willing to pay a lower or higher than average price for its competitor. We discuss structural properties of the response function, show the existence of unique price equilibrium, and present interesting comparative statics of the game for the case where the willingness-to-pay random variables take a particular bivariate exponential distribution.

Revenue Management

Contributed Session

Chair: Peter McGlaughlin, University of Illinois at Urbana-Champaign, Urbana, IL, United States, mcglghl2@illinois.edu

1 - The Interaction between Product Rollover Strategy and Pricing Scheme

JingChen Liu, Peking University, Yiheyuan Road 5th, Haidian District, Beijing, 100871, China, liujingchen@pku.edu.cn, Xin Zhai, Lihua Chen

This study proposes a two-period model incorporating forward-looking consumers and market heterogeneity to explore the interaction between rollover strategy and pricing scheme of an innovating firm offering trade-in program. The firm uses either single or dual rollover to launch new generation, and chooses from price skimming and penetration pricing for consumer segment. We find that the optimal pricing scheme and rollover strategy depends on the innovation increment of new product, the salvage value of old product and how strategic consumers are. Moreover, the firm can be worse off deploying trade-in especially when innovation increment is not sufficient or consumers are relatively myopic.

2 - Product Recall through Group-buying with out Deadline

JingChen Liu, Peking University, Yiheyuan Road 5th, Haidian District, Beijing, 100871, China, liujingchen@pku.edu.cn, Ming Hu, Xin Zhai

This study considers a monopolistic firm selling one contemporary product to consumers with heterogeneous valuation who arrive according to a Poisson process. In order to better price discriminate between high- and low-end consumers, the firm can set up a product recall program, under which the firm will offer the recalled product to consumers who join if the sign-up number reaches the pre-announced threshold. We find that product recall program can perform as a win-win solution, namely the firm can improve its own profit without harming the consumers.

3 - An Analysis of Buy X Get 1 Free Reward Programs

Yan Liu, Tianjin University, Room C1211, The 25th Building, Tianjin University, No. 92 Weijin Road, Tianjin, 300072, China, hnnyly@gmail.com, Dan Zhang

"Buy x, get 1 free" reward programs are widely observed in practice. We model such programs as an infinite horizon stochastic game between a monopolistic seller and a population of customers with different product valuation and shopping frequencies. We characterize conditions under which the programs are profitable and discuss their welfare implications. Moreover, we show that "buy 1, get 1 free" program provides a tight bound on seller revenue and is optimal under certain conditions.

4 - Reinforcement Learning for Network Revenue Management

Peter McGlaughlin, Graduate Student, University of Illinois at Urbana-Champaign, 409 W. Elm St, Apt 12, Urbana, IL, 61801, United States, mcglghl2@illinois.edu

Network Revenue Management concerns the optimal allocation of a fixed set of resources across various segments of market demand. Applications require heuristic solutions as the underlying optimization problem is intractable. We propose reinforcement learning as an alternative. Recently, these algorithms enjoyed widely popularized success in solving large, challenging sequential decision making problems. Thus, reinforcement learning seems a natural candidate for a new approach to network revenue management. Numerical experiments show significant revenue increases, about 10%, over existing heuristics.

Scheduling with Applications

Invited: Project Management and Scheduling

Invited Session

Chair: Rodrigo A. Carrasco, Ph.D., Universidad Adolfo Ibáñez, Santiago, 7941169, Chile, rax@uai.cl

1 - Incorporating Suppliers into Capital Project Scheduling

Arman Jabbari, University of California-Berkeley, 2012 Del Norte, Berkeley, CA, 94707, United States, a.jabbari@berkeley.edu, Philip Kaminsky

The majority of capital projects are completed after their intended completion date and over budget, often due to inefficiencies in the way their supply chains are managed. After conducting extensive with practitioners in the oil and gas industry, we have identified the relationship between the project schedule and the procurement plan as one cause of these problems. As part of a larger project to develop approaches to simultaneously develop schedules and plan procurement, we need to bound certain online scheduling problems. Here, we prove that the DSPT algorithm is 2-competitive for the online version of minimizing modified total tardiness.

2 - Preemptive Parallel-machine Scheduling Problem of Maximizing the Number of On-time Jobs

Marc E. Posner, Ohio State University, 296 Baker Systems Engineering, 1971 Neil Avenue, Columbus, OH, 43210-1271, United States, posner.1@OSU.edu, Hui-Chih Hung, Bertrand M.T. Lin, Jun-Min Wei

We study the classical preemptive parallel-machine scheduling problem of maximizing number of on-time jobs. While known to be NP-hard, no theoretical analysis of approximation algorithms exists. We propose heuristics based on different design strategies, which have asymptotically tight relative errors of 1/2. Experimental tests evaluate computational performance. As part of the analysis, a new non-standard mixed integer formulation is developed.

3 - Cutting-plane Methods for Resource-constrained Project Scheduling Problems in Strategic Mine-planning

Alessandro Hill, Universidad Adolfo Ibanez, Santiago, Chile, alessandro.hill@uai.cl, Marcos Goycoolea

We consider resource-constrained project scheduling problems which are powerful models for mine planning. These notoriously hard problems aim at scheduling given tasks under bounded availability of multiple resources per time period, while respecting given precedence relations, in order to minimize the total project duration or maximizing a profit function. We present novel polyhedral techniques based on various problem-specific cuts. In our mathematical programming framework, we borrow fast enumeration subroutines from constraint programming. We show the detailed potential of our approaches within branch and cut algorithms for literature instances as well as real-world problems.

4 - Activity Scheduling in Mine Construction

Valentina Rojas, Universidad de Chile, Santiago, Chile, vjrojasc@gmail.com, Rodrigo A. Carrasco, Alessandro Hill, Nelson Morales

Construction of a mine is critical because it defines the available area for production, but proper model of a plan schedule can be hard, because there may be different ways to reach certain part of the mine, different potential technologies to use or because some activities may collaborate in order to achieve a common goal. In this talk we present a MIP model that abstracts these considerations and compare solution approaches on several mining methods.

Leveraging Online Platforms to Manage Services

Sponsored: EBusiness

Sponsored Session

Chair: Sreekumar R. Bhaskaran, Southern Methodist University, Dallas, TX, 75275, United States, sbhaskar@mail.cox.smu.edu

1 - Leveraging Online Platforms to Manage Services

Sanjiv Erat, University of California-San Diego, Rady Sch. Mgmt. Otterson Hall, 9500 Gilman Drive MC 0553, La Jolla, CA, 92093-0553, United States, serat@ucsd.edu

Many large firms are increasingly relying on open innovation, often requesting their own customers to brainstorm and come up with new products and services. While firms are becoming more adept at using IT to collect ideas from outside the firm boundaries, the evaluation and filtering of ideas is still a costly and labor intensive process. This talk shall discuss how some recent innovations in natural language processing can be effectively leveraged to automate the evaluation and filtering of large idea pools, thus making open innovation accessible and affordable even for smaller firms.

2 - Strategies of Coupon Issuance in Service Industries

Simin Li, Kellogg School of Management, Northwestern University, 2211 Campus Drive, Evanston, IL, 60208, United States, simin.li@kellogg.northwestern.edu, Kejia Hu, Martin Lariviere

We empirically study how service providers strategically design coupons, based on marginal service cost (MSC), to facilitate demand-supply coordination during rush hours. We find service providers with higher MSC launch coupons earlier with less discount. We confirm strategic coupon issuance effectively shift demand of experienced coupon users. Via counterfactual analysis, we propose a strategy tailoring to MSC and customer responsiveness.

3 - Platform Preannouncement Strategies: the Strategic Role of Information in Two-sided Markets Competition
Rajiv Mukherjee, Southern Methodist University, 11113 New Orleans Dr, Frisco, TX, 75035, United States, rajiv.mukherjee@gmail.com, Ramnath K. Chellappa

We use a game theoretic model to study the role of information contained in the firm's preannouncement strategy before releasing a new version of its platform to a two sided market in a competitive setting. We also explore the impact of installed base, switching and multi-homing on such strategies.

4 - On the Reliability of Online Reviews of Physicians
Atanu Lahiri, University of Texas at Dallas, University of Texas - JSOM, 800 W. Campbell Rd, #SM33, Richardson, TX, 75080, United States, atanu.lahiri@utdallas.edu, Danish Saifee, Vijay S. Mookerjee

We look at the reliability of online reviews of physicians by comparing such reviews with other data sources as well as by examining their ability to predict clinical outcomes.

Behavioral Operations: Theory Development and Hypothesis Testing

Sponsored: Behavioral Operations Management

Sponsored Session

Chair: Xiaoyang Long, HKUST University, xlongaa@connect.ust.hk

Co-Chair: Javad Nasiry, Hong Kong University of Science and Technology-HKUST, Lee Shau Kee Business Building, Room 4079, Hong Kong, 00000, Hong Kong, nasiry@ust.hk

1 - Transparency in Procurement Mechanisms
Ignacio Rios, Stanford University, 63 Abrams Ct., Apt. 519, Stanford, CA, 94305, United States, iriosu@stanford.edu, Ruth Beer, Daniela Saban

Motivated by the recent initiatives to increase the transparency in procurement in both in the public and private sector, we experimentally investigate the impact of different levels of transparency on a procurement game in which the director of an organization delegates purchasing decisions to the employees. We posit that, when purchasing decisions are delegated to agents, increased transparency can affect agents' actions through peer effects.

2 - Reciprocity in Demand Allocation Games
Yinghao Zhang, University of Cincinnati, 614A Carl H. Lindner Hall, 2925 Campus Green Dr., Cincinnati, OH, 45221, United States, zhang5y7@ucmail.uc.edu, Lin Tian, Tianjun Feng

We consider a situation with two competing retailers who make inventory decisions. The total market demand is divided proportional to their stocking levels. Experimental results suggest that human subjects' decisions systematically deviate from the Nash Equilibrium. We use theory of reciprocity to explain this off-equilibrium behavior.

3 - A Data-driven Approach for Promotions and Rewards Programs
Rim Hariss, Massachusetts Institute of Technology, Operations Research Center, 1 Amherst Street, Cambridge, MA, 02142, United States, rhariss@mit.edu, Georgia Perakis, Yanchong Zheng

Consumer-facing companies often adopt promotions and loyalty/rewards programs to attract customer demand and keep retention. In this work, we investigate the impact of promotions and rewards programs on customer choices and behaviors, develop a data-driven framework to accurately and dynamically predict market demands, then develop a prescriptive model for promotions and loyalty programs, such as advising on frequency and design of such programs.

4 - Designing Seat Belts for Boundely Rational Contract Designers. A Choice Set Reduction Experiment.
Valery Pavlov, Senior Lecturer, University of Auckland Business School, University of Auckland, Private Bag 92019, Auckland, 1142, New Zealand, v.pavlov@auckland.ac.nz, Bingkun Zhu

Supply chain contracting experiments commonly find that retailers often reject suppliers' "take-it-or-leave-it" offers. Dealing with rejections, suppliers face a cognitively demanding task of designing contracts that optimally trade off their profit and the probability of rejection. As a result of the problem complexity, suppliers' offers exhibit a substantial degree of bounded rationality. In our laboratory experiment, we test predictions of random choice models that eliminating suboptimal contracts from the supplier choice set improves the performance of a two-part tariff contractual form.

Practice/eBusiness III

Contributed Session

Chair: Xing Liu, Huazhong University of Science and Technology, Luoyu Road 1037, Wuhan, China, Wuhan, 1, China, 1393096617@qq.com

1 - Exploring the Relationship Between Offline Locations and Online Rating Behavior
Dominik Gutt, Paderborn University, Warburger Str 100, Paderborn, 33098, Germany, dominik.gutt@uni-paderborn.de, Juergen Neumann, Dennis Kundisch

This study examines the relationship between rating outside of a customer's home area and the magnitude of online ratings. We employ a data-driven identification of a customer's geographic home area and use variation in this variable to identify the consequences for the magnitude of online ratings. We find that customers who give a rating while traveling give, on average, higher ratings than locals. However, this relationship is moderated by the posting time of a review relative to consumption, with more negative ratings posted by travelers during or shortly after consumption. These results come with substantial implications for a business's average rating and for customer decision making.

2 - The Importance of Multisensory Feedback and Sensory Congruence in Virtual Product Experience
Cheng Luo, Tianjin University, Tianjin, China, cheng.luo@tju.edu.cn

As mouse-driven desktops give way to touchscreen and mid-air gesture-based devices, inquiries into the design and use of new interaction technologies deserve further investigation. This study explores how multisensory feedback and sensory congruence provided by interaction technologies shape virtual product experience. Drawing on literature on virtual product experience and sensory-based interaction, we propose that visual feedback and haptic feedback would enhance product tangibility and thus reduce consumers' shopping risk perceptions. Furthermore, the interaction effect between visual and haptic feedback on product tangibility would be moderated by sensory congruence.

3 - A New Application for Worst Case Resistance Testing
Stephen France, Mississippi State University, 324 McCool Hall, 40 Old Main, Mississippi State, MS, 39762, United States, sfrance@business.msstate.edu, Frank Adams, Myles Landers

Wave analysis assessments of non-response bias seem inadequate when internet samples can complete data collections in minutes. We adapt an extant procedure - worst-case resistance testing, often used to assess the file-draw problem in meta-analysis - to address the problem. The procedure assesses a study's non-response bias vulnerability based on the sample size, mean and standard deviation of specific survey item replies.

4 - How Internet Celebrity Attract Our Customers? the Effects of Internet Celebrity E-commerce Attractiveness on Customers' Repurchase Intention
Xing Liu, Huazhong University of Science and Technology, Luoyu Road 1037, Wuhan, China, Wuhan, China, 1393096617@qq.com

The success of emerging Internet celebrity e-commerce (ICEC) depends on the repurchase of their customers. Drawing on attractive and identification theories, we examine the role of ICEC attractiveness (in terms of product attractiveness, live streaming attractiveness, and internet celebrity attractiveness) in influencing internet celebrity identification and the influence of such identification on customers' repurchase intention. The findings of this study contribute to a better understanding how Internet celebrity e-commerce attract and retain repeat customers through their attractiveness.

Connected and Automated Transportation

Sponsored: TSL, Urban Transportation

Sponsored Session

Chair: Husain Abdul Aziz, PhD, Oak Ridge National Laboratory, Oak Ridge National Laboratory, 1 Bethel Valley Road, Oak Ridge, TN, 37831, United States, azizh@ornl.gov

1 - Simulating the Operations of Shared Autonomous Vehicle Fleets
Krishna Gurumurthy, University of Texas-Austin, Stop C1700, Austin, TX, 78712, United States, na, Kara Kockelman

Simulation of fleets of shared autonomous vehicles (SAVs) exist for various travel settings, using Austin, Texas data. Reliance on all-electric vehicles lowers replacement rates (from 1 SAV for 9 household vehicles to 1-to-5, in some cases) and raises empty-mileage (to 20% of fleet VMT). Dynamic ride-sharing (among strangers) raises replacement rates (to 10:1, for example) and lowers empty-VMT (becoming negative in some cases). Increasing a served region's size, to enable all trip distances, does not appear to raise empty-VMT, but response times are higher in exurban settings, and untenable with all-electric fleets.

2 - Automated Vehicle Performance at Intersection. Integration of Empirical Evidence with Simulation
Ramin Arvin, Graduate, University of Tennessee-Knoxville, 325 John D. Tickle Building, Knoxville, TN, United States, rarvin@vols.utk.edu

Automated Vehicles (AV) can potentially improve the current state of transportation by reducing human errors, and improving safety and reliability. In this paper, we develop crash scenarios using early empirical evidence from real-life AV-involved crashes in a simulation framework. The Wiedemann car-following model in SUMO simulates both traffic flow and crashes. Therefore it was used to quantify crash rates under different AV market penetration scenarios.

3 - Roads in Transition: Integrated Modeling of a Manufacturer-traveler-road Infrastructure System in a Mixed Autonomous/Human Driving Environment
Bo Zou, Assistant Professor, University of Illinois at Chicago, 2073 Engineering Research Facility, 842 W. Taylor Street, Chicago, IL, 60607, United States, bzou@uic.edu, Mohamadhossein Noruzoliaee, Yang Liu

This study develops an integrated modeling framework for autonomous vehicle (AV) manufacturer-traveler-road infrastructure system in a futuristic, mixed traffic environment. The modeling system involves manufacturer decision, multiclass traveler decision on vehicle and routing choice, and variable road capacity, and is formulated as an MPCC. To solve the MPCC to global optimality, multiple MILP-based approximation techniques are developed. The effectiveness of the solution approach is demonstrated with extensive numerical experiments in a Singapore case study.

4 - Machine Learning Based Traffic Signal Control Algorithms for Connected and Automated Transportation
Husain Aziz, Dr., Oak Ridge National Laboratory, 1 Bethel Valley Road, Oak Ridge, TN, 37831-6017, United States, azizh@ornl.gov

The anticipated deployment of the connected and automated vehicles (CAVs) offer the opportunity to leverage connectivity and automation for efficient operations of signalized intersection in transportation networks. CAVs can act as mobile sensors with a unique opportunity for data collection that can be used for real-time optimization of traffic signal settings. Machine learning based signal control techniques are expected to adapt to the changing traffic condition both temporally and spatially. We developed a machine-learning based signal control scheme that leverages the available data in a CAV environment and accounts for energy and mobility.

Recommender Systems

Sponsored: Information Systems

Sponsored Session

Chair: Konstantin Bauman, New York University, New York, NY, 10012, United States, kbauman@stern.nyu.edu

1 - Boosting Recommendation Diversity through Stochastic Item Selection
Kartik Hosanagar, University of Pennsylvania, 3730 Walnut Street, 500 Jon M.Huntsman Hall, Philadelphia, PA, 19104-6340, United States, kartikh@wharton.upenn.edu, Alex Miller

The standard k-nearest neighbor collaborative Filtering algorithm is well known to exhibit systematic popularity bias, by which products with higher market shares are disproportionately more likely to be recommended. We propose a novel method that recommends items with probabilities proportional to each item's sales or views among similar users. Using a dynamic simulation analysis, we show that our approach dramatically increases both aggregate and individual-level recommendation diversity while simultaneously increasing recommendation accuracy.

2 - Comparing the Effects of Disparate Sources of Information on Consumers' Product Selection: A Process-oriented View
Jingjing Zhang, Indiana University, 1309 E 10th St, HH4143, Bloomington, IN, 47405, United States, jjzhang@indiana.edu, Binny Samuel, Vijay Khatri

The objective of this project is to develop an understanding of consumers' information integration process in the online shopping setting. We are interested in identifying the sequence in which consumers use to integrate different sources of information (i.e., product description, online word-of-mouth, and personalized recommendations) in their product selection process.

3 - Recommender System and Cross-selling: Monopoly and Duopoly
Abhijeet Ghoshal, University of Louisville, Room 377, College of Business, Louisville, KY, 40292, United States, abhijeet.ghoshal@louisville.edu, Sumit Sarkar, Vijay Mookerjee

Recommendations provided by firms change how customers search products by helping customers find their preferred products. In the process, firms learn the preferences of customers and make cross-selling offers. Considering these factors, we study how firms price products in monopolistic and duopolistic markets and highlight the role of cross-selling. In duopoly, cross-selling may compel the firm with inferior recommender system to reduce its price when the superior firm improves its system, a counter-intuitive result since improvement of the system of the latter firm decreases competition.

Energy

Contributed Session

Chair: Deepak Rajan, Lawrence Livermore National Laboratory, Livermore, CA, United States, rajan3@llnl.gov

1 - Impact of Various Cascading Assumptions on Defensive Investments
Sinan Tas, Assistant Professor, University of Wisconsin-Platteville, 1 University Plaza, Platteville, WI, 53818, United States, sinantas@gmail.com

Cascading failure is often overlooked when analyzing how vulnerable power grids, or similar capacity-constrained networks, are. In this study, we first model cascading failure probabilistically, and then analyze how various cascading assumptions about the network and the attacker can change our investments to make the system more secure or resilient.

2 - Optimal Allocation of HVDC Interconnections for the Exchange of Energy and Reserve Capacity Services
Stefanos Delikaraoglou, Technical University of Denmark, Akademivej, Building 358, Kgs. Lyngby, 2800, Denmark, sdelikaraoglou@gmail.com

The European market structure separates energy and reserve trading leading to inefficient utilization of HVDC interconnections, since their capacity must be ex-ante allocated between these services. To improve market efficiency, we propose a decision-support tool that enables an implicit temporal coupling of the different trading floors, using as control parameters the inter-area transmission allocation between energy and reserves and the reserve requirements. The proposed mechanism, formulated as a stochastic bilevel program, is aligned with the existing market and reduces expected system cost for high shares of intermittent renewables.

3 - Efficient Design for Short Term Markets in the European Electricity System - First Results from a Stochastic Multi Stage Energy System Model
Frieder Borggrefe, German Aerospace Center, Pfaffenwaldring 38-40, Stuttgart, 70563, Germany, frieder.borggrefe@dlr.de

This paper introduces an integrated model for short-term markets within the European electricity system. Aim of the model is to analyze and compare future market designs. The paper shows first results from a simplified commitment and dispatch model including day-ahead, intraday & balancing markets and imbalance settlement rules.The second part compares market designs and influence of uncertainty on market decisions. Due to complexity of the model it is difficult to scale it to the full European market. The paper outlines next steps to expand this model and discusses challenges when applying it HPC. The model results are part of the BEAM-ME project.

4 - Prediction Based Electricity Forward Pricing Model in Japan Electric Power Exchange

Yuji Yamada, Professor, University of Tsukuba, 3-29-1 Otsuka Bunkyo-ku, Tokyo, 112-0012, Japan, yuji@gssm.otsuka.tsukuba.ac.jp

In this paper, we demonstrate the prediction based electricity forward pricing model in JEPX, where we decompose the log-price process into the trend function and its residual based on the generalized additive model (GAM). We then apply the autoregressive moving average model (ARMA) for the residuals to estimate the conditional expectation of JEPX spot price, and derive the forward price with arbitrarily delivery period based on the Esscher transformation.

5 - Accelerating Scenario Decomposition Schemes using Optimal Scenario Grouping

Deepak Rajan, Lawrence Livermore National Laboratory, Box 808, L-495, Livermore, CA, 94551, United States, rajan3@llnl.gov, Kevin C. Ryan, Shabbir Ahmed, Santanu Subhas Dey

We present a scenario grouping scheme for accelerating scenario decomposition algorithms to solve stochastic integer programs. The scenario grouping scheme is quite general and applicable to any scenario decomposition scheme, which can be implemented in a distributed framework. We illustrate the effectiveness of the proposed scheme on hard-to-solve stochastic unit commitment instances.

1 - A Soft System Based Framework for Sustainable Freight Transportation

Ravi Shankar, Professor, Indian Institute of Technology Delhi, New Delhi, India, ravi1@dms.iitd.ernet.in, Vijayta Fulzele

The major challenge for any freight transporter is to effectively develop proper fit between organisation goals and sustainability initiatives. Soft System Methodology has been adopted to design this framework. This fundamental and comprehensive framework helps in better adoption of sustainability in freight operations.

2 - Energy-efficient Peer-to-peer Ridesharing Optimization

Yanshuo Sun, Research Scientist, Univ of Maryland, 1173 Glenn Martin Hall, College Park, MD, 20742, United States, gexingba@gmail.com, Zhi-Long Chen, Lei Zhang

The Peer-to-peer (P2P) dynamic ridesharing has been promoted as a promising mobility option to reduce the system-wide cost by consolidating similar trips into one. As the problem shares some features with pickup and delivery problems, even static problem instances are computationally very expensive and exact solutions can be found only for small or medium-sized problems. A highly efficient set packing type formulation is thus proposed to solve relatively large problems (e.g., 500 vehicles and 1000 riders) optimally in almost real-time. Real-world tests in the Washington DC-Baltimore region are performed to explore the potential of dynamic P2P ridesharing for system-wide energy use reduction.

3 - Modeling Enablers of Dedicated Freight Corridor for Sustainable Freight Transportation

Ravi Shankar, Professor, Indian Institute of Technology-Delhi, New Delhi, 110016, India, r.s.research@gmail.com, Devendra Kumar Pathak, Devendra Choudhary

India is witnessing an unprecedented decline in modal share of rail freight transportation. Dedicated freight corridors (DFCs) are being implemented to reduce carbon emissions and decongest freight traffic. This study attempts to identify enablers of DFC to achieve sustainability in freight transportation. Exploratory factor analysis is employed to identify hidden constructs and total interpretive structural modeling has been used to explicate the inter-relationship among these enablers.

4 - The Impact of a Mandatory Program for Measuring and Reporting Co2 Emissions on Environmental Practices: the Case Study of Road Transportation in France

Gisele Mendy Bilek, Associate Professor, IAE Business School, University of Pau and the Adour countries, 8 Allees des Platanes, Bayonne, 64100, France, gisele.mendy-bilek@univ-pau.fr, Nathalie Fabbe-Costes, Arnaud Bilek, Elodie Kacoui Maurin

Since 2013, a mandatory program to inform CO2 emissions of transport services on French territory has been implemented. This research analyzes the motivations and constraints associated with the application of the device and the impact on environmental practices. On the basis of a national survey, the researchers propose a typology of companies applying the decree, identifies factors of influence and possible avenues for improvement. A model based on systems dynamics theory makes it possible to simulate several scenarios with regard to the evolution of the device.

1 - Assessing In-stent-restenosis Risks of Patients After Coronary Stent Placement

Halenur Sahin, Middle East Techical University, Ankara, Turkey, halenur.sahin@metu.edu.tr, Serhan Duran, Ertan Yakici

Aging and some lifestyle habits cause plaque accumulation in cardiac veins and narrows the arteries. Stents are used in balloon angioplasty to keep the vessel open but the stented vessel has a risk of re-narrowing due to recovery response of the stented segment. It is called in-stent-restenosis. Our objective is to develop a model to classify patients due to their risks of restenosis by using OR and statistical tools. With this model, it is intended to bring patient specific follow-up proposals to protect them from an emergency case, more medication requirement, and risk of losing effectiveness of treatment. In this context, mathematical models and effective solution methodologies will be presented.

2 - A Discussion of the Capital and Human Resources of the Aging Care System in Taiwan

Ching Ying Huang, Assistant Professor, National Cheng Kung University, Tainan, Taiwan, isastat@mail.ncku.edu.tw

Aging in place let the elderly stay in the familiar environment not feel be abandoned. How the local community provides the care assistance to the aging population and increases their independence is an issue. In Taiwan, the care organizations are classified into three levels, A, B, and C that helps the daily life of the local elderly. Under limited resources, how to run the care system in an efficient way is difficult. We mimic the system of an A-class care organization with ARENA. Four types of the aging services, energy station, day care center, dementia day care, and housing are discussed. The research attempts to answer how much the capitals and the resources should input in an A-class care organization.

3 - Competition Between For-profit and Not-for-Profit Hospitals

Steven Mark Shugan, University of Florida, 2030 NW. 24th Avenue, Gainesville, FL, 32605, United States, steven.shugan@warrington.ufl.edu, Jihwan Moon

For-profit and not-for-profit hospitals differ on many factors including their objectives. Using a two-stage game theoretic optimization, we model competition between these hospitals. With an extensive database of US hospitals, we show, consistent with model predictions, nonprofits are more profitable than for-profits, nonprofits have higher equilibrium prices than for-profits, competition increases the differences between these hospitals, and nonprofit make greater investments in premium medical services. We provide additional empirical findings and implications for hospital and public policy.

4 - Measuring Complexity in Healthcare Systems

Farzad Zaerpour, University of Calgary, 407 10 Brentwood CMNW, Calgary, AB, T2L2L6, Canada, farzad.zaerpour@haskayne.ucalgary.ca, Diane P.Bischak, Mozart Batista de Castro Menezes

In this work we study a complexity measure and its relationship with performance measures within the healthcare system. We borrow the measure from manufacturing systems to assess how well a healthcare system can manage the complexity induced by the patient group mix. We illustrate the use of the measure in an emergency department (ED) setting. An emergency department is a complex system with random arrivals of patients who may have different classifications based on personal history and health condition. We present findings on the impact of complexity levels on ED quality performance.

5 - Homophily Effect of Doctor Behavior Over Time in Online Healthcare Communities: Evidence from China

Panpan Wang, Shanghai Jiao Tong University, Shanghai, China, wpp_cq@qq.com, Jifeng Luo

This research empirically investigate the patterns of physicians' adoption and usage behaviors in online healthcare community over time across locations. Based on existing literature, we propose that doctors' adoption behavior is more influenced by their peers similar both in geography and demography. We collected data on historical online activities of 26499 physicians in 31cities of China from a large Chinese healthcare website. We use logit model to study doctors' adoption behavior. Homophily effect(i.e. demographic similarity and geographical proximity) of doctor's behavior over time will be reported.

6 - Vendor Selection in Hospitals for Consumables and Non-consumables

Bhavin J. Shah, Associate Professor, Indian Institute of Management, Indore, Faculty Office # C-206, First Floor,, Prabandh Shikhar,, Indore - Madhya Pradesh, 453556, India, bhavinj@iimidr.ac.in, Hasmukh Gajjar, Peeyush Pandey

We study various parameters governing vendor selection in hospitals for consumables and non-consumables category. We come up with unique membership functions for each category to select the vendor.

Chair: Raghu Pasupathy, Purdue University, pasupath@purdue.edu

1 - Exact and Inexact Subsampled Newton Methods for Optimization

Raghu Bollapragada, Northwestern University, Evanston, IL, United States, raghu.bollapragada@u.northwestern.edu, Richard Byrd, Jorge Nocedal, Albert Solomon Berahas

In this talk, We study the solution of stochastic optimization problems in which approximations to the gradient and Hessian are obtained through subsampling. We first consider Newton-like methods that employ these approximations and discuss how to coordinate the accuracy in the gradient and Hessian to yield a superlinear rate of convergence in expectation. We also consider inexact Newton methods and investigate what is the most efficient linear solver in terms of computational complexity.

2 - Optimizing the Design of a Latin Hypercube Sampling Estimator

Alexander Zolan, University of Texas-Austin, 204 E Dean Keeton Street, Stop C2200, Austin, TX, 78712, United States, alex.zolan@utexas.edu, John Hasenbein, David Morton

We present a method of reducing the variance of a Latin hypercube sampling (LHS) estimator by using an approximation of the estimator's variance and formulating a nonlinear program. We solve this problem exactly via a dynamic program for each random component, using a discrete set of candidate stratum boundary points. We present conditions for this technique to guarantee variance reduction, compared to LHS with equal-probability strata. We assess the impact of our sampling method on bias in optimal values obtained via solving stochastic programs, versus common techniques in the literature.

3 - The Adaptive Sampling Line Search Method for Unconstrained Stochastic Optimization

Raghu Pasupathy, Purdue University, West Lafayette, IN, 47906, United States, pasupath@purdue.edu, Fatemeh S. Hashemi, Michael R. Taaffe

We present the adaptive sampling line search method for solving unconstrained stochastic optimization problems where the objective function can only be estimated using an inexact oracle, e.g., Monte Carlo, QMC, or numerical quadrature. We will discuss two flavors (fixed-step and backtracking search) of the proposed method along with convergence calculations and global complexity results. The complexity results are especially illuminating when compared with classical results on the complexity of line search methods in presence of an exact oracle.

1 - Multiple In-the-aisle Pick Positions AS/RS with Class-based Storage

Faraz Ramtin, Carian Consulting Group, South Plainfield, NJ, United States, faraz.ramtin@knights.ucf.edu, Jennifer A. Pazour

An automated storage and retrieval system with multiple in-the-aisle pick positions (MIAPP-AS/RS) is a semi-automated case-level order fulfillment technology. The put-away to the storage locations and replenishment to pick positions are performed by the crane and the in-the-aisle case-picking is done by order pickers. We develop closed-form expected travel time models for the class-based storage assignment policy. Also, we develop optimization models to find the optimal boundary of the classes as well as allocation of the SKUs to classes. The objective of the models is to minimize the expected travel time subject to different operating policies, demand profiles, and shape factors.

2 - Model Based Approach to Smart Warehousing

Leon McGinnis, Georgia Institute of Technology, Isye Dept, 755 Ferst Drive, Atlanta, GA, 30332-0205, United States, leon.mcginnis@isye.gatech.edu, Camilo Bernal-Nisperuza, Francisco Perez Hellec, Mohamed El Tonbari

A formal warehouse system model integrates multiple viewpoints, and supports design, planning and control to achieve "smart warehousing." It also provides a basis for automating the generation of a range of analysis models to support design decision making. The use case is a highly automated facility for dispensing drugs.

3 - Integrated Cross-docking and Assignment

Arpan Rijal, Erasmus University, Rotterdam, Netherlands, rijal@rsm.nl, René B.M. De Koster, Marco Bijvank

Companies use cross-docking to simultaneously minimize transport and inventory holding cost. We study scheduling and dock assignment of inbound and outbound trucks at an LTL cross-dock. We develop an ALNS-based heuristic that beats state-of-the-art sequential truck scheduling and assignment methods both in solution quality and speed and that works for real-life instances. Tests on instances based on operations of a Dutch retailer reveal that the integrated model can vastly reduce internal transport and late departures.

4 - An Analysis of Storage Policies on a Multi-dock Unit-load Warehouse with Contour-line Shaped Storage Regions

Mahmut Tutam, PhD Candidate, University of Arkansas, 1359 N Leverett Avenue, Fayetteville, AR, 72703, United States, mtutam@uark.edu, John A.White

In this paper, the performance of a unit-load warehouse is studied when storage regions can be any shape under class-based storage policies. Specifically, unit-loads are assigned to storage regions on a priority basis. Storage regions are either rectangle shaped or contour-line shaped. Expected distance traveled with rectangle-shaped storage regions are compared with their counterpart contour-line based storage regions. Minimizing expected round-trip distance, the best rectangle-shaped storage regions are determined for different locations of docks

5 - Robotic Warehouses; State-of-the-art and Research Opportunities

René B.M. De Koster, professor of Logistics and Operations Management, Erasmus University-Rotterdam, Rotterdam, Netherlands, rkoster@rsm.nl

The new generation of warehouses will be fully robotized. Managers can select from different competitive robotic techniques to fulfill the customer orders. We develop analytical performance models and use them to optimally size the systems for costs, throughput and response time, and for comparison between the most popular robotic techniques. However, so far many new systems and techniques have not received any research attention.

Joint Session RAS/Practice: Yard Perfomance Modeling

Sponsored: Railway Applications

Sponsored Session

Chair: Michael F. Gorman, University of Dayton, Dayton, OH, 45469, United States, michael.gorman@udayton.edu

1 - A Multipurpose Yard Simulation Model

Michael F. Gorman, University of Dayton, 300 College Park, Dayton, OH, 45469, United States, michael.gorman@udayton.edu

In practice, it is a challenge to estimate yard capacity. Yard simulations attempt to describe yard operations to allow evaluation of changes in policy at a yard. Unfortunately, yard simulations are highly specific to the layout of a specific yard, and are not reusable. I develop a general purpose, reusable yard simulation model that gives good high-level estimates of yard performance and can be applied to many different yards. Model input requirements are minimal. The model provides insight int receiving and departure track use, bowl inventory levels, and car, block and train throughput. To my knowledge, no other multipurpose yard simulation is found in the literature or in use at railroads.

2 - Investigating the Relationship Between Volume, Blocking Complexity and Railway Classification Yard Performance with Simulation

Tyler Dick, University of Illinois at Urbana-Champaign, 1241 Newmark Lab MC-250, 205 N Mathews Avenue, Urbana, IL, 61801, United States, ctdick@illinois.edu, Nao Nishio

In designing a train plan for a railway network, one decision is to determine the number of blocks to be handled by each train and the number of blocks to be assembled at each classification yard while maintaining a certain level of service. This research uses simulation and factorial experiment design to investigate the relationship between yard throughput volume, the total number of blocks processed and the level of service. Following this initial analysis, the research will be expanded to examine the influence of train arrival rate, overall yard configuration and other yard operational factors on the developed capacity relationship.

3 - Yard Planner: A Digital Force Multiplier for Railroad Classification Yards

Jeremiah Dirnberger, Product Manager, GE Transportation, Jacksonville, FL, United States, jeremiah.dirnberger@ge.com

GE's Yard Planner, part of a broader "Yard of the Future" vision, is a decision support system designed to aid the planning of activities in classification yards. It provides real time planning and optimization for all car processing activities, such as train-to-track assignments, block-to-track assignment, build sequence, etc. The pilot is being developed for hump yards with Norfolk Southern, but efforts are already under way at GE to expand the product to support flat-switching operations of varying size and complexity. This presentation will discuss the solution approach, lessons learned through the development process, and planned/actual results from the pilot roll-out at Macon Yard.

Addressing Challenges in Teaching Analytics

Sponsored: INFORMEd

Sponsored Session

Chair: Janet M. Wagner, Stockton College of New Jersey, 101 Vera King Farris Drive, Galloway, NJ, 08205, United States, janet.wagner@stockton.edu

1 - A Process Mining Approach Towards Identification of Recurring Behavioral Patterns in Course Sequences

Jie Tao, Assistant Professor in Information Systems, Fairfield University, 1073 N.Benson Rd, Fairfield, CT, 06824, United States, jtao@fairfield.edu

Course planning at universities have received increasing interests from both researchers and practitioners. In this article, I propose an analytical framework in order to identify recurring course behavioral patterns from course sequencing datasets. The framework processes and analyzes the raw course sequencing datasets for the purpose of presenting insightful, actionable rules. A case study is then conducted in order to demonstrate and evaluate the proposed framework, with the course sequencing data of MBA students at XYZ University. After empirical evaluations , the findings from the case study are correct and actionable, in both contexts of course sequencing/planning and process mining.

2 - Teaching Students to Frame the Analytics Problem

Satish V. Nargundkar, Clinical Professor, Georgia State University, 2802 Fairlane Dr., Atlanta, GA, 30340, United States, snargundkar@gsu.edu, Subhashish Samaddar

Students often have difficulty interpreting a business case and framing it as an analytics problem when needed. Specifically, learning to identify a dependent variable, and determining if a continuous or binary dependent is more appropriate is the first step. Identifying an outcome period and a time frame from which to collect sample data is the next task. Finally, what questions should one ask of the client before the project begins? Examples are presented to help students understand these critical tasks at the start of an analytics project.

3 - Insights to the Usefulness of More Gamification in Classrooms

Sinan Tas, University of Wisconsin-Platteville, 1 University Plaza, Platteville, WI, 53818, United States, tass@uwplatt.edu, Pamela Tas

Gamification is using game elements in a classroom setting in order to make classes more engaging for an effective learning experience. Many educators may find it challenging to figure out how much to gamify their classes. Is there too little or too much gamification? In this empirical study, we compare different levels of gamification to determine if there are significant differences in student learning and motivation.

4 - Specification Grading in an Introductory Business Analytics Course

Janet M.Wagner, Dean, Stockton University, 101 Vera King Farris Drive, Galloway, NJ, 08205, United States, janet.wagner@stockton.edu

Specification grading is an alternative to common "points based" grading systems, and its proponents claim it supports course rigor, increases student motivation, while simultaneously reducing the instructor's grading time. In this talk I will discuss how I set up a core undergraduate course in Business Analytics (in the Information Systems Curriculum) around specification grading, and discuss how well this system did or didn't support the three goals above. Spoiler alert: it worked pretty well.

1 - Optimized Team Scheduling for Collegiate Baseball Summer Leagues

Benjamin Grannan, Assistant Professor, Furman University, Greenville, SC, 29601, United States, grannanb@gmail.com

An optimization based approach to team scheduling for collegiate summer baseball leagues is presented.

2 - Airline Revenue Management for Mega Sporting Events

Yuqi Peng, University of South Carolina, Columbia, SC, United States, Yuqi.Peng@grad.moore.sc.edu, Mark Ferguson, Ovunc Yilmaz

Using game information from the 2012 NCAA Men's Basketball Championship and an extensive database of air travel ticketing data, we explore the connection between the knockout game results (Sweet Sixteen and Elite Eight) and air travel demand for the neutral site where the next stage (Final Four) will be played. We use a difference-in-differences approach to identify specific demand patterns and present market-level heterogeneity. Based on our findings, we offer a new pricing strategy to help the airline industry improve their revenue management solutions around sporting events.

3 - Round-robin Tournaments Generated with the Circle Method Have Maximum Carry-over

Dries Goossens, Ghent University, Tweekerkenstraat 2, Gent, 9000, Belgium, Dries.Goossens@ugent.be, Frits C.Spieksma, Annette Ficker, Erik Lambrechts

The Circle Method (aka the polygon method, or the canonical procedure) is widely used in the field of sport scheduling to generate schedules for round-robin tournaments. The so-called carry-over effect value is a number that can be associated to each roundrobin schedule; it represents a degree of balance and fairness of a schedule. We prove that, for an even number of teams, the Circle Method generates a schedule with maximum carry-over effect value, answering an open question.

4 - Predicting MLB Game Outcomes through Simulation

Justin Long, Slippery Rock University, 5902 Westridge Circle NW, North Canton, OH, 44720, United States, jbl1005@sru.edu

In this study, Major League Baseball is explained using a Markov Chain Method, as each game state is independent of all previous states excluding the one immediately prior. To model this, data from every game in the 2010 through 2015 seasons are used to calculate probabilities of all possible state transitions. Offensive playing ability and home-field advantage are taken into consideration by partitioning probabilities into different transition matrices. For a given team, simulations are utilized to mimic the series of an entire season; this result provides an overall expected win-percentage. Predictions can be used by managers, players, and fans for varying purposes.

1 - Information Theoretic Multistage Sampling Framework for Medical Audits

Tahir Ekin, Texas State University, 601 University Dr. Mccoy 451, San Marcos, TX, 78666, United States, t_e18@txstate.edu, Rasim M. Musal

The sampling resource allocation decisions for medical audits are crucial and challenging because of the large payment amounts and heterogeneity of the claims. This talk introduces an iterative stratified sampling method that uses Lindley's entropy measure to evaluate the expected amount of information. We use U.S. Medicare Part B claims outpatient payment data and investigate the versatility of the framework for different overpayment scenarios and resource allocation designs. The proposed method results in reasonable coverage and lower estimation errors while outperforming Neyman Allocation. The framework also can be used to make probability statements on variables of interest.

2 - New Maximum Entropy Newsvendor Models

Mahsa Mardikoraem, University of Wisconsin-Milwaukee, 1560 N Prospect Ave, Milwaukee, WI, 53202, United States, mardiko2@uwm.edu, Amirsaman Hamzeh Bajgiran, Ehsan S. Soofi

We use the maximum entropy procedures that provide new models for the distribution of demand in the newsvendor problem. Our proposed models include the generalized error family with members such as the normal and Laplace distributions. We also include partial information about the demand provided by under and over stock costs in the maximum entropy calculation via local information constraints. This formulation gives change point demand distributions. Examples include two-piece demand distributions with uniform, exponential, or truncated normal for demand below the order quantity and exponential or truncated normal for demand above the order quantity.

3 - Entropy of Stock-out Distribution and Bayes Risk of the Mean Stock-out

Ehsan S.Soofi, University of Wisconsin-Milwaukee, Milwaukee, WI, United States, esoofi@uwm.edu, Majid Asadi, Nader Ebrahimi, Khosro Pichka

We study uncertainty and prediction of the stock-out as functions of the inventory level. The distribution of the stock-out, given the inventory, is the residual of the demand. The residual entropy of the stock-out measures the uncertainty and the mean stock-out is the optimal prediction under the quadratic loss. We present applications of the available results for the residual entropy and the mean residual to the stock-out and give new results. Considering variation of the inventory level, we use the expected entropy to measure anticipated uncertainty about the stock-out and compute Bayes risk of the mean stock-out.

4 - Augmented Probability Simulation for Accelerated Life Test Designs

Refik Soyer, PhD, George Washington University, Washington, DC, United States, soyer@gwu.edu, Nicholas Polson

Designing accelerated life tests presents a number of conceptual and computational challenges. We propose a Bayesian decision-theoretic approach for selecting an optimal design, and develop an augmented probability simulation approach to obtain the optimal design. The notion of a "dual utility probability density" enables us to invoke the concept of a conjugate utility function. For accelerated life tests, this allows us to construct an augmented probability simulation which simultaneously optimizes and calculates the expected utility. To illustrate our methodology, we consider a single-stage accelerated life test design; our approach naturally extends to multiple stage designs.

1 - Non Price Reactions to Price Competing Entry

Amirhossein Alamdar Yazdi, PhD Candidate, University of Massachusetts, Isenberg School of Management, 121 Presidents Drive, Amherst, MA, 01003, United States, aalamdaryazd@som.umass.edu

I study non-price responses to price competition in the airline industry. I look at how incumbent carriers adjust service quality and supply in response to low-cost carrier entry. Our initial results show that incumbent firms service quality improves in the threat-of-entry period but worsens after the entrance of a low-cost carrier.

2 - Sequencing Triple-spreader Crane Operations: Mathematical Formulation and Genetic Algorithm

Shabnam Lashkari, PhD. Student in Industrial Engineering, University of Wisconsin-Milwaukee, 1559 N Prospect Avenue, Apt 202, Milwaukee, WI, 53202, United States, lashkari@uwm.edu, Matthew Petering, Yong Wu

This paper investigates the problem of scheduling a triple-spreader (i.e. tandem-lift) crane when lifts are subject to a weight limit. We formulate the problem as an integer linear program and develop a fast method for computing a lower bound on the optimal objective value. In addition, we devise a genetic algorithm that produces high quality solutions for small, medium, large, and very large problem instances.

3 - Local Container Drayage Problem under a New Operation Mode

Zhaojie Xue, Shenzhen University, Room A423, Civil Engineering Building,, Shenzhen University, Nanshan District, Shenzhen, China, zjxue@szu.edu.cn

This study examines the Local Container Drayage Problem (LCDP) under an operation mode in which a tractor can be detached from its companion trailer and assigned to a new task. We have incorporated a set of temporal constraints into the classical VRP to realize this operation by utilizing the idle time available to tractors and coordinating the empty containers moving between customers. A combinatorial benders' cuts algorithm and a tabu search algorithm are proposed. Some numerical experiments are conducted to assess the performance of the proposed algorithm, quantify the benefit of the new operation mode, and identify the conditions under which the mode is effective.

4 - A Robust Approach to Airport Gate Assignment with a Solution-dependent Uncertainty Budget

Chao Zhang, Sun Yat-Sen University, No. 135, Xingang Xi Road,, Zhenghuantang B509, Guangzhou, China, chaozhang1209@gmail.com, Liang Xu, Fan Wang, Feng Xiao

Airport gate assignment (AGA) aims to assign flights to gates according to their arrival and departure times. To tackle flight delays in airports, we propose a robust airport gate assignment (RAGA) to maximize the probability that the total real-time gaps between consecutive flights at the same gate is no less than a pre-specified target. Then we develop an asymptotically tight upper bound for the violation probability. Based on the upper bound, a solution-dependent uncertainty budget is introduced to develop a robust counterpart for the RAGA. Empirical study on ShuangLiu International Airport (CTU) indicates that our proposed robust approach for AGA outperforms existing methods.

5 - Combinatorial Bid Generation for TI Services Procurement

Monia Rekik, Associate Professor, Universite Laval, 2325 rue de la Terrasse, Quebec, QC, G1V. 0A6, Canada, monia.rekik@cirrelt.ca, Farouk Hammami, Leandro C. Coelho

We address the Bid Generation Problem in combinatorial auctions for the procurement of TL transportation services. The objective is to identify profitable transportation contracts to bid on based on the carrier existing network and other operational constraints. An Adapted Large Neighborhood Search heuristic is proposed. Computational results show that the ALNS heuristic performs well in terms of CPU time and solution quality.

1 - Fitting Phase-type Distribution to Healthcare Transition Data

Wanlu Gu, 827 E Drachman St, Tucson, AZ, 85719, United States, wanlugu@email.arizona.edu, Neng Fan

The length of stay (LOS) is a term to describe the duration of a single stay in hospital, it as well as the time interval between a discharge and the next admission are important measures of healthcare utilization. In this talk, we fit a phase type distribution to LOS data from The University of Arizona Cancer Center. In order to eliminate confounding factors, we study data of patients with one typical type of disease at a time. By selecting proper number of phases (LOS groups), we can grasp the heterogeneity of these phases and connect it with the patients' trace after discharge. Then some actions can be taken to improve the efficiency of healthcare utilization.

2 - Distributionally-robust CVAR Formulation of SVMs using Wasserstein Metric

Ammon Washburn, University of Arizona, 2525 N Los Altos Avenue, Apt 155, Tucson, AZ, 85705, United States, wammonj@email.arizona.edu, Neng Fan, Helen Zhang

There has been many variants of Support Vector Machines that use different norms or penalty functions in order to accomplish feature selection, good generalization and robustness to outliers. We propose to unify all of them under a framework that comes CVaR in financial applications. Then we will show properties of the resulting quadratic program as a function of parameters and provide an algorithm that will compute the whole solution path for two out of three of the parameters in about the time it takes to solve one using interior points methods.

3 - Use of Phase Type Distribution in ALT Data Analysis

Samira Karimi, University of Arkansas, 1219 Storer Ave, Apt 39, Fayetteville, AR, 72703, United States, sakarimi@email.uark.edu, Haitao Liao

Accelerated life testing (ALT) is a powerful tool for estimating a product's reliability. In ALT, a spectrum of accelerated conditions (such as pressure, temperature, voltage, stress, etc.) is utilized to generate failures in a shorter period of time in comparison to normal conditions. To model and analyze the resulting lifetime and censoring data, one is required to relate the data to the applied stress factors over time. In this research, ALT data is modeled by a phase-type distribution, and an Expectation-Maximization algorithm is developed to estimate the model parameters. A numerical study is presented to illustrate the performance and precision of the proposed method.

4 - Graph Clustering with Uncertainty

Yujia Zhang, 4901 E Sunrise Drive, Apt 1013, Tucson, AZ, 85718, United States, yujiazhang@email.arizona.edu

During this talk we will review certain models and algorithms for clustering of data with uncertainty. First the methods for modeling uncertainty data will be reviewed. Then we concentrate on the graph models for clustering. In the end we will review and compare algorithms for solving these models.

Sponsored Session

Chair: I-Lin Wang, National Cheng Kung University, Industrial Information Management, 1 University Road, Tainan, 70101, Taiwan, ilinwang@mail.ncku.edu.tw

1 - Optimal Fleet Deployment for Electric Vehicle Sharing Systems

Chung-Cheng Lu, National Chiao Tung University, Hsinchu City, Taiwan, jasoncclu@nctu.edu.tw

This study deals with the fleet deployment problem for electric vehicle (EV) sharing systems that service tourists in scenic areas. The problem aims to determine the number of plug-in EVs deployed at each rental station such that the profit of the system operator is maximized. The operational aspects of plug-in EVs are taken into account, including electricity energy consumption, battery capacity and charging requirements. A mathematical programming model of the problem is developed.

2 - Ship Routing and Freight Assignment Problem for Liner Shipping Considering Northern Sea Route

Dung-Ying Lin, National Cheng Kung University, 1 University Road, Transportation Management, Tainan City, Taiwan, dylin@mail.ncku.edu.tw

In recent years, the Northern Sea Route (NSR) has attracted significant attention with respect to liner shipping. In this research, we investigate the NSR planning problem and construct a time-space network-based mathematical formulation to analyze the ship routing and freight assignment problem in liner shipping. To solve the resulting program, we propose a Lagrangian relaxation-based decomposition algorithm that facilitates the network features. The proposed framework is empirically applied to a case from Company C. The results show that navigation skill, bunker price, delay penalty and service commitment are the primary factors that affect the NSR's commercial practicability.

3 - On Multi-parametric Costs Perturbation of the Integer Program with a Motivational Problem of the Dynamic Ambulance Allocation

Yu-Ching Lee, National Tsing Hua University, No 101, Section 2, Kuang-Fu Road, Engineering Building I, Hsinchu, Taiwan, ylee77@uiuc.edu, Chor-Yiu Sin, Albert Y. Chen

A two-stage stochastic integer programming model is developed to minimize the expected response time in every designated period by dynamically deciding the numbers of the ambulances to be allocated and re-allocated at each base. Practically, the expected response time is approximated by a finite number of draws of the scenarios whose probabilities are forecasted based on the historical counts of the ambulance requests. We evaluate the robustness of this allocation model with regard to the accuracy of the forecasted probabilities by the technique of the multi- dimensional cost sensitivity for the IP.

4 - Optimal Security Deployment over Moving Trains in Rail Transit Networks

I-Lin Wang, National Cheng Kung University, Industrial Information Management, 1 University Road, Tainan, 70101, Taiwan, ilinwang@mail.ncku.edu.tw, Tai-Chia Huang, Shiue-Mei Sun, Yun-Hsuan Lu

Rail transit systems usually operate with fixed routes and schedules to provide more reliable and less polluted commuting services to move more people within urban areas. Due to their predictable schedules, attacks over trains may lead to severe casualties. Yet current practices usually deploy security on static stations rather than moving trains. We investigate effective security deployment over moving trains by mathematical programming models. Maximum coverage to passengers on trains can be calculated. We also consider a variant of network interdiction problem to deploy security so that the maximum number of passengers affected by a single attack over a train segment can be minimized.

5 - Price Strategy and Capacity Allocation for Crystal Cycle of TFT-LCD Industry

Kang-Ting Ma, Post-doctor Researcher, National Tsing Hua University, Hsinchu, Taiwan, ktma@ie.nthu.edu.tw, Che-Wei Chou, Chen-Fu Chien

Variances of supplies and demands in TFT-LCD industry fluctuate prices namely crystal cycle. By the contrast, as supplies are shortage, manipulating prices affect the demands. A two-stage mathematical model is proposed to maximize profit of the manufacturer that determines the price strategy of product portfolio. Manufacture resources are allocated in the first stage. Rising prices for brand's demand fulfillment are provided, and a new capacity will be reallocated in second stage. A hybrid particle swarm optimization algorithm is developed to solve the nonlinear two-stage mathematical model, and the algorithm is quite efficient by designing of initial solutions and local search procedure.

1 - A Multi-task Learning Approach for Improved Forecast of Passenger Inflow Time Series

Zhenli Song, HKUST, Hong Kong, Hong Kong, zsongae@connect.ust.hk, Ke Zhang, Fugee Tsung

Public transportation services such as, Urban Railway Transit (URT) systems, play an increasingly important role in people's commute. However, there has been little research on the influence of passenger crowding on the URT systems. To fill this research gap, we propose a state space model to predict the passenger inflow time series under the multi-task learning framework. By incorporating engineering knowledge into the prior, the methodology would produce more accurate and robust estimate of the parameters. We adopt the EM algorithm and Laplace's method for MAP estimate of the parameters. A real case study on Hong Kong's MTR passenger flows is presented to illustrate the effectiveness of our model.

2 - System-wide Prediction and Visualization of Passenger Distribution in Urban Rail Transit Network with Automatic Fare Collection Data

Andi Wang, Georgia Institute of Technology, Atlanta, GA, United States, andi.wang@connect.ust.hk, Min Jiang, Fugee Tsung

We propose a scheme to achieve real-time passenger distribution prediction in the urban metro system, based on the entry and exit time stamps generated by the automatic fare collection system. First, we infer each individual's travel pattern and location distribution with historical data, and store the information in the data center. Then the information is integrated with real-time entry and exit data streams to achieve passenger distribution prediction with acceptable computational cost. The effectiveness of the scheme is validated with real data set from the MTR system in Hong Kong.

3 - Functional Data Based Computer Model Calibration for Design Optimization

Wenbo Sun, University of Michigan, 2013 Medford Road, Ann Arbor, MI, 48104, United States, sunwbgt@umich.edu, Judy Jin, Matthew Plumlee

Computer simulations are widely used to improve system design. This often requires to firstly calibrate the computer simulation model by using a UQ (uncertainty quantification) method and then search for an optimal design solution. The existing methods require explicitly defined simulation parameters (e.g. to minimize the simulation model's bias) and a well fitted metamodel that can accurately surrogate the simulation behaviors, which are hard for complex systems. We presented a new approach to search for the optimal design from a set of parameters that subject to constraints on simulation model's bias. A case study is illustrated for the vehicle design optimization to minimize injuries in crash.

4 - Structural Degradation Modeling Framework for Sparse Data Sets with an Application on Alzheimer's Disease

Abdallah A. Chehade, University of Michigan-Dearborn, Dearborn, MI, United States, abdallahch89@gmail.com, Kaibo Liu

The accessibility and development of information technologies have facilitated the collection and storage of information from a massive number of operating units, which provides a great opportunity to better understand the degradation process. While in practice the number of recorded units can be large, there are often limited available observations in most of the units. To address the unique challenges in the "sparse data environments", this paper proposes a structural degradation modeling (SDM) framework. On one hand, our idea is inspired by the recommender system. On the other hand, the proposed SDM is also tailored to the needs of degradation modeling.

1 - A Regression Tree Method to Analyze Data in Functional Brain Activation Experiments

Doowon Choi, doowon.choi@tamu.edu

Functional brain activation experiments are widely conducted in neuroimaging research. In the experiment, behavior and functional brain activation of people under certain task are measured in an attempt to understand the underlying neural correlates in human brain. This work proposes a regression tree based methodology to analyze data in such experiments. In the case study, this method is applied to data from a functional near-infrared spectroscopy (fNIRS) study using a risk decision-making task and insightful inference is obtained.

2 - A Dictionary Learning Based Contemporaneous Health Index for Degenerative Disease Monitoring

Aven Samareh, University of Washington, Seattle, WA, 98105, United States, asamareh@uw.edu, Shuai Huang

We present a general formulation for personalized data fusion of multivariate longitudinal clinical measurements to create a contemporary health index (CHI) to monitor patient condition over time. Named as DL-CHI, our model combines longitudinal data fusion, classification, and dictionary learning and is applied on two real-world problems, Alzheimer's disease and surgical site infection.

3 - Optimal Coverage Control in Body Sensor Networks for Spatiotemporal Cardiac Monitoring

Rui Zhu, Pennsylvania State University, University Park, PA, United States, rzz45@psu.edu, Bing Yao, Hui Yang

Body Sensor Networks (BSNs) has emerged as a key technology for improving the quality of life through wearable sensing, smart health monitoring. However, a fundamental problem in BSN design is the optimal sensor placement. For example, sensors are approximately uniformly distributed on the body surface in current ECG systems. Little has been done to optimize the location and number of sensors. This paper proposes a new strategy for the optimal sensor placement to capture a complete picture of cardiac dynamics. Furthermore, this novel methodology is applicable to network design with nonstationary distribution in many other disciplines, e.g., environment surveillance network, facility layout.

4 - Osteonecrosis in Chilean Patients with Systemic Lupus Erythematosus

Jennifer Mendoza-Alonzo, University of South Florida, Tampa, FL, United States, jennifermend@mail.usf.edu, José Zayas-Castro, Karina Soto-Sandoval

Systemic Lupus Erythematosus (SLE) is chronic, incurable, and autoimmune disease. A secondary disease associated with SLE is Osteonecrosis (ON). The objective of this study is to develop a model to determine if a Chilean patient who has already SLE can be diagnosed with ON at an early stage. The sample size is 41 Chilean patients with SLE. The input variables are pharmacological, demographic, and risk factors suggested by the literature. The outcome variable is the development of the disease ON. With this study is expected to contribute with more information about the multiple-factors that influence the development of ON to allow early detection of this diseases in patients with SLE.

Spatial Optimization and Conservation Reserve Design

Sponsored: Energy, Natural Res & the Environment Environment & Sustainability

Sponsored Session

Chair: Bistra Dilkina, Georgia Institute of Technology, Atlanta, GA, 30332, United States, bdilkina@gmail.com

1 - A Robust Optimization Approach for Solving Problems in Conservation Planning

Zulqarnain Haider, University of South Florida, ENG 302, University of South Florida, Industrial and Management Systems Engineering, Tampa, FL, 33620, United States, zulqarnain@mail.usf.edu, Hadi Charkhgard, Changhyun Kwon, Julien Martin

In conservation planning, the data related to specie populations is sparse, and unreliable. Thus, applying deterministic or stochastic approaches to the problems in conservation planning either ignores the uncertainty completely or does not accurately account for the nature of uncertainty. We propose a robust optimization (RO) approach to problems in conservation planning. We explore the reserve selection and invasion control problems to show the value of the RO approach. Several novel techniques are developed to compare the results by the RO approach and the deterministic approach. It is demonstrated that the proposed approach finds more applicable conservation planning strategies.

2 - Wildlife Corridor Sub-network Selection Optimizing for Probability of Connectivity

Bistra Dilkina, Georgia Institute of Technology, 1304 Klaus Bldg, 266 Ferst Dr, Atlanta, GA, 30332, United States, bdilkina@gmail.com

Corridor analysis results in a network representing the best pathways connecting pairs of habitat areas. One widely-used metric in ecology for the overall network connectivity is Probability of Connectivity (PC), where link probabilities are an exponential function of link resistance length. Due to limited budgets, the full corridor network usually cannot be conserved. Hence, we propose the PC-based Corridor Sub-network selection problem to select a subset of the corridor links of limited size or cost, while maximizing the PC of the protected part of the network. We present both a MIP model for finding optimal solutions of small networks, as well as a highly-scalable and effective greedy algorithm.

3 - Dynamic Optimization of Landscape Connectivity Embedding Spatial-capture-recapture Information

Yexiang Xue, Cornell University, Institute for Computational Sustainability, 344 Gates Hall, Ithaca, NY, 14853-7501, United States, yx247@cornell.edu

Maintaining landscape connectivity is increasingly important in wildlife conservation, especially for species experiencing the effects of habitat fragmentation. We propose a novel approach to dynamically optimize landscape connectivity. Our approach is based on a mixed integer program, embedding a spatial capture-recapture model that estimates the density, space usage, and landscape connectivity for a given species. Our method takes into account the fact that local animal density and connectivity change dynamically and non-linearly with different protection plans. We show that our method scales to real-world size problems and outperforms the solution quality of competing approaches.

1 - Development of a Dynamic Tool for Continuous Survival Analysis Transplant Survivor

Hamidreza Ahady Dolatsara, Auburn University, 311 West Glenn Ave., Apt. 28, Alabama, Auburn, AL, 36830, United States, hamid@auburn.edu, Fadel Mounir Megahed, Ali Dag, Ying-Ju Chen

The objective of this study is presenting a tool that can be utilized for data cleaning, feature extraction, and prediction on transplants' survival analysis. Investigated transplants are kidney, heart, Lung, and intestine. Based on the dependent variable a dynamic process perform data cleaning process on the dataset. The cleaned data goes through feature selection and prediction phases. Well known machine learning algorithms are utilized in order to extract important features and develop predicting models. Finally, the output of models and other relevant information will be shown or emailed to the investigator(s).

2 - A Method to Measure Mobile Applications User Engagement (MAUE)

Lior Turgeman, IBM.Research Laboratories, Haifa, Israel, tur.lior@gmail.com, Idan Ben Harush, Otis Smart, Max Jacubowsky, Nicole Jayne, Nili Ifergan

We propose a new method to measure User engagement (UE) with mobile applications by analyzing temporal changes in a defined set of usage metrics, yielding a general metric - mobile applications user's engagement (MAUE). Our proposed approach has been applied to the usage data of 40004 users of The Weather Company (TWC) application. Based on our results, we propose two new engagement measures, "engagement stability", and "engagement breakpoint", allowing monitoring UE of users' segments, as well as gaining deeper understanding of the influence of different app updates, or certain features, on their usage behavior.

3 - A Customized Spectral Clustering Approach for Pre Selection on Dynamic Taxi Sharing Trips

Yeming Hao, University of Maryland-College Park, College Park, MD, 20740, United States, yhao@umd.edu, Ali Haghani

A customized spectral clustering approach is developed to narrow down the searching space for dynamic taxi sharing. Both taxi route geographical locations and heading directions are considered in the approach. Real world taxi data (New York City taxi data) is used in the implementation and results show the approach can reduce the taxi sharing matching calculation time while maintain beneficial (for both taxi providers and users) matching results.

4 - Modelling Passengers' Airport Choice in Multi-airport Regions: A Data Mining Approach

Misuk Lee, Assistant Professor, Seattle University, 901 12th Ave, Seattle, WA, 98122, United States, leem@seattleu.edu

Air travelers' airport choice is a critical component of transportation planning in many multi-airport regions. This study proposes the use of data mining models in passengers' airport choice. We compare different data mining and statistical models using data collected in the Seoul/Incheon metropolitan area.

1 - Time-varying Linear and Semidefinite Programs

Bachir El Khadir, Princeton University, Princeton, NJ, United States, bkhadir@princeton.edu, Amir Ali Ahmadi

We study linear semidefinite programs whose data (e.g., the matrices A, b and c in the LP case) are not constant but vary polynomially with time. We show that, under some conditions, we can approximate the optimal value of these problems arbitrarily well by searching for solutions that are polynomial functions of time themselves. Furthermore, we show that the problem of finding the optimal polynomial solution of a given degree can be cast exactly as a semidefinite program.

2 - Hypergraph Theoretic Polyhedral Relaxation of a Class of 0-1 Polynomial Program

Dongwoo Kang, Korea University, 145 Anam-Ro, Seongbuk-Gu, Seoul, 02841, Korea, Republic of, towarmer@korea.ac.kr, Hong Seo Ryoo

Logical Analysis of Data (LAD) is a combinatorial optimization-based machine learning methodology. A key stage of LAD is pattern generation that can be cast as a 0-1 multilinear program in maximization form. We study its Boolean multilinear polytope via hypergraph theoretic analysis of the 0-1 representation of a set of data under analysis and discover a new class of strong(-er) valid inequalities, including facet defining inequalities. We demonstrate the usefulness of new results on benchmark data mining datasets.

3 - Accurate Beamforming by using Population Based Optimization Method

Ismet Shin, Texas Southern University, Houston, TX, United States, isahin@gmail.com, Nuri Yilmazer

In this paper, we have presented an accurate beamforming technique, which is a spatial filtering used in smart antenna technology, relies on population based optimization. The proposed algorithm uses a single snapshot of data taken from a Uniform Linear Array (ULA). Population based optimization algorithms are used to determine the optimal values of the complex valued antenna array weights. The complex antenna weight vectors adjust the phase shift at the output of each antenna element in a ULA which is analogous to the phase shifter in the analog system. The simulation results show that proposed algorithm accurately maximizes the signals in the direction of Signal of Interest and null Jammers.

4 - Electrical Power Grid Optimization using Semi-markov Decision Process (SMDP)

Ismet Sahin, Texas Southern University, 3100 Cleburne Street, Houston, TX, United States, isahin@gmail.com, Abayomi Ajofoyinbo

This paper presents a semi-Markov decision process (SMDP)- based model for electric power grid optimization in terms of available power and distribution configurations. For this purpose, a novel SMDP- based model is constructed for maximizing delivery configurations subject to power flowing through transmission line. Through optimal analysis, the conclusion is reached that the technique presented in this paper provides optimal performing configuration.

1 - Rate of Convergence of the Bundle Method and Selective Linearization Algorithm for Large Scale Convex Optimization

Yu Du, Assistant Professor, University of Colorado Denver, 1475 Lawrence St, Denver, CO, 80202, United States, duyu197@gmail.com, Andrzej Ruszczynski

The number of iterations needed by the bundle method for nonsmooth optimization to achieve a specified solution accuracy can be bounded by the product of the inverse of the accuracy and its logarithm, if the function is strongly convex. The result is true for the versions of the method with multiple cuts and with cut aggregation. We also illustrate the related efficient selective linearization algorithm on the large scale statistical learning problems.

2 - Maximizing Resilience of Transmission Power Grids through a Bi-level Restoration Model

Saeedeh Abbasi, University of Houston, 2821 Greenridge Dr, Apt 100, Houston, TX, 77057, United States, sabbasi5@uh.edu, Masoud Barati, Gino J.Lim

Power grid's outdoor facilities are vulnerable to extreme events, and their failure could trigger the failure of the whole network. The imposed complete blackout lasts for a long period while terribly costs. Therefore, it is so crucial to make the grid resilient, and an appropriate fast restoration is demanded to mitigate these impacts. In this study, the power grid resiliency is quantified and maximized in a bi-level optimization framework and solved through an iterative optimization algorithm (IOA) and a mathematical program with equilibrium constraint (MPEC). The model's performance is analyzed with 6- and 118-bus IEEE test systems.

3 - Survivable All-optical Networks: Extensions to the Routing and Wavelength Assignment Problem

Mehdi Hemmati, Sharif University of Technology, Tehran, Iran, Islamic Republic of, soheilmn@gmail.com, Cole Smith

All-Optical Networks (AONs) form the foundation of the Internet backbone. They transmit the data over light rays, which require dedicated wavelengths. Hence, the routing problems in AONs are coupled with wavelength assignment tasks, which result in the Routing and Wavelength Assignment (RWA) problem. Due to the massive amount of data transmission over AONs, their vulnerability to disruptions are of high importance. We discuss variations of the RWA problem to study the resilience of AONs in the presence of intentional or unintentional disruptions. We propose multi-level integer programs and investigate the solution techniques by studying the solution space of the related optimization problems.

4 - Probabilistic Interdiction for Power Systems

Kaarthik Sundar, Post-doctoral Researcher, Los Alamos National Laboratory, 3000 Trinity Drive, Apt 40, Los Alamos, NM, 87544, United States, kaarthik01sundar@gmail.com, Carleton Coffrin, Harsha Nagarajan, Russell Bent

A probabilistic version of the N-k interdiction problem in power transmission networks is considered. The probability of failure of each component in the network is known a priori and the goal of the problem is to find a set of k components that maximizes disruption to the system loads weighted by the probability of simultaneous failure of the k components. The resulting problem is formulated as a bilevel mixed-integer nonlinear program. Convex relaxations, linear approximations, and heuristics are developed to obtain feasible solutions that are close to the optimum via a cutting-plane algorithm. Extensive numerical results corroborate the effectiveness of the proposed algorithms.

5 - An Auction-driven Mechanism for Electric Transmission Network Design

Juan Andrade, PhD Student, University of Texas-Austin, 1616 Guadalupe Street, Austin, TX, 78701, United States, jandraderam@utexas.edu, Ross Baldick

This paper proposes a combinatorial auction formulation for electric transmission network design, where market participants can bid for the geographic location of their points of interconnection and its capabilities, according to their willingness to pay. The formulation proposed identifies the projects that maximize the social welfare, and obtains the network topology necessary to support those projects. The proposed approach allows to consider quantitatively the perspective of different market participants at the early beginning of transmission planning. This may reduce the negative consequences of transmission shortfall, without over building transmission infrastructure.

6 - Distribution Network Reconfiguration Considering Decentralized Autonomous Electric Vehicles

Zhi Zhou, Argonne National Laboratory, 9700 South Cass Avenue, Bldg 221, Argonne, IL, 60439, United States, zzhou@anl.gov, Zhaomiao Guo

Autonomous electric vehicles (AEVs) provide unique opportunities to cope with the uncertainties in electricity distribution network (DN), but the effects are limited by the inherent radial topology. We investigate the potential benefits (e.g. reducing line losses, battery degradation, etc.) of dynamic DN reconfiguration (DDNR) based on AEVs spatial-temporal availability. A mixed integer programming model is proposed to optimally coordinate the charging/discharging of AEVs with day-ahead DDNR plan, while satisfying AEVs' daily travel demand in a two-settlement setting. Numerical findings will be presented through the IEEE 33-node test feeder and Sioux Falls transportation network.

Meta-Algorithmics

Invited: Operations Research and the Future of Computing

Invited Session

Chair: Holger Hoos, University of British Columbia, Vancouver, NB, N6T I24, Canada, hoos@cs.ubc.ca

1 - Algorithm Selector and Prescheduler in the ICON Challenge

François Gonard, INRIA, Paris, France, francois.gonard@inria.fr

Algorithm portfolios are known to offer robust performances, efficiently overcoming the weakness of every single algorithm on some particular problem instances. In order to get the best out of an algorithm portfolio, one can either use an algorithm selection (AS) approach, or define a scheduler, sequentially launching a few algorithms on a limited computational budget each. The ASAP system presented here relies on the joint optimization of a pre-scheduler and a per instance AS, selecting an algorithm well-suited to the problem instance at hand. ASAP has been thoroughly evaluated against the state-of-the-art during the ICON challenge for algorithm selection, receiving an honourable mention.

2 - A Machine Learning Approach to Re-designing Branch-and-Bound Search

Bistra Dilkina, Georgia Institute of Technology, 1304 Klaus Bldg, 266 Ferst Dr, Atlanta, GA, 30332, United States, bdilkina@gmail.com, Elias Khalil

Branch-and-Bound approaches have been improved over many years by a series of ideas from operations research and computing. However, many of the components of this complex complete search strategy used in state of the art solvers are highly engineered and to a large extent static. We investigate the use of machine learning ideas to re-vamp diverse aspects of the branch-and-bound search in order to discover new strategies and heuristics in a data-driven and adaptive way that can be useful both broadly as well as fine-tuned to domain-specific families of instances.

3 - Generation Techniques for Linear and Mixed Integer Programming Instances with Controllable Properties

Simon Bowly, Monash University, Clayton, 3800, Australia, simon.bowly@monash.edu, Kate Smith-Miles, Davaatseren Baatar, Hans Mittelmann

The results of empirical analysis of optimisation algorithm performance are highly dependent on the quality of test instances available. Real world data sets may lack diversity in feature and performance data spaces, while random generation can produce instances which are not applicable to the problem being studied. We propose a new framework which shifts test instance generation to an encoded space. Through its application to the generation of linear and mixed integer programming test cases we demonstrate the potential to improve the quality of metadata used in algorithm analysis.

4 - How Simple is Too Simple: Evaluating Increasingly Sophisticated Techniques for Algorithm Portfolios

Chris Cameron, University of British Columbia, Vancouver, BC, Canada, chris.cameron.queens@gmail.com, Holger Hoos, Frank Hutter, Kevin Leyton-Brown

State-of-the-art methods for building algorithm portfolios have achieved notable success on computationally-hard problems such as SAT. While these methods are often quite complex, we are not aware of any previous, systematic study of the extent to which this complexity is warranted. We created a wide design space of algorithm portfolio techniques and evaluated the resulting designs on a comprehensive set of benchmarks (ASlib 2.0), which includes industrial problems in SAT and CSP. In particular, we investigated three design axes: (1) model sophistication (from model-free to model-based cost-sensitive classification), (2) feature sophistication

1 - Snug Simplices

Ghasemali Salmani Jajaei, Virginia Commonwealth University, Richmond, VA, United States, salmanijajaeg@vcu.edu

We propose procedures for enclosing convex hulls of finite m-dimensional point sets with simplcies. A simplex is called snug if it intersects the convex hull in some way. The procedures will assess how the snug simplices generated contain the convex hulls by comparing their volumes. In general, calculating the volume of general polyhedra is difficult, however, we are able to find closed form formulas for certain simplices. Our goal is to find a tight simplex, one in which its facets coincide perfectly with the facets of the convex hull.

2 - Approximate Convex Hulls

Robert Graham, McGill University, Montreal, QC, Canada, robert.graham2@mail.mcgill.ca

This talk will cover joint work with Adam Oberman on the pixel purity algorithm for computing approximate convex hulls. I will explain how the algorithm computes the curvature of points and prove consistency and convergence. I will also extend the algorithm to compute approximate convex hulls described in terms of hyperplanes

3 - Linear Optimization Over the Field of Puiseux Fractions

Benjamin Schroter, TU. Berlin, Berlin, Germany, schroeter@math.tu-berlin.de

The field of real Puiseux Series is a real closed field which extends the real numbers by an infinitesimal element t. This field is again totally ordered, i.e, t is smaller than any positive real number but larger than zero. In particular Puiseux Series allow to study aspects of algebraic geometry via polyhedral geometry. They are an important link between linear optimization and tropical optimization.

We present our implementation of a well suited subfield for exact computations, which we call the field of Puiseux Fractions. Our implementation in the software polymake allows to compute linear programs and convex hulls of polyhedra over rationals extended with the indeterminate t.

4 - The Recommender Problem with Convex Hulls

Marie-Laure Bougnol, Professor of DSIM, Jacksonville University, mbougno@ju.edu, Jose H. Dula

Consider a collection of users and items they may score using an ordinal scale. Consider a specific user and an item yet unscored by this user. The challenge in this version of the recommender problem is to estimate this user's score for the item. An idea central to this problem is the identification of "like-minded peers" and use their scores to make the estimate We propose procedures based on computationally geometry to identify peers and use them to estimate scores.

Sponsored Session

Chair: Damek Davis, dsd95@cornell.edu

1 - Generic Acceleration Schema Beyond Convexity

Courney Paquette, PhD, University of Washington-Seattle, Seattle, WA, United States, cykempton@gmail.com

We introduce a generic "acceleration" scheme that can leverage arbitrary linearly convergent convex optimization algorithms to solve possibly nonconvex optimization problems. The proposed

approach simultaneously enjoys best known complexity bounds up to log terms for both convex and nonconvex settings. A class of problems for which the technique is not applicable consists of minimizing compositions of nonsmooth convex functions and smooth maps. I will describe how a simple Gauss-Newton algorithm combined with smoothing and fast-gradient subproblem solves yields a scheme with overall efficiency $O(1/e^3log(1/e))$. This appears to be the best know complexity bound for this problem class.

2 - Taming Nonconvexity with Data

Zhaoran Wang, PhD, Princeton, NJ, United States, zhaoranwang@gmail.com

In this talk, I will illustrate how statistical thinking enables us to harness the power of nonconvex optimization. In specific, I will present an algorithmic framework for exploiting the latent geometry induced by the randomness of data. By integrating three new global exploration meta-algorithms — namely, homotopy continuation, tightening after relaxation, and noise regularization — with local search heuristics — such as the variants of gradient descent — this unified framework leads to new nonconvex optimization algorithms for a broad variety of challenging learning problems.

3 - Proximally Guided Stochastic Subgradient Method for Nonsmooth, Nonconvex Problems

Damek Davis, Cornell University, 218 Rhodes Hall, Hoy Road, Ithaca, NY, 14850, United States, dsd95@cornell.edu

We introduce a stochastic projected subgradient method for a wide class of nonsmooth, nonconvex functions, which includes the additive and convex composite classes. At a high-level the method is an inexact proximal point iteration in which the strongly convex proximal subproblems are quickly solved with a specialized stochastic projected subgradient method. The primary contribution of this work is a simple proof that the proposed algorithm converges at the same rate as the stochastic gradient method for smooth nonconvex problems. This result validates the use of stochastic subgradient methods in nonsmooth, nonconvex optimization as is common when optimizing neural networks.

4 - The Radial Subgradient Method

Benjamin Grimmer, Cornell University, Ithaca, NY, United States, bdg79@cornell.edu

We present a subgradient method for minimizing non-smooth, non-Lipschitz convex optimization problems. We extend the work of Renegar by taking a different perspective, leading to an algorithm which is conceptually more natural, has notably improved convergence rates, and for which the analysis is surprisingly simple. At each iteration, the algorithm takes a subgradient step and then performs a line search to move radially towards (or away from) a known feasible point. Our convergence results have striking similarities to those of traditional methods that require Lipschitz continuity. Costly orthogonal projections typical of subgradient methods are entirely avoided.

1 - On Relaxations of Products of Functions

Taotao He, 1303 Palmer Drive, Apt 212, West Lafayette, IN, 47906, United States, he135@purdue.edu, Mohit Tawarmalani

We develop a new relaxation that exploits function structure while convexifying a product of d functions. The function structure is encapsulated using at most n over and underestimators. We convexify the function product in the space of estimators. The separation procedure generates facet-defining inequalities in time polynomial in d. If the functions are non-negative, the concave envelope can be separated in O(d nlog(n)). We extend our construction to infinite families of under and overestimators. Finally, we interpret the relaxation procedure for non-negative functions as expressing the product as a telescoping sum followed by a simple relaxation operator.

2 - Incorporating Decision Diagrams into MIP Solving

Christian Tjandraatmadja, Carnegie Mellon University, Tepper School of Business, 5000 Forbes Avenue, Pittsburgh, PA, 15213, United States, ctjandra@andrew.cmu.edu, Willem-Jan Van Hoeve

We present techniques that use decision diagrams to enhance mixed-integer programming solvers. Decision diagrams are embedded into the branch-and-bound tree and yield cutting planes and bounds that aid the solving process. We provide computational experiments that show these methods are effective in situations that admit strong decision diagram relaxations.

3 - Multi-objective Maximization of Monotone Submodular Functions
Rajan Harish Udwani, Massachusetts Institute of Technology, 70 Pacific Street, 809, Cambridge, MA, 02139, United States, rudwani@mit.edu

The best known algorithm for multi-objective maximization of monotone submodular functions, from Chekuri et.al. (2010), is a randomized (1-1/e)-\epsilon approximation algorithm for maximization subject to a Matroid constraint. However, the runtime scales exponentially in the number of functions, limiting this number to be a small constant. We focus on the special case of multi-objective maximization subject to a cardinality constraint (say k elements), and show constant factor approximations for up to o(k) many functions (problem is known to be inapproximable for \Omega(k) functions). We extend the (1-1/e) algorithm from above but also give a simpler and much faster (1-1/e)^2 approximation.

4 - A Logic-based Benders Approach to Home Healthcare Scheduling
Ryo Kimura, Carnegie Mellon University, 5000 Forbes Avenue, Pittsburgh, PA, 15213, United States, rkimura@andrew.cmu.edu, John Hooker, Aliza R.Heching

We propose an exact optimization method for home healthcare scheduling based on logic-based Benders decomposition (LBBD). The objective is to match patients with healthcare aides and schedule multiple home visits over a given time horizon, so as to maximize the number of patients served. Using LBBD, we decompose the problem into a master problem, solved by mixed integer programming, and several small scheduling subproblems, solved by constraint programming. We find that LBBD is far superior to mixed integer programming and optimally solves problems of realistic size, if the aim is to conduct staff planning on a rolling basis, and if there are a limited number of temporal dependencies between visits.

1 - Scenario Based Economic Dispatch with Adaptable Risk Levels in Uncertain Power Systems
M. Sadegh Modarresi, Research Assistant, Texas A&M.University, 1907 Dartmouth St, Apt 602, College Station, TX, 77840, United States, sadegh.modarresi@tamu.edu, Hao Ming, Le Xie

This paper presents a data-driven scenario approach to 1- dispatching power systems with high levels of uncertain resources in the real-time stage, and 2-at the day-ahead electricity market clearing process with the presence of demand response providers. By taking historical samples and generating appropriate sample-based uncertainty sets, this approach quantifies the relationship between the risk of violating the constraints and the cost conservativeness of the dispatch. Numerical simulations suggest that this approach could be a promising alternative in future electricity markets with uncertain load and generation resources.

2 - Parametric Analysis of Semidefinite and Second Order Conic Optimization
Ali Mohammad-Nezhad, PhD Student, Lehigh University, 200 W Packer Ave., Bethlehem, PA, 18015, United States, alm413@lehigh.edu, Tamas Terlaky

We consider the parametric analysis of semidefinite and second-order conic optimization problems when the right-hand side or the objective coefficients vector is perturbed along a certain direction. We introduce the concept of the optimal partition to characterize the optimal value function and the optimal set mapping and highlight the contrast with the case of LO. We show that under a nondegeneracy condition, the optimal set mapping is continuous, but in order to gain Lipschitz continuity, we need strict complementarity condition too. Further, we show that at a transition point, where the optimal partition changes, the higher order derivatives of the optimal value function do not exist.

3 - Finding Infimum Point with Respect to the Second Order Cone
Marta Cavaleiro, Rutgers University, Management Science and Informations Systems, 100 Rockefeller Road, Piscataway, NJ, 08854, United States, marta.cavaleiro@rutgers.edu, Farid Alizadeh

We define the notion of infimum and supremum of a set of points with respect to the second order cone. These problems can be formulated as second order cone optimization and thus solved by interior point methods in polynomial time. We present an extension of the simplex method to solve these problems and show some applications.

4 - Cluster Analysis is Convex
Madhushini Narayana Prasad, PhD Student, The University of Texas at Austin, 9226 Jollyville Road, Unit 150, Austin, TX, 78759, United States, madhushini@utexas.edu, Grani Adiwena Hanasusanto

In this work, we show that the popular k-means clustering problem is amenable to an exact conic programming reformulation. The emerging convex problem is NP-hard but admits a tractable polynomially solvable semidefinite programming (SDP) relaxation. We prove that this resulting SDP is equivalent to the state-of-the-art SDP approximation scheme and enjoys the same 2-approximation ratio. In contrast to this scheme, our proposed SDP reformulation yields solutions that can be used to directly identify the clusters. We assess the performance of our reformulation in numerical experiments and demonstrate its superiority over the state-of-the-art scheme and the classical Lloyd's algorithm.

5 - A Stochastic Frank-wolf Algorithm for Sparse and Non-stationary Environments
Davoud Ataee Tarzanagh, University of Florida, 1400 Stadium Rd, University of Florida, Gainesville,, FL, 32611, United States, Tarzanagh@ufl.edu, George Michailidis

The conditional gradient method, also known as -Ω for convex problems has lately regained popularity thanks to its projection-free property and its ability to exploit the structured constraints appearing in machine learning and big data applications. However, our understanding of this algorithm in the online and non- stationary setting is fairly limited, especially for problems with very noisy and/or sparse gradients. In this talk, we propose a stochastic variant of the Frank-Wolfe algorithm, based on adaptive estimates of lower-order moments. Our method is aimed towards problems involving large data sets and/or sparse gradients.

6 - Separable Convex Optimization with Nested Lower and Upper Constraints
Thibaut Vidal, PUC-Rio, Departamento de Informatica, Rua Marques de Sao Vicente, 225, Rio de Janeiro, 22453-900, Brazil, vidalt@inf.puc-rio.br, Daniel Gribel, Patrick Jaillet

We study a generalized convex resource allocation problem arising in production planning, vessel speed optimization, and support vector machine applications. We propose a decomposition algorithm, which uses monotonicity properties to generate bounds from recursive calls and eliminate linking constraints. These principles are very different from the usual greedy-scaling or even flow-propagation methods currently known. It improves upon the best known complexities, producing an integer or continuous solution in linearithmic time, and solving problems with one million variables in one minute.

Low-Carbon Power Sector: Policy and Technology Analysis

Sponsored: Energy, Natural Res & the Environment Electricity

Sponsored Session

Chair: Afzal Siddiqui, University College London, University College London, London, United Kingdom, afzal.siddiqui@ucl.ac.uk

1 - Regional Carbon Policies in an Interconnected Power System. How Expanded Coverage Could Enhance Prospects for Emissions Leakage
Makoto Tanaka, National Graduate Institute for Policy Studies (GRIPS), 7-22-1 Roppongi, Minato-ku, Tokyo, 106-8677, Japan, mtanaka@grips.ac.jp, Verena Viskovic, Yihsu Chen, Afzal Siddiqui

Reaching objectives under unilateral CO2 reduction policies can be delayed by carbon leakage. In the context of power markets, this is of concern in regional interconnected power systems with inconsistent policies. Using a stylised bi-level model of such a market where regions are connected with a congested line, we explore the effects of mitigating leakage by accounting for emission from the non-regulated region when setting the policy in the regulated region. We find that the overall emissions in the system decrease; however, the marginal value of transmission capacity increases, thus, providing more incentive for expanding the capacity of the line, which could potentially lead to more leakage.

2 - Evaluating an Interconnection Project: Do Strategic Interactions Matter?

Sebastien Debia, GERAD / HEC Montreal, 6100 Avenue Wilderton, Montreal, Canada, sebastien.debia@hec.ca, David Benatia, Pierre-Olivier Pineau

High-Voltage Direct Current (HVDC) merchant transmission lines allows trade across separate power markets and often in different countries. The flows on existing cross-border lines are often assessed as suboptimal, which may be due to the light regulation that often prevails in this case. We use a two-stage game formulated as an Equilibrium Problem with Equilibrium Constraints (EPEC) to model the strategic trade between the New York (US) and Quebec (Canada) systems. The impact of trade on local price levels may be of concern and calls for the functional unbundling of traders and generators.

3 - The Impact of Forward Contracts on Market Equilibrium in Renewable Energy Policy

Ryo Ito, 7416606@ed.tus.ac.jp, Ryuta Takashima

Recently various policies for reducing greenhouse gas emissions have been implemented by concerns about global warming. Those policies include schemes for promoting renewable energy such as feed-in tariff, feed-in premium, and renewable portfolio standards. Those policies directly impact the power prices by favoring power produced by renewables. On the other hand, it is shown that forward contracts mitigate market power in Allaz and Vila (1993). In this work we investigate a relationship between forward contracts and renewable energy policy for the competitive equilibrium. We show an effect of forward contracts and renewable energy scheme on market power on the spot market.

4 - Enhanced Representative Days and System States Modeling for Energy Storage Investment

Diego Tejada, Universidad Pontificia Comillas, Comillas, Spain, diego.tejada@iit.comillas.edu

In this work, we analyze the impact of different options to represent the operation decisions in the study of energy storage (ES) investment for long-term planning models. We compare the representative days and the system-states approaches for the representation of these operation decisions. We proposed enhanced versions of these approaches to improve the ES investment approximation. An Spanish case study is evaluated and the results are used to identify the potential profits that energy storage investment can obtain.

Chair: Kemal Gursoy, Rutgers University, Piscataway, NJ, United States, kgursoy@business.rutgers.edu

1 - Research on Synergy Degree Between Tech-innovation and Sci-tech Capital

Yanqiu Song, Central University of Finance and Economics, Haidian, 39th South College Road, Beijing, China, sunny_syq@163.com, Chang Yuan, Li Huijia

The coordinated development of technology innovation and capital is vital to achieve high industry value in China. Interactively considering the technology outcome and investment performance, this study aims to measure the synergy degree of 30 provinces(autonomous regions and municipalities) in China between 2000 and 2013. A synergy degree measure model based entropy is adopted to calculate the order degree of each sub-system and evaluate the coordinated situation of the integral system. The results show that the synergy between tech-innovation and sci-tech capital system shows a downward trend. There isn't mutually promoting coordinated development mechanism in China.

2 - Game Theoretic Approach in Capacity and Production Decisions for Indium

Sang-Phil Kim, Winona State University, Somsen 406, Winona, MN, 55987, United States, Ksphil@me.com, Chul Hun Choi, Jinjian Cao, Seokcheon Lee, Fu Zhao

Clean energy technologies, a solution to global warming challenge, require some rare materials and concerns about their rapid increasing demand have been raised recently. Indium, critical for thin-film solar photovoltaic and LED lighting, is one of the materials. Moreover, it is a by-product of zinc production thus the supply heavily relies on the production quantity of zinc. Therefore, simultaneous decisions in capacity and production quantity for both materials are necessary for sustainable supply of indium. Game theoretic approach (under duopoly market condition) is applied to seek the equilibrium values for capacity and production quantity of both materials in different market scenarios.

3 - China's Synergy Degree of Water-energy-food Nexus Basing on Entropy-based Collaboration Model

Guijun Li, Professor, Central University of Finance and Economics, 39th South College Road, Haidian District, Beijing, 100081, China, ligj@cufe.edu.cn, Yulong Li, Daohan Huang

The collaboration development of water, energy and food resources is vital to achieve sustainability in China. Basing on interactions in the processes of production, consumption and management, this paper first builds the index system at the country level. And then using the index system, a collaboration model basing on information entropy is adopted to calculate the synergy degree of water-energy-food nexus (WEF-Nexus) in China between 2002 and 2015, together with the order degree of subsystems and the development level of WEF-Nexus. Results show that the synergy of WEF-Nexus in China is uptrend from severe disorder to coordination during 2002-2015, and is also sensitive to external drivers.

4 - Biosystems Characterization, Modeling and Optimization

Yazeli E. Cruz-Rivera, The Applied Optimization Group, UPRM, PO Box 9000, Mayaguez, PR, 00681, United States, applied.optimization@gmail.com, Clara Isaza, Steven Mirsky, Mauricio Cabrera-Ríos

In everyday life, we are surrounded by systems of living organisms that can influence the behavior of other living organisms, i.e. by biosystems. Biosystems encompass topics from agriculture to health diseases. There is a need for interdisciplinary work to better understand, represent, and make competitive decisions in regards of these systems. In this work biosystems understanding is sought through statistical characterization, representation through statistical modeling, and decision-making through optimization, all within a biological framework. Two biosystems are studied: hairy vetch as a cover crop for corn, and the identification of important genes in Alzheimer's Disease.

5 - Extended Kalman Filter for Predicting Sustainability

Kemal Gursoy, Assistant Professor of Professional Practice, Rutgers University, 100 Rockafeller Road, Building A, Room 5146, Piscataway, NJ, 08854, United States, kgursoy@business.rutgers.edu

In order to survive, we must learn how to measure the magnitude of the impact we make to our environment and predict the change in our environment. This brings an immense challenge of collecting facts, and extracting sufficient, reliable, information from this incoming stream of immense amount of observations. In this work, we present an extended Kalman filter for predicting sustainability.

Application of OR and Analytics in the Energy Sector

Invited: OR and Oil and Gas

Invited Session

Chair: Peter Schipperijn, Chevron, Houston, TX, 77002, United States, apsc@chevron.com

1 - Asset and Project Valuation from Portfolio Optimization

Anthony Kenck, Chevron, Houston, TX, United States, anrk@chevron.com, Mal Wright, P. Val Kranak

The efficient frontier concepts developed by Markowitz, which compare return to standard deviation are of marginal use for most corporations in their decision-making. Executives are faced with more mundane tradeoffs, such as evaluating the difference between investing for growth vs striving for return on capital. We show an approach to balance competing objectives in order to ascertain the portfolio value of an asset or investment opportunity. The portfolio value of an opportunity is a function of the opportunity itself, portfolio requirements, constraints, and the inventory of opportunities. This framework can also be used when the information around a given opportunity is sparse.

2 - Application of Data Science in Chevron Upstream Sector

Yuanbo Lin, YLCV@chevron.com

Chevron has been leveraging data science to drive functional excellence and deliver business value in the upstream sector over the past several. This talk will showcase advanced modeling and analytics in addressing challenges in upstream activities like drilling, completions, asset development, and operations. The associated business value and impact will be highlighted for the four use cases discussed. We attribute much of the success to management support, close collaboration between business and analytics team, and a clear value-driven approach.

3 - When to Walk Away – Assessing Net Pay Thresholds in an Exploration Well

Patrick Burdett, Chevron, Houston, TX, United States, PBurdett@chevron.com

With drilling costs exceeding a million dollars per day in deep water wells, it is essential to understand when, in real time, to walk away from an exploration well that is sub-economic. A critical indicator of the economic viability of a field is the net pay thickness seen in the exploration well. This presentation address how a minimum economic pay thickness can be calculated beforehand that will give a real-time signpost on economic viability, and how that threshold can be adjusted on the fly for other information obtained from the well.

4 - A New Approach to Analyzing Data Acquisition Programs Before and After Data Come in

Jincong He, Chevron, Heyj@chevron.com

Data acquisition programs, such as surveillance and pilot, play an important role in reservoir management and are crucial for minimizing subsurface risks and improving decision quality. However, these projects often involve significant cost in terms of both capital investment and production downtime. In this talk I will present some recently developed methodologies to maximize "the bang for the buck", i.e., to optimize the program design before data come in, and rapidly integrate and interpret the data after they come in.

5 - Decisions using Monte Carlo: More Samples May not be Better

Mark A.Powell, Attwater Consulting, Webster, TX, United States, mark.powell@attwaterconsulting.com

Monte Carlo is one of the most ubiquitous analytics tools used in risk and decision making. The literature on Monte Carlo errors is rich, and the general consensus is that more samples reduce the errors. Quantification of the absolute error in any particular Monte Carlo however remains elusive. A new method to quantitatively bound Monte Carlo errors for any simulation using any number of samples will be presented, along with a decision strategy to take advantage of these error bounds. We will find that many decisions do not require tons of expensive Monte Carlo samples using this strategy.

Resilience in the Energy Sector

Sponsored: Energy, Natural Res & the Environment, Energy

Sponsored Session

Chair: Spada Matteo, Paul Scherrer Institute, Villigen PSI, 5232, Switzerland, matteo.spada@psi.ch

Co-Chair: Feng Qiu, Argonne National Laboratory, Lemont, IL, 60439, United States, fqiu@anl.gov

1 - Resilience of the European Natural Gas Network

Peter Lustenberger, Future Resilient Systems (FRS), Singapore-ETH Centre (SEC), Singapore, Singapore, lustenberger@frs.ethz.ch, Patrick Gasser, Wansub Kim, Matteo Spada, Peter Burgherr, Stefan Hirschberg, Bozidar Stojadinovic

Energy systems are regularly subjected to major unforeseen disruptions that are triggered by natural and human-made causes, which affect the economy and society. This calls for resilience assessment, including consideration of disruption and recovery processes of the system under investigation. This study presents, on the one hand, an assessment of probabilistic disruption processes caused by both natural hazards and technical failures and, on the other hand, potential recovery processes, applicable to the European natural gas network and its components.

2 - Smart and Resilient Energy

Matthew Wood, United States Army Engineer R&D Center, 686 Virginia Road, Concord, MA, 01742, United States, Matthew.D.Wood@usace.army.mil, Igor Linkov

There is a growing effort in the electricity generation and distribution industry to use smart technologies to promote efficiency and minimize the frequency and duration of outages. Smart energy technologies collect, analyze and utilize data in real time, and include SCADA systems, unmanned aerial vehicle surveillance, remote vibration monitoring, etc. Many smart technologies contribute to energy sector resilience. However, the reliance on highly-connected smart technologies leaves the energy sector vulnerable to unanticipated or targeted disruptions. This presentation serves to discuss the contribution, both positive and negative, of smart energy technologies on system resilience.

3 - Optimal Post-disruption Resilience-oriented Restoration for Interdependent Infrastructure Network

Yasser Adel Almoghathawi, University of Oklahoma, 1506 E Lindsey St., Apt. P, Norman, OK, 73071, United States, moghathawi@ou.edu, Kash Barker

We propose a multi-objective optimization model using mixed-integer programming for restoring the interdependent infrastructure networks after a disruptive event. The model considers the availability of limited time and resources with two disruption scenarios, complete and partial, for the disrupted network components, nodes or links. It aims to (i) minimize the total cost of restoration, and (ii) maximize the combined resilience of interdependent infrastructure networks considering the physical interdependencies between them. The proposed model is illustrated through a set of interdependent infrastructure networks after hypothetical earthquakes in Shelby County, TN, United States.

4 - Quantifying and Visualizing the Economic Impact of Commercial Districts Due to an Electric Power Outage

Jose Emmanuel Ramirez-Marquez, Stevens Institute of Technology, Castle Point on Hudson, School of Systems & Enterprises, Hoboken, NJ, 07030, United States, jmarquez@stevens.edu, Andrea Garcia tapia, Kash Barker

The level of dependence of communities on electric power, from social behavior to economic productivity, is significantly high, revealing how vulnerable communities are to a power outage. Assessing the economic impact of electricity outages after a disruption in the service is a challenging task, especially when costumer's interruption costs vary from type of user. A geospatial visualization is presented to observe and compare the areas that are more vulnerable in terms of economic impact based on the areas covered by each distribution substation.

Dynamic Robust Optimization and Learning

Sponsored: Optimization, Optimization Under Uncertainty

Sponsored Session

Chair: Yehua Wei, Boston College, Chestnut Hill, MA, 02467-3809, United States, yehua.wei@bc.edu

Co-Chair: Dan Andrei Iancu, Stanford University, Stanford, CA, 94107, United States, daniancu@stanford.edu

1 - Monitoring with Limited Information

Do Young Yoon, 37 Angell Ct, Apt 319, Stanford, CA, 94305, United States, doyoung@stanford.edu, Dan Andrei Iancu, Nikolaos Trichakis

We study a dynamic decision problem under limited information, in which a decision maker chooses when to monitor a system - which allows gaining more information about current and future states of the system - as well as whether to stop the monitoring process and take a particular action. With robust optimization framework, we solve for a monitoring policy that maximizes the worst-case stopping reward. Our main results show that, under mild conditions, a static monitoring policy is equivalent to a fully dynamic policy along the worst-case path. We then provide several methods for obtaining an optimal static monitoring policy and present a robust optimal algorithm for the dynamic decision problem.

2 - Discrete Convexity and Dynamic Robust Optimization

Dan Andrei Iancu, Stanford University, 655 Knight Way, Stanford, CA, 94107, United States, daniancu@stanford.edu, Yehua Wei

We discuss necessary and sufficient conditions for the optimality of specific classes of policies in dynamic robust optimization. We then focus on the specific case of affine policies, and show how our conditions can be used to recover and generalize several existing results in the literature. Our treatment draws interesting connections with the theory of discrete convexity (L-natural / M-natural convexity and multimodularity) and global concave envelopes, which may be of independent interest.

3 - A Constraint Generation Algorithm for Two-stage Robust Network Flow Problem

Yehua Wei, Boston College, 140 Commonwealth Avenue, Chestnut Hill, MA, 02467-3809, United States, yehua.wei@bc.edu, David Simchi-Levi, He Wang

We propose a new method for solving two-stage robust network flow problems with polyhedral uncertainty set. By exploiting the network structure of the problem, we suggest a reformulation where its number of constraints is exponential with the number of nodes in the network, but independent with the number vertices in the uncertainty set. We then develop an effective constraint generation algorithm for solving the two-stage robust optimization problem, and apply our method to several application domains.

4 - Out-of-Sample Analysis of Robust Empirical Optimization

Andrew Lim, National University of Singapore, 15 Kent Ridge Drive, Mochtar Riady Building, Singapore, 119245, Singapore, andrewlim@nus.edu.sg

We study the out-of-sample performance of distributionally robust data driven optimization. The key result is that the reduction in the variance of the out-of-sample reward that results from "robustifying" empirical optimization is an order of magnitude greater than the impact on the mean. Implications for calibration of robust optimization models is also discussed.

Recent Advances in Multistage Stochastic Programs

Sponsored: Optimization, Optimization Under Uncertainty

Sponsored Session

Chair: Yongjia Song, Virginia Commonwealth University, Richmond, VA, 23284, United States, ysong3@vcu.edu

1 - Two-stage Linear Decision Rules for Multistage Stochastic Programming

Merve Bodur, University of Toronto, 5 King's College Road, Toronto, ON, M5S.3G8, Canada, bodur@mie.utoronto.ca, James Luedtke

Multistage stochastic linear programs (MSLP) can be approximated by applying linear decision rules (LDR) on the recourse decisions. This reduces MSLP (its dual) into a static problem which provides an upper (lower) bound on the optimal value. We introduce two-stage LDR whose application reduces MSLP (or its dual) into a two-stage stochastic LP. In addition to yielding better policies and bounds, this approach requires many fewer assumptions than are required to get an explicit reformulation when using the static LDR approach. On a capacity expansion model, we find that the two-stage LDR policy has expected cost 20-34% lower than the static LDR policy, and yields lower bounds that are 0.1-3.3% better.

2 - Regularized Decomposition Methods for Multistage Convex Optimization Problems

Miguel Lejeune, Professor, George Washington University, Washington, DC, 20052, United States, mljne@yahoo.com, Vincent Guigues, Walid Tekaya

We design regularized variants of the Dual Dynamic Programming (DDP) and Stochastic Dual Dynamic Programming (SDDP) algorithms to solve dynamic convex programming problems. We show the convergence of the proposed algorithms and study their computational performance. The algorithms are used on portfolio optimization problems with direct and indirect transaction costs. In particular, we propose a risk-neutral portfolio selection model included market impact costs and cast as a multistage stochastic second-order cone programming problem.

3 - Speeding-up a Modified SDDP Method for Risk-averse Energy Storage Optimization using Importance Sampling

Juliana Nascimento, Princeton University, Sherrerd Hall, Operations Research and Fincl. Engineering, Princeton, NJ, 08544, United States, jnascime@princeton.edu, Joe Durante, Daniel Jiang, Warren B.Powell

Stochastic dual decomposition procedure (SDDP) has been widely used for stochastic linear programs. We study SDDP in the context of optimizing grid-level storage, using a new hidden semi-Markov model (HSMM) for modeling the behavior of wind. Our HSMM has been shown to accurately reproduce the crossing-time behavior of the wind, which captures the amount of time that actual wind sample paths are above or below forecasts. The HSMM requires that we capture complex temporal interdependencies, but provides more robust solutions. We use an additive utility function and demonstrate a novel importance sampling technique to speed-up the backward pass of SDDP.

4 - Regularized Decomposition Methods for Multistage Stochastic Linear Programs

Yongjia Song, Virginia Commonwealth University, 1015 Floyd Avenue, P.O. Box 843083, Richmond, VA, 23284, United States, ysong3@vcu.edu, Wim van Ackooij, Welington de Oliveira

We consider well-known decomposition techniques for multistage stochastic programming and a new scheme based on normal solutions for stabilizing calculations as the iteration process progresses. The given algorithms combine ideas from finite perturbation of convex programs and level bundle methods to regularize the so-called forward step of these decomposition methods. We also improve the backward step (that generates cuts, approximating the cost-to-go functions) by employing an adaptive partition-based approach to reduce the computational burden. Numerical experiment results on a hydrothermal scheduling problem will be shown.

Optimization, Robust

Contributed Session

Chair: Yang Zhan, City University of Hong Kong, Kowloon, Hong Kong, yangzhan3-c@my.cityu.edu.hk

1 - Optimizing Black Box Functions with Xpress

Majid Bazrafshan, Lead Consultant, FICO, 3957 Rue Berri, Montreal, QC, H2L.4H2, Canada, majidbazrafshan@fico.com, Zsolt Csizmadia

Optimization of black box functions are challenging due to the lack of information that defines them. The best method depends on the application; and while there may be no free lunch one property seems common: the expensive part is often the evaluations. A tempting solution is to use a solver that uses multiple evaluations per iteration organized into parallel calls. Doing so faces the same black box challenge; while the modeler knows the assumptions of the black-box, the solver is unlikely to offer just the right facilities to accommodate those. We show how FICO Xpress comes around these problems by providing automatic generation of parallel versions for user functions that remain fully customize-able.

2 - Solving L0-constrained Sparse Inverse Covariance Estimation

Dzung Phan, IBM.Research, 1101 Kitchawan Road, P.O. Box 218, Yorktown Heights, NY, 10598, United States, phandu@us.ibm.com, Matt Menickelly

Sparse inverse covariance matrices are utilized to model conditional dependences between variables in a network. Sparsity is often used for either interpretability of model or to avoid overfitting. We directly constrain sparsity by specifying a maximally allowable number of nonzeros. We present an efficient proximal projected Newton algorithm with warm starts for solving the l0-constrained GGM learning problem.

3 - A Second Order Method for Non-convex Optimization with Logarithmic Complexity

Santiago Paternain, University of Pennsylvania, Philadelphia, PA, United States, spater@seas.upenn.edu, Aryan Mokhtari, Alejandro Ribeiro

The problem of minimizing non-convex functions is central to many applications such as neural networks and matrix factorization. The main issue in solving these problems origins in the proliferation of saddle points. In this work, we present a modified Newton's method by replacing the negative eigenvalues of the Hessian by their absolute values to correct the curvature of the descent direction. This modification leads to a novel method that escapes the saddles exponentially fast. Moreover, we show that with probability 1-p the proposed algorithm outputs a solution within the epsilon radius of a local minimum of the objective function after running for O(log(1/p)+ log(eps)) iterations.

4 - Robust Operational Decisions for Multi Period Industrial Gas Pipeline Networks under Uncertainty

Pelin Cay, PhD Candidate, Lehigh University, Harold S. Mohler Laboratory, 200 W. Packer Ave, Bethlehem, PA, 18015, United States, caypelin@gmail.com, Camilo Mancilla, Robert H. Storer, Luis F. Zuluaga

Industrial gas companies plan daily gas production levels to minimize total production cost per day. While meeting the customer demand and physical constraints in a gas pipeline network leads to a challenging optimization problem, daily planning requires multi-period formulation with ramping limitation of the plants. In this study, we apply a heuristic approach to find a feasible solution for industry-sized problems. Moreover, we provide a lower bound solution to produce global optimality gap of the heuristic solution by the convex reformulation of the standard problem. Numerical experiments show advantages of using the developed heuristic compared to solving the standard formulation.

5 - A Smooth Path Following Algorithm for Market Equilibrium under a Class of Piecewise Smooth Concave Utilities

Yang Zhan, City University of Hong Kong, Kowloon, Hong Kong, yangzhan3-c@my.cityu.edu.hk, Chuangyin Dang

This paper presents a smooth path-following algorithm for computing market equilibrium in a pure exchange economy under a class of piecewise-smooth concave utilities, which can be expressed as $u(x)=\min_l\{f_l(x)\}$ with $f_l(x)$ being a smooth concave function for all l. As a result of a smooth technique for minimax problems, a smooth homotopy mapping is derived from the introduction of logarithmic barrier terms and an extra variable. With this mapping, it is proved that there always exists a smooth path leading to a market equilibrium as the extra variable approaches zero. Numerical results are given to further demonstrate the effectiveness and efficiency of the algorithm.

Tuesday, 12:30 - 2:30PM

■ Tuesday Poster

Exhibit Hall

Tuesday Poster Session

Poster Session

1 - The Effect of Air-high Speed Railway Joint Transport on Inland Air Harbor Hinterland

Si Chen, Southwest Jiaotong University, Chengdu, China, chensi@swjtu.cn, Mi Gan, Mi Gan, Mi Gan, Shuai Yang, Mingfei Wang

To estimate the impact of air-high speed railway freight transport in China, we applied the improved gravity model and data visualization to express the changes of strength about inland air harbor appeal to its hinterland. Through the comparison of changes in hinterland intensity and scope of service, the advantage of air-rail intermodality has been proved.

2 - Uncertainty Analysis of Species Distribution Models

Xi Chen, University of Texas at Austin, 3500 Greystone Drive, Apt 271, Austin, TX, 78731, United States, carol.chen@utexas.edu

Species distribution models (SDM) are commonly used to predict the geographic distributions of animals or plants species. However, most of SDM methodology produces point estimates. We present two strategies for quantifying the uncertainty of maximum entropy SDM methods: a bootstrap method, and an analytic method. We describe both methods, and compare and contrast their performance on two examples of different sizes. Both Dengue importation probability and Aedes aegypti mosquito suitability examples show that the methods generate comparatively the same results and the novel analytic method we introduce is dramatically faster than the bootstrap method.

3 - Investment Plan Against Malicious Attacks on Power Networks: Multilevel Game-theoretic Models with Shared Cognition

Hamzeh Davarikia, Research Assistant, University of Arkansas at Little Rock, 2801 S.University Avenue, Little Rock, AR, 72204, United States, hxdavarikia@ualr.edu

We developed a tool for utility transmission planners to protect power network from potential attacks. An extended tri-level mixed-integer linear-programming interdiction-model returns the best-protecting strategy. Deception is an integral part of the mathematical model, accomplished by releasing misinformation based on shared cognition theory. In addition, the multi origin-destination model allows the impact of disabled facilities to become transparent. The results from IEEE 24 and 118 Bus Test Systems show the viability of the model, including its capacity to impute the worth of deception.

4 - Value of Information for Systems Inspection

Joao Jose de Farias Neto, Doctor, Collective Decisions Ltda., Sao Jose dos Campos, Brazil, joaojfn@ig.com.br

The compromise between over-inspection (due to unwarranted fears) and under-inspection (due to excessive confidence) depends on two factors: the reliability level considered as satisfactory and the amount of effort (time and money) worth dedicating. Since inspecting a system means acquiring information about its subsystems, we propose the use of the concept of Value of Information (VoI), to achieve the balance in a rational manner. For that, the joint VoI of sets of subsystems must be evaluated; a special software - VIPDecisions (R) - is presented, that allows it. An example is given as a toy-problem.

5 - A New Linear Programming Algorithm for Big Size Problem Based Direction of Zoutendijk

Ivan Derpich, Dr., University of Santiago of Chile, Av Ecuador 3769, Santiago, Chile, ivan.derpich@usach.cl

A new algorithm to solve problems of linear programming for big size problems is presented. It is based on directions of Zoutendijk and it presents polynomial complexity.

6 - IPREP: Improving Perioperative Efficiency and Patient Throughput

Ged Doyle, Lead Practitioner, University Hospitals Birmingham, Mindelsohn Way, Edgbaston, Birmingham, B15 2TH, United Kingdom, ged.doyle@uhb.nhs.uk, Laura Boyle, Adele Marshall, Anthony Staines

The challenge is to reduce delays and 'silo' working. The technique involves modelling preliminary patient movement data using SIMUL8 to identify bottlenecks. Discrete Event Simulation has been used to observe the effects of introducing new approaches to improving the patient pathway. A clinical intervention trial will be selected from the DES output.The focus of the research is to establish a cohesive pathway for surgical patients where all the hospital departments work together to ensure improved throughput and efficiency.

7 - Scheduling Optimization of Local Farmers

sefakor Fianu, North Carolina A&T.State University, 1601 E.Market St, Greensboro, NC, 27411, United States, sfianu@aggies.ncat.edu, Lauren Berrings Davis

Local farmers face challenges such as; seasonality, transportation, food safety, and packaging requirements that prevent them from meeting the demand of institutions like universities. This research is part of the University Food Systems project aimed at connecting local farmers and universities in North Carolina. We solve the transportation problem by developing weekly schedules that minimizes the distance traveled by farmers to drop off their produce at crossdocking facilities. The schedules addresses capacity, collection frequency and food spoilage constraints.

8 - Efficiency Analysis of Basic Public Health Care Units that Operate under Brazilian Unified Health System

Carlos Ernani Fries, Associate Professor, Federal University of Santa Catarina, Caixa Postal 5185, Florianopolis, 88040-970, Brazil, carlos.fries@ufsc.br, Eduardo W. Benvenuti, Ricardo F. Giglio

The UBSs (basic health units) play a fundamental role in guaranteeing integral health care in Brazil. However, economic flutuations and federal government financial difficulties have imposed challenges in order to maintain public health care services. This work aims at contributing to better managerial practices focusing on improvements in the basic health care services. We have applied statistical techniques and DEA models in data from a medium-sized city. Results suggest characteristics that might have influence on the UBSs' efficiencies and the potential to guide other cities to perform systematic efficiency evaluations in their health services, thus facilitating better resource usage.

9 - A Robust Optimization Model for an Invasive Species Management Problem

Nahid Jafari, Assistant Professor, SUNY, Farmingdale, 2350 Broadhollow Road, Farmingdale, NY, 11550, United States, jnahid@hotmail.com

Invasive species pose a significant threat to global biodiversity. Managing invasive species often involves modeling the species' spread pattern, estimating control costs and damage costs due to the invasion, designing control efforts, and accounting for uncertainties in model parameters. Dealing with uncertainty is the most important part of the process, since biological, environmental, and economic factors can cause parameter values to vary greatly. We present a robust spatial optimization model (an integer programming model) to select treatment sites in a way that maximally reduces the size of an invasive population, given a constraint on financial resources.0

10 - System Monitoring with Sensor Time Series Data from Manufacturing Process

Youngseon Jeong, Chonnam National University, 77 Yongbong-ro, Buk-gu, Gwangju, 61186, Korea, Republic of, youngseonjeong@gmail.com

This research proposes a new statistical process control procedure for time series data having systematic variations of curves at local regions. To monitor possible systematic changes of curves at certain local regions, in this paper, we use the selected coefficients in the wavelet domain. Evaluation with real-life data sets shows that the proposed procedure performs better than several techniques extended from methods based on single-curve-based data reduction.

11 - VMT Impact of Shared Autonomous Vehicle in Orange County, California: Simulation Approach

Jae Young Jung, Operations Research Scientist, Ford Motor Company, 15403 Commerce Drive South, Dearborn, MI, 48120, United States, jjung22@ford.com, R. Jayakrishnan

Although Shared Autonomous Vehicles (SAVs) with self-driving capabilities will have benefits on driving efficiency and traveler convenience, there has been a growing concern about increasing Vehicle-miles traveled (VMT) due to empty hauls with SAVs, limiting the sustainability benefit. First, this simulation study demonstrates SAVs fleet operations in Orange County, California and identifies VMT increase compared to private vehicle usage. Second, the study suggests a ride-share strategy with SAVs and explores the potential benefit of ride-sharing to maximize the SAVs utilization.

12 - A Spatial Analysis for Airport Congestion

Fecri Karanki, Research Assistant, North Dakota State University, FARGO, ND, United States, fkaranki@gmail.com

In recent years, airport congestion has been a topic of much discussion. This study will show that one of the most important reason of airport congestion is the neighbor airport proximity. While airport capacity is taken as the main reasons for airport congestion, airspace capacity is ignored. However, airports, which are very close with each other, have to share the airspace. Thus, in this study, the capacity of airports is analyzed in 3 factors: gate(terminal), runway and air space. The effects of airspace capacity on congestion will be shown by the proximity between airports. The preliminary results of this study show that less distance between neighboring airports causes more delays at airports.

13 - Job Shop to Cellular Manufacturing: An Implementation in RF/microwave Manufacturing

Okan Karatay, Production Manager, Aselsan, Konya Yolu 8 km Ogulbey Mh. 3051 sk no:3, Ankara, 06830, Turkey, okaratay@aselsan.com.tr, Yuce Cinar Baysal

Nowadays, one of the effective ways of dealing with manufacturing drawbacks in a high mix low volume environment is the Cellular Manufacturing (CM). In this study, we first propose a manufacturing cell that is designed to replace the traditional job shop layout of Aselsan Inc. based on lean perspective. Secondly, we focus on the scheduling that creates the continuous flow and provides the line balance. In addition, employee originated challenges of adopting CM are also deeply investigated. Thirdly, we evaluate the performance of the CM with the conventional production layout by using the company's KPI. Finally, we derive some suggestions on how human aspects of CM can be improved for future studies.

14 - Learning in Discrete Optimization

Elias B.Khalil, PhD Student, Georgia Tech, North Avenue, Atlanta, GA, 30332, United States, lyes@gatech.edu

The branch-and-bound algorithm for solving Mixed Integer Programs (MIP) involves decisions that are currently addressed heuristically. Instead, we propose to use machine learning (ML) to make better-informed, input-specific decisions in MIP branch-and-bound. For branching and primal heuristic selection, our ML approaches significantly improve solver performance on heterogeneous MIPLIB instances and certain homogeneous families of instances. For some classical combinatorial problems, we propose a deep graph embedding framework for learning powerful greedy heuristics, and show that the learned heuristics are competitive with existing heuristics for VertexCover, MaxCut and TSP.

15 - Development of Accelerated Reliability Demonstration Test Plan under a Nonlinear Random-coefficients Model

Seongjoon Kim, Assistant Professor, Chosun University, 3F Dept. of IE, 2nd Engineering Building, 309 Pilmun-daero, Dong-gu, Gwangju, 61452, Korea, Republic of, seongjoon.kim@chosun.ac.kr, Suk Joo Bae

Due to tight time-to-market constraints, manufacturers have to assure product reliability in a short period of time and with limited resources. In this circumstance, reliability demonstration test(RDT) is widely used to demonstrate whether a product meets a pre-determined reliability level. In this research, we propose a method for Reliability Demonstration by Accelerated Degradation Test in the context of a nonlinear random-coefficients model. The proposed method is illustrated with display back-light unit(BLU) case and is applied to demonstrate the luminosity reliability.

16 - Millennials' Social Networking Behavior

Anita Lee-Post, University of Kentucky, Department of Marketing and Supply Chain, 435Q.Business & Economics Bldg, Lexington, KY, 40506, United States, dsianita@uky.edu

The purpose of this research is to further our understanding on Millennials' social networking behavior. Past literature has characterized Millennials as narcissists with a high level of technological competency but a low level of privacy concerns and commitment. A correlation study is sought to investigate the relationships among the characteristics of Millennials and their social networking behavior using a survey methodology. Theoretical and practical implications of findings from this study will be presented.

17 - A Semiparametric Trajectory Model to Predict Cognitive Decline in Lewy Body Dementia

Xiaoxia Li, North Dakota State University, Fargo, ND, 58102, United States, xiaoxia.li.lisa@gmail.com, Cannan Bilen-Green, Kambiz Farahmand, Linda Langley

Lewy bodies dementia (LBD) is a neurocognitive disorder that result in memory loss and other cognitive or functional decline. LBD progression is highly diverse, and the symptoms vary differently from case to case. However, it is essential to map the cognitive decline to the severity of the impact of the symptoms on daily life. Clinical Dementia Rating SUM score (CDR SUM score) is a comprehensive evaluation tool. In this study, we built a semiparametric model showed robustness in both explaining the data and predictions. The study results revealed the factors associated with cognitive decline rate in terms of CDR SUM score, and gave implications on accurate CDR SUM score prediction.

18 - Handling Passenger Flows and Transfers in Flight-to-gate Reassignment Procedures During Schedule Disruptions

Moschoula Pternea, PhD Candidate, University of Maryland, College Park, MD, 20742, United States, mpternea@umd.edu, Ali Haghani

The problem of reassigning flights to airport gates arises when unexpected disruptions render the planned assignment infeasible or impractical. In this context, one of the biggest challenges is to handle passenger flows, which are involved in the prevention of missed transfers, as well as the optimization of total walking distance for connecting passengers. We present an IP-based framework to handle the computational complexity of passenger flows by considering the layout of the airport and scheduled flights of the aircraft for the same day in order to prevent delay propagation across the whole network. Our experiments reveal the tradeoffs between different aspects of the solution quality.

19 - Assessing the Health and Wellness Outcomes of Infants Born to Teen Mothers

Toyya A.Pujol, PhD Student, Georgia Institute of Technology, Atlanta, GA, United States, pujol@gatech.edu, Nicoleta Serban, Julie L.Swann

The research will explore the impact of teen pregnancy on the health and wellness outcomes of infants. Causal effects of teen pregnancy were found by matching teen and adult mothers and performing a pairwise comparison for each outcome. The mothers were matched using demographics, health status, and Medicaid eligibility. Outcomes of the infants were restricted to the first year of birth and included addiction rates, health status, foster care, number of Emergency department and wellness visits. Analysis of outcomes includes using the Poisson means test and binomial proportion test.

20 - An Evolutionary Approach to Finding Improved Airplane Boarding Order

Ed Ramsden, Murata Power Solutions, 1080 County Street, Attleboro, MA, 02703, United States, ed@edscave.com

This project proposes a method for improving seat-to-zone assignments for boarding passenger aircraft. A simulation model is used to generate overall boarding times for different passenger seat-to-zone assignments, and an evolutionary algorithm uses the results of the simulation model to search for seat-to-zone assignments which result in minimal boarding times.

21 - Intensity Based Resilience Metric: An Exploration in Social and Physical Systems

Daniel Hernando Romero, University of South Florida, 4411 Shady Terrace Ln, Unit A, Apt 212, Tampa, FL, 33613, United States, danielromero@mail.usf.edu
Daniel Hernando Romero, Universidad del Norte, Barranquilla, Colombia, danielromero@mail.usf.edu, Alex Savachkin

A new resilience metric is proposed and evaluated in social and physical systems. The intensity based metric includes the disruption magnitude to enable a fair comparison when different events are studied. The analysis is carried out in a community under a pandemic influenza outbreak and in a supply chain. The results are contrasted with traditional average performance metrics.

22 - Spatio-temporal Characteristics of Freeway Traffic State Transitions

George Saman, California State University-Fullerton, Fullerton, CA, United States, georgesaman@csu.fullerton.edu, Paulina Reina

Empirical data at a freeway site was analyzed to investigate features of traffic state transitions from free-flow to congested state and vice versa. It was observed that transition durations range approximately from 15 to 35 minutes on average during congestion onset and clearance. Results also suggest that the rate of transition growth increases as the transition zone travels upstream of the bottleneck and that merges and diverges have no effect on the transition mechanism. These findings can have significant implications on the effectiveness of traffic management strategies during periods of transitions.

23 - An Approach Towards Automation of Model Selection

Mohammadali Shirazi, Texas A&M University, College Station, TX, United States, alishirazi@tamu.edu, Dominique Lord

We present an alternative to typical Model Selection strategies. Unlike typical methods, our approach looks at the characteristics of data to come with the best model. Our approach is easy to use and do not need any post-modeling inputs. It is particularly most suitable for instances when many alternatives with different complexities exist or the analyst deals with big data.

24 - Sustainable Supply Chain Management and the Issue of Social Sustainability

Bruno Silvestre, Associate Professor, University of Manitoba, Winnipeg, MB, Canada, b.silvestre@umanitoba.ca, Dafne Moraes

The social dimension of sustainability has been poorly investigated when compared to the environmental dimension in sustainable supply chain management studies. This lack of attention is problematic for the theory and practice of sustainable supply chains. We employ the concepts of supply chain engagement and motivation to shed light on the topic and improve our understanding of supply chain social sustainability. We selected eight cases of social initiatives undertaken by companies and used them as examples of the four different supply chain approaches to social sustainability. We finish the paper with implications for the practice and contributions to the supply chain management theory.

25 - A Modified Pharmacokinetic/pharmacodynamic Model for the Electrically Activated Silver-titanium Implant System

George Tan, Assistant Professor, Texas Tech University, Box 43061, 905 Canton Ave, Lubbock, TX, 79409, United States, george.z.tan@ttu.edu

Silver-based systems activated by low intensity direct current continue to be investigated as an alternative antimicrobial for infection prophylaxis and treatment. The objective of this study was to develop a semi-mechanistic pharmacokinetic/pharmacodynamic (PK/PD) model providing the quantitative relationship between the critical system parameters and the degree of antimicrobial efficacy. The model allowed the determination of the effective ranges of current intensity and anode surface area, within which the system has the optimal antimicrobial efficacy.

26 - Impacts of Height Restriction and Relaxation by Sky Factor Focusing on Digestion Floor Area Ratio and Building Height

Hiroko Watanabe, Graduate Student, The University of Tokyo, Ce-408, 4-6-1, Komaba, Meguro, Tokyo, 153-8505, Japan, hiroko@iis.u-tokyo.ac.jp, Yudai Honma, Kentaro Honma, Kotaro Imai

In this paper, we compare the impacts of height restriction and relaxation by sky factor in terms of digestion floor area ratio and building height. By considering the various site shape and building shape, we evaluate how these regulation affects the digestion floor area ratio and building height. The analyses enable us to grasp the situations which a relaxation by sky factor have large advantages. Main results of this paper are as follows: (i) a relaxation by sky factor is advantageous when the site has large frontage; (ii) by utilizing the setback regulation, it is possible to acquire enough floor are ratio when the site of depth becomes large.

27 - New Approach for Failure Mode and Effect Analysis using Linguistic Distribution Assessments and Todim Method

Hu-Chen Liu, Shanghai University, Shanghai, China, huchenliu@foxmail.com, Lu Zhen, Jianxin You, Jianxin You, Mengmeng Shan

This paper applies linguistic distribution assessments to represent FMEA team members' risk evaluation information and employs an improved TODIM (an acronym in Portuguese of interactive and multicriteria decision making) method to determine the risk priority of failure modes. Both subjective weights and objective weights of risk factors are taken into account while conducting the risk analysis process. Finally, an empirical case concerning the risk evaluation of a grinding wheel system is presented to demonstrate the practicality and effectiveness of the proposed new FMEA model.

28 - Does Sharing Bicycles Hurt Traditional Public Transportations

Ling Gai, Shanghai University, Office 432, School of Managent, Shanghai University, No. 599 Shangda Road, Shanghai, 201444, China, lgai@shu.edu.cn

Sharing bicycles with the characteristics of easier access and lower price come into people's daily life, they are becoming one of the primary traffic modes besides public bus and taxi. In this paper, we study the influences of sharing bicycles on the traditional public transportation system, including the market demand, their pricing policy and net profits. We also consider the case that the government joins in the market by imposing carbon taxes. The ring Hotelling model is applied to fulfill the analysis.

29 - A View From the Top: An Examination of Innovation Idea Selection Factors in Large Organizations, from the Executive Perspective

Troy A.Montgomery, University of South Florida, Tampa, FL, United States, tmontgomery@mail.usf.edu

Factors impacting the front end of innovation are vital to the overall success of the innovation process and have received considerable attention. However, factors that impact the specific activity of idea selection in large organizations have received less attention. This research utilized the proven methods of grounded theory to address the question: what are the critical factors large organizations consider when selecting innovation ideas? Data from 28 senior level executives provided a view from the top into these critical factors.

30 - Examining the Effect of the Price Display Format in Advertisement on Consumer Perception

Yoshiyuki Okuse, Professor, Senshu University, 2-1-1 Higashi Mita, Tama-ward, Kawasaki City Kanagawa Pref, 214-8580, Japan, okuse@senshu-u.jp

The purpose of this research is (1) to examine the relationship between price perception and the layout in the advertisement, and (2) to examine the influence of psychological distance on price perception.

31 - Interventional Radiology Resource Modeling and Simulation – A Case Study

Michael Prokle, Data Scientist, Philips Research North America, 371 Broadway, Apt 3, Cambridge, MA, 02139-1722, United States, michael.prokle@philips.com, Sebastian Flacke, Christoph Wald, Paul W. McGunigle, Robert San Soucie, Joanie Davis, Ranjith Tellis, Nandini Raghavan, Sandeep Dalal, Eran Simhon, Christopher S. Hall

We model and simulate an interventional radiology department (IR-Dept) seeking to decrease patient wait times. An IR-Dept's performance depends on the simultaneous availability of professional resources (e.g. physician, nurse), physical assets (procedure room, equipment), clinical workflow (e.g. prep-procedure-recovery) and its ability to handle inherently stochastic processes (e.g. patient arrivals, procedure times). We show how these aspects can be simulated and validate the model's output (i.e. patient wait times) against an actual day in a hospital's IR-Dept. Further, we use this model to show how this IR-Dept can optimize its staffing schedule to improve patient wait times.

32 - Optimizing Transportation Network for SF Express

Ziheng Liu, Machine Learning Engineer, SF Technology Co.,Ltd., Software Industry Base 1B, Shenzhen, 518000, China, liuziheng@sf-express.com

SF Express is a express services company based in Shenzhen, China. Established in 1993, SF has extended its services to all over Mainland China with more than 13,000 service points and approximately 15,000 operating vehicles. Rapid expansion of the business has posed challenges to SF and necessitated innovations. In order to promote the long-term development of SF Express, we have initiated two nationwide projects - business region partitioning and transit center selection to lower the operating cost of SF's transportation network. Multiple operations research and machine learning algorithms were utilized to solve the problems.

33 - Forecasting Delivery Amount for SF Express

Benyu Wang, SF Technology Co., Ltd., Software Industry Base 1B, Shenzhen, 518000, China, wangbenyu@sf-express.com

SF Express is a delivery service company based in Shenzhen,China. Established in 1993, SF has extended its services to all over Mainland China with more than 13,000 service points approximately 15,000 operating vehicles. Rapid expansion of the business has posed challenges to SF and necessitated innovations. In order to make staffing decisions and build work schedules for SF express, we have initiated a forecasting project for different types of delivery services and three different time units. Various time series, deep learning and machine learning models were utilized to solve the problems.

34 - Teaching Operations Research with MATLAB

Mary C. Fenelon, Product Marketing Manager, MathWorks, 3 Apple Hill Dr., Natick, MA, 01760-2098, United States, mary.fenelon@mathworks.com, Teresa Hubscher-Younger

This presentation shows how to use MATLAB tools for statistics, machine learning, optimization and discrete event simulation in an operations research course. Use Live Scripts and Apps for interactive lectures. Develop optimization models for decisions and design taking advantage of the newest MATLAB features. Develop simulation models to simulate different test scenarios and collect data that you could use for analysis and prediction. Access MATLAB Online through a browser or MATLAB Mobile from your phone. Create and grade assignments with Cody Coursework.

35 - Chance Constrained Programs with Mixture Distributions

Sun Wenjie, Mr, Tongji University, Shanghai, China, r13381638770@sina.com, Zhaolin Hu

Chance constrained programs (CCP) are important models in stochastic optimization and risk management. In the conventional literature on CCPs, underlying distribution modeling the randomness of the problem is usually assumed to be given in advance. However, in practice, such a distribution needs to be specified by the modelers based on the information available. This is called input modeling. In this paper we consider input modeling in CCPs. We propose to use mixture distributions to fit the data available and to model the randomness. We demonstrate the merits of using mixture distributions and show how to handle the CCPs with mixture distributions under several scenarios.

36 - A Randomized Strategy for Fare Inspection in Santiago Transit System.

Carlos Bonet Flores, Universidad de Chile, Republica 779, Santiago, Chile, carlos.bonet@ing.uchile.cl, Jose Correa, Andreas Wiese, Bastian Matias Bahamondes, Fan Wang

We implement a randomized strategy for fare inspection in Santiago transit system. We used a model based on bilevel programming, in wich first the leader determines probabilities for inspecting at diferent locations, and then the evaders respond by optimizing their routes given the inspection probabilities and travel times.

37 - School Choice Mechanism in Chile.

Natalie Epstein, Universidad de Chile, Fernandez Concha 477, Santiago, Chile, natalie.epsteinr@gmail.com, Jose Correa, Juan Escobar, Carlos Bonet, Bastian Matias Bahamondes, Martin Castillo, Maria Angelica Bosh

We describe the main challenges in the recent implementation of a stable matching algorithm for the Chilean primary and secondary school systems. The system successfully run in 2016 in the small region of Magallanes with almost 4000 applications. This year the system scales to about 80.000 applications and in steady state regime there will be about 500.000 applications per year.

38 - A Regularized Inverse Optimization Method to Decide Optimal Product Characteristic Combination and Consumer Taste Segmentation

CY (Chor-yiu) Sin, National Tsing Hua University, Kuang-Fu Road, Hsinchu, 30013, Taiwan, cysin@mx.nthu.edu.tw

Recent advances of the random coefficient demand model uses the constrained optimization modeling technique of mathematical program with equilibrium constraints (MPEC) and connects the specially-interested problem to the continually-developing power of nonlinear programming solvers. In this work, we construct a semi-nonparametric MPEC by relaxing the distributional assumption on the random coefficient. The empirical study investigating the UK vehicle market share of 212 vehicle models in UK with a large number of potential customers from Year 2001 to Year 2015 shows the effectiveness of this approach. We predict the responses in both the business market and the consumer market.

39 - Reverse Logistics and Shipping Waste Modeling

Mazen I. Hussein, Assistant Professor, University of Wisconsin-Platteville, 150 Stonebridge Road, Apartment 206, Platteville, WI, 53818, United States, mazenhussein2212@gmail.com

A model based on theory and several modeling techniques is used to estimate and predict the movement and flow of different kinds of waste. Variety of data resources was used. The results can be used as an input to other projects regarding the flow of commodities, logistics, and transportation.

40 - A Dynamic Programming Approach to Determining Residential Thermostat Set Points for Demand Response

Arnab Roy, Graduate Fellow, University of Louisville, 3177 South 3rd Street, Louisville, KY, 40214, United States, arnab.roy@louisville.edu, Lihui Bai

We propose a dynamic programming approach to determine the optimal set point for a smart thermostat during periods surrounding a Demand Response event. The objective is to minimize the total energy consumption during the peak period (high price) period while keeping the inside temperature within user-defined tolerable range. It is applied in three stages of the event: pre-, during and post-event. The algorithm is tested on three prototypical homes with low, medium, 41

41- A Machine Learning Framework for Industrial Energy Assessments at Small and Medium-sized Enterprises

Hadi Karimi, Clemson University, 1108 Tiger Blvd., Apt. 117, Clemson, SC, 29631, United States, hkarimi@clemson.edu, Sandra D. Eksioglu, Jay Devkota

In this study we are developing a machine learning framework to facilitate the industrial energy assessment process at small and medium size enterprises. The machine learning framework has two main stages: at first stage, we develop a predictive model to characterize baseline energy use by taking into account the climate conditions and production factors. At second stage, we measure the industrial energy savings by developing a multivariate regression equation and disaggregating the savings after taking the total derivative of the energy use equation.

42 - Confidence Regions for the Location of the Global Optimum of a Polynomial Model

Adam Meyers, Pennsylvania State University, 1006 Golfview Avenue, Apt 3, State College, PA, 16801, United States, acm4688@gmail.com

Our problem is to find a confidence region (CR) for the location of the global optimum of a polynomial model. Previous work culminated in an R package that finds CRs for quadratic polynomial regression and thin plate spline models. Our goal is to extend this package to accommodate polynomial models of higher degree and with a larger number of variables. In particular, we will discuss the solution method of the problem of finding the global minimum of a polynomial subject to polynomial inequalities. This involves solving semidefinite programming relaxations of increasing order whose solutions are guaranteed to converge monotonically to the global optimum. We will also discuss its implementation in R.

43 - Multi Attribute Trade Off in Supplier Selection Problem

Somaye Ramezanpour Nargesi, University of Texas at Arlington, 807 S.Center Street, Apt 108, Arlington, TX, 76010, United States, somaye.ramezanpournargesi@mavs.uta.edu

Supplier selection has been known as one of the most critical business decisions . In this research, we are going to use discrete choice setting to study how people do trade-off among price, availability and quality of the products offered by different suppliers, when they are actually choosing suppliers in an incentivized experimental setting. Aside from studying multi-attribute trade off, we will look at potential decision biases and the effect of number of choice on those biases.

44 - New Algorithms for Inference in Dynamic Stochastic Block Models

Mehrnaz Amjadi, PhD Student, College of Business, University of Illinois at Chicago, University hall, 601 S.Morgan St, 24th floor, UH2401, Chicago, IL, 60607, United States, mamjad2@uic.edu, Theja Tulabandhula

Although the computational and statistical trade-offs for modeling single graphs are relatively well understood, extending such results to sequences of graphs is difficult. In this work, we propose two models for such sequences that capture: (a) link persistence between nodes across time, and (b) community persistence of each node across time. In the first model, we assume that the latent community of each node does not change, and in the second model we relax this assumption. For both models, we propose computationally efficient inference algorithms, which leverage community detection methods that work on single graphs. We provide simulation results validating their performance.

45 - A Decomposition Framework for System Optimal Dynamic Traffic Assignment Problem

Mehrzad Mehrabipour, Graduate Research Assistant, Washington State University, 1630 NE Valley Road, Pullman, WA, 99164, United States, mehrzad.mehrabipour@wsu.edu, Ali Hajbabaie

Computational complexity of cell transmission model based Dynamic Traffic Assignment (DTA) limits its applications to large transportation networks. This study develops a scheme to decompose the network into several sub-problems. The proposed methodology is applicable to larger transportation networks and finds solutions that are within 5% gap with the optimal solution in various case study networks.

46 - Redesign of Patient Flow and Resource Allocation in a High Volume Emergency Department

Melih Celik, Middle East Technical University, ODTU. Endustri Muh. Bolumu, Universiteler Mh. Dumlupinar Bl. No: 1, Ankara, 06800, Turkey, cmelih@metu.edu.tr, Sakine Batun, Nur Keskin, Alpin Ilayda Ozmen, Deniz Tanrikut, Medya Tekes, Gokcem Yigit

We consider the operations of a high-volume emergency department where the waiting times are above the acceptable levels for a significant proportion of the patients. We describe the system by using a simulation model and utilize this model evaluate the impact of various improvement opportunities such as using different policies about the patient flow (e.g., triage method, patient prioritization, patient streaming) and resource allocation (e.g., allocation of staff to shifts and patient groups).

47 - Thresholding Link Weights in Complex Networks as a Percolation Process

Farnaz Zamani Esfahlani, PHD Candidate, State University of New York-Binghamton, 33 Schiller Street, Apt 3N, Binghamton, NY, 13905, United States, fzamani1@binghamton.edu, Hiroki Sayama

Thresholding link weights is a common technique to reduce the complexity and computational time of analyzing complex networks. However, the majority of thresholding techniques alter the properties of weighted networks and therefore influence the results of the analysis. Here we propose a percolation-based thresholding method which can preserve the macro/microscopic properties of the weighted networks more effectively.

48 - A Brain Computer Interface Approach to Examine Changes in Motion Patterns While Walking in a Virtually Infinite World

Rachneet Kaur, Student, University of Illinois at Urbana Champaign, TB 21, Department of Industrial and Enterprise Systems Engineering, 104 S.Mathews Ave, Urbana, IL, 61801, United States, rk4@illinois.edu, Richard Sowers, Ma nuel Hernandez, Daan Michiels

This research focuses on creating virtual reality components of a test bed for understanding responses to visual stimuli and their relation to movement disorders such as Parkinson's disease. With electroencephalography (EEG) as brain-computer interface (BCI), we measure neurological responses of a person walking through a virtual world that elicits nervousness, compute their real time neural state and adapt the virtual world accordingly to diminish fall related anxiety. The objective is to synthesize a self-monitoring and regulated personalized VR environment based on the user's uneasiness that allows to decrease anxiety levels in balance demanding walking conditions.

49 - Modeling Lane Changing Behavior Based on Snowdrift Coordination Game

Saeed Reza Ramezanpour Nargesi, UTA, 500 S Senter St, Apt 117, Arlington, TX, 76010, United States, saeedreza.ramezanpournargesi@mavs.uta.edu

In this research, we are going to model lane changing behavior, using game theoretical approach, to take the interdependency of drivers' decision making into microscopic traffic analysis. The model will include mandatory and discretionary lane changing behaviors in a snowdrift type of coordination game with two players (Target and Lag vehicles), complete information and static setting. Target vehicle aims to gain speed while trying to avoid collision. Lag vehicle tries to maintain its current speed subject to safety constraint.

50 - Machine Learning for Safer Roads

Haridut Athi Shyam Sundar, University of Illinois at Urbana-Champaign, 405 E Stoughton, Apt 20, Champaign, IL, 61820, United States, haridut2@illinois.edu

This research primarily focuses on finding interesting and hugely informative patterns in fatal road accidents. Further, it explores how machine learning can be applied to predict fatalities on the roads given the circumstances of a collision. Our work draws inspiration from Los Angeles' and New York's 'Vision Zero' initiative which aims to achieve zero road fatalities by 2025. Though our initial research is based out of these two city's public data, our larger objective is to build robust machine learning models that could generalize well to most of the cities.

51 - Sustainable Electricity Markets

Mohammad Rasouli, Sustainable Electricity Markets, University of Michigan, 2829 Catalpa Circle, Apt 12, Ann Arbor, MI, 48108, United States, rasouli@umich.edu, Mohammad Rasouli

Electricity policy target in majority of the countries is to achieve sustainable and reliable electricity with efficient prices for uncertain future demand.. We provide a model of the industry with the policy targets propose market-based implementations of the electricity policy targets.

52 - Decoding Nonlinear Brain Dynamics from Human EEG

Miaolin Fan, Northeastern University, 360 Huntington Avenue, Boston, MA, 02115, United States, fan.mi@husky.neu.edu, Chun-An Chou

Decoding EEG activity through pattern recognition helps understand human conscious, perceptions and experiences. However, EEG is a highly complex system driven by nonlinear dynamics. In our study, we characterized the human EEG dynamics based on chaos theory and spectral graph theory. Experiment 1 presents a seizure detection study where graph theoretic method is combined with Recurrence Plots for detecting abnormal state transients using epileptic EEG recordings. In Experiment 2 an emotion recognition task was performed, and we applied RP-based feature extraction method to classify patterns form different emotional states. In conclusion, our method achieved a good accuracy and low latency.

53 - Efficient Algorithms for Some Graph Inverse Problems

Jonathan Celaya, Rice University, 6360 S.Main Street, Houston, TX, 77005, United States, jsc7@rice.edu

Solving the inverse of a weighted graph problem P entails finding the least modification of weights so that X becomes an optimal solution for P. We present polynomial time algorithms for the inverses of the maximum clique and minimum vertex cover problems on bipartite graphs, and also for the former on block graphs. Both under the 1 and infinity norms.

54 - Understanding Consumers' Impulse Buying Behavior in Social Commerce Platforms

Samira Farivar, PhD Candidate, DeGroote School of Business, DSB A211, DeGroote School of Business, McMaster University, 1280 main street west, Hamilton, ON, l8s 4m4, Canada, farivas@mcmaster.ca, Yufei Yuan

Social commerce has identified as a new online commerce platform which enhances users' information contribution and interaction. Thus, social aspects are the main focus of these environments. Nonetheless, the role of social facets in influencing social commerce users' behaviors is not yet fully understood. In this study, we are interested in examining social aspects that exist in the social commerce and their influence on users' buying behavior. Drawing from Latent State-Trait theory, we build our model which suggests that users' personality traits, environmental cues (social factors), and interactions between these two elements drive users to buy impulsively.

55 - Doubling Supply Chain Profits the Theory of Constraints Way: A Case Study

Harshal Lowalekar, Associate Professor, Indian Institute of Management-Indore, Prabandh Shikhar, Rau-Pithampur Road, Indore, 453331, India, lwlherschelle@gmail.com

We describe the implementation of Theory of Constraints (TOC) at a large consumer durables company in India. Using TOC's thinking process the constraints that limited company's performance in production and distribution were identified and eliminated. TOC's unique approach helped in drastic reduction of inventories in the supply chain. Shortage and excess of SKUs in distribution almost vanished. Lead times for make-to-order (MTO) items decreased by 75% while the availability of make-to-stock (MTS) items increased to 100%. ROI for the distributors and retailers on the company's products more than tripled while the profits of the company doubled during the Great Recession of 2008 due to TOC.

56 - Space Efficient Layouts for Block Stacking Warehouses

Shahab Derhami, Postdoctoral Fellow, Georgia Institute of Technology, 755 Ferst Drive, NW, Atlanta, GA, 30332, United States, shahab.derhami@isye.gatech.edu

In block stacking warehouses, pallets of stock keeping units are stacked on top of one another on the warehouse floor. The arrangement of lanes in the layout of this storage system affects utilization of the storage volume. Existing research that studies space utilization exclusively attempts to find the optimal lane depth and does not address the design of a space-efficient layout. We describe a model for block stacking warehouses that chooses a set of bay depths and arranges them in a layout to minimize wasted space. We use simulation to evaluate performance of the proposed model through an experimental analysis that covers small to industrial-sized warehouses.

■ Tuesday Poster Competition

Exhibit Hall

Tuesday Poster Competition

Competition Poster Session

Chair: Sergiy Butenko, Texas A&M University, 4037 Emerging Technologies Building, Mail Stop 3131, College Station, TX, 77843-3131, United States, butenko@tamu.edu

Co-Chair: Jeffrey W Herrmann, University of Maryland-College Park, Department of Mechanical Engineering, College Park, MD, 20742, United States, jwh2@umd.edu

1 - A Sequential Game of Defense and Attack on Interdependent Systems

Fei He, Texas A&M.University-Kingsville, MSC 191, 700 University Blvd, 700 University Blvd, Kingsville, TX, 78363, United States, fei.he@tamuk.edu, Chiamaka J. Agwuegbo

This research studies the defense strategy of an interdependent system in the face of rational attacks. We propose a sequential game between an attacker and a defender on an interdependent system of systems (SoS) to explore the effect of interdependency on the optimal defense strategy. An algorithm of backward induction is developed to determine the equilibrium path of the game. The attacker is the first mover as he applies an attack strategy on constituent systems that maximize his utility. The defender observes and responds by an optimal defense strategy which maximizes her utility. The utility is evaluated as the difference between a player's reward and the cost of the action. The sensitivity analysis is carried out to compare the effects of different parameters on the attacker and defender's strategies such as the effectiveness of defense, the effectiveness of attack, the unit cost of defense and the unit cost of attack on constituent systems.

2 - Using Drones to Minimize Delivery Time in Disaster Relief Operations

Mohammad Moshref-Javadi, Purdue University, 315 N Grant St., Room 324E, Purdue University, West Lafayette, IN, 47907, United States, moshref@purdue.edu, Lee Seokcheon

Drone is an emerging technology which can be used for distribution of products and services. To benefit from advantagesof drones and deal with their limitations, we design a combined system of drones and trucks in which trucks carry bothsupplies and drones and stop at some points in their routes to launch the drones to deliver supplies. The goal is to minimizethe waiting time of the recipients by deciding about the number of drones, launch locations, victims visited by drones, andsequence of visits. The results of the worst-case analysis and case study in Virginia show that this approach can lead tomore than 58% faster delivery.

3 - Ultra-high Precision Predictive Assembly of Composite Fuselage Joins via Surrogate Model Based Control

Xiaowei Yue, Georgia Institute of Technology, 755 Ferst Drive NW, ISYE, Atlanta, GA, 30332, United States, xwy@gatech.edu, Yuchen Wen

Ultra-high precision predictive assembly is vital for large-scale aircraft production. Passive manual adjustment in current practice is low efficient, non-optimal and experience-dependent. We propose an automated optimal shape control system that can adjust composite parts to an optimal configuration efficiently. The objective is accomplished by (i) building and validating a finite element platform; (ii) developing a surrogate model considering various uncertainties to achieve predictive performance; (iii) conducting feed-forward control to determine the optimal actions. We show the system can significantly reduce assembly time and dramatically improve dimensional quality.

4 - Ranking Alternatives with Partial Information Based on Flexible Interactive Tradeoff

Eduarda Frej, Universidade Federal de Pernambuco, Recife, Brazil, eafrej@gmail.com, Adiel de Almeida

A new approach for ranking alternatives in multicriteria decision making based on the Flexible and Interactive Tradeoff is presented. FITradeoff is a partial information method for elicitation of criteria weights in additive models. The decision aiding is conducted through a structured elicitation process based on tradeoffs, in which the Decision Maker interactively compares consequences by providing strict preference statements, in such a way that less cognitive effort is spent in the decision making process. An application of a supplier selection problem in a food industry is presented in order to show how this method can be applied to solve real-world cases.

5 - Learning in Discrete Optimization

Elias B.Khalil, PhD Student, Georgia Tech, North Avenue, Atlanta, GA, 30332, United States, lyes@gatech.edu

The branch-and-bound algorithm for solving Mixed Integer Programs (MIP) involves decisions that are currently addressed heuristically. Instead, we propose to use machine learning (ML) to make better-informed, input-specific decisions in MIP branch-and-bound. For branching and primal heuristic selection, our ML approaches significantly improve solver performance on heterogeneous MIPLIB instances and certain homogeneous families of instances. For some classical combinatorial problems, we propose a deep graph embedding framework for learning powerful greedy heuristics, and show that the learned heuristics are competitive with existing heuristics for VertexCover, MaxCut and TSP.

6 - An Investigation on Aggregate Production Planning with Flexible Requirement Profiles (FRP) with Stochastic Uncertainty

Setareh Torabzadeh, The University of North Carolina-Charlotte, 9101 Olmsted Dr Apt6, Charlotte, NC, 28262, United States, storabza@uncc.edu, Ertunga C. Ozelkan

This paper investigates production planning problem, using a flexible approach, called: Flexible Requirement Profile, enforcing flexible bounds on production levels in different periods to improve the stability of the production plans. Due to uncertainty of data in the future periods, stochastic programming approach is utilized. We investigate how stochastic FRP aggregate production planning compares with the deterministic FRP aggregate production planning and deterministic and stochastic aggregate production planning. For this aim, we develop chance constraint FRP aggregate production planning model. Results show the FRP models result in better stability and comparable costs.

7 - A Multi-objective Maintenance Strategy through Component Reassignment

Jiangbin Zhao, Northwestern Polytechnical University, 554 Mail Box, No.127 Youyi Western Road, Xi'an, 710072, China, zhaojiangbin@mail.nwpu.edu.cn, Shubin Si, Zhiqiang Cai

System reliability can be improved by corrective maintenance or pro-active replacement, which could be expensive or uneconomical. Reassigning components is a better method to improve the system reliability for linear-consecutive-k-out-of-n systems. We investigate a multi-objective maintenance strategy by seeking the reassignment with the lowest maintenance cost and highest system reliability. A multi-objective optimization model is formulated. A genetic algorithm based on the maintenance cost and system reliability is developed to search for the Pareto solution. The effectiveness is further compared with the popular non-dominated sorting genetic algorithm.

8 - Condition Monitoring of Vessel's Main Engine: A Case Study

Young-Mok Bae, M.S.Candidate, Pohang University of Science and Technology, Nam-gu Chungam-ro 77, Engineering bld 4, Pohang, 37673, Korea, Republic of, ymbae@postech.ac.kr, Min Jun Kim, Kwang-Jae Kim, Chi-Hyuck Jun, Sang-Su Byeon, Kae-Myoung Park

Condition monitoring of a vessel's main engine is a crucial aspect of maintenance since main engine failures may lead to major accident. Recently the advancement of Information and Communications Technologies(ICT) has allowed massive amounts of vessel's condition related data to be collected. The data used in this study comes from a main engine in an actual vessel, collected from recent operations. This study reviews various variables related to the condition of the main engine, and detects abnormalities and their trend. This study is expected to provide a basis for preventive maintenance and proactive management of vessel's main engines.

9 - Minimizing Levelized Cost of Onsite Generation: Towards a Zero Energy Supply Chain

An Pham, Texas State University, San Marcos, TX, 78666, United States, a_p276@txstate.edu, Tongdan Jin, Clara Novoa, Cecilia Temponi

We formulate a linear optimization model to investigate whether it is feasible to operate a net-zero carbon supply chain via 100 percent of onsite wind and solar generation. The study aims to allocate renewable technology, placement and capacity in a three-tier supply chain network with the goal of minimizing the levelized energy cost. The zero-carbon supply chain model is tested on a network comprised of 20 factories, 2 distribution centers, and 30 retail stores under various wind and weather conditions. We also compare the cost effectiveness of onsite generation assuming net metering and variable feed-in-tariff policies, and interesting managerial insights are derived accordingly.

10 - Modeling and Analysis of Sustainable Supply Chain Dynamics

Gang Wang, University of Massachusetts Dartmouth, 285 Old Westport Rd, Room 214, North Dartmouth, MA, 02747, United States, gwang1@umassd.edu, Angappa A.Gunasekaran

This paper studies the dynamic behavior of the interaction between sustainable supply chains and the environment. A mathematical model based on the nonlinear dynamic system is presented to describe the dynamics of the impact of supply chains on the environment while achieving sustainable supply chains. To better understand the dynamic mechanism of this proposed system, performance analysis is conducted with respect to three parameters: (a) design production capacity; (b) environmental cost; and (c) demand rate. Analytical results validate the dynamic interaction of supply chains with the environment and justify the environmental and economic significance of supply chain sustainability.

11 - Budgeting Dredging Projects to Improve Resilience of the Inland Waterway Network

Khatereh Ahadi, PhD Candidate, University of Arkansas, 4207 Bell Engineering Center, Fayetteville, AR, 72701, United States, kahadi@uark.edu

We consider the problem of selecting a budget-limited subset of maintenance actions to maximize the expected tonnage of commodities that can be transported through the inland waterway system. Uncertainty in our model is the budget required at each district for emergency dredging arises from unpredictable conditions. Thus, our main decision is allocating budget to each district to cover the cost of emergency dredging. Then, with the remaining budget routine jobs can be completed. We model this problem as a stochastic programming model, develop solution approaches, and analyze computational results.

12 - Robust Synthetic Control

Muhammad J. Amjad, Massachusetts Institute of Technology, 235 Albany Street, Suite 3121A, Cambridge, MA, 02139, United States, mamjad@mit.edu, Devavrat Shah, Dennis Shen

We present a robust generalization of synthetic control that features a distinguishing data de-noising process via singular value thresholding. Consequently, our method is robust in multiple facets: it automatically identifies a good subset of donors, functions without extraneous covariates (vital to existing methods), and handles missing data (never been addressed). To our knowledge, we provide the first theoretical finite sample analysis for a more general model than previously considered in literature, and show our estimator is asymptotically consistent. We also introduce a Bayesian framework that allows practitioners to quantitatively measure the uncertainty of their estimates.

13 - Sustainable Electricity Markets for Restructured Electricity Industry

Mohammad Rasouli, University of Michigan, 404 Wildwood Avenue, Apt 1, Ann Arbor, MI, 48104, United States, rasouli@umich.edu

We consider emerging electricity technological changes and design electricity markets that are reliable, sustainable and price efficient. We start by modeling an oligopoly of electricity generation companies which interact over the electricity network for a long horizon and have uncertainties with respect to the future. Then we propose efficient capacity, carbon permit, transmission right, and electricity spot markets.

14 - Smart Hospitals: Application and Evaluation of 'Internet of Healthcare Things (IoHT)' in a Hospital Unit

Michael W. Carter, University of Toronto, 5 King's College Road, Toronto, ON, M5S.3G8, Canada, carter@mie.utoronto.ca, Tahera Yesmin

Internet of healthcare things (IoHT) has become an emerging technology which can substantially change the mode of care delivery and therefore improve the care provided. Many researchers have exhibited the working methodology and application of IoHT in various aspects of patient care. However, very few researches have evaluated the outcomes. This research demonstrates the effects of IoHT in one of the hospitals of Ontario, Canada. With the help of various tools of data mining, statistics and industrial engineering this study measures the impact of IoHT. Thus findings of the research indicate the effectiveness of the intervention and hence hold the potential for decision making in care improvement.

Decision Analysis in Public Policy

Sponsored: Decision Analysis

Sponsored Session

Chair: Jonathan Welburn, RAND Corporation, 4570 Fifth Ave #600, Pittsburgh, PA, 15213, United States, jwelburn@rand.org

1 - Allocating Resources to Account for Multiple Levels of Uncertainty

Lei Yao, Iowa State University, Ames, IA, 50011, United States, lyao@iastate.edu, Cameron MacKenzie

Mathematical models to help public policy decision makers often have a great amount of uncertainty. This uncertainty includes uncertainty about parameters, models, decision maker risk attitudes, and even functional forms in the models. Policy makers may also be skeptical about solely relying on model recommendations with only optimal solutions. A solution to this uncertainty and decision makers' skepticism is to find intervals as model outputs rather than a single optimal solution. This presentation will identify intervals for resource allocation models in which every objective function value evaluated by the interval differs from the minimum objective function value by a predetermined gap.

2 - Supporting Policy Decisions through Text Analytics

Seifu John Chonde, Associate Operations Researcher, RAND Corporation, 1200 South Hayes Street, Arlington, VA, 22202, United States, schonde@rand.org, Timothy Stacey, William Marcellino, Ryan Brown

RAND will discuss lessons learned in the development and application of multilingual text analysis tools to support policy decision makers. In recent work, we created a suite of data storage, natural language processing, and presentation tools. These tools are used across a range of tasks including lexical analysis, stance analysis, topic modeling, text classification, and advanced text clustering. The talk will focus on our latest developments in advanced text clustering. By walking through examples we will illustrate how text clustering is useful in public policy and highlight open research questions for the decision analysis community.

3 - Multinational Direct Investment and Political Uncertainty

Omar Sherif Elwakil, Massachusetts Institute of Technology, 1 Amherst Rd., Cambridge, MA, 02139, United States, oelwakil@mit.edu

Recent developments in the general equilibrium theory of multinationals emphasize the importance of multilateral considerations. Yet, existing explanations and corresponding estimations of FDI patterns have largely limited political and institutional investment impediments to a bilateral framework. Through the application of spatial econometric techniques, I show that the presence of both domestic and regional political uncertainty generate real options effects that lead to the delay or redirection of FDI. The magnitude and direction of these effects is conditional upon the host country regime type and the predominant multinational integration strategies in the region.

4 - Perceptions of Income Tax Evasion and Tax Moral: A Survey to Inform an Agent-based Model

Raffaele Vardavas, RAND Corporation, Santa Monica, CA, United States, rvardava@rand.org

We built an agent-based computational simulation model of income tax evasion. Within the simulation, individuals' compliance behavior changes through an adaptation process based on their past experiences with audits and tax evasion penalties, their perception of the fairness in taxation rates and social interactions with people in their social networks. To inform the model we have conducted a survey on a nationally representative sample on the perceptions of tax fairness. We present how our model was informed by our survey and show some initial model results.

Probability Judgments

Sponsored: Decision Analysis

Sponsored Session

Chair: Asa Palley, Indiana University, Bloomington, IN, 47405, United States, apalley@gmail.com

1 - One-Shot Forecast Aggregation under a Mixture of Measurement Error and Information Diversity

Ville Satopaa, INSEAD, Paris, France, ville.satopaa@insead.edu

In this work, we develop methodology for the "one-shot" prediction environment, where each forecaster predicts a single outcome. Our aggregator arises from a mixture model of measurement error and information diversity, and is therefore, to the best of our knowledge, the first method that addresses both sources of variation simultaneously. Estimation relies on Bayesian statistics, leading to a posterior distribution of the consensus aggregate. Our methodology is illustrated on real-world and synthetic forecasting data.

2 - Quantifying Uncertainty using the Mean and Variance of a Collection of Point Estimates

Asa Palley, Indiana University, 1275 E 10th St, Bloomington, IN, 47405, United States, apalley@gmail.com

The wisdom of crowds—combining information from a collection of individual judgments—offers a useful method for quantifying an unknown variable. Averaging point estimates has proven to be effective in reducing error in the consensus estimate. Often, however, the decision maker requires an assessment of the full distribution. Using a Bayesian model of information, I show that the mean and variance of a variable of interest can be estimated as a function of the mean and variance of a collection of individual judgments, and derive the crowd consensus distribution. This provides a procedure that is easy to implement to estimate a predictive distribution from a collection of point estimates.

3 - A General Method for Addressing Forecasting Uncertainty in Inventory Models

Dennis Prak, University of Groningen, Nettelbosje 2, Groningen, 9747 AE, Netherlands, d.r.j.prak@rug.nl, Ruud Teunter

We derive a framework for addressing the estimation uncertainty, applicable to any inventory model and demand distribution. The (random) estimation errors are modeled and substituted into the inventory model, and the expectation of the objective function is taken with respect to the errors. When estimates are based on 10 observations, relative savings are typically between 10% and 30%. They are larger when estimates are based on fewer observations, when backorders are costlier, and when the lead time is larger. The method applies to any field where forecasts are used in optimization models.

4 - Estimation Error in Portfolio Optimization: Extra Constraints or More Diversification?

Luis Chavez-Bedoya, Universidad Esan, Nestor Bermudez 191, Chorrillos, Lima, LIMA 9, Peru, l.chavezbedoya@northwestern.edu

We study the relationship between extra constraints and diversification when reducing estimation risk in portfolio optimization. By adding a set of linear constraints to the original mean-variance portfolio problem, we prove that the portfolio with the minimum loss caused by parameter uncertainty consists on the combination of two sample portfolio with minimum risk and another one with zero exposure to a set of factors. Also, we claim that the best set of constraints corresponds to statements regarding the sample tangent portfolio. Finally, we give an explanation of the portfolio weights of Kan and Zhou (2007) and the portfolio rule of MacKinlay and Pástor (2000).

Location Models for Emergency Service Applications

Invited: Tutorial

Invited Session

1 - Location Models for Emergency Service Applications

Vladimir Marianov, Pontificia Universidad Catolica de Chile, Department of Electrical Engineering, Vicuna Mackenna 4860, Santiago, 782-0436, Chile, marianov@ing.puc.cl

The term "emergency services" commonly refers to medical, firefighting or police services, although emergency repair can also be included in this category. All these services can be found in both public and private sectors. The design of police services requires mainly districting, dispatching, routing, and scheduling of police beats. Medical and firefighting services, on the other hand, mainly involve locating infrastructure and finding an initial or "idle" site where vehicles wait for an emergency to occur. Thus, the design of medical and firefighting systems benefit the most from the use of location models, and we concentrate in these two types of services. We do not perform a thorough review of the literature related to the application of location models to these services. Rather, we follow some of the successive model innovations that have addressed the main issues and added increasing degrees of reality to the modeling, with a didactic goal. We thus apologize to colleagues who have made significant contributions not included in this chapter.

Energy & Uncertainty: Optimization & Control

Sponsored: Applied Probability

Sponsored Session

Chair: Adam Wierman, California Institute of Technology, Pasadena, CA, 91125, United States, adamw@caltech.edu

1 - Distributed Optimization Decomposition for Joint Economic Dispatch and Frequency Regulation

Enrique Mallada, Johns Hopkins University, Baltimore, MD, 21201, United States, mallada@jhu.edu

This work studies the joint problem of co-optimizing economic dispatch and frequency regulation resources in power systems. We provide sufficient conditions under which the joint problem can be decomposed without loss of optimality into slow and fast timescale problems. These problems have appealing interpretations as the economic dispatch and frequency regulation problems respectively. Moreover, the fast timescale problem can be implemented using distributed load and/or generation control. We apply this optimal decomposition to propose an efficient market mechanism for economic dispatch that coordinates with frequency regulation.

2 - Opportunities for Price Manipulation by Aggregators in Electricity Markets

Navid Azizan Ruhi, California Institute of Technology, 1200 E. California Blvd., MC 305-16, Pasadena, CA, 91125, United States, nazizanr@caltech.edu, Krishnamurthy Dvijotham, Niangjun Chen, Adam Wierman

Aggregators are playing an increasingly crucial role in the integration of renewable energy in power systems. However, the intermittent nature of renewables makes market interactions difficult to monitor and regulate, raising concerns about potential market manipulation by aggregators. We study this issue by quantifying the profit an aggregator can obtain through strategic curtailment of generation. We show that, while the problem of maximizing the benefit from curtailment is hard in general, efficient algorithms exist when the topology of the network is acyclic. Further, we highlight that significant increases in profit are possible via strategic curtailment in practical settings.

3 - Cascading Failures in Power Grids: A Large Deviations Approach

Alessandro Zocca, Caltech, Pasadena, CA, United States, zocca.ale@gmail.com, Tommaso Nesti, Bert Zwart

Power grids are increasingly affected by uncertainty due to the intermittent nature of renewable generation. In this talk I will present a stochastic model of power grids under uncertainty, aiming to get insight in the interplay between renewable energy sources and grid reliability. Using the DC approximation and large deviation techniques, we investigate line overload probabilities in a small-noise regime and identify the most likely way for overloads to occur. We also investigate how such overloads and failures lead to cascades. In particular, such cascading failures do not propagate in a nearest neighbor fashion, unlike epidemic models, and we illustrate this analytically in our model.

4 - Interaction Between Retail and Wholesale Electricity Markets: Modeling and Stability Analysis

Thiagrajan Ramachandran, Pacific Northwest National Laboratory, Richland, WA, 99354, United States, thiagarajan.ramachandran@pnnl.gov, Krishnamurthy Dvijotham, Karanjit Kalsi

As power systems cope with increasing amounts of renewable generation, there is an increasing need to engage flexible demand-side resources into power systems operations. Retail markets can facilitate this by providing a platform to aggregate demand-side flexibility and bid the aggregate flexibility into wholesale markets. However, flexible loads have physical dynamics that couples their capacity over time which could have unintended and undesirable consequences. We develop a simple model to capture evolution of load flexibility over time and analyze stability of the market dynamics under this model. We prove that oscillations cannot occur and prices converge to a equilibrium levels quickly.

Information Markets and Learning

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Ali Makhdoumi, Massachusetts Institute of Technology, 77 Massachusetts Ave. , 32D-640, Cambridge, MA, 02139, United States, makhdoum@mit.edu

Co-Chair: Kimon Drakopoulos, Massachusetts Institute of Technology, Los Angeles, CA, 90066, United States, kimondr@mit.edu

1 - Information Revelation and Consumer Privacy

Alessandro Bonatti, MIT, Cambridge, MA, United States, bonatti@mit.edu, Rossella Argenziano, Gonzalo Cisternas

We develop a dynamic model in which a forward-looking consumer interacts with heterogeneous sellers. In each period, the consumer makes both a purchase decision that is imperfectly observed by future firms. We characterize the amount of information the consumer's equilibrium actions reveal about her true preferences. Because consumers are wary of revealing information through purchases, sellers lower their prices to stimulate demand. These results have implications for privacy regulation that restricts the flows of information.

2 - Learning from Reviews

Ali Makhdoumi, Massachusetts Institute of Technology, 77 Massachusetts Ave. , 32D-640, Cambridge, MA, 02139, United States, makhdoum@mit.edu

Many online platforms present summaries of reviews by previous users. Even though such reviews could be useful, previous users leaving reviews are typically a selected sample of those who have purchased the good in question, and may consequently have a biased assessment. We construct a model of dynamic Bayesian learning and profit-maximizing behavior of online platforms to investigate whether such review systems can successfully aggregate past information and the incentives of the online platform to choose the relevant features of the review system.

3 - Origins and Control of Misinformation

Gad Allon, gadallon@wharton.upenn.edu, Kimon Drakopoulos, Vahideh Manshadi

During the last several years we have witnessed a dramatic change in the way information is being distributed to citizens and consumers: From a market controlled by several key players we moved to a highly fragmented market with many players. The paper is motivated by the the observation that while on the one hand, we see more of these independent news organizations, we also see an increased level of polarization even when it come to agreeing about facts. In order to study this phenomenon, we aim to study the role social networks, and these independent news organization play in discovering and transmitting the real "truth" when the information is discovered sequentially.

4 - Small-loss Online Learning with Partial Information

Thodoris Lykouris, Cornell University, 107 Hoy Rd, Ithaca, NY, United States, teddlyk@cs.cornell.edu, Karthik Sridharan, Eva Tardos

In many applications (online advertising, internet routing, clinical decisions), decisions are based on past experience. Online learning algorithms trade off exploiting knowledge about options chosen in the past and exploring new options to gain useful information for the future. In this talk, we focus on two challenges. First, we discuss the effect of side-information: learners collecting information about options relevant to the ones selected. Second, we consider evolving settings, in which players learn in repeated games where some parameters (e.g. set of opponents) change over time. We provide a black-box framework to make full information learning algorithms robust in both settings.

Food Supply Chain Analytics

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Retsef Levi, MIT, Cambridge, MA, 02142, United States, retsef@mit.edu

1 - Network Based Risk Analytics in Global Food Supply Chains

Tauhid R. Zaman, Massachusetts Institute of Technology, MA, United States, zlisto@mit.edu, Amine Anoun, Retsef Levi

We develop a network-based approach to identify high-risk food importing consignees. We illustrate the power of the approach by applying it to consignees of shrimp, a product subject to high food safety and adulteration risks. Using detailed shipment data, as well as F.D.A. site inspection and shipment sampling records, we construct a set of novel network features which predict the risk of individual shrimp consignees failing site inspection. We find that increased supply chain network complexity correlates with increased risk. Our results suggest that network-based risk analytics could significantly improve the effectiveness of regulatory activities related to food supply chains.

2 - Novel Methods for Identifying Shell Companies

Nicholas J. Renegar, Massachusetts Institute of Technology, Cambridge, MA, United States, renegar@mit.edu

Motivated by transshipping networks in the import/export industry, we explored novel methods of identifying shell companies. Using website information and business databases we were able to create an automated method of predicting shell companies. This information will be useful in identifying illegal shipping activity, among many widespread applications.

3 - Inferring the Causes Behind Fresh Food Spending

Elisabeth Paulson, Massachusetts Institute of Technology, Cambridge, MA, United States, epaulson@mit.edu

A growing number of strategies are being proposed and tested to increase consumption of healthy food in poor or underserved neighborhoods. While there is agreement that the food environment is linked to diet and health outcomes, there is surprisingly little agreement about the factors that cause this relationship, due in part to the observational and sparse nature of most data. Thus, arguments in favor of various strategies for increasing healthy food consumption are typically based on tenuous observed relationships. In this paper we analyze the impact of access to grocery stores and value of nutrition on fresh food spending among SNAP households using the Food Acquisition and Purchase Survey (FoodAPS) dataset. Using the methodology of causal inference, we are able to quantify and compare the causal effects of both access and value. We find that the effects of both are significant among certain populations, but that they impact household's decisions differently. Finally, we discuss which strategies for increasing fresh food spending are promising among various populations.

MSOM Sustainable Operations

Sponsored: Manufacturing & Service Oper Mgmt, Sustainable Operations

Sponsored Session

Chair: Isil Alev, Boston College, Chestnut Hill, MA, 02467, United States, alev@bc.edu

1 - Extended Producer Responsibility in Developing Economies – Design Incentives and Infrastructural Development

Luyi Gui, The Paul Merage School of Business, UC Irvine, University of California, Irvine, Irvine, CA, 92697-3125, United States, luyig@uci.edu

Producers' investment and effort in building recycling infrastructure can be observed in practice especially in developing countries where such infrastructure is missing. Motivated by these examples, this paper studies the cost efficiency and environmental impact such as producers' eco-design incentives when infrastructure investment decisions are endogenized.

2 - An Analysis of Time-based Pricing in Electricity Supply Chains

Asligul Serasu Duran, Kellogg School of Management, 825 W Cornelia Avenue, Apt GDN, Chicago, IL, 60657, United States, a-duran@kellogg.northwestern.edu, Baris Ata, Ozge Islegen

This study builds a framework for the retail electricity market to empirically evaluate the impact of time-based tariffs on the electricity supply chain. We find that optimal time-based tariffs reduce peak demand, but do not change consumers' total demand or electricity bills significantly. Time-of-use tariffs with predetermined rates can capture most of the benefits of real-time prices. The environmental impact of time-based tariffs depends on the characteristics of the electricity market under study.

3 - Fair Labor Practices and Increasing Returns to Scale

Susan A. Slotnick, Cleveland State University, OSM Department, BU 542, Cleveland, OH, 44115, United States, s.slotnick@csuohio.edu, Matthew J.Sobel

This paper investigates the tradeoffs involved in a firm's efforts to ensure that its products are manufactured using fair labor practices. We use a Markov decision process model of a firm that sources from one supplier and decides whether to cut its profit margins and/or expend resources to ensure fair labor practices at the supplier. Retail demand is influenced by reputation: if unfair labor practices come to light, reputation deteriorates, hence demand and profit diminish. Analytical and computational methods yield insights into the firm's profit maximizing behavior, including the result that the firm experiences increasing returns to scale as a function of its reputation.

4 - On Recycling of Post-Disaster Debris

Andriy Shapoval, Georgia Tech, 1449 Willow Lake Dr NE, Apt B, Atlanta, GA, 30329, United States, ashapoval3gt@gmail.com, Pinar Keskinocak, Beril Toktay

This work studies emerging recycling policies regarding post-disaster debris management. We develop a game-theoretic model of sequential decision makers utilizing debris removal funding, including state and local government and recyclers, and analyze the total welfare of policies incentivizing recycling. We determine conditions for effective policies under conflicting stakeholder preferences.

Data Analytics in Healthcare

Sponsored: Health Applications

Sponsored Session

Chair: Mahboubeh Madadi, Louisiana Tech University, Ruston, LA, 71272, United States, madadi@latech.edu

1 - Bi-level Heterogeneous Degradation Modeling of Functional Performance for the Aging Population

Nazmus Sakib, INFORMS.chapter at University of South Florida, 2319 Campus Lake CT, Apt 204, Tampa, FL, 33612, United States, nsakib@mail.usf.edu, Xuxue Sun, Nan Kong, Hongdao Meng, Mingyang Li

Quantifying heterogeneity among the elderly with functional performance degradation is crucial for effective long-term care planning and delivery. Existing studies mainly model degradation heterogeneity at either sub-population or individual level. This work proposes a bi-level heterogeneity modeling and quantification framework. At sub-population level, a Bayesian non-parametric model is proposed to relax the assumption of pre-specifying the number of sub-populations and realize the joint model estimation and selection. At individual level, functional data analysis tools are considered to extract temporal degradation signatures with risk/protective factors identified.

2 - Identifying Smoking Status from User-generated Content in an Online Community for Smoking Cessation

Xi Wang, University of Iowa, 810 W Benton St B213, Iowa City, IA, 52246, United States, xi-wang-1@uiowa.edu, Kang Zhao

Online communities for smoking cessation are increasingly popular sources of information and support for smokers who want to quit. The ability to automatically find smoking status from user-generated content in such an online community can help to provide better interventions. This study developed a machine-learning-based approach to identify individuals' abstinence from their posts. Augmenting the traditional bag-of-words model, our approach leveraged three new types of features: context-specific features, author-based features, and thread-based features. The evaluation outcomes show that the three types of new features all contribute to the better classification performance.

3 - Detecting Patient-specific Abnormal Synchronization Pattern of Epileptic Seizures

Miaolin Fan, Northeastern University, Boston, MA, United States, fan.mi@husky.neu.edu, Chun-An Chou

In this study, we propose an efficient approach to detecting abnormal synchronization phenomena of epileptic seizures in a multivariate EEG system. The proposed method aims at characterizing the nonlinear dynamics of spatio-temporal EEG recordings using recurrence network and spectral graph theory. We present the computational results for CHB-MIT Scale EEG Epilepsy Database in various experimental settings, which validate the efficiency of detecting seizure onsets, as well as robustness to the noisy EEG data.

4 - Inpatient Discharge-by-Noon: Are Fewer Better Than All?

Pratik Parikh, PhD, Wright State University, Dayton, OH, United States, pratik.parikh@wright.edu, Nicholas Ballester

Discharge before noon has rapidly emerged as an unspoken golden standard in hospitals nationwide. While research has indicated a strong link between earlier inpatient discharges and better patient outcomes, especially upstream patient boarding, quantitative analysis of the expected benefits of discharging all patients before noon is lacking. Building upon our previous work, we explore the expected benefits of discharging fewer or all medically-ready patients by noon. Our findings suggest the law of diminishing returns applies; benefits decrease with an increase in the number of such patients.

Decision-making in Healthcare

Sponsored: Health Applications

Sponsored Session

Chair: Vishal Ahuja, Southern Methodist University, Dallas, TX, 75275, United States, vahuja@smu.edu

1 - Inferring Doctor Decisions: Post-stent Patient Streaming using Personalized Medicine

Kellas Ross Cameron, Boston University, 62 Bay State Road, Apt. #1, Boston, MA, 02215, United States, kellas@bu.edu, Nitin Joglekar, Nachiketa Sahoo, Jugnu Jain

We develop a structural econometric model to analyze doctors' choice of medication after cardiac stent surgery. The estimated model shows the role of patient's medical, as well as economic conditions in their choice. The model can be used to improve personalized medication processes by streaming those who will benefit the most from a new genomic test-based treatment instead of assigning them to a conventional trial and error process.

2 - Investigating Steroid with drawal Strategies for Kidney Transplant Recipients

Yann Ferrand, Clemson University, Department of Management, 101 Sirrine Hall, Clemson University, Clemson, SC, 29634, United States, yferran@clemson.edu, Christina M.Kelton, Vibha Desai, Teresa M. Cavanaugh, Jaime Caro, Jens Goeble, Pamela C. Heaton

We study long-term complications associated with various steroid withdrawal strategies for kidney transplant recipients. We develop a model calibrated with an econometric study of patient data from a national registry to simulate the long-term course of these patients, and derive patient outcomes based on the characteristics of patient population. We focus part of the investigation on the effect of induction therapy.

3 - Designing Liver Allocation System using Neighborhoods

Sanjay Mehrotra, Northwestern University, Dept of I.E./ M.S.C246 Tech Inst, 2145 Sheridan Road, Evanston, IL, 60208-3119, United States, mehrotra@iems.northwestern.edu

We present approaches used to design a liver allocation system to address geographic disparity in liver transplantation. This design is being considered for public comments. We will also discuss the complexity of national public policy change that is model driven.

4 - An Analytics-driven Approach for Optimal Diabetes Screening Decisions

Michael Hahsler, Southern Methodist University, Bobby B. Lyle School of Engineering, P.O. Box 750123, Dallas, TX, 75275, United States, mhahsler@lyle.smu.edu, Vishal Ahuja, Farzad Kamalzadeh, Michael Bowen

About 10% of the US adult population have diabetes and almost 40% are at risk of developing diabetes. Screening can be used to identify these individuals. Population-based screening is an expensive task and thus prioritizing whom to screen and how often to screen becomes of interest from a decision-making point of view. We develop a Markov Decision Process (MDP) to model disease progression and find the optimal screening policy. For parameter estimation, we suggest the use of Hidden Markov Models. To produce individualized screening recommendations we incorporate predictive diabetes risk modeling. We will present results for electronic health record data from the Parkland Health & Hospital System.

Optimization in Radiation Therapy

Sponsored: Health Applications

Sponsored Session

Chair: David Papp, North Carolina State University, Raleigh, NC, 27695, United States, dpapp@ncsu.edu

1 - DVH-driven Direct Machine Parameter Optimization for Adaptive IMRT and VMAT Radiation Therapy Treatment Planning

Troy Long, University of Texas Southwestern Medical Center, Dallas, TX, United States, troy.long@utsouthwestern.edu, Steve Jiang, Joshua T. Margolis, Weiguo Lu

In conventional fractionated radiation therapy, an overall treatment plan is developed with pre-treatment imaging and then delivered over a number of treatment fractions. However, patient geometry changes between treatment fractions, and physicians often will adapt the existing treatment plan to the new geometry. We study automatically generating adapted IMRT and VMAT plans that (1) attempt to reproduce the original plan's dose-volume histogram (DVH) characteristics and (2) keep the updated machine parameters close to the original plan.

2 - Automated IMRT Treatment Planning using Hierarchical Constrained Optimization

Masoud Zarepisheh, Memorial Sloan Kettering Cancer Center, New York, NY, United States, zarepism@mskcc.org, Linda Hong, James G. Mechalakos, Margie A. Hunt, Gig S. Mageras, Joseph O. Deasy

This study formulates IMRT treatment planning as a hierarchical constrained optimization (HCO) problem (also known as prioritized optimization). HCO prioritizes the clinical goals and optimizes them in ordered steps. We introduce a novel idea to speed up the optimization process by sparsifying the influence matrix and then solving an extra unconstrained optimization problem to compensate for the inaccuracy caused by sparsity. The commercial treatment planning system API is used to automate the entire workflow and our package is currently being used in clinical environment to automate the treatment planning process.

3 - Generating High-quality DMPO Seeds for Single- and Multiple-arc Treatment Plans using a Conformal Arc/VMAT Hybrid Planning Model

Joshua T. Margolis, Clemson University, 277 Freeman Hall, Clemson University, Clemson, SC, 29634, United States, jtmargo@clemson.edu, Scott J. Mason, Weiguo Lu, Steve Jiang, Troy Long

In radiation therapy, conformal arc therapy uses a coplanar moving gantry to continuously deliver radiation to cancerous tissue and has little difficulty in passing post-planning quality assurance. However, plan quality suffers when specific organ-at-risk sparing does not explicitly influence aperture shapes, such as in the more-involved volumetric modulated arc therapy (VMAT). We study a conformal arc/VMAT hybrid planning model use dose volume histogram-driven direct machine parameter optimization (DMPO) to find a locally optimal solution for a given set of apertures. We study how to generate high-quality DMPO seeds for single- and multiple-arc treatment plans.

4 - Optimization of Nonuniformly Fractionated Radiotherapy Treatments with Bounds on the Achievable Benefit

David Papp, North Carolina State University, 3222 SAS.Hall, Campus Box 8205, Raleigh, NC, 27606, United States, dpapp@ncsu.edu, Melissa R. Gaddy, Jan Unkelbach, Sercan Yildiz

Radiotherapy treatments are fractionated, meaning that the radiation dose is delivered over several days rather than in a single session. In current clinical practice, the same dose is delivered on each treatment day. We formulate an optimization model to assess the achievable benefit of altering the dose from day to day. The model is large-scale and nonconvex. Using clinical cases, we show that even locally optimal nonuniform treatments yield a substantial improvement over conventional ones. SDP relaxation bounds show that the computed locally optimal treatments are nearly globally optimal.

Disaster and Emergency Management

Contributed Session

Chair: Damitha Bandara, Albany State University, Albany, GA, United States, damitha.bandara@asurams.edu

1 - Distributionally Robust Optimization of an Emergency Medical Service Station Location Problem

Kanglin Liu, PHD Candidate, Tsinghua University, Tsinghua University, 30 Shuangqing Road, Beijing, 100084, China, lkl15@mails.tsinghua.edu.cn, Zhihai Zhang

Locations and capacities in the emergency medical service (EMS) system are key issues of humanitarian logistics. This paper proposes a distributionally robust model to optimize the location, number of ambulances and demand assignment in an EMS system by minimizing the expected total cost. The model guarantees a high probability of satisfying demand in the entire geographical area by introducing joint chance constraints, and identifies the total expected cost by a data-driven approach. The model is approximated as a tractable second-order cone problem and efficiently solved by an Outer Approximation approach. Extensive numerical results and a real case of Beijing show the validly of the program.

2 - Continuous Location Model for Mobile Fire Fighting Resources
Pablo Escalona, Universidad Técnica Federico Santa María, Av Espana 1680, Valparaíso, 2390123, Chile, pablo.escalona@usm.cl, Monica Lopez-Campos, Mario Navarrete

The Valparaiso region (Chile) has suffered more than 16,000 fires between 1998 and 2015, including a year surpassing 1,300 fires (CONAF, 2015). For its special topographic characteristics, air resources have a high degree of significance. A modified version of the "Queuing Location Problems on the Plane" model (Drezner et al., 1990) has been selected to determine the optimal location of airbases, in an attempt to minimize the amount of burned hectares by wildfires. The computational study determines: the optimum location of the base, which parameters have greater influence in the optimum location, and which parameters have greater influence in the computational times.

3 - A Resource Allocation Model for Large Scale Bio-security Events
Lauren Gardner, Senior Lecturer, University of New South Wales, Kensington Campus, Building H20, Sydney, 2052, Australia, l.gardner@unsw.edu.au, David Rey

Real-time strategies for control are required to minimize the spread of newly emerging infectious diseases at a national and international level. Currently, there is a gap in the literature for optimization-based decision control models that account for the heterogeneous nature of the air travel patterns and infectious disease spreading dynamics. In this work a bi-level optimization model is proposed where the objective is to minimize the risk of a contagion spreading via the air traffic network, where the decision is the allocation of control resources to airports during an on-going event.

4 - Modelling Ambulance Dispatch Systems During Extreme Weather Events
Eric B. DuBois, University of Wisconsin-Madison, Industrial & Systems Engineering, 1513 University Avenue, Madison, WI, 53706, United States, edubois2@wisc.edu, Laura Albert

A moderate, but prolonged increase in patient arrivals, as often occurs during severe weather events, can overwhelm emergency responders and lead to patient queuing and patient health deterioration. To examine this issue we develop a Markov decision process to determine a policy for withholding ambulances from less serious patients in the expectation of more emergent future calls. We further develop heuristics, which capture most of the benefit of the optimal policy while allowing for easier implementation by dispatchers. The results are illustrated with computational examples.

5 - Optimizing Healthcare Facility Locations to Intervene a Fast Spreading Epidemic
Gonca Yildirim, Asst. Prof., Cankaya University, Eskisehir Yolu 29 km Yukariyurtcu Mah., Mimar Sinan Cad. No 4, Ankara, 06790, Turkey, goncayildirim@cankaya.edu.tr, Ayyuce Aydemir-Karadag

Emerging and re-emerging epidemic diseases such as Ebola continue to threaten the global health security. During an outbreak, timely case management is crucial to interrupt chains of transmission and prevent further spread of the infection. The most effective intervention policies are to remove infected individuals from the population by quarantine and provide treatment in healthcare facilities. We consider a fast-spreading epidemic with a short incubation period and take into account forecast models developed for the progression of the outbreak in an environment with scarce resources in an integer programming model to determine locations of healthcare facilities dynamically over time.

6 - Location and Allocation of EMS Vehicles in Dougherty County, Albany, GA
Damitha Bandara, Assistant Professor, Albany State University, 504 College Drive, Albany, GA, 31705, United States, damitha.bandara@asurams.edu

Dougherty County EMS is an advanced life support ambulance service that provides quality pre-hospital medical care and transportation to the citizens of Dougherty County. The contribution of this research towards improving the efficiency of the Dougherty County EMS system is twofold. One is to determine the optimal locations for EMS system stations and the other is to determine the response territory for each EMS vehicle. A mathematical model will be developed to obtain the optimal locations and response boundaries of EMS system in Dougherty County. Computational results will be used to compare the performance of the proposed EMS system as opposed to the existing system.

Learning, Information, and Games

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Kostas Bimpikis, Stanford University, 655 Knight Way, Stanford, CA, 94305, United States, kostasb@stanford.edu

1 - Learning in Repeated Auctions with Budgets: Regret Minimization and Equilibrium
Yonatan Gur, Stanford University, Knight Management Center, 655 Knight Way, Stanford, CA, 94305, United States, ygur@stanford.edu, Santiago Balseiro

We study how budget-constrained advertisers may compete in sequential auctions for available ad slots in the presence of uncertainty about future opportunities and competitors' heterogeneous preferences, budgets, and strategies. We introduce a family of dynamic bidding strategies we refer to as adaptive pacing strategies, in which advertisers adjust their bids throughout the campaign according to the sample path of expenditures. Under arbitrary competitors' bids, we establish through matching lower and upper bounds the asymptotic optimality of this class of strategies. Moreover, we characterize a regime under which these strategies approximate Nash equilibrium in dynamic strategies.

2 - Optimal Learning from Multiple Information Sources
Xiaosheng Mu, Harvard University, Cambridge, MA, United States, xiaoshengmu@fas.harvard.edu, Annie Liang, Vasilis Syrgkanis

Consider a decision-maker who sequentially acquires Gaussian signals from heterogeneous sources for a future decision. Which sources should he choose to observe in each period? In environments that we characterize, it turns out that the dynamically optimal path of signal acquisitions: (1) exactly coincides at every period with the myopic path of signal acquisitions, and (2) achieves "total optimality," so that at every late period, the decision-maker will not want to revise his previous signal acquisitions even if given this opportunity. We show that generically, these properties hold at all sufficiently late times, so that the dynamically optimal path and myopic path are eventually equivalent.

3 - Learning and Efficiency in Games with Dynamic Population
Thodoris Lykouris, Cornell University, 107 Hoy Rd, Ithaca, NY, United States, teddlyk@cs.cornell.edu, Vasilis Syrgkanis, Eva Tardos

We study multi-player game settings (online advertising, internet routing, and bandwidth allocation) where the player set is dynamically evolving over time and participants apply online learning algorithms to adapt to the changing environment. Traditional equilibrium notions require too much information for the players (since they need to form perfect beliefs about the identity and the behavior of other participants) to extend to dynamic settings. In contrast, we show that, in a broad class of games, learning agents that can adapt to the changing environment reach outcomes of high social welfare even when there is a high turnover in the population, extending traditional price of anarchy bounds.

4 - Information Aggregation in Heterogenous Markets
Yaarit Even, Columbia University, 25 Claremont Ave #1c, New York, NY, 10027, United States, yeven18@gsb.columbia.edu, Alireza Tahbaz-Salehi, Xavier Vives

This paper argues that the presence of heterogeneity in traders' trading costs/risk aversion can reduce price informativeness and result in an informational externality. We show that in the presence of heterogeneity, the information content of the price is biased towards the private signals of agents with lower trading costs, thus reducing the informativeness of the price. More importantly, we show that such heterogeneity results in an informational externality with first-order welfare implications.

Role of Transparency and Incentives in Managing Services and Supply Chains

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Damian Beil, University of Michigan, Ann Arbor, MI, 48109-1234, United States, dbeil@umich.edu

1 - Lifting the Veil: the Benefits of Cost Transparency

Ryan Buell, Harvard Business School, Morgan Hall 429, Boston, MA, 02163, United States, rbuell@hbs.edu, Bhavya Mohan, Leslie John

Firms typically treat their costs as tightly-guarded secrets. We test the effect of cost transparency on purchases. We begin with a natural field experiment conducted with an online retailer, in which cost transparency increased sales. We subsequently replicate this field experiment in a controlled lab setting and differentiate cost transparency from other forms of transparency, show that the effect is mediated by consumers' trust in the firm, and demonstrate that cost transparency only boosts purchase interest when it is voluntarily instated by the firm. These results imply that the proactive revelation of costs can improve a firm's bottom line.

2 - Risk Drivers for Economically Motivated Food Adulteration in China's Farming Supply Chains

Yanchong Zheng, Massachusetts Institute of Technology, Cambridge, MA, United States, yanchong@mit.edu, Yasheng Huang, Retsef Levi, Stacy Springs, Shujing Wang

We employ Heckman's sample selection framework to empirically investigate whether and how structural properties of China's farming supply chains (across five industries) and the strength of governance (measured based on factual as opposed to perception data) within the regions in which the supply chains operate jointly influence the risks of economically motivated adulteration (EMA) of food. Our results highlight that both supply chain dispersion and weak local governance are associated with higher EMA risks. Our insights could help food manufacturers, importers, and regulators to proactively and systematically identify, prevent, and mitigate EMA risks.

3 - Performance Based Contracts for Energy Efficiency Projects

Sam Aflaki, Associate Professor of Operations Management, HEC Paris, 1 Rue De La Liberation, Jouy en Josas, 78351, France, aflaki@hec.fr, Liang Ding, Roman Kapuscinski

Energy efficiency projects are often executed by specialised entities, namely energy service companies (ESCOs). A typical ESCO's core business is conducted using performance-based contracts, whereby payment terms depend on the energy savings achieved. This paper studies ESCO contract design issues, focusing primarily on the residential market for energy efficiency. We study the coordination potential of multiple piecewise linear contracts including shared savings contracts, guaranteed savings contracts and 'chauffage' contracts that are used in practice. We show that although coordinating contracts do not exist, simple practical contracts work reasonably well.

4 - Using Transparency to Manage the Sourcing of Complex Non-routine Litigation Services

Jacob Chestnut, University of Michigan, Ann Arbor, MI, United States, jacobpc@umich.edu, Damian Beil

Complex services, such as non-routine litigation (approximately $50 billion in 2015), are often billed on an hourly basis. This arrangement creates opportunities for the supplier (i.e. outside counsel) to drive up costs for the buyer (i.e. general counsel) through the inefficient use of time and resources. A critical hurdle preventing better management and oversight by the buyer is the lack of transparency regarding the work to be done by the supplier. In this paper, we investigate how to achieve this transparency, and what the benefits are of doing so. In particular, we study a buyer who creates a "process map" of litigation, which then serves as the basis for transparency with the supplier.

Sponsored Session

Chair: Opher Baron, University of Toronto, Toronto, ON, M5S 1L7, Canada, opher.baron@rotman.utoronto.ca

1 - Dynamic Scheduling of Home Care Patients to Medical Providers

Andre Augusto Cire, University of Toronto Scarborough, Department of Management, UTSC, 1265 Military Trail, Toronto, ON, M1C-1A4, Canada, acire@utsc.utoronto.ca, Adam Diamant

Home care aims at providing personalized medical care and social support to patients within their own home. Since 2014, it has been the fastest-growing US industry attending to more than 14 million patients per year. In this work, we propose a dynamic scheduling framework to assist in the assignment of patients to practitioners. Our technique formulates the assignment problem as a discrete-time Markov decision process, which is tackled by a policy improvement heuristic that builds upon the agencies existing assignment strategies. We show numerical results assessing the quality of our policies with data from a Canadian home care provider.

2 - How do Perception and Self Interests of Patients Affect Emergency Department Crowding in Hospitals

Shrutivandana Sharma, Singapore University of Technology and Design, 8 Somapah Road, Singapore, 487372, Singapore, shrutivandana@sutd.edu.sg, Ying Xu, Manu Kumar Gupta

We investigate the crowding problem in hospitals' emergency departments (EDs) from the perspective of demand management. We propose a novel congestion game model that provides the first systematic methodology to simultaneously analyze the effects of ED resource allocation as well as patients' perception and self-interests when they can choose between ED and primary care. We perform extensive numerical experiments to study the impact of perception errors and patients' self-interests on ED demand and resulting crowding, and compare them with optimum social welfare maximizing patient flows.

3 - M/M/C Queues with Two Priority Classes and Abandonment

Jiamfu Wang, Nanyang Technological University, Singapore, Singapore, wangjf@ntu.edu.sg, Tianshu Lu, Opher Baron

In this paper, we consider a system with two priority classes and abandonment. The high-priority customers are infinitely impatient, while the low-priority customers are finitely impatient. This system is modeled as a two-dimensional Markov chain. We show the difficulty in solving this model and propose a new method in finding its steady state distribution. Such a system has many applications in practice, including machine breakdown, network service, call centers, and healthcare. Some management insights are shown for the above applications. The method we develop can be applied to other multi-dimensional Markov chains. We briefly discuss the generalizability of our method.

4 - Effect of Emergency Room Priority Rules on TPIA and LOS

Tianshu Lu, Rotman School of Management, University of Toronto, 105 St George St, Toronto, ON, M5S.3E6, Canada, Tianshu.Lu15@Rotman.Utoronto.Ca, Dmitry Krass, Opher Baron

Excessive waiting in emergency departments, particularly before the initial physician assessment (known as TPIA) can lead to tragic outcomes. One hospital in Ontario has achieved large decreases in TPIA by re-configuring the system and changing the priority rules between new and in-process patients. However, these changes increase variability of waiting time and may increase the average Length of Stay (LOS). Using the empirical data, we estimate the ratio of changes in TIPA and LOS. Our results show that the relative increase in LOS is negligible compared to the decrease in TPIA.

1 - Pass Programs and Loyalty Programs for Transit Agencies

Mehdi Nourinejad, Postdoctoral Fellow, University of Toronto, St. George, Toronto, ON, L4B4G6, Canada, mehdi.nourinejad@mail.utoronto.ca, Amir Gandomi, Joseph Y.J. Chow, Matthew Roorda

The proliferation of smart cards in public transportation has paved the way for successful implementation of two prominent discount policies: pass programs and loyalty programs. While pass programs have been around as early as the 1970s, loyalty programs are only becoming popular. In a loyalty program, riders get a discount on their fare if they complete a given number of trips within a time period. In this paper, we derive the optimal pass and loyalty program, and we investigate if one is superior. The pass program is superior for public transit agencies because it offers a higher social welfare, but the loyalty program is better for private agencies because it generates a higher profit.

2 - Optimal Bus Type and Number of Bus Stops in Public Transportation under Random Demand and Sustainability Adoption Levels with in the Community

Elif Elcin Gunay, Iowa State University, Ames, IA, United States, eekabeloglu@gmail.com, Kijung Park, Gul Kremer

This study develops a stochastic optimization model for deciding both the bus size and the number of bus stops to minimize the public transportation cost under randomness of demand and sustainability adoption levels in a community. In addition to transportation costs, we consider social costs, i.e. waiting and riding time of passengers in the model. We model social cost as a factor of the sustainability adoption levels. The number of bus stops and the bus sizes are adapted subject to the fluctuation in demand for different bus lines. In the numerical study, we consider different levels of demand and sustainability adoption levels and conduct a trade-off analysis between decreasing cost and social costs.

3 - A Heuristic Algorithm for Improving the Quality of Service in Paratransit by Considering Schedule Reliability

Chung-Wei Shen, Assistant Professor, National Cheng Kung University, Tainan, Taiwan, cwshen@mail.ncku.edu.tw

With the increasing aging and disabled population and the trend toward on-demand transportation, more and more people are relying on door-to-door shared transportation services. Few studies have been conducted on the quality of service for operating dial-a-ride (DAR) services for elderly/disabled passengers. In this paper, we consider a fundamental feature determining the quality of service of DAR services: the reliability of the trip schedule. An algorithm integrating the measure of schedule reliability will be developed such that it is efficient enough to solve large-sized problems. The objective of this paper is to better understand the tradeoffs between reliability and operational costs.

4 - Designing Lines and Frequencies for Public Transportation using Benders Decomposition

Mor Kaspi, Postdoctoral Researcher, Ecole Polytechnique Federale de Lausanne (EPFL), EPFL-ENAC-INTER-LUTS, Room GC C2 389, Lausanne, CH-1015, Switzerland, mor.kaspi@epfl.ch, Martin Repoux, Nikolas Geroliminis

We formulate an integrated line selection, vehicle assignment and passenger assignment problem for public transportation as an MILP. The quality of service is represented by the total journey time of passengers, composed of riding times and waiting times at origin and transfer stations. The resulting formulation is of high dimensionality. In order to solve large instances, we develop a Benders decomposition approach in which solutions of the sub-problems are obtained in linear time. The effectiveness of our approach is demonstrated using instances derived from a real-world application.

Game Theory

Contributed Session

Chair: Ulas Ozen, Ozyegin University, Istanbul, Turkey, ulas.ozen@ozyegin.edu.tr

1 - A Principal-agent Problem with Heterogeneous Demand Distributions

Wenbo (Selina) Cai, New Jersey Institute of Tech, Mec 308, University Heights, Newark, NJ, 07102, United States, cai@njit.edu, Dashi Singham

Mechanism design problems optimize contract from a principal to agents who have private information about their demands for a product or a service. We study the implications of uncertainty in agents' demands on the principal's contracts. Specifically, we consider the setting where agents' demands follow heterogeneous distributions and the principal offers a menu of contracts stipulating quantities and transfer payments for each demand distribution. We present analytical solutions for the special case of two distributions and a method for deriving analytical solutions from numerical solutions. We show that the optimal solution depends on the ordering of the demand levels across distributions.

2 - Responsible Supplier Selection

Wenqing Zhang, University of Minnesota Duluth, 1318 Kirby Drive, Labovitz School of Business and Economics, Duluth, MN, 55812, United States, zhangwenqing@gmail.com, Jiujiu Shen, Huaping Gong

This paper studies the pricing and sourcing choices in a two-echelon supply chain selling a procure-to-stock product to a price-sensitive and social welfare conscious market. We assume that the manufacturer can decide between two different sourcing options, i.e., insourcing and outsourcing, without friction costs. We illustrate the significance of the social image in a company's sourcing decision. Our results explain, from a managerial point of view, whether or why, if applicable, low manpower cost countries are losing their competitive advantages.

3 - On the Core of M-attribute Cooperative Games

Ulas Ozen, Associate Professor, Ozyegin University, Cekmekoy Campus, Nisantepe District, Orman Street, Istanbul, 34794, Turkey, ulas.ozen@ozyegin.edu.tr, Marco Slikker

We study cooperation between several parties by pooling their m-types of resources to improve overall system performance, i.e., maximize total profit or minimize total costs. This type of cooperation leads to "m-attribute" games whose characteristic function is embedded in an m-dimensional function. We derive the necessary and sufficient conditions on the latter function such that all embedded games have a non-empty core. We also study other important properties of m-attribute games, e.g., convexity.

Sponsored Session

Chair: Pengyi Shi, Purdue University, West Lafayette, IN, 47907, United States, shi178@purdue.edu

Co-Chair: Nan Liu, Columbia University, New York, NY, 10032, United States, nl2320@columbia.edu

1 - Design and Analysis of Integrated Practice Units

Douglas Morrice, University of Texas at Austin, Irom Department, 2110 Speedway Stop B6500, Austin, TX, 78712-1750, United States, douglas.morrice@mccombs.utexas.edu, Jonathan F. Bard, Karl Koenig

An important strategy for delivering high-value, patient-centered care is for providers to organize into dedicated teams around a patient's condition and provide a full cycle of care in an Integrated Practice Unit (IPU). We discuss the use of simulation and optimization to design and analyze IPUs. We illustrate our work with a Joint Pain IPU example.

2 - Scheduling in Operating Theatres with an Entropic Index
Jin Qi, Hong Kong University of Science and Technology, Room 5559C, Department of Industrial, Engineering and Logistics Management, Hong Kong, Hong Kong, jinqi@ust.hk, Han Ye

In this talk, we propose a simple index to study the scheduling problem in the Operating Theatres (OT). We first use empirical data to explore the features of the scheduling issue in OT. Specifically, many surgeries can start earlier than the scheduled time. Then we formulate the scheduling problem such that the waiting time for each surgery and overtime should meet the service requirement. We propose an index named Entropic Deviation to capture both the variance and skewness of the uncertain surgery time. By simply ranking the Entropic Deviation for each type of surgery, we can make the sequencing decisions and achieve relatively good performance.

3 - Off-placing Patients in Hospital Wards: the Value of Flexibility in Healthcare
Vahid Sarhangian, Univeristy of Toronto, Toronto, ON, Canada, sarhangian@mie.utoronto.ca, Carri Chan, Yuan Zhong

When congestion is high, a common practice used in many hospitals is the off-placement of admitted emergency department (ED) patients to a non-primary inpatient ward (IW). We evaluate and compare the performance of practical flexible designs for routing patients from the ED to IW. We consider a multiclass queueing system with multiple server pools (wards) and allow the customers to be served by servers from a non-primary pool (determined through the flexible design) with a reduced service rate to capture the effect of off-placement.

4 - Inpatient Overflow: An Approximate Dynamic Programming Approach
Pengyi Shi, Purdue University, 403 W. State St, Krannert School of Management, Kran 472, West Lafayette, IN, 47907, United States, shi178@purdue.edu, Jim Dai

Inpatient beds are usually grouped into several wards, with each dedicated to a "primary" medical specialty. However, when a patient waits too long to get a primary bed, hospital managers may assign her to a non-primary bed though it is undesirable. Deciding when to use such "overflow" practice in real time can be challenging. We develop an approximate dynamic programming (ADP) algorithm to aid the decision making. A key step is to choose appropriate basis functions, for which we use a novel combination of fluid control and single-pool approximation. We demonstrate, via experiments in realistic hospital settings, that our ADP algorithm is remarkably effective in finding good overflow policies.

Sponsored Session

Chair: Joline Uichanco, University of Michigan, Ross School of Business, Ann Arbor, MI, 48109-1234, United States, jolineu@umich.edu

1 - The Role of Consumer Return Policies in Omnichannel Operations
Leela Aarthy Nageswaran, Carnegie Mellon University, 308 GSIA, Tepper School of Business, 5000 Forbes Avenue, Pittsburgh, PA, 15213, United States, lnageswa@andrew.cmu.edu, Soo-Haeng Cho, Alan Scheller-Wolf

We study the pricing and return policy decisions of an omnichannel retailer serving customers who differ in how they realize their valuation for the product — by inspecting in-store before purchase or by purchasing online and possibly returning misfit products. When the salvage value for returned products is low, we find that the firm may prefer full refunds to no refunds, in contrast to prior research showing that full refunds are never preferred at low salvage values in an online-only market. Furthermore, the optimal refund is often larger than the salvage value, which could explain generous refunds seen in practice.

2 - Optimizing SKU Selection for Promotional Display Space at Grocery Retailers
Olga Perdikaki, University of South Carolina, Darla Moore School of Business, 1014 Greene Street, Columbia, SC, 29208, United States, Olga.Perdikaki@moore.sc.edu, Olga Pak, Mark Ferguson, Su-Ming Wu

Promotional displays are a powerful tool to boost consumer engagement. We propose a multi-step methodology to identify a profit-maximizing selection of products for promotional display using grocery store sales transaction data. Our methodology results in a 5% to 23% improvement in profit when compared to an industry benchmark.

3 - Optimizing E-commerce Order Sourcing: A Big Data Analytics and Total Margin Optimization Solution
Ali Koc, IBM.Research, IBM.Research, Yorktown Heights, NY, 10598, United States, akoc@us.ibm.com, Ajay Deshpande, Brian Quanz

As online demand is growing rapidly, retailers are increasingly using their ship from store network with thousands of diverse nodes for online order fulfillment with conflicting business objectives. To overcome these challenges, we have developed a cloud-based solution for order fulfillment utilizing predictive analytics and multi-objective optimization to determine optimal total-margin fulfillment decisions. In this talk, we will present some key aspects of this solution and results.

4 - The Two-Phase Newsvendor Problem with Optimally-Timed Additional Replenishment
Yale Herer, Israel Institute of Technology, Haifa, 32000, Israel, yale@technion.ac.il, Dina Smirnov, Assaf Avrahami

We utilize in-cycle demand information, available from modern information systems, to optimize a newsvendor system with an option of an additional inventory review (AR) and replenishment at an endogenously determined, a priori set time during the period. We jointly optimize the AR timing and order quantities at each ordering opportunity.

1 - Total Cost Effects of the Interaction of Capacity, Periodic Release and Transportation for a Repair Shop
Henny van Ooijen, Dr., Eindhoven University of Technology, P.O. Box 513, Eindhoven, 5600MB, Netherlands, h.p.g.v.ooijen@tue.nl

A repair shop serves industrial customers that operate a commoditized capital good. The shop provides for availability of the capital good. Upon failure of a good, a substitute good, rented from a third party, is installed, and a logistics service provider is informed for transporting good. After arrival at the repair shop the failed good is repaired and returned to the customer; then the rent of the substitute good ends. We are interested under what condition periodic order release at the repair shop leads to cost benefits.

2 - Lean Six Sigma Techniques and a Practise in the Food Company
Harun Karakoç, Industrial Engineer, Erciyes University, Erciyes Teknopark Tekno-3 Binası No: 28, Kayseri, Turkey, harunkarakoc@gmail.com

Keeping the customer satisfaction in a high level and surviving with enough benefit level is getting harder to have at the same time with each passing day. Trading enterprises must minimize their costs while maintaining their certain quality level for completing this task. In this study, firstly Six Sigma and Lean terms have been examined and then integration of lean to six sigma studies has been examined and mentioned. In final part, non-quality reasons in a food company have been eliminated using Six Sigma techniques and optimum production rates have been designated via mathematical model created in Lean logic have been mentioned.

3 - Using Multi-variate Regression and Simulation to Identify a General Formula for Throughput of Flow Manufacturing Lines with Similar Stations
Xiaojun (Gene) Shan, University of Houston-Clear Lake, Houston, TX, 77058, United States, shan@uhcl.edu, Samrawi Berhanu

Accurately estimating throughput of a manufacturing line is important for planning. This paper use simulation and multivariate regression to estimate a generic equation to determine the throughput. Minitab was used to create random data that follow normal distributions: Station Speed, Mean time between failure, Mean time to repair, buffer capacity and line length. One thousand different random manufacturing lines were developed and modeled using PlantSim. The outputs were then used to run a multi-variate regression analysis to find an equation that best fits the data. A regression equation with R2 equal 92% was found. The station speed has the largest impact on throughput.

4 - Outsourcing Maintenance in the Presence of Cyber Threats
Anh Ta, University of North Texas, Denton, TX, 76201, United States, Anh.Ta@unt.edu, Hakan Tarakci, Shailesh S. Kulkarni

Outsourcing minimal repair and preventive maintenance is very important to any system. This study develops a model to maximize the profit of a manufacturer who utilizes an external contractor to maintain its manufacturing system. Later, we extend the study to a system with the existence of cyber threats.

Service Queues

Sponsored: Applied Probability

Sponsored Session

Chair: Rouba Ibrahim, University College London, University College London, London, WC1E 6BT, United Kingdom, rouba.ibrahim@ucl.ac.uk

1 - Choice Models, Queueing Theory, and Delayed Information
Jamol Pender, Cornell University, Ithaca, NY, United States, jjp274@cornell.edu

Many service systems provide queue length information to customers thereby allowing customers to choose among many options of service. However, queue length information is often delayed and is often not provided in real time. Recent work by Dong et al. explores the impact of these delays in an empirical study in U.S. hospitals. In this talk, we prove an appropriately scaled queueing model with customer choice and constant delays converges to a delay differential equation. We analyze these delay differential equations and derive the exact threshold that determines whether the queues have asynchronous dynamics.

2 - Maximizing Ridership in Bicycle Sharing Systems using Empirical Data and Stochastic Models
Pradeep Kumar Pendem, University of North Carolina, Chapel Hill, 110 Mistywood Cir, Apt S, Chapel Hill, NC, 27514, United States, pradeep.pendem@gmail.com, Vinayak V. Deshpande

We analyze the optimal allocation of bikes in a network of stations to improve ridership and service level under non-stationarity demand and station substitution. Our stochastic demand model captures both bike pickups and drop-offs, as well as demand non-stationarity and substitution under stockout. We utilize large datasets on trips, real time inventory information at stations, distances between stations in combination with the model to estimate demand parameters. The optimal allocation of bikes across stations to maximize ridership is determined using a dynamic program. The optimal policy informed by our model could improve ridership and service level by 7.60% and 1.69% to current policy.

3 - Managing Customer Expectations and Priorities in Service Systems
Gad Allon, The Wharton School, Philadelphia, PA, United States, gadallon@wharton.upenn.edu, Qiuping Yu, Achal Bassamboo

We study how to use delay announcements to manage customer expectations while allowing the firm to prioritize among heterogeneous customers. When the firm has information about the state of the system, yet lacks information on customer types, delay announcements play a dual role: they inform customers about the state of the system, while they also have the potential to elicit information on customer types based on their response to the announcements. The tension between these two goals has implications to the type of information that can be shared credibly.

4 - Announcing Delays when the Present Depends on the Future
Rouba Ibrahim, University College London, MS& I.department, UCL, Gower Street, London, WC1E 6BT, United Kingdom, rouba.ibrahim@ucl.ac.uk, Achal Bassamboo

We investigate the accuracy of announcing the waiting time of the Last customer to Enter Service (LES) in a queueing model with multiple customer classes and a priority service discipline. We present ways of exploiting this historical information to design new and improved announcements and supplement our theoretical results with an empirical study.

Chair: Linwei Xin, University of Illinois at Urbana-Champaign, Urbana, IL, 61801, United States, lxin@illinois.edu

1 - Using Multi-stage Stochastic Programs for Inventory Position Coordination in Assemble-to-order Inventory Systems
Qiong Wang, University of Illinois at Urbana-Champaign, Urbana-Champaign, IL, United States, qwang04@illinois.edu, Marty Reiman, Haohua Wan

To manage Assemble-to-Order (ATO) inventory systems efficiently, the inventory positions of components should be aligned with the availability of other components with longer lead times. Independent base stock policies do not feature such a coordination mechanism and existing schemes with proven optimality are only for single-product systems. We have formulated a multi-stage Stochastic Program (SP) and shown its optimal solutions coordinate inventory positions for minimizing inventory cost in multi-product ATO systems with a general Bill of Materials. We will discuss properties of SP solutions that allow their implementation in dynamic ATO systems.

2 - Learning Algorithms in Inventory and Pricing Models
Cong Shi, University of Michigan, 2257 Woodhaven Court, Ann Arbor, MI, 48105, United States, shicong@gmail.com, Xiuli Chao, Boxiao Chen, Huanan Zhang

In recent years, online retailing firms have been experimenting and implementing innovative dynamic pricing strategies and inventory policies to better match demand with supply. In many cases, the decision maker may not know the demand distributional information of a given product a priori, and can only rely on sales data. We propose nonparametric learning algorithms for several fundamental inventory and pricing models with unknown demand functions under censored demand information. We show that the proposed algorithms converge to the clairvoyant optimal policies as the planning horizon increases, and obtain the convergence rate of regret.

3 - Dynamic Pricing and Inventory Control with Large Replenishment Lead Times
Linwei Xin, University of Chicago, 5807 S Woodlawn Avenue, Chicago, IL, 60637, United States, Linwei.Xin@chicagobooth.edu, Xin Chen, Yuanling Gan

We consider a joint pricing and inventory control problem with positive replenishment lead times. Although this problem has been extensively studied in the literature, the structure of the optimal policy remains poorly understood. In this work, we propose a class of so-called constant-order list-price policies. We prove that the best constant-order list-price policy is indeed asymptotically optimal as the lead time grows large, which is exactly the setting in which the problem becomes computationally intractable due to the curse of dimensionality. We also show that the best constant-order list-price policy can be computed effectively.

Wind Power

Sponsored: Energy, Natural Res & the Environment Environment & Sustainability

Sponsored Session

Chair: Amelia Musselman, Georgia Institute of Technology, Atlanta, GA, 30318, United States, amusselman@gatech.edu

1 - Integrated Predictive Analytics & Optimization for Opportunistic Maintenance and Operations in Wind Farms
Murat Yildirim, Georgia Institute of Technology, 765 Ferst Drive NW, # 415, Atlanta, GA, 30332, United States, murat@gatech.edu, Nagi Gebraeel, Andy Sun

We propose an integrated framework for wind farm maintenance that combines i) predictive analytics methodology that uses real-time sensor data to predict future degradation and remaining lifetime of wind turbines, with ii) a novel optimization model that transforms these predictions into profit-optimal maintenance and operational decisions for wind farms. To date, most applications of predictive analytics focus on single turbine systems. In contrast, this presentation provides a seamless integration of the predictive analytics with decision making for a fleet of wind turbines scattered across multiple wind farm locations.

2 - Considerations for Modeling the Integration of Wind Power in the Electric Power Sector
Kelly Eurek, National Renewable Energy Laboratory, Golden, CO, United States, Kelly.Eurek@nrel.gov

Because wind power is a rapidly growing component of the electricity system, robust representations of wind technologies should be included in capacity-expansion models. This is a challenge because modeling the electricity system—and, in particular, modeling wind integration within that system—is a complex endeavor. This presentation highlights the major challenges of incorporating wind technologies into capacity-expansion models and shows examples of how NREL's Regional Energy Deployment System (ReEDS) model address those challenges.

3 - Optimizing Wind Farm Siting to Reduce Variability Impacts of Wind Power

Amelia Musselman, Georgia Institute of Technology, 1040 Huff Road NW, Apt 1218, Atlanta, GA, 30318, United States, amusselman@gatech.edu, Valerie Thomas, Dima Nazzal

We present a multi-objective optimization model to strategically locate wind farms to reduce wind power variability. In order to model the impact of wind variability without explicitly modeling the full electricity system we develop a metric, which we call demand deficit, to measure the load that the remainder of the system would need to account for under wind fluctuations. By selecting which sites to construct from a set of potential wind farm locations our model minimizes both demand deficit and the maximum change in demand deficit over a given period. We solve our model for a case study of the Southwest Power Pool and develop an efficient frontier to compare the trade-offs between the two objectives.

Information Systems

Contributed Session

Chair: Ozay Ozaydin, Dogus University, Istanbul, Turkey, ozay.ozaydin@gmail.com

1 - Budget Management in International Humanitarian Organizations

Milad Keshvari Fard, ESSEC Business School, 3 Avenue Bernard Hirsch, Cergy, 95021, France, milad.keshvarifard@essec.edu, Felix Papier

Humanitarian Organizations (HO) have to allocate their limited budget to countries and missions at the beginning of each year. Since the budget comes from donations, it is uncertain and may be partly earmarked for specific uses. Considering an HO's objective to improve the social welfare of the beneficiaries and to meet the target fill rates, budget allocation is a challenging problem. We model budget allocation as a two-stage decision process: In the first stage, the HO decides the budget target for each country and in the second stage, the HO determines the optimal allocation of the non-earmarked budget.

Resilient Infrastructure and Community Networks

Invited: InvitedNatural Hazard Planning

Invited Session

Chair: Kash Barker, University of Oklahoma, University of Oklahoma, Norman, OK, 73019, United States, kashbarker@ou.edu

1 - Building Resilience through Redundancy in a Multi-echelon Supply Chain

Jose Emmanuel Ramirez-Marquez, Stevens Institute of Technology, Castle Point on Hudson, School of Systems & Enterprises, Hoboken, NJ, 07030, United States, jmarquez@stevens.edu, Araceli Zavala

Due to the complexity of supply chains (SC) they must increase their resilience to meet demand. A multi-echelon supply chain is analyzed using Discrete Event Simulation (DES) for measuring the effects of disruptions downstream the supply chain - modeled in a probabilistic manner with different impact levels. An experimental design is conducted on multiple input parameters to illustrate the model application and behavior. To lessen the effects of the disruptions, this model considers redundancy as a supply chain capability and aid managers in identifying SC nodes vulnerable to disruptions. SC can increase resilience and a rapid recovery to optimal operation levels.

2 - Analytically Comparing Disaster Resilience across Multiple Dimensions

Christopher Zobel, Virginia Tech, 1007 Pamplin Hall, Dept of Business Info Tech, Blacksburg, VA, 24061-0235, United States, czobel@vt.edu

It is important to be able to compare the resilience of a community to different types of disaster event in order to assess both its vulnerabilities and the opportunities available to address them. Since resilient behavior can be complex and multi-dimensional, however, one must be able to characterize the different ways in which that behavior is actually exhibited in practice. This presentation explores an approach for visualizing and analyzing the relationships between each of the individual resilience dimensions.

3 - Maximal Expected Coverage for Network Restoration and Emergency Response After Disrupted Events

Suzan Afacan, University of Wisconsin-Madison, 27D University Houses, Madison, WI, 53705, United States, iloglu@wisc.edu, Laura Albert

Infrastructure recovery is important for delivering time-sensitive services and commodities after a disaster while also repairing network damage. To examine this issue, we present an extension of the maximal covering problem in the case of extreme events. In the model, we coordinate two types of service providers: (1) recovery crews who repair disrupted roads and (2) emergency responders who deliver services and commodities by relocating emergency service responder between potential locations with restricted access. The objective is to maximize the covered demand with backup coverage over the time horizon. The model is illustrated with a computational example.

4 - An Optimization-based Restoration Approach for Enhanced Interdependent Infrastructure Network Resilience

Yasser Adel Almoghathawi, University of Oklahoma, 1506 E Lindsey St., Apt P, Norman, OK, 73071, United States, moghathawi@ou.edu, Kash Barker

Infrastructure networks such as power, water, and gas are increasingly becoming more interdependent to be functional, potentially making them highly vulnerable to any disruptive event, which makes their restoration more challenging. We propose a resilience-driven solution approach for the restoration problem of interdependent infrastructure networks following a disruptive event. The proposed approach is based on an optimization model considering fixed and variable recovery times for disrupted network components. The proposed approach is illustrated through generated interdependent networks with different sizes and topologies considering different disruption sizes and scenarios.

Innovations in Pricing

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Adam Elmachtoub, Columbia University, New York, NY, 10027, United States, adam@ieor.columbia.edu

1 - The Value of Personalization in Limited Information Markets

Michael Hamilton, Columbia University, 500 West 120th Street, New York, NY, 10027, United States, mh3461@columbia.edu, Adam Elmachtoub, Vishal Gupta

We study a one product pricing problem, and quantify the revenue difference between optimal single price strategies and fully personalized ones based on simple summary statistics about the market. Namely using only the mean, range and volatility of the market, we characterize the best and worst case "gaps" between an optimal one price strategy and fully personalized one. As an application of our work we give a simple, distribution-free and near optimal algorithm for market segmentation.

2 - A Joint Framework for Market Segmentation and Price Curve Estimation

Ryan McNellis, Columbia University, New York, NY, 10027, United States, rtm2130@columbia.edu, Adam Elmachtoub

We propose a new methodology for incorporating feature information into price-setting problems. Relevant applications include the recommendation of personalized discounts and customizing bids for advertising exchanges. Our method uses recursive partitioning to segment the feature space into a collection of regions. A probability model involving only the decision variable (i.e., price) is then fit locally in each region. A key strength of our method is its interpretability, as the resulting market segmentation is easily visualized and understood. We explore new training algorithms to ensure scalability in the face of high-dimensional data.

3 - Primal-dual Algorithms for Revenue Management Problems with Unknown Demand Model

He Wang, Georgia Institute of Technology, Atlanta, GA, 30332-0205, United States, he.wang@isye.gatech.edu

In this talk, we consider a general class of revenue management problems with finite inventory and finite selling horizon. In addition, we assume the customer demand model is unknown prior to the selling season. We propose a primal-dual algorithm that simultaneously estimates the customer demand model and the bid prices associated with inventory constraints.

Revenue Management with Consumer Analytics

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Joline Uichanco, University of Michigan, Ross School of Business, Ann Arbor, MI, 48109-1234, United States, jolineu@umich.edu

1 - Data-driven Pricing for a New Product

Mengzhenyu Zhang, University of Michigan, Ross School of Business, Ann Arbor, MI, 48105, United States, zhenyuzh@umich.edu, Hyun-Soo Ahn, Joline Uichanco

Due to the lack of relevant data, decisions regarding new products are difficult to make, and any mistake has grave consequences to the firm's bottom line. The famous Bass model for new product adoptions requires a priori knowledge on certain parameters which can be determined only after collecting demand data. We study a problem of pricing for a new product under stochastic Bass model when market parameters are uncertain. We propose simple and efficient data-driven pricing approaches and characterize their performances. Our framework is sufficiently flexible to be applied to real time parameter learning in other general diffusion processes along with control reoptimization.

2 - Value of Delayed Incentive: An Empirical Investigation of Gift Card Promotions

Bharadwaj Kadiyala, Univ at Texas-Dallas, 2400 Waterview Parkway, Apt 831, Richardson, TX, 75080, United States, bxk121930@utdallas.edu, Ozalp Ozer, Serdar Simsek

Gift cards have become a popular vehicle for promotional campaigns run by many departmental, consumer electronic, and online retail stores. Using a proprietary data set from a large department store, we investigate how customers respond to these promotions as well as its effectiveness as a promotional vehicle for retailers.

3 - Customer-trends for Personalized Demand Estimation and Targeted Promotions

Kiran Venkata Panchamgam, Oracle America Inc., 78 Kendall Ct, Bedford, MA, 01730, United States, kpanch@gmail.com, Georgia Perakis, Setareh Borjian, Lennart Baardman, Tamar Cohen

Detecting trends in fashion can help retailers determine effective personalized promotion plans more easily. Access to social media data can be important in order to be able to understand these trends. Unfortunately, social data is usually unavailable. We introduce a personalized demand model that captures customer trends and show an efficient method for estimating it from transaction data. Last, we show that the promotion targeting problem is NP-hard to solve exactly, and develop an efficient greedy approach that scales to large datasets and finds provably near-optimal solutions.

4 - A Dynamic Clustering Approach to Data-driven Assortment Personalization

Sajad Modaresi, Duke University, Durham, NC, United States, sajad.modaresi@duke.edu, Fernando Bernstein, Denis R. Saure

A retailer faces heterogeneous customers with initially unknown preferences. The retailer can personalize assortment offerings based on available profile information; however, users with different profiles may have similar preferences, suggesting that the retailer can benefit from pooling information. We propose a dynamic clustering policy that adaptively adjusts customer segments and personalizes the assortment offerings. We test the policy's performance using a dataset from a Chilean retailer.

Ride-sharing Platforms I

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Ozan Candogan, University of Chicago, Chicago, IL, 27708, United States, ozan.candogan@chicagobooth.edu

Co-Chair: Daniela Saban, Stanford GSB, Palo Alto, CA, 94304, United States, dsaban@stanford.edu

1 - On Pricing and Matching in Ridesharing Systems

Erhun Ozkan, University of Southern California, 3670 Trousdale Pkwy, Bridge Hall, 401, Los Angeles, CA, 90089, United States, erhunozkan@gmail.com, Ramandeep Randhawa, Amy Ward

Ridesharing platforms are two-sided matching markets that pair customers and drivers. The ridesharing company would like to ensure there is always a nearby driver to offer an arriving customer. The difficulty is that drivers choose when to work, how long to work, and where to go to search for customers. The result can be dramatic changes over time in customer demand and driver supply across different locations, which can result in driver shortages. One common operational strategy is to match customers with the closest driver, and to use pricing to incentivize drivers to move to undersupplied locations. This motivates a joint pricing and matching problem, and we discuss steps for its solution.

2 - Ride-hailing Networks with Platform Control

Zhe Liu, Columbia Business School, New York, NY, United States, zliu18@gsb.columbia.edu, Costis Maglaras, Philipp Afeche

We are motivated by the emergence of ride-hailing platforms that match demand (passengers) with service capacity (drivers) over a geographically dispersed network. Drivers are self-interested and can decide whether to join the network and whether to reposition their car when idling at a low demand location. Passenger demand is potentially unbalanced across the network in the sense that the natural passenger flow of cars need not supply sufficient capacity across network locations. The platform can exercise demand-side admission control - which passengers to match to drivers, and supply-side repositioning control - which idling drivers to move (or incentivize to do so) to high demand locations.

3 - Spatial Pricing in Ride-sharing Networks

Ozan Candogan, University of Chicago, Booth School of Business, Chicago, IL, 27708, United States, ozan.candogan@chicagobooth.edu, Kostas Bimpikis, Daniela Saban

We explore spatial price discrimination in the context of a ride-sharing platform that serves a network of locations. Riders are heterogeneous in terms of their destination preferences and their willingness to pay for receiving service. Drivers decide whether, when, and where to provide service so as to maximize their expected earnings, given the platform's prices. Our findings highlight the impact of the demand pattern on the platform's prices, profits, and the induced consumer surplus. In particular, we establish that profits and consumer surplus are maximized when the demand pattern is "balanced" across the network's locations.

4 - Bicycle Redistribution Network Design using Crowdsourcing

Jinjia Huang, Sun Yat-sen University, 135 Xingang Xi Road, Guangzhou, China, jinjiahuang@gmail.com

Jinjia Huang, National University of Singapore, Singapore, Singapore, jinjiahuang@gmail.com, Mabel C.Chou, Linfeng Li, Chung-Piaw Teo

Bicycle redistribution constitutes a major part of the operating cost for bicycle-sharing systems. To economize on the redistribution operations, we aim to incentivize users to take trips that can help to rebalance the network. Considering the feasibility of implementing such a system, we study whether it is enough to encourage trips on certain links of the network. We show that a system with a mix of bicycle redistribution by depot and redistribution on a small set of links suitably chosen from the full network performs almost as well as the fully flexible redistribution system using crowdsourcing.

1 - Investigating the Impact of Digital Business Strategy on Hospitals' Performance

Hossein Kalantar, PhD Student, Business School, University of Colorado Denver, 1475 Lawrence St., Suite 3501, Denver, CO, 80202, United States, hossein.kalantar@ucdenver.edu, Jiban Khuntia, Jahangir Karimi

With the introduction of government mandates in the recent years, the adoption of Information Technology has significantly increased in healthcare organizations. However, not all healthcare organizations can fully leverage IT to enhance their performance. A clear digital business strategy can help these organizations to integrate business capabilities with new IT-based capabilities. In this study, we investigate the impact of hospitals' digital business strategy on their performance. For this study, we conduct hospitals executive survey and combine it with secondary data from the American Hospital Association's (AHA) and the Healthcare Information and Management System Society (HIMSS).

2 - Can We Trust Online Physician Ratings? Evidence from Cardiac Surgeons in Florida

Susan F. Lu, Purdue University, Krannert 441, West Lafayette, IN, 47907, United States, lu428@purdue.edu, Huaxia Rui

Despite heated debate about the pros and cons of online physician ratings, little systematic work has examined the correlation between physicians' online ratings and their actual medical quality. Using the ratings of cardiac surgeons at RateMDs and the patient outcomes of coronary artery bypass graft surgeries in the 2013 Florida Hospital Inpatient Discharge Data, we investigate whether online ratings are informative about physicians' medical quality.

3 - A Big Data Driven Framework for Optimizing the Marketing Mix ROI using Fuzzy Neural Network

Ajay Kumar, Indian Institute of Technology Delhi, Ajay Kumar, Room No - Eb-03,, Girnar Hostel, Iit Delhi , Hauz Khas, New Delhi, 110016, India, ajaytomar.dce@gmail.com, Ravi Shankar

This study aims to investigate the contributions of promotional marketing activities as predictors and develops a big data driven framework for optimising marketing mix ROI using fuzzy neural network.Companies want to sense demand signals and shape future sales using historical demand, price, promotion and others economic factors so that they can react immediately to customer's orders.This study improves the quality of sales forecasts using historical demand and sales data combined with advertising effectiveness,promotions and marketing events data,and provides important implications for practitioners as they can better understand how promotional marketing can influence product sales.

4 - Game-theoretic Analysis of Zero-rating Plans: The Importance of Context

Neena Pandey, Doctoral Candidate, Indian Institute of Management, Bangalore, India, neena.alok@gmail.com, Manaswini Bhalla

Considering the contrasting implications that zero-rating plans in the Internet domain are argued to have on society, we study the role of context (extent of digital divide) on these implications. Contrary to the belief that Internet Service Providers will allow only the content providers (CPs) with higher revenue generating capability to zero-rate their data and hence act as a gate-keeper to the Internet access, we find that the ISP will have the incentive to choose the different options (none, one or both CPs) in different context. We provide further direction to policymakers by analysing and comparing consumer and total surplus in each of the cases.

5 - Incorporating Diversity in Recommender Systems using Optimization Approaches

Ibrahim Muter, Dr., University of Bath, Bath, United Kingdom, i.muter@bath.ac.uk

Recommender systems have become one of the main components of web technologies, which helps people to cope with the information overload. These systems are based on the analysis of past behavior of users to develop user models that can filter items according to users' likes and interests. Two of the most important metrics used to analyze the performance of these systems are accuracy and diversity of the recommendation lists which emerges in various forms such as aggregate diversity and individual diversity. In this study, we integrate these objectives using multi-objective optimization approaches and solve them using scalable optimization approaches.

Social Media Analytics II

Invited: Social Media Analytics

Invited Session

Chair: Karthik Kannan, karthikbabu.nk@scheller.gatech.edu

1 - Bias in Online Reviews: Variety and Atypicality in Online Gaming

Pranay Jinna, Emory University, Atlanta, GA, United States, pjinna@emory.edu

In this paper, I study self-selection bias in online reviews which can occur because the propensity of certain segments of users to opt in to review a product is different compared to other segments. Using a unique data set of 1.4 million individuals and their playing history across more than 3900 games, I find that high variety seeking consumers are more likely to post reviews compared to consumers who are low variety seeking. Further, these high variety seeking consumers have a different appeal for atypical games compared to low variety seeking consumers. I also find that users who have more friends on the platform are more likely to opt in to review.

2 - An Investigation of Information Technology and Complementarities in Innovation

Patricia Angle, Georgia Institute of Technology, Atlanta, GA, United States, Patricia.Angle@scheller.gatech.edu, Chris Forman

This study is an investigation into complementarities between IT and a firm's intellectual property (IP) protection strategy, in the context of product innovation. An IP protection strategy is the way a firm protects its innovations from being appropriated for outside interests. Whether IT is complementary with an open strategy, such as the use of patents, or a closed strategy, such as trade secrets, is unclear. This early-stage research represents a novel investigation into the relationship between IT investments and a firm's innovative strategy.

3 - Big Data Location Analytics - Predicting Purchase Location with Mobile Location Data

Karthik Babu Nattamai Kannan, Scheller College of Business, Georgia Tech, 800 West Peachtree NW, Atlanta, GA, 30308, United States, karthikbabu.nk@scheller.gatech.edu, Sridhar Narasimhan

We work with a leading national mobile carrier in the USA to explore how its customers choose the location of brick-and-mortar store to purchase or upgrade wireless service. We explore how understanding people's travel patterns is helpful in choosing the optimal number of stores in a given market based on maximum coverage model. We explore literature on firm expansion and franchising to develop a machine learning based heuristic solution procedure (work in progress).

4 - Public Reaction to Supply Chain Glitches: A Twitter Sentiment Analysis

David Wuttke, EBS.University, Burgstr. 5, Oestrich-Winkel, 65375, Germany, david.wuttke@ebs.edu, Christoph G. Schmidt, H. Sebastian Heese

Supply chain glitches have become an inherent business risk and bad news spreads quickly through social media and can negatively affect sales. Our study investigates whether and how supply chain glitches evoke public reaction on Twitter in terms of attention and sentiment. We apply the event study method to 126 glitches, analyzing sentiments using machine learning. We find that public attention triples in response to glitches, and sentiments turn to negative. To examine the drivers of public reaction, we use attribution theory, and find that sentiment shifts are stronger when glitches result from stable, internal, and specific causes; thus helping managers to allocate resources more efficiently.

Approximation in Auctions

Invited: Auctions

Invited Session

Chair: Rakesh Vohra, University of Pennsylvania, rvohra@seas.upenn.edu

1 - A Duality Based Framework for Bayesian Mechanism Design

Yang Cai, 65 Sherbrooke Est, Apt. 1711, Montreal, QC, H2X1C4, Canada, cai@cs.mcgill.ca, S. Matthew Weinberg, Nikhil Devanur

It is well-known by now that the simple mechanisms used in practice are rarely, if ever, optimal. Recent work has aimed to understand this through the lens of approximation and has successfully shown that while virtually never optimal, these simple mechanisms are often approximately optimal. Still, the techniques used to prove these claims were setting-specific and therefore limited their applicability to broad settings. We provide a principled approach to design and analyze these simple mechanisms based on duality theory. Our approach unifies and improves previous results, and greatly extend known settings where simple mechanisms are approximately optimal.

2 - Robust Mechanisms under Common Valuation

Songzi Du, Simon Fraser University, Burnaby, BC, Canada, songzid@sfu.ca

We study robust mechanisms to sell a common-value good. We assume that the mechanism designer knows the prior distribution of the buyers' common value but is unsure of the buyers' information structure about the common value. We use linear programming duality to derive mechanisms that guarantee a good expected revenue for all information structures and all equilibria. Our mechanism maximizes the revenue guarantee when there is one buyer. As the number of buyers tends to infinity, the revenue guarantee of our mechanism converges to the full surplus. We numerically demonstrate that the revenue guarantees of our mechanisms are generally close to optimal when there are two buyers.

3 - Informationally Robust Optimal Auction Design

Benjamin Aaron Brooks, University of Chicago, Becker Friedman Economics, 1126 E.59th Street, Chicago, IL, 60637, United States, ppivoriu@uchicago.edu

A single unit of a good is to be sold by auction to one of two buyers. The good has either a high value or a low value, with known prior probabilities. The designer of the auction knows the prior over values but is uncertain about the correct model of the buyers' beliefs. The designer evaluates a given auction design by the lowest expected revenue that would be generated across all models of buyers' information that are consistent with the common prior and across all Bayesian equilibria. An optimal auction for such a seller is constructed, as is a worst-case model of buyers' information. The theory generates upper bounds on the seller's optimal payoff for general manyplayer and common-value models.

Manufacturing

Contributed Session

Chair: Jorge Fresneda, Drexel University, Philadelphia, PA, United States, jef78@drexel.edu

1 - Online Reputation Analysis by Social Network

Jing Luo, University of Pittsburgh, 5712 Beacon Street, Pittsburgh, PA, 15217, United States, JIL204@pitt.edu

The goal of this study is to find a way to detect the real reputation of the online business roles. We will use network science methods to find the real reputation of the supplier and customer by their previous purchase history. From the network, we will see the change of strong links and weak links by each group. Then we will study the change of network structure to find the reputation of the roles. We could find how the previous data could work for the future purchase. Then this network result could help to set the current transaction cost.

2 - Predicting Fashion Branding Effects using User Generated Brand Network

Tawei Wang, DePaul University, 1 East Jackson Blvd, DePaul Center 6028, Chicago, IL, 60604, United States, wang131@gmail.com, Yusan Lin

Social media increases the visibility of young designer fashion brands but makes the competition more fierce due to the proliferation of social media channels. However, the branding effects of fashion brands on social media are challenging to capture due to the domination of major national brands' marketing campaigns. In order to understand the branding effects among various types of fashion brands, this study examines and predicts the branding effects of fashion brands on a user generated brand network by using network analysis. Our findings demonstrate that both network information and brand preferences can improve our understanding of the choice of posting outfits with different brands.

3 - The Effect of a Front-of-pack Nutrition Labeling System to Promote Healthier Purchase Decisions

Jeremy C. Young, Professor, Pontificia Universidad Javeriana, Bogota, Colombia, jeremyyoung@javeriana.edu.co, Claudio Mora, Luisa Fernanda Tobar, Pamela Elizabeth Vallejo

Our intervention aims to study if food purchasing decisions can be improved by using a simple, informative, front-of-package label. In contrast to previous studies, our design uses controlled randomization that can disentangle whether the label itself or the information on the label is causing behavior change in a real-world setting. Our paradigm utilizes the 5-Color Nutrition Label, which exploits the nutritional information of products to inform consumers about each products' nutritional contents in an easy-to-understand manner that promotes product comparison. We utilize all sales data and intervene in the 21 cafeterias and shops run by Food Services at Pontificia Universidad Javeriana.

4 - All That Glitters is Not Gold: Extracting Product Information from Online Consumer Reviews

Jorge Fresneda, Drexel University, 3220 Market Street, Philadelphia, PA, 19104, United States, jef78@drexel.edu

This study shows empirically that Online Consumer Reviews (OCR) may be understood as composed of three main elements: information, emotions, and how accessible each OCR was for consumers. This approach allows academic researchers and practitioners to develop a better classification of OCRs regarding their information content -as this article test empirically- and gain a more accurate knowledge of consumers' opinions in the electronic marketplace. But this approach can benefit consumers as well, since making more helpful information accessible can assist them better in making purchase decisions and overcome information overload, especially for very popular products with hundreds of reviews.

Tutorial Erlang Queueing Models

Sponsored: Applied Probability

Sponsored Session

1 - Tutorial on Erlang – A Queueing Dynamics

Jamol Pender, Cornell University, 206 Rhodes Hall, Ithaca, NY, 14850, United States, jamol.pender@gmail.com, William A. Massey

Since 2017 is the 100th anniversary for the Erlang-B formula, we consider the Erlang-A queueing model. It is defined to be a Markovian multi-agent, infinite buffer service system that permits customer abandonment. We also assume non-homogenous Poisson arrivals with exponentially distributed service and abandonment times. We use dynamical systems to analyze the transient dynamics of this queue. We obtain dynamic performance metrics for the queueing process and customer delays. Also, these differential equations motivate dynamic optimization methods for new service staffing control algorithms.

Risk Analysis

Contributed Session

Chair: Chanjoo Lee, InterContinental Hotels Group, Atlanta, GA, United States, chanjoo.lee@ihg.com

1 - Evolution of Revenue Management System at IHG

Chanjoo Lee, Manager Revenue Optimization, InterContinental Hotels Group, 3 Ravinia Drive, Suite 100, Atlanta, GA, 30346, United States, chanjoo.lee@ihg.com

IHG's PERFORM Price Optimization project started in 2005 to drive key strategic priorities such as brand performance enhancement and excellent hotel returns. The project was the first large-scale enterprise implementation of price optimization in the hospitality industry and provided a 2.7% increase in revenue as verified in the IHG 2009 Annual Report. In this talk, we will discuss how the IHG Revenue Management Systems including PERFORM Price Optimization evolved to increase user acceptance from the hotels and drive revenue improvement over the years.

2 - Pull and Push Contracts in a Decentralized Assembly System with Random Component Yields
Yanling Feng, Beihang University, Haidian District, Xueyuan Road No. 37, Beijing, 100191, China, fengyanling.1@163.com

This paper investigates how random component yields could influence the pricing and production decisions. Both suppliers' yields are assumed to be random and all information is symmetric. The equilibrium solutions are studied under pull and push contracts. Compared results show that under the push contract the suppliers always achieve the first mover advantage, but this may not be true for the manufacturer under the pull contract. Sensitivity analysis are also performed to study the impact of random yields and the retail price on the equilibrium solutions. We then extend our analysis to a more general case of n suppliers.

3 - Assortment Optimization Considering Consumers Heterogeneity
Shunichi Ohmori, Assistant Professor, Waseda University, Room 0903A, Okubo 3-4-1, Shinjuku, Tokyo, Japan, ohmori0406@gmail.com, Kazuho K. Yoshimoto

We propose an assortment optimization model in which customer heterogeneity is considered. We used id-pos data to estimate parameters of a demand model, considering brand loyalty of each customer heterogeneity. We build an optimization model to maximize total revenue.

4 - Determine the Customer Compensation for an Overbooked Flight
Lijian Chen, Assistant Professor, University of Dayton, 300 College Park Ave, Dayton, OH, 45469-0001, United States, lchen1@udayton.edu

We study the monetary impact of denying customers to board an overbooked flight. Overbooking has been a common practice of major airlines for decades to minimize the spoilage, i.e., the empty seats caused by no-shows. The airlines demand a quantitative measure to determine the monetary impact and we model the seat allocation problem with overbooking as a chance-constrained optimization. We compare our model with the seat allocation models without overbooking to gain insights regarding the benefit of overbooking and the related cost of denying economy customers. In addition to our analysis, we also present numerical results to support our conclusions.

Supply Chain, Shipping and Transportation

Contributed Session

Chair: Yuhong Li, Virginia Tech, Blacksburg, VA, United States, yuhongli@vt.edu

1 - Host National Strategy Impact on Supply Chains: Consequences of Gaining Legitimacy via Supplier Development
Remi Charpin, PhD Candidate, Clemson University, 250 Elm Street, Apt 501, Clemson, SC, 29631, United States, rcharpi@clemson.edu, Erin Powell, Aleda Roth

The recent protectionist and nationalist waves coupled with the renaissance of industrial policies have pushed foreign firms to reconsider the role played by host governments.This study intends to understand how host policies impact foreign firms' operations strategy. We use a grounded theory approach to explore how foreign managers' sensemaking of the host national strategy towards foreign entities impact their decision-making. We extend the legitimacy-based view theory to the operations and supply chain fields and find that firms implement supplier development programs to increase their legitimacy in the host country at the risk of enabling their own competition.

2 - Performance Assessment of Traditional Inventory Policies as Resilience Strategy.
Weimar Ardila, University of South Florida, Tampa, FL, United States, weimar@mail.usf.edu, Alex Savachkin, Daniel Romero

One of the resilience improvement strategies widely referenced in the literature is inventory redundancy, which basically consists of maintaining high levels of inventory to respond adequately to failures presented in the operation. The main problem with these types of strategies is the difficulty of its implementation, since it is an alternative that against the reduction of costs and efficiency. Therefore, this work aims to evaluate the performance of different traditional inventory policies, and to determine which one offers the best balance between resilience and efficiency.

3 - The Impact of Supply Chain Risk Announcements on Stock Market Performance
Laharish Guntuka, Robert H. Smith School of Business, University of Maryland, 4335 Rowalt Drive, # 301, College Park, MD, 20740, United States, lguntuka@rhsmith.umd.edu, Xiaodan Pan, Thomas M. Corsi, Curt Grimm

We explore the effects of supply chain risks with major emphasis on plant- and labor-related risks on the stock market reaction. Focusing on main upstream manufacturing industries, we collected data on day-to-day basis for a period of 1 year (2015) by using "early monitoring system" created by Lexis Nexis which collects and scores risk announcements. We find the stock market reaction is notably negative in the face of plant- and labor-related risks.

4 - Cash Hedging in a Supply Chain
Yixuan Xiao, City University of Hong Kong, 83 Tat Chee Avenue, Kowloon, Hong Kong, yixuxiao@cityu.edu.hk, Panos Kouvelis, Xiaole Wu

We study hedging cash flow risks in a bilateral supply chain. Hedging reduces expected cost for firms due to the convexity of production cost in capital investment, while not hedging provides the flexibility for firms to adjust their operational decisions in response to different cash flow realizations. We quantify the tradeoff between the cost reduction effect and the flexibility effect of hedging, and characterize the firms' hedging decisions in the supply chain.

5 - Network Characteristics and Supply Chain Disruption Resilience
Yuhong Li, Virginia Tech, 301 Piedmont Street, Apt 8, Blacksburg, VA, 24060, United States, yuhongli@vt.edu, Christopher Zobel, Onur Seref

Inspired by the growing needs to understand supply chain network structure and its impact on supply chain resilience, this study focuses on investigating the relationships between network characteristics and supply chain resilience. Specifically, we select the key influential characteristics and study how they influence network resilience. Then we conduct a case study to show how practitioners can use these characteristics to gain a knowledge of supply chain resilience and support decision making.

Empirical Research on Air Transportation

Sponsored: Aviation Applications

Sponsored Session

Chair: Milind Sohoni, Indian School of Business, Hyderabad, 500032, India, milind_sohoni@isb.edu

1 - An Analytical Approach to Predicting Airline Planned Maintenance Inspections
Shervin Beygi, Boeing, 441 Smith Avenue, Seattle, WA, 98109-2155, United States, shervin@umich.edu

Airlines regularly perform major planned maintenance inspections on their fleet. Predicting such events is key for providers of spare parts and technical services to predict future demand. We present a data-driven model to determine airlines' past maintenance logic and use it to predict future events. The model uses flight leg data to find gaps in the flight schedule of each airplane. A statistical model is used to determine if the detected gaps can be attributed to scheduled maintenance events, and then predicts when the next check will occur, for each tail number, up to three years before the actual event. Test cases illustrate that the proposed model can successfully predict major scheduled checks.

2 - Network Design and Fleet Management for Air Cargo Operations
Timothy L. Jacobs, Amazon, 415 W. Larona Lane, Tempe, AZ, 85284, United States, tljacobs61@gmail.com, Hoda Parvin, David Michael

Amazon's Middle Mile Planning and Research Science (PROS) team is responsible for the design and implementation of optimization models and algorithms to design the air network and better utilize the Amazon air transportation assets. In 2017, PROS developed a network design and fleet assignment model to plan the air network for fall 2017 and beyond. The model uses a mixed integer programming approach that simultaneously builds the flight schedule, assigns fleets to flights, and determines how best to flow all air packages throughout the network. This model provides both tactical and strategic solutions taking into account available aircraft, station and hub capacity, the use of point to point and hub and spoke configurations, and other operational restrictions. Amazon uses the model to help select new stations, determine operating strategies at the hub, and to evaluate network topology. This talk will describe the major components of the model and our general solution approach.

3 - Analyzing How Individuals Filter and Screen Alternatives for Discrete Choice Modeling Applications
Virginie Lurkin, Ecole Polytechnique Fédérale de Lausanne, Route Cantonale, Lausanne, 1015, Switzerland, vlurkin@ulg.ac.be, Laurie Garrow

There has been little research into whether state of the art consumer welfare models accurately capture consumers' decision-making process. Both the itinerary choice and welfare estimation literatures generate a "complete" set of itineraries and assume individuals look at and evaluate all itineraries in the choice set. This may not be a realistic assumption. We designed an online experiment to capture how individuals filter and screen alternatives for discrete choice modeling applications. We present preliminary results analyzing screening rules that have been used by respondents.

4 - Quantile Regression Based Estimation of Statistical Contingency Fuel

Mark M. Hansen, University of California-Berkeley, 114 McLaughlin Hall, Berkeley, CA, 94720, United States, mhansen@ce.berkeley.edu

We use quantile regression to estimate statistical contingency fuel based on the specific circumstances of a given flight, and the fuel savings that could result from using this approach compared to current practice.

Supply Chain Optimization

Contributed Session

Chair: Vinay Gonela, Texas A & M University, Killeen, TX, United States, vinay.gonela@tamuct.edu

1 - Mixed-fleet Sizing and Routing with Electric Vehicles for Maximum Profit

Isil Koyuncu, Teaching and Research Assistant, The University of Alabama, Alston Hall Box 870226, Tuscaloosa, AL, 35487, United States, ikoyuncu@crimson.ua.edu, Mesut Yavuz

This talk presents a maximum profit mixed-fleet electric VRP with traditional and electric vehicles. A set of customers are willing to pay an EV premium to reduce their supply chain carbon footprint. We investigate the exact solution of the problem via Branch and Price Algorithm and compare with heuristic algorithms.

2 - Potential Revenue of Wasted Plastic Bottle Auction in Japan

Kazuaki Okubo, Associate Professor, Ehime University, 3 Bunkyo machi, Matsuyama city, Matsuyama, 790-8577, Japan, okubo@cee.ehime-u.ac.jp

This study explores the potential revenue of municipalities, who collect and sell waste plastic bottles to recycling firms on auctions. I use the auction data in Japan to estimate potential bids and formulated a mixed integer programming model to derive the optimal combination of municipalities and recycling firms that maximizes municipalities' revenue. I found that the revenue in the optimal combination is larger than in the observed combination, especially in Kanto region where there are relatively many recycling firms. The distances between municipalities and recycling firms become smaller in the optimal combination to reduce transportation cost.

3 - Carbon Emission Reduction Strategies for Two Competing Firms under Cap and Trade Regulation with Consumers Preference

Tao Li, Santa Clara University, 2730 Park Ave, Apt 3, Santa Clara, CA, 95050, United States, tli1@scu.edu

This paper develops price and low-carbon competition models between one socially responsible manufacturer and one regular manufacturer under the influences of consumers' low-carbon preference. We assume that the responsible manufacturer is a pioneer in low-carbon market. Our research questions address how the regular manufacturer's low-carbon production choice is affected by factors such as cap-and-trade policy and competitive environment.

4 - Improving Environmental Sustainability within Emission Control Areas in Liner Shipping: Review and Analysis of Different Regulations

Maxim A. Dulebenets, Florida A&M.University-Florida State University, 2300 Bluff Oak Way, Apt. 8408, Tallahassee, FL, 32311, United States, mdlbnets@gmail.com, Ren Moses, Eren Erman Ozguven, Thobias Sando

Emissions produced by oceangoing vessels negatively affect the environment and living organisms. Several regulations were released by the International Maritime Organization (IMO) to alleviate negative externalities from maritime transportation. Certain polluted areas were designated as "Emission Control Areas". This study aims to perform a comprehensive review of the existing IMO regulations and conduct the assessment of advantages and disadvantages from introducing restrictions on the emissions produced within "Emission Control Areas".

5 - Designing a Sustainable Biomass Based Electricity Supply Chain

Vinay Gonela, Assistant Professor, Texas A.& M.University, FH 218K, 1001 Killeen Place, Killeen, TX, 76549, United States, vinay.gonela@tamuct.edu, Iddrisu Awudu

This paper focuses on designing a sustainable biomass based electricity supply chain (BESC) under uncertainties. All the three economic, environmental and social aspects of sustainability are considered. A Multi-objective stochastic mixed integer linear programming model is developed that aims to design optimal BESC under carbon tax and unemployment rate considerations. The result provides strategic BESC decisions. In addition, sensitivity is conducted to determine the impact of various factors on the BESC design.

Project Management

Contributed Session

Chair: Homayoun Khamooshi, George Washington University, 2201 G Street NW, Funger 415, Washington, DC, 20052, United States, hkh@gwu.edu

1 - Multi-mode Resource-constrained Project Scheduling with Uncertain Activity Cost

Fang Xie, Shandong Technology and Business University, Shandong Province Yantai I City Laishan District #191, Yantai, 264005, China, xiefangmm@163.com, Haitao Li, Zhe Xu

In this paper, we study the multi-mode resource-constrained project scheduling problem under uncertain activity cost. A nonlinear integer programming model with the minimum risk of project cost overrun is formulated. To overcome the computational challenge of solving large instances, several heuristic algorithms are proposed and implemented to obtain quality solutions in reasonable computational time. Through extensive computational experiments, the effectiveness of our algorithms are demonstrated. Furthermore, related conclusions are also discussed.

2 - Reactive Scheduling Procedures for Project Resource Leveling with Uncertain Activity Durations

Hongbo Li, Assistant Professor, Shanghai University, Baoshan District, Shangda Road 99, Shanghai University, Shanghai, 200444, China, ishongboli@gmail.com

Recent research in the area of project resource leveling has paid attention to robust resource leveling, which aims at obtaining a robust baseline schedule by considering both resource leveling and activity start time stability. However, such a schedule may still not fully protect a project from disruptions in uncertain environments. Therefore, we study reactive scheduling procedures for resource leveling. We try to repair a disrupted schedule, such that the recovered schedule deviates as little as possible from the original one while maintaining a leveled resource usage. Extensive computational experiments on benchmark instances are conducted to evaluate the proposed procedures.

3 - The Integration of Resource Allocation and Time Buffering for Bi-objective Robust Project Scheduling

Yangyang Liang, Huazhong University of Science and Technology, Wuhan, Hubei , P.R. China, China, yangliang0419@sina.com, Nanfang Cui

In this paper, we aim at constructing a proactive schedule that is not only short in time but also less vulnerable to disruptions. Firstly, a bi-objective scheduling model is proposed in the presence of activity duration variability. Then a two-stage algorithm is developed which deals with a robust resource allocation problem in the first stage and optimally determines the position and the size of time buffers using a simulated annealing algorithm in the second stage. Finally, an extensive computational experiment demonstrates the superiority of the combination between resource allocation and time buffering.

4 - Solution Approaches for a Project Scheduling Problem with Multiple Modes and a Single Nonrenewable Resource

Cansu Altintas, Research Assistant, Middle East Technical University, Odtu Kampusu Endustri Muhendisligi, Oda136, Ankara, 06800, Turkey, cansubulutaltintas@gmail.com, Meral Azizoglu

We study a project scheduling problem with multiple activity modes where mode is defined by an activity duration and resource consumption amount. We assume that there is a single nonrenewable resource and it is released in scheduled times at specified quantities. Our problem is to select the modes and activity timings to minimize the project makespan. We give an efficient mathematical formulation and propose an alternative combinatorial solution approach. We discuss and compare the efficiencies of both methods, mathematical formulation and combinatorial algorithm.

5 - Managing Service Systems via Disguised Queues

Eren Basar Cil, University of Oregon, Lindquist College of Business, Eugene, OR, 97403-1208, United States, erencil@uoregon.edu

Touristic attractions, such as observatory decks, boat tours, museums, have recently started to manage their operations via disguising parts of their waiting lines. If customers are not aware of the hidden queues, the firm can easily boost its revenues by engaging in queue disguising behavior. Our goal in this paper is to investigate the impacts of strategic customer behavior on the firm's queue disguising decisions and profits. We show that the firms can significantly benefit from disguised queues if customers act strategically, especially when the queue disguising is harmful under non-strategic customers.

6 - An Integrated Model for Assessing Project Performance
Homayoun Khamooshi, Associate Professor, George Washington University, 2201 G Street NW, Funger 415, Washington, DC, 20052, United States, hkh@gwu.edu

Project performance assessment traditionally is focused on measuring schedule performance index and cost performance index. These two measures do not provide a full picture of performance of a project. A two dimensional model is developed for assessing the performance of a project by focusing on project success and project management success. For assessing the performance of a project from delivery perspective, time, cost, quality, scope and risk measures are used whereas for business case success (project success) the business objectives realization (benefit realization) is evaluated. The integration of the two dimensions provide an overall assessment of the performance of the project.

Models for Multicriteria Group Decision and Negotiation - Joint Session of MCDM and GDN Sections.

Sponsored: Multiple Criteria Decision Making

Sponsored Session

Chair: Danielle Costa Morais, Universidade Federal de Pernambuco, Rua Conselheiro Portela, 169/701, Espinheiro, Recife, 52020-030, Brazil, dcmorais@cdsid.org.br

Co-Chair: Adiel Teixeira De Almeida, PhD, Universidade Federal de Pernambuco, Recife, Brazil, almeida@cdsid.org.br

1 - Multicriteria Group Decision using FITradeoff for Preference Elicitation
Adiel Teixeira De Almeida, Federal University of Pernambuco, Cx Postal 7462, Recife PE, 50630-970, Brazil, adielta@gmail.com, Eduarda Asfora

One of the most relevant tasks in multicriteria group decision process is preference elicitation of Decision Makers (DMs). The facilitation process demands contributions in the intersection of many topics, such as: analytical normative models, cognitive process of individuals and the social interaction of a DMs' group. This work deals with the use of FITradeoff (Flexible and Interactive Tradeoff) method for preference elicitation in this kind of problem, using partial information for additive models in MAVT scope. This method reduces DM's cognitive effort, contributing for reducing inconsistences in the elicitation process.

2 - Negotiation Model to Aid a Brazilian Retail Company with Logistics Problems
Jose Leao Silva Filho, Universidade Federal de Pernambuco, Brazil, zeleao@gmail.com, Danielle Morais, Thomas Gonçalo

The retail industry is characterized by extreme competition among various retailers and requires much efficiency in its processes. Selecting and negotiating with transport suppliers, in turn, is a very complex process because of the great number of suppliers available. Consequently, a negotiation support system is proposed to guide decision making in the selection of hauliers that meet the transportation demands of a retail organization. A numerical application was developed for the case of a major Brazilian retail

3 - A Group Decision Model to Establish a Preventive Maintenance Policy for a Low-income Water Supply System
Danielle Costa Morais, Universidade Federal de Pernambuco, Rua Conselheiro Portela 130A, apt. 1402, Espinheiro, Recife - PE, 52020-212, Brazil, dcmorais@cdsid.org.br,
Adiel T. De Almeida-Filho, Madson B. Monte

Water supply system aging cause failures and then, demand imbalance. It becomes unable to supply all users continuously, emphasizing the role of maintenance. This study presents the process for defining the optimal preventive maintenance interval considering a group of stakeholders, including population, in a multicriteria decision process. The criteria were described by maintenance engineering variables and the individual preferences were aggregated trough a voting procedure. The result is the best-poised alternative for the group's views and shows the impact of contemplating population opinion, being this approach quite adequate for this type of decision.

1 - Entrepreneurs in Advanced Analytics and Operations Research
G. Jack Theurer, G. Theurer Associates, Inc., 215 West 92nd Street, Suite 7F, New York, NY, 10025, United States, theurer@aol.com

This session is the new format of the Isolated Practitioner Workshop that so many have attended at national meetings over the years. Topics in this series address timely issues of interest to the entrepreneur community of Advanced Analytics/OR/MS ("Lone Ranger" practicing the profession independently or within a large organization) while also having a universal appeal to a broader audience of practitioners from all walks of life in the profession. This is the 34th in the series of workshops sponsored by the Practice Section of INFORMS since the first one at the 1992 fall meeting in San Francisco. The workshops have spanned a spectrum of topics from the serious ("Business as an Independent Practitioner " - 2008) to the timely ("The Lone Ranger of OR/MS and Surviving the Great Recession" - 2009) to the cutting edge ("Current Technology Trends and Future Growth of the Optimization Market" - 2012) to the cross-cultural ("Doing Business in Japan" - 1998) and much in between ("Experiences Consulting in the Healthcare Industry Dos and Don'ts" - 2011) including lighter entertaining fare. This year's session with speakers (TBA) continues a new format for the workshops. It is now presented as part of the technical session program rather than the previous evening session with reception.

Chair: Farbod Farhadi, Roger Williams University, Bristol, RI, United States, ffarhadi@rwu.edu

1 - Proactive Inpatient Bed Reservations for Admissions from Emergency Department
Seung-Yup Lee, PhD Candidate, Wayne State University, 4815 Fourth, Room 1070, Detroit, MI, 48201, United States, seung.lee@wayne.edu, Ratna Babu Chinnam, Evrim Dalkiran, Seth Krupp, Michael Nauss, Michael Welchans

One of the main factors driving Emergency Department (ED) crowding is boarding delay, where admitted patients are held up in an ED while waiting for inpatient beds to be identified and prepared. We propose a queueing network model that allows for the development of 'proactive' coordination strategies. In particular, under the proposed setting, the inpatient bed preparation process precedes ED patient disposition, and beds are reserved for ED patients. Model also accounts for the performance of the predictive analytics model in predicting disposition decisions. We present analytical results and insights through experiments motivated by a large Midwest healthcare facility.

2 - Confirmatory Data Analytics to Reduce Excess Days in Hospitals
Shaghayegh Norouzzadeh, Program Manager, Northwell Health, 1 Fairhaven Mall, Apt B83, Mineola, NY, 11501-8517, United States, snorouzzad@northwell.edu, Christina Mouradian

The objective of this study is to determine and reduce the frequency and reasons for medically unnecessary hospital days also contributing to excess days. Additional length of stay creates risk for communication errors and hospital acquired adverse events. This study focuses on reducing the turnaround time (TAT) from when patient is medically ready to be discharged to actual discharge. A staged configuration is designed to integrate the qualitative and quantitative data analysis for administrative decision making in two inpatient units. The results indicate that the average TAT and variation improved by minimum of 21% and 26% respectively. Correspondingly, excess days decreased by 45%.

3 - Service and Price Design for Healthcare Information Service Platform
Shifu Pan, PhD Candidate, University of Southeast, No. 2, Southeast University Road, Jiangning D, Nanjing, 211189, China, shifupan@outlook.com

In order to study the sustainable operation mechanism of health information service platform, we construct a supply chain consisting of medical data providers, health information service platforms and medical information demanders. We design the service content of health information service platform and discuss pricing strategies for health information service platforms that maximize the supply chain revenue.

4 - Weighted Yield Bundle to Quantify Patient Experience in Hospitals
Shaghayegh Norouzzadeh, Program Manager, Northwell Health, 1 Fairhaven Mall, Apt B83, Mineola, NY, 11501-8517, United States, snorouzzad@northwell.edu, Nancy Riebling, Ryan Cowan, Christina Mouradian, Eric Chen, George Reeder

Strategies to target patient experience typically rely on a random sample of post-discharge satisfaction surveys and Likelihood to Recommend (LTR) scores. This study's purpose is to enhance the patient experience by reducing the avoidable defects in hospital service delivery. This study presents an innovative two-stage approach. A patient experience bundle© development with a weighted yield model to quantify the qualitative parameters in the process and concurrently measure patient experience, followed by specification of process inefficiencies for improvement. Overall bundle compliance improved on average by 41% with a relative LTR improvement of 5.8%ile.

5 - A Markov Chain Analysis for Medical Resource Allocation for Disease Outbreaks
Farbod Farhadi, Roger Williams University, 1 Old Ferry Road, Bristol, RI, 02809, United States, ffarhadi@rwu.edu

We encounter many disease outbreaks around the world every year. In year 2016 alone, there were 136 disease outbreaks with variety of impacts recorded by the World Health Organization (WHO). Every disease outbreak affects populations and economies negatively in multiple dimensions. For instance, the Ebola outbreak of West Africa in 2014 caused over 28 thousand suspected cases and more than 14 thousand deaths. In this study, we develop a markovian chain process to propose an efficient allocation of medical resources for disease outbreak containment.

Sponsored Session

Chair: Leila Hajibabai, Ph.D., Stony Brook University (SUNY), Stony Brook, NY, 11794, United States, leila.hajibabaidizaji@stonybrook.edu

1 - Optimal Control Logic for Intersection Management in an Autonomous Vehicle Environment
Amir Mirheli, Stony Brook University, 30 Piedmont Dr. Apt 9, Stony Brook, NY, 11776, United States, amir.mirheli@stonybrook.edu, Leila Hajibabai, Ali Hajbabaie

This research presents an optimal control logic to minimize travel delay while upholding safety constraints. The problem is formulated into a dynamic programming model, where vehicular information is obtained from neighboring intersection approaches. A stochastic look-ahead model is developed based on Monte Carlo Tree Search algorithm to determine the optimal vehicle trajectories that prevent movement conflicts. Numerical results confirm that reliable coordination between connected autonomous vehicles can effectively address the consequences of traffic signals.

2 - Real-time Dynamic Traffic Metering in Connected Urban Street Networks
Rasool Mohebifard, Washington State University, 1630 NE Valley Road, Apt B204, Pullman, WA, 99163, United States, rasool.mohebifard@wsu.edu, Ali Hajbabaie

This study develops a real-time optimization algorithm to determine dynamic metering rates at entry gates to urban street networks. The proposed approach decomposes the problem into smaller sub-problems with the objective of reducing the computational complexity while creating effective coordination among them to improve the quality of the solutions. The proposed approach was tested on a realistic case study network and found dynamic metering rates in real-time that improved network performance.

3 - Dynamic Speed Harmonization in Connected Urban Transportation Networks
Mehrdad Tajalli, Washington State University, 210 SE McKenzie St, Pullman, WA, 99163, United States, mehrdad.tajalli@wsu.edu, Ali Hajbabaie

This study develops a mathematical linear program for dynamic speed harmonization in connected transportation networks. The solution algorithm decomposes the network to several sub-networks to reduce computational complexity of the problem and improve its runtime. At the same time, the decisions of various sub-problems are coordinated to push the solutions towards optimality. The results show that the proposed algorithm finds real-time solutions in networks of various scales that significantly reduce the number of stops and travel time while increasing the number of completed trips.

4 - Distributed Coordination and Optimization for Optimal Signal Control under Various Connected Vehicle Penetration Rates
S.M. Islam, Washington State University, Pullman, WA, United States, smabinal.islam@wsu.edu, Ali Hajbabaie

This research presents distributed coordination and optimization algorithms for real-time optimal signal control with various connected vehicle penetration rates. The algorithm distributes the optimization to the intersection-level to improve the run-time and scalability, and creates effective coordination between neighboring intersections to push solutions towards optimality. Besides, we developed an algorithm to incorporate point detector data and car following models to predict the location of unconnected vehicles. The results indicated significant improvement in network performance under various connected vehicle penetrations rates compared to solutions found by VISTRO.

Chair: Ebru Korular Bish, Virginia Tech, Blacksburg, VA, 24060, United States, ebru@vt.edu

Co-Chair: Hrayer Aprahamian, ahrayer@vt.edu

1 - Robust Prevalence Rate Estimation under Limited Resources
Ngoc Nguyen, Virginia Tech, Blacksburg, VA, 24060, United States, ntn@vt.edu, Ebru Korular Bish

Prevalence rate estimation is essential to surveillance studies in public health, and is normally conducted via pooled testing. However, as the optimal pooling design relies on the true and unknown prevalence rate, it is often determined under uncertainty. We take a robust optimization approach to prevalence rate estimation by minimizing the maximal regret in the estimate mean squared error, given an interval in which the true prevalence is presumed to be. We then compare the numerical results from the robust optimization model to those obtained from an expectation-based pooling design model to demonstrate the benefits of robust optimization in pooling design for prevalence estimation.

2 - Resource Allocation Policies for Post-disaster Relief Operations with Explicit Consideration of Human Choice Behavior
Xinchang Wang, Assistant Professor, Mississippi State University, 324C McCool Hall, Marketing Department, P.O. Box 9582, Mississippi State, MS, 39762, United States, xwang@business.msstate.edu

It has been seen that disaster-affected victims choose to visit a point of distribution (POD) to acquire life-sustaining commodities from a set of alternatives after disasters. We study a variety of post-disaster resource allocation models with victim choice to minimize the total unmet demand. These models are non-differentiable and non-convex due to nonlinear utility functions capturing the reality that no informed victim would visit a POD with no inventories. We fully characterize the optimal policies for these models under a homogeneous case. For a general non-homogeneous case, we provide a partial characterization of the optimal policies and propose a search method to find optimal policies.

3 - Benefits of Optimal Testing Schedules for Sequential Adaptive Clinical Trials

Alba Rojas-Cordova, Assistant Professor, Southern Methodist University, Caruth Hall 339, Dallas, TX, 75205, United States, alba@smu.edu, Ebru Korular Bish

Existing sequential analysis methodologies can be applied to sequential clinical trials with interim analyses to preserve the statistical significance and power levels of a fixed sample size trial. These methodologies, however, do not prescribe the number of patients that need to be recruited and analyzed every period, nor incorporate financial constraints, and do not allow for learning. We utilize a stochastic dynamic programming model with Bayesian updates to derive an optimal testing schedule and an optimal futility threshold, which can be combined with a wide range of sequential stopping methodologies that address stopping for benefit.

4 - Optimal Post-donation Nucleic Acid Testing of Donated Blood Considering Viral Load Growth Curves and Donor Characteristics

Hadi El-Amine, George Mason University, 4310 Cotswolds Hill Ln, Fairfax, VA, 22030, United States, helamine@gmu.edu, Ebru Korular Bish, Douglas R. Bish

Blood product safety, in terms of being free of transfusion-transmittable infections (TTIs), is crucial. Nucleic Acid Testing (NAT) technology enables earlier detection of infections but is more expensive, hence, most blood centers administer NAT to pools of blood samples from multiple donors. Since some donor characteristics are uncertain, we develop a chance-constrained model that determines the optimal NAT pool sizes for various TTIs, considering both non-universal (where first-time donors undergo more extensive screening), and universal (i.e., common testing for all donors) strategies, so as to minimize the TTI risk, while remaining within the testing budget with a high probability.

1 - Simulation of Inventory Systems with Unknown Input Models

Canan Gunes Corlu, Assistant Professor, Boston University, 808 Commonwealth Avenue, Boston, MA, 02215, United States, canan@bu.edu, Alp Akcay

Assuming the availability of limited demand data, we consider the stochastic simulation of an inventory system with unknown demand distributions. Building on a nonparametric Bayesian approach, we propose a simulation replication algorithm that estimates a service level for the inventory system without making any assumptions on the functional form of the demand models. We illustrate our approach in a single-product inventory simulation.

2 - Newsvendor Problem and Approximate Solutions under Price Dependent Intensity

Ahasan Harun, University of North Texas, 316 Fry Street, Apt 203, Denton, TX, 76201, United States, MdAhasanUddin.Harun@unt.edu

Approximate solutions have been proposed to the newsvendor problem when the demand is a compound Poisson and with price dependent intensity. The distribution of the selling time may not necessarily follow an exponential distribution as is typically assumed. The normal distribution provides a good empirical fit for fast moving items. However, in practice, only the first two moments may be known. Examining approximations and the optimal price for order quantity items under limited information about distributions may provide insights into new guidelines for modeling this complex problem.

3 - Skill-based Performance Model of Heterogeneous Multi-skilled Workers in Seru Production Systems

Yin Gai, Dongbei University of Finance & Economics, 217 Jianshan Street, Shahekou District, DaLian, 116025, China, gaiyin@dufe.edu.cn

Effective cross-training for multi-skilled workers is viewed as a critical factor when it comes to enhancing the performance of seru production system (SPS). Responding to this importance, we develop a skill-based analytical model of the performance of heterogeneous multi-skilled workers accounting for individual learning/forgetting curves in different types of serus. The proposed analytical model has been successfully applied to a practical case using a discrete event simulation model, and the result justifies incorporating skill-based modeling into cross-training of SPS results in an accurate analyses and informed decisions of actual and future workforce performance.

4 - Operations Research in the Management of Linen in Indian Railways

Balaraman Rajan, Assistant Professor, California State University East Bay, 25800 Carlos Bee Blvd, Hayward, CA, 94542, United States, balaraman.rajan@csueastbay.edu, Ravichandran Narasimhan

Indian railways operates 12,000 trains a day ferrying 23 million passengers a day. About 9,000 couches use linen and 1.8 million pieces are washed everyday by Indian railways. The infrastructure includes 41 mechanized laundries and estimated expense of Rs. 36 per linen set. This paper traces the life cycle of a linen, outsourcing options, capacity and their location, inventory, and flow management. It reviews the existing practice and identifies modelling opportunities to improve operations.

5 - Retailer's Efforts on Quality Assurance under Manufacturer Encroachment

Mao Yuan, Huazhong University of Science and Technology, Luoyu Road 1037, Wuhan, 430074, China, myuan@hust.edu.cn, Wanjiang Deng, Shihua Ma

We study a two-echelon supply chain where a manufacturer produces and distributes products through an independent retailer or direct channel. The production may yield defective units, and the retailer conducts an inspection to assure quality. We exam the impact of manufacture encroachment on retailer's quality assurance level, and the results show that manufacturer encroachment will induce the retailer to enhance quality assurance level,and the manufacturer may decrease the wholesale price. We also find that the encroachment may lead to win-win outcomes and lose-lose outcomes for the manufacturer and the retailer.

6 - Using Simulation to Bridge the Theory-practice Gap

Lauri Saarinen, University of Lausanne, Lausanne, Switzerland, lauri.saarinen@unil.ch, Kyle D.Cattani, Katariina Kemppainen, Suzanne de Treville

Scheduling a production facility around a product portfolio that combines products varying in time sensitivity makes it possible to combine responsiveness with effective deployment of capacity. This volatility-portfolio theory emerges from quantitative finance: Typical managers lack the background to carry out the calculations so hesitate to implement the theory, which is nonlinear and counterintuitive. We describe use of simulation modeling in two companies to help managers get comfortable with implementation. Managers then suggested additions to the model that gave insight into boundary conditions of the theory.

Retail Management

Contributed Session

Chair: Sajjad Farahani, University of Wisconsin-Milwaukee, Milwaukee, WI, United States, farahani@uwm.edu

1 - Production Planning of a Remanufacturing System with Variable Quality Returns in Reverse Logistics Environment

Sajjad Farahani, PhD Candidate, University of Wisconsin Milwaukee, WI, 53211, United States, farahani@uwm.edu, Wilkistar A.Otieno

In this paper, proposed a general framework for a remanufacturing environment and a mathematical model to maximize the profit by optimally deciding the quantity of products to be remanufactured and number of products disassembled or disposed.

2 - Optimization of Warranty Period and Product Price for Remanufactured Products using Mathematical Method

Amir Kordijazi, Teaching Graduate Assistant, PhD Candidate, University of Wisconsin-Milwaukee, 1133 E Pleasant St, Apt # 103, Milwaukee, WI, 53202, United States, kordija2@uwm.edu, Yuxi Liu, Wilkistar A.Otieno

Warranty is an important factor in building a good manufacturer—consumer relationship. Manufacturers pursue to minimize warranty costs and at a same time they try to offer a warranty which promises acceptable product quality and reliability. This study considers a remanufactured electrical product under a tiered warranty policy and try to presents an optimal warranty period from the perspective of a manufacturer to maximize the total expected profits, while ensuring sustained consumer relation. Real data from a local company with a global supply chain was used to provide a numerical example.

3 - Pricing in Remanufacturing Operations
Akshay Mutha, Pennsylvania State University, Smeal College of Business, 454 Business Building, University Park, PA, 16802, United States, axm536@psu.edu, Saurabh Bansal, V. Daniel R. Guide

We consider a firm that can remanufacture products after the demand is realized. We analyze the effect of postponing remanufacturing operations on the pricing decisions of a firm. We show the application of our model using industry data.

4 - Optimal Core Pricing and Financing Strategies at Different Stages for Remanufacturing Products under Different Quality Levels
Qianru Li, Southeast University of China, Nanjing, China, 230169156@seu.edu.cn, Weida Chen

This paper studies an acquisition pricing and financing problem in the payback period or production period in a remanufacturing system under independently uncertain demand and capital constraints, where the remanufacturer acquires and produces high- and low-quality cores in a single period setting. The acquisition pricing is viewed as a convex optimization problem, which is formulated by a nonlinear programming model. Finally, numerical experiments are conducted to show that through some key parameters, the optimal decisions can be determined to improve profits of the remanufacturer.

5 - A Two Stage Stochastic Programming Approach for Capacity and Inventory Planning for A Manufacturing Remanufacturing System
K. Nageswara Reddy, Research Scholar, Indian Institute of Technology Kharagpur, Academic Area, Kharagpur, West Bengal, 721302, India, knreddy@iitkgp.ac.in, Akhilesh Kumar

In this paper, we developed a two-stage stochastic model to optimize capacity and inventory decisions jointly while considering demand, supply and yield uncertainties. We have considered a scenario where new and remanufactured products don't compete with each other and sold in primary and secondary markets respectively.

Teaching Project Management 1

Invited: Project Management and Scheduling

Invited Session

Chair: Nicholas G. Hall, Ohio State University, Columbus, OH, 43210-1144, United States, hall.33@osu.edu

1 - Design of a Graduate Business Elective in Project Management
Nicholas G.Hall, Ohio State University, 658 Fisher Hall, 2100 Neil Avenue, Columbus, OH, 43210-1144, United States, hall.33@osu.edu

This presentation describes in detail the development of a graduate business elective course in project management. Among the components discussed are: lecture content, online simulations, integration of guest speakers, in-class games and exercises, business cases, case reports and presentations, and class participation. Course objectives and learning outcomes are also discussed.

2 - Teaching Project Management's Four Letter Word: Risk
Theodore D. Klastorin, University of Washington, ISOM Department, Box 353226, Seattle, WA, 98195-3226, United States, tedk@u.washington.edu, Gary Mitchell

Arguably, the most important concept in project management is risk: studies have shown that risk management is a project manager's most important responsibility. In this talk, we discuss ways to teach PM risk management, including the management of a complex project that operates under the threat of a possible disruptive event that will stop all work on the project although overhead/indirect and possible penalty costs will continue to accrue. We describe a short case that illustrates these concepts and relates risk management to standard PM time-cost trade-offs.

3 - Web-based Applications and Games in a Quant Project Management Course
Rainer Kolisch, Technical University of Munich, Arcisst 21, Munich, 80333, Germany, rainer.kolisch@tum.de

I have been teaching an undergraduate course in project management using operations research models and methods for several years. Recently I introduced the web-based applications RESCON and Project Management Team Builder (PTB) as well as the Marshmallow Game into the course. I will be sharing my experience with the course, its new elements and their alignment with quantitative topics.

4 - Teaching Agile Project Management
Enno Siemsen, University of Wisconsin-Madison, Wisconsin School of Business, 975 University Avenue, Madison, WI, 53706, United States, esiemsen@wisc.edu

Agile project management has become more prevalent in practice; yet it is not clear how to effectively teach agile project management in the classroom. In this session, I will report on an exercise using Legos that helps students understand the differences between traditional and agile project management.

Risk Management and Cybersecurity

Sponsored: EBusiness

Sponsored Session

Chair: Jingguo Wang, PhD, The University of Texas at Arlington, Arlington, TX, 76019, United States, jwang@uta.edu

1 - Using Machine Learning to Improve Phishing Detection Training
Zhe Shan, Univeristy of Cincinnati, shanze@ucmail.uc.edu, Andrew Harrison

Fraudulent phishing attacks cost firms and consumers billions of dollars annually. Despite the widespread use of automated classification systems developed to stop phishing attacks, phishing has evolved and continues to pose threats to people and organizations. To fight these dynamic malicious behaviors, researchers have called for better integration of behavioral factors into antiphishing efforts. Our research is motivated to combine the insights gleaned through automated detection systems with behavioral training methods to improve people's abilities to detect deception.

2 - Information Security Investment with Externalities and Heterogeneous Firms – Theory and Government Policies
Jie Zhang, University of Texas at Arlington, Arlington, TX, United States, jie.zhang2@mavs.uta.edu, Kay-Yut Chen, Jingguo Wang

How to ensure business entities spend enough effort to protect their information assets has been a challenge for regulators. In this paper, we investigate how externalities and firm heterogeneity impact firms' level of information security investment . Consistent with prior studies and practical observations, our results indicate that firms tend to under-invest if they make independent, self-interested decisions without any government interventions. We explore two possible governmental policies such as mandatory security investment standard and subsidies that can help alleviate the under-investment problem.

3 - Evolution of Intellectual Structure of Cybersecurity within the Last 25 Years
Rahul Dwivedi, PhD Student, University of Texas, 701 S Nedderman Drive, Arlington, TX, 76019, United States, rahul.dwivedi@mavs.uta.edu, Sridhar P.Nerur, Jingguo Wang

Cybersecurity is an area of predominant research both for academicians and practitioners. With organizations scrambling to keep up with growing cybersecurity concerns, we see a tremendous growth in the number of articles published in this area. The purpose of this research is to examine the conceptual foundations of the field of cybersecurity based on detailed analysis of research articles published within the last 25 years (1992 - 2015). Using a combination of citation analysis and text analysis techniques, our study aims to identify the most discussed topics, their relationships and evolution over time.

4 - Multilateral Contracts in Information Security Outsourcing
Ming Zhao, University of Houston, 334 Melcher Hall 290F, C.T. Bauer College of Business, Houston, TX, 77204, United States, mzhao@bauer.uh.edu

We present a comprehensive investigation of multilateral contracts, and analyze the influence of externalities and breach probabilities on contingent payments. The results show that a normalized externality, the ratio between a firm's externality and its investment efficiency, dictates the levels of contingent payments in multilateral contracts.

5 - Bringing Cyberinsurance and Managed Security Services to ISPS: A Game Theoretic Analysis
Yun-Sik Choi, University of Texas at Austine, Austin, TX, United States, yunsik@cs.utexas.edu, Jin Hyuk Choi, Gene Moo Lee, Andrew B.Whinston

We propose a new business model for Internet Service Providers (ISPs), which providing managed security service and cyberinsurance in addition to the traditional Internet service. We develop a dynamic game model to build a theoretical foundation of this business model. The Bayesian Nash equilibrium of the game characterizes the strategic interaction between an attacker and a defender. The analysis of the model implies that the defender's role of updating suspicion level and blocking suspicious users are crucial as the attacker's capacity increases. These observations support our claim that the ISPs are in the suitable position to provide managed security service and cyberinsurance.

361A

Social and Environmental Responsibility in Supply Chains: Behavioral Insights

Sponsored: Behavioral Operations Management

Sponsored Session

Chair: Karen Donohue, Carlson School of Management, University of Minnesota, Minneapolis, MN, 55455, United States, donoh008@umn.edu

1 - The Effect of Visibility on Consumer Trust of Social Responsibility Disclosures

Leon Matias Valdes, MIT.Sloan School of Management, 77 Massachusetts Avenue, E62 - 459, Cambridge, MA, 02139, United States, lvaldes@mit.edu, Tim Kraft, Yanchong Zheng

We conduct an incentivized human-subject lab experiment to investigate the role of supply chain visibility on consumer trust of firms' social responsibility (SR) communications. Specifically, we analyze via a three-player game how consumer trust and firm trustworthiness are affected by the quality of the information that the firm has about its supplier's SR practices. Our results suggest that consumer trust, as measured by their willingness-to-pay for a product, is higher when the firm has better visibility into its supplier's SR. Furthermore, consumer players who demonstrate a high prosocial orientation display a lack of trust under low visibility.

2 - Randomness and Correlations in Willingness-to-Pay for Remanufactured Products

Anton Ovchinnikov, anton.ovchinnikov@queensu.ca, James Duane Abbey

This paper questions a common assumption in modeling consumer behavior in purchasing remanufactured products: that the willingness-to-pay (WTP) for such products is perfectly correlated to that for the new products. We present experimental evidence suggesting that there is a degree of randomness in WTP. We then build a model to explicitly account for such randomness and, show that, surprisingly the firm benefits from uncertainty in WTP. We finally characterize the correlation structures that enhance versus reduce such benefit.

3 - Sustainable Operations Versus Corporate Social Responsibility: A Cross-country Analysis of Value Chain Transparency

Basak Kalkanci, Georgia Institute of Technology, 3151 Stillhouse Creek Dr SE, Apt 25517, Atlanta, GA, 30339, United States, basak.kalkanci@scheller.gatech.edu, Ryan Buell

We conduct experiments to study the effect of transparency into a company's internal sustainable operations initiatives (such as paying living wages or reducing emissions) relative to transparency into external CSR initiatives (such as contributing to social causes or offsetting emissions) on customers and prospective employees in the US and India. Although transparency boosts consumer choice, not all initiatives perform equally well. Internal sustainability initiatives lead to higher purchase intentions and are perceived as more sincere in the social domain. However, consumers perceive internal and external initiatives to be substitutable in the environmental domain.

4 - Encouraging Energy Efficiency Investment in a Supply Chain: A Behavioral Investigation

Karen Donohue, University of Minnesota, SCO.Department, 321 19th Street Avenue S, Minneapolis, MN, 55455, United States, donoh008@umn.edu, Jason Nguyen, Behrooz Pourghannad

While there are different mechanisms from both buyers and third-party organizations to assist suppliers in investing in Energy Efficiency (EE) improvements, suppliers' propensity to accept this assistance and undertake investments can be elusive. Through a series of controlled behavioral experiments, we study how the source of external assistance, contract framing and characteristics of the investment, including the initial assessment costs and uncertainty of returns, influence the supplier's propensity to perform the initial assessment and subsequently invest in EE improvements.

Practice/Healthcare II

Contributed Session

Chair: Yajun Ding, Baylor College of Medicine, One Baylor Plaza, Houston, TX, 77030, United States, Yajun.Ding@bcm.edu

1 - The Impact of EMR on Patient Care Evidence from LOS Reduction for HF Patients in Developing Countries

Yazan Alnsour, Assistant Professor, University of Illinois Springfield, Springfield, IL, 62703, United States, yalns2@uis.edu, Mohammad Alsharo

Researchers are arguing that EMR systems have a positive impact on healthcare especially in reducing unnecessarily cost. In this paper, we examine the impact of using EMR systems on healthcare cost in one of the developing countries. We argue that EMR help providers in reducing hospital length of stay (LOS). Our findings show that EMR systems can reduce unnecessary hospital LOS which subsequently reduce cost and the risk of hospital-acquired conditions. We empirically examine and find support for the hypothesized relationships using an archival data set for1,979 cognitive heart failure (CHF) patients. We discuss the practice implications and contributions of the findings.

2 - Family Medicine Resident Rotation Schedule Design using a Sequential Optimization Method

Allison Koram, Health Systems Engineer, Mayo Clinic, Jacksonville, FL, United States, koram.allison@mayo.edu, Yu Li Huang

Scheduling Family Medicine (FM) residents is a multifaceted task when considering the required amount of other medical services for each year of residency, the schedule flexibility of these services, the policies of FM resident and advisor staffing requirements as well as required shifts and patient volumes. The study proposed a sequential optimization model to determine the combinations of medical services in each year of residency so that the family medicine training policies can be met. The model produces a year of rotation schedule template for FM residents at an academic medical facility.

3 - Effective and Equitable Appointment Scheduling in Rehabilitation Centers

Idil Arsik, Georgia Institute of Technology, 391 17th St NW. Apt. 4054, Atlanta, GA, 30363, United States, idilarsik@gatech.edu, Pinar Keskinocak, Jennifer Coppola, Kirthana Hampapur, Yitong He, Haozheng Jiang, Dani Regala, Nick Tailhardat, Kristin Goin

Appointment scheduling in rehabilitation centers is a complex process; unlike in a primary care clinic setting, patients need a combination of services to be scheduled over multiple days and time slots with different providers. The goal in scheduling is to provide the ideal care to patients with different needs while efficiently utilizing resources. In a collaborative project between Shepherd Center, a rehabilitation institute for patients with brain injuries, and Georgia Tech, we developed a decision support-tool which employs heuristics and mixed integer programming models for efficient and effective scheduling.

4 - Simulation Based Evaluation for Point of Care Testing

Reed Harder, Dartmouth College, 14 Engineering Drive, Hanover, NH, 03755, United States, reed.haseltine.harder.TH@dartmouth.edu, Keji Wei, Vikrant Vaze, James Stahl

In order to compare Point-of-Care Testing, Central Lab Testing and Point-of-Care Sample Acquisition testing regimes in a clinical environment, we develop a computer simulation of a primary care clinic. Using data on clinic workflow, test cost and test performance characteristics, we simulate a clinical workflow over the course of a year in different settings, including clinics in rural, retail/semi-public, outpatient, and hospital based scenarios. We then analyze system performance in terms of time, economic cost, staff utilization and treatment effectiveness, and analyze trade-offs between testing regimes in different scenarios.

5 - Using GIS and Optimization for Optimal Organ Allocation for Heart Transplant

Monica Gentili, University of Louisville, JB Speed Building, Room 304, Louisville, KY, 40292, United States, monica.gentili@louisville.edu, Fatemeh Karami, Mehdi Nayebpour, Naoru Koizumi

Heart transplantation is the definitive therapy for the end-stage heart failure patients with the post-transplant survival rate of over 70%. However, the number of transplants has been limited by a growing supply-demand mismatch, and geographic disparity in access to heart transplant has been reported as one of the significant problems. The proposed research will explore different heart allocation boundaries derived from our mathematical optimization models and evaluate them by means of simulation models

6 - Discrete-event Simulation of HIV Drug Resistance from Antiretroviral Therapy in South Africa

Ume Abbas, Baylor College of Medicine, Houston, TX, United States, Ume.Abbas@bcm.edu, Yajun Ding, Robert Glaubius

Expanded access to antiretroviral therapy (ART) for HIV raises concern about drug-resistance spread. We developed a novel discrete-event simulation model of the HIV epidemic in KwaZulu-Natal, including ART and drug-resistance mutations, and evaluated HIV drug-resistance by 2030. Our model predicts that if access to second-line ART is limited, resistance to current first-line ART will increase, with potential decrease in efficacy.

Fleet and Marketplace Optimization for Mobility-on-Demand (MoD) Systems with Ridepooling

Sponsored: TSL, Urban Transportation

Sponsored Session

Chair: Samitha Samaranayake, Cornell University, Ithaca, NY, 14853, United States, samitha@alum.mit.edu

1 - Large-scale On-demand Micro-transit and Integration with Mass-transit Systems

Samitha Samaranayake, Cornell University, School of Civil & Environmental Engineering, 220 Hollister Hall, Ithaca, NY, 14853, United States, samitha@alum.mit.edu

This presentation will discuss two approaches for improving the scalability of on-demand ridesharing systems. The first approach is a micro-transit system that serves passenger demand using a fleet of high capacity shuttles, while still assigning passengers to vehicles and routing vehicles in real-time. A novel solution framework is used to solve the problem at scale. The second approach considers integrating on-demand ridesharing with mass-transit. Large-scale simulations of both approaches, using real taxi trip data from NYC, demonstrate the efficiency gains made possible by these systems.

2 - Pricing and Optimization in Shared Vehicle Systems

Siddhartha Banerjee, Cornell University, 229 Rhodes Hall, Ithaca, NY, 14853, United States, sbanerjee@cornell.edu, Daniel Freund, Thodoris Lykouris

We develop a framework for optimizing shared-vehicle systems, modeled using closed queueing networks. Our approach gives the first efficient algorithms with rigorous guarantees for several common demand-supply balancing controls, including pricing, rebalancing and matching, in the process simplifying and extending several recent results. Moreover, our framework, which is based on a novel convex relaxation coupled with a new infinite-projection and pullback technique, may prove useful for proving approximation bounds in other settings.

3 - Estimating Willingness to Carpool at Uber

Peter Frazier, Cornell University, School of Operations Research, and Information Engineering, Ithaca, NY, 14853, United States, pf98@cornell.edu

We consider estimation of a rider's willingness to use rideshare-based carpooling as a function of inconvenience created by carpooling, price of the carpool product, and the price of a non-carpool alternative. Such estimates are critical for pricing rideshare based-carpooling, and for designing the matching algorithm and constraints that determine inconvenience. We present estimation methodology and insights from applying this methodology at Uber.

4 - Enhancing Urban Mobility: Integrating Ride-sharing and Public Transit

Niels Agatz, Erasmus University, Rotterdam School of Management, Burg. Oudlaan 50, Rotterdam, Netherlands, nagatz@rsm.nl, Mitja Stiglic, Martin W. P.Savelsbergh

Seamless integration of ride-sharing and public transit may offer fast, reliable, and affordable transfer to and from transit stations in suburban areas thereby enhancing mobility of residents. We investigate the potential benefits of such a system, as well as the ride-matching technology required to support it, by means of an extensive computational study. Our study shows that the integration of a ride-sharing system and a public transit system can significantly enhance mobility and increase the use of public transport.

361E

Energy

Contributed Session

Chair: Amandeep Gupta, Cornell University, Ithaca, NY, United States, ag729@cornell.edu

1 - A Building Thermal Model for Humidity Prediction

Jingyang Xu, Innovative Decisions & Analytics LLC, 6991 Brescia Way, Orlando, FL, 32819, United States, jxu7@buffalo.edu, Daniel Nikolaev Nikovski

In this talk, we'll show you a grey-box model to predict temperature and humidity in a building with active control of HVAC (heating, ventilation and air conditioning) systems. Various factors are considered, such as weather, human activity, radiation, moisture absorption/desorption, ventilation, condensation, etc. Accurate prediction results are obtained using data collected from a physical building. The prediction time step is 5 mins, which is much short than existing models and made it possible for the model to support optimal control of HVAC for better thermal comfort and energy consumption.

2 - Bioenergy Facility Location: A Dynamic Problem to Address Electricity Demand and Supply Gap

Raza Ali Rafique, Assistant Professor, Lahore University of Management Sciences (LUMS), Sector 'U', DHA, Lahore Cantt., Lahore, 54792, Pakistan, raza.ali@lums.edu.pk, Mohsin Nasir Jat

In this research, the optimal locations of bioenergy facilities are sought. We propose a mixed integer linear programming (MILP) approach for minimization of energy gap (between demand and supply) at district levels with defined biofuel potential and targeted electricity capacity. Our study is based on real data collected across 135 districts of Pakistan. The proposed optimization tool can assist policy makers for strategic planning and development of biofuel energy in Pakistan.

3 - Planning for Electric Taxi Charging System from the Perspective of Transport Energy Supply Chain- A Data Driven Approach

Yinghao Jia, PhD Candidate, Tsinghua University, Beijing, 100084, China, jyh12369@126.com

Yinghao Jia, PhD Candidate, Sparkzone Research Group, Beijing, China, jyh12369@126.com, Ziyang Guo, Zhuying Jiang, Yu Xin, Yide Zhao, Fang He

Administration in big cities is strongly promoting electric taxis (ETs) by providing purchasing subsidies, public charging facilities and many other encouraging policies. However, how to allocate the limited resources to optimize the benefits brought by ETs remains a headache for most researchers. Applying data mining technology, this research gathers real-time vehicle trajectory data of 39,053 urban conventional taxis (CTs) and 408 suburban ETs in Beijing for 4 weeks to extract the model of customers' travel demand and ET driving patterns. Based on the transport energy supply chain derived from GPS data, we develop a data-driven method to design ET charging infrastructure in the near future.

4 - Storage Dam and RUF off River Hydroelectric Power Generation and Distribution Planning

Govind Joshi, Colorado School of Mines, Golden, CO, United States, gobndjoshi@gmail.com, Ebisa Wollega

We present power delivery planning problem for integrated storage dam and run-off-river (ROR) hydroelectric power plant projects under supply uncertainties. We formulate the problem as a two-stage stochastic program, where the storage dam projects are considered as a first stage, the ROR projects are considered as the second stage of the program. Numerical comparisons of stochastic solution, expected value solution, and wait and see solution are made to provide the economic dispatch of generators and optimal delivery plan that the power system operators can use to coordinate, control, and monitor the hydroelectric power generation and distribution system.

5 - Bus Ranking Method for Robust Optimization

Amandeep Gupta, Cornell University, 316 Highland Road, Ithaca, NY, 14850, United States, ag729@cornell.edu, Lindsay Anderson

Interest in efficient and flexible stochastic methods for unit commitment has been growing steadily in answer to increasing renewable energy resources on the grid. This work describes a statistical bus ranking methodology that identifies the most critical buses based on criteria such as economic dispatch cost, or ramping needs to provide a robust unit commitment solution. The method is illustrated via a case study on the IEEE 30-bus system and compared to other established approaches to demonstrate the efficacy of obtained solutions. Results show that the bus ranking method performs as well as the best of these methods, with the provision of additional flexibility and potential for parallelization.

361F

Hazardous Materials Transportation

Invited: TSL, Intelligent Transportation Systems (ITS)

Invited Session

Chair: Pirmin Fontaine, Technical University of Munich, Arcisstrasse 21, LST Minner, Munich, 80333, Germany, pirmin.fontaine@tum.de

1 - Simulation and Analyzing the Hazardous Materials Transportation Interdependent Network

Peng Hu, Southwest Jiaotong University, Erhuanlu Beiyiduan No. 111, Chengdu, 610031, China, hupengbaby@163.com, Bin Shuai, Zhenyao Wu

Hazardous Materials Transportation Network has very tightly coupling with Traffic Flow Network of Hazmat Transportation. We build the interdependent system for the two networks. We build the interdependent system and analyze it through simulation method for knowing the robustness of the interdependent transportation network.

2 - Managing Rail-truck Intermodal Transportation for Hazardous Materials: A Scenario-based Robust Optimization Model

Ginger Yi Ke, Memorial University of Newfoundland, St. John's, NL, Canada. gke@mun.ca, Arifusalam Shaikh

Combining multiple transportation modes, intermodal transportation has been widely used in shipping hazardous materials (hazmat). But the corresponding research is still limited, especially when the planning environment contains uncertainties. Herein we propose a bi-objective robust optimization approach to determine the best shipment plan for transporting hazmat in intermodal networks. Both minmax and regret based techniques are applied and compared to find robust solutions. Managerial insights are generated through discussions of the effectiveness and efficiency of our model.

3 - Fair Risk Distribution for the Multi-mode Hazmat Transport Network Design Problem

Pirmin Fontaine, Technical University of Munich, Munich, 80333, Germany, pirmin.fontaine@tum.de, Teodor Gabriel Crainic, Michel Gendreau, Stefan Minner

To fairly distribute the risk in hazardous material shipment, we propose a population-based risk definition that evaluates the risk in each population center. Moreover, we propose different objective functions for equilibrating the risk and extend the bilevel Hazmat Transport Network Design Problem by considering several transportation modes. We show that both objectives have a positive convex correlation and therefore a significant improvement in risk distribution can be achieved at the cost of just a small increase in total risk. The cities with high risk benefit from the risk redistribution in the beginning. However, strong equilibrations just penalize cities with low risk.

4 - Considering Dangerous Goods in Container Stowage Problems

Kiros Kebedow, PhD Student, Hawassa University, Ethiopia, Hawassa University, 05, Hawassa, 05, Ethiopia, kirosmaths@gmail.com, Johan Oppen

Container stowage problems are rich optimization problems with both high economic and environmental impact. These problems are typically decomposed into a master bay planning phase, which distributes containers to bay sections of the vessel, and a slot planning phase, which assigns a specific slot within the bay section to each container. In this talk, we extend existing models for slot planning by considering containers with dangerous goods and containers of length 45'. We show that our model can be solved to optimality in reasonable time using standard software.

Waste and Hazardous Material Routing

Sponsored: Transportation Science & Logistics

Sponsored Session

Chair: Roger Chen, Rochester Institute of Technology, 111 Lomb Memorial Drive, 81-2178, Rochester, NY, 14623, United States, rbcgis@rit.edu

1 - Conditional Value at Risk Model for Rail Transportation of Hazardous Material with Demand Due Date

Ginger Yi Ke, Associate Professor, Memorial University of Newfoundland, Faculty of Business Administration, Memorial University of Newfoundland, St. John's, NL, A1B 3X5, Canada, gke@mun.ca, Kan Fang, Tingting Cheng

The conditional Value-at-Risk (CVaR) model is employed to generate route choices for the multi-trip rail transportation of hazardous materials, where each demand has an associated due date and each train can run at various train speeds. We investigate the structural properties of the corresponding CVaR model, and provide analytic methods to determine optimal scheduling and routing plans as well as the train speed at each arc, such that the total transportation cost is minimized.

2 - Economic Analysis of Residential Garbage Collection Operations: Case of the City of Kingsville

Sachinkumar Prajapati, Texas A&M.University-Kingsville, 1414, W Santa Gertrudis, Apt#702, Kingsville, TX, 78363, United States, prajapatisachin11@yahoo.com, Joon Yeoul Oh, Amir Gharehgozli

The quantity of residential garbage increases every year. Along with that, the cost and time of garbage collection increase. The objective of this research is to find an effective yet efficient way to collect residential garbage. To achieve this goal, first, data on the current garbage collection operations is collected and analyzed. Second, Arena simulation is used to improve the operations for the city of Kingsville. Finally, an economic analysis is performed to compare the current and proposed garbage collection operations. The results show that the proposed garbage collection method is 35%-40% less costly compared to the current method.

3 - A Meta-heuristic for the Vehicle Routing Problem with Crossdocking

Changsheng Wu, Student, New York Institute of Technology, Manhattan, NY, 10023, United States, cwu25@nyit.edu, Birasnav Muthuraj

This study focuses on developing a meta-heuristic for routing vehicles operated by third party logistics service providers to pick up hazardous materials from manufacturing companies and to deliver these materials to customers through crossdocking facility. This study compares the solutions of this meta-heuristic with the solutions derived from exact methods.

4 - Expected Value of Perfect Information of Demand in Propane Distribution Problem

Nichalin S. Summerfield, Assistant Professor, University of Massachusetts Lowell, One University Avenue, Lowell, MA, 01854, United States, nichalin_summerfield@uml.edu, Moshe Dror

Recent advancement in sensors allows companies to remotely monitor propane levels in customers' tanks and plan their daily distribution operations. In this work, we study the expected value of perfect information (EVPI) of demand in Propane Distribution Problem (PDP) to decide if it is profitable to install the sensors. Specifically, we compare the solution cost when the levels of propane are known, against the solution cost when customers' consumption levels are forecasted. In our setting, split deliveries are allowed and any stockout is replenished by a costly special delivery. We use a state-of-the-art heuristic solution for PDPs that minimizes the expected replenishment costs per year.

5 - Organic Waste Recovery: Routing, Siting and Blending

Roger Chen, Assistant Professor, Rochester Institute of Technology, 111 Lomb Memorial Drive, 81-2178, Rochester, NY, 14623, United States, rbcgis@rit.edu, William Armington

In the US, an estimated 63 million tons of food product is discarded annually, leading many regions to consider diverting food waste from landfills towards other more sustainable technology alternatives. Heterogeneity and inconsistency in the food waste composition, combined with technology constraints require trade offs in optimizing the recycling process, including the routing of organic waste streams. Within this context, this work considers three class of problems: (i) vehicle routing of organic waste streams; (ii) facility location decisions for organic waste recycling technologies; and (iii) waste blending and composition balance.

Topics In Finance II: Behavioral Finance and Economics

Sponsored: Financial Services

Sponsored Session

Chair: Xuedong He, The Chinese University of Hong Kong, Hong Kong, xdhe@se.cuhk.edu.hk

Co-Chair: Nan Chen, Chinese University of Hong Kong, Shatin N T, Hong Kong, nchen@se.cuhk.edu.hk

1 - A New Preference Model that Allows for Narrow Framing

Xuedong He, The Chinese University of Hong Kong, Room 609 William M.W. Mong Engineering Bldg, Shatin, Hong Kong, xdhe@se.cuhk.edu.hk, Jing Guo

Barberis and Huang (2009) propose a preference model that allows for narrow framing and apply it to explain individuals' attitudes toward timeless gambles and high equity premia in the market. To uniquely define the utility process in this preference model and to yield a unique solution when the model is applied to portfolio selection problems, one needs to impose some restrictions on the model parameters, which are too tight for many financial applications. We propose a modification of Barberis and Huang's model and show that (i) the modified model admits a unique utility process and a unique solution in portfolio selection problems and (ii) it is more tractable than Barberis and Huang's model.

2 - Naive Behavior in Continuous-time Mean-variance Model

Lin Chen, Columbia University, New York, NY, 10025, United States, lc3110@columbia.edu, Xunyu Zhou

This project is concerned with the naive behavior in continuous-time mean-variance model. The objective is obtain the wealth process and portfolio process if we redo naive behavior at each time. By cutting the time interval into many equal length parts and in each part we use the precommitted strategy. By doing so, we can obtain the corresponding wealth process and portfolio process. When the number of cutting parts goes to infinity, we prove that, under some bounded conditions, both of the wealth process and portfolio process will converge. We also find the limits of both processes.

3 - Limited Foresight Strategy in Multi-period Mean-variance Framework

Xiangyu Cui, Shanghai University of Finance and Economics, School of Statistics and Management, Room 2218, Shanghai, 200433, China, cui.xiangyu@mail.shufe.edu.cn, Duan Li

In multiperiod mean-variance framework, the investor suffers time inconsistency. The current solution schemes either assume the investor does not possess any foresight or assume the investor possesses unlimited foresight. However, in reality, the investor often has limited foresight and can only influence his own investment behaviors over a relative short time interval. Thus, we integrate the limited foresight of the investor into the model and formulate the problem as a planner-middleman-doer game. We derive the explicit expression of the equilibrium strategy, which is called limited foresight strategy, and analyze the properties of the equilibrium strategy.

4 - Stock Trading with Realization Utility in a Regime-switching Model

Shengcheng Shao, The Chinese University of Hong Kong, Hong Kong, scshao@se.cuhk.edu.hk, Xuedong He

We consider a stock trading model in which the stock price follows a regime-switching process with observable regimes. The agent buys and sells the stock sequentially to maximize her terminal wealth utility and realization utility, where the latter is derived from the realized gains and losses at the sale times. We solve the optimal strategy in closed form and show that the agent holds the stock at a deep loss even in the bear market but sells the stock at a gain even in the bull market. We find that the more the agent weights the realization utility, (i) the more frequently she trades and (ii) the lower the expected terminal wealth.

Logistics

Contributed Session

Chair: Jihyun Jo, Pennsylvania State University, University Park, PA, United States, JZJ5077@psu.edu

1 - Dual Channel Warehouse with Uncertain Demands

Guoqing Zhang, University of Windsor, Dept of MAME, 401 Sunset Avenue, Windsor, ON, N9B 3P4, Canada, gzhang@uwindsor.ca

With the emergence of online sales channels, a warehouse has come to commonly fulfil demands for both offline and online channels. To optimize operations, such a warehouse is usually divided into two areas: one for the process of fulfilling online orders and one for storing products and filling offline orders. This paper discusses multi-item product inventory policies with both stochastic online and offline demands for a dual-channel warehouse. Such a discussion has not been addressed in existing literature. Both a mathematical model and a solution approach are proposed. The impacts of uncertainty and the warehouse space have been analyzed.

2 - Robust Optimization of Biomass Logistics Supply Chain Design

Babak Badri Koohi, PhD Candidate in Operations Research, Virginia Tech, Blacksburg, VA, 24061, United States, babakbk@vt.edu, Subhash C. Sarin

Optimizing the design of biomass logistics supply chain plays a crucial role in utilizing biomass as a source of renewable energy. Nevertheless, there are some uncertainties associated with biomass logistics such as availability of necessary equipment, and the amount of seasonal or periodical supply and demand. In this research study, we address these uncertainties using a robust optimization approach.

3 - Identifying Noise Level in Military Logistics under Anti-access/Area-denial Environment

Rosemonde Ausseil, University of New Haven, West Haven, CT, United States, rauss1@unh.newhaven.edu, Ridvan Gedik, Amy Bednar, Mark Cowan

In modern warfare, the US military is increasingly faced with anti-access/area-denial challenges, which threaten its power projection operations. By analyzing the US military's logistics, adversaries could infer and anticipate the US military's mission objectives. Identifying which factors are predominant in determining these intentions leads us to develop a denial and deception technique of introducing noise into the US military's movements, with the aims of obscuring its logistics activities and disrupting the adversary's decision-making process. The mathematical model quantifies the noise and gives greater insight into what is a sufficient noise level for adversary deception.

4 - Heuristic Algorithm for Megacity Vehicle Routing Problem

Jihyun Jo, Pennsylvania State University, 234 Leonhard Building, University Park, PA, 16802, United States, JZJ5077@psu.edu, Soundar Kumara, Venky Shankar

The main objective of this study is generating the daily delivery routes under the conditions of m depots and n vehicles in urban transportation network and some other restrictions. Considering these characteristics, we first create the cost matrix of this routing problem using google maps API to adapt the current road conditions of the operating area. To solve the problem, we generate the delivery sequence of entire network like TSP by using genetic algorithm and the we distribute the vehicle routes with the given resource and time constraints. To speed-up the TSP solution generating process, we generate and solve the multiple subnetworks problem and then link the subnetwork solutions.

Scheduling

Contributed Session

Chair: David Johnson, Purdue University, West Lafayette, IN, United States, davidjohnson@purdue.edu

1 - Using Cluster Analysis to Develop a Risk Taxonomy for Small Unmanned Aircraft System

Dothang Truong, Professor, Embry-Riddle Aeronautical University, 600 S.Clyde Morris Boulevard, Daytona Beach, FL, 32114, United States, truongd@erau.edu

The growing demand for Small Unmanned Aircraft System (sUAS) in the past two years has increased the number of sUAS encounters with manned aircraft or airports, raising the risk of collision. The purpose of this research is to develop a taxonomy of risk factors for sUAS operations in National Airspace System. Specifically, this research presents a process of analyzing the sUAS sighting data using cluster analysis to classify sUAS encounter incidents into different groups based on a set of selected variables in the dataset. The taxonomy will allow authorities to understand the nature, characteristics, and risk factors for each group of sUAS encounter incidents.

2 - Team Based Task Assignment for Air Cargo Operations

Yong-Hong Kuo, Assistant Professor, The University of Hong Kong, Department of Industrial and Manufacturing Systems Engineering, The University of Hong Kong, Pokfulam Road, Hong Kong, yhkuo@hku.hk, Janny M. Y. Leung

Our work is motivated by a real-world task assignment problem when managing air cargo operations. The tasks are assigned to teams based on considerations such as manpower requirements, team shift times, workload balance, and meal and rest break requirements. We have developed an optimization tool to aid decision-making.

3 - A Railroad Track Geometry Life Analysis

Behnam Rahimikelarijani, Lamar University, Department of Industrial Engineering, Beaumont, TX, 77710, United States, brahimikelar@lamar.edu, Maryam Hamidi

This paper analyses railroad track geometry degradation based on the data gathered by geometry cars. The life data is used for reliability analysis of the track. A Weibull distribution whose scale parameter is assumed to be a function of stress factors is fitted. Accumulated tonnage and average running speed are considered as the stress factors affecting degradation of the track. The analysis can next be used in minimizing life cycle cost of tracks by determining the optimal maintenance schedule. By predicting track failure and proactively maintaining them, our methodology avoids considerable costs such as revenue loss, costs of damage to other parts, and random failures.

4 - Estimating the Potential for Cost Effective Nonstructural Flood Risk Reduction in Coastal Louisiana

David Richard Johnson, Assistant Professor, Purdue University, 315 N.Grant St, West Lafayette, IN, 47907-2023, United States, davidjohnson@purdue.edu, Zening Chen

Louisiana's 2017 coastal Master Plan allocates $6.1B for nonstructural flood risk reduction measures, such as elevating homes and floodproofing commercial properties. We outline the methods used to estimate the cost effectiveness of these options and present results from the Master Plan projects. We also derive the maximum potential for nonstructural risk reduction across the coast and compare optimal standards to the current standards used for flood insurance, which are based on FEMA's estimate of the "100-year" flood depth, and to the standards used by the Master Plan. Uncertainty in future conditions is also considered.

Sponsored Session

Chair: Ibrahim Capar, Bowling Green, OH, United States, icapar@bgsu.edu

Co-Chair: Burcu Keskin, bkeskin@cba.ua.edu

1 - A Steiner Zone Heuristic for the Close-Enough Traveling Salesman Problem

Xingyin Wang, Singapore Univeristy of Technology and Design, 8 Somapah Road, #05-101, Singapore, 487372, Singapore, xingyin_wang@sutd.edu.sg, Bruce L.Golden, Edward Andrew Wasil

In the close-enough traveling salesman problem (CETSP), a truck starts at a depot and serves all customers on a Euclidean plane before it returns to the depot. The truck only has to get close enough to a customer to make a delivery. The objective is to minimize the total distance traveled by the truck. The CETSP has real-world applications including meter reading. We develop a heuristic based on Steiner zones that identifies regions close enough to multiple customers and connects them by the shortest route. When compared to existing algorithms on benchmark instances, our heuristic produces results of comparable quality with much shorter computation times.

2 - The Mothership and Drone Routing Problem

Stefan Poikonen, University of Maryland-College Park, 3406 Tulane Dr., Apt 22, Hyattsville, MD, 20783, United States, spoikone@math.umd.edu, Bruce L.Golden

The mothership and drone problem (MADP) considers the use of two vehicles: a large "mothership" and a small "drone". It is assumed both mothership and drone are free to move by the Euclidean metric. There exists a set of targets ("buoys") that must be visited. The drone is launched from the mothership, visits a buoy, and returns to the mothership. The original objective is to minimize the total time required to visit all buoys and return the drone to the mothership. A branch and bound method is used and a second order cone program defines a lower bound at each node. Modified objective functions and a "close-enough" variation for signals collection will also be presented.

3 - Dynamic Discretization Discovery Approach for Deliveryman Problem with Time Windows

Minh Duc Vu, Quinlan School of Business, Loyola University Chicago, 16 E.Pearson St, Chicago, IL.60611, Chicago, IL, 60611, United States, dvu3@luc.edu, Mike Hewitt

In this talk, we study the Delivery Man Problem with Time Windows (DMPTW), a problem belonging to the Traveling Salesman Problem with Time Windows (TSPTW) and its variants. Unlike TSPTW and its counterpart Delivery Man Problem (DMP), research works for DMPTW are quite scarce. We present the first exact method based on Dynamic Discretization Discovery approach and partially time-expanded networks to solve the problem. Experiments on a set of 310 instances indicate that the algorithm is capable of finding good feasible solutions with 251 optimal or close-to-optimal solutions. Based on insights from the computational experiments, we conclude with future research directions.

4 - Attractive Orienteering Problem with Proximity and Timing Interactions

Ibrahim Capar, Bowling Green State University, Department of ASOR, 355 Business Administration Building, Bowling Green, OH, 43403, United States, icapar@bgsu.edu, Nickolas K. Freeman, Burcu B. Keskin

We consider an attractive orienteering problem for planning entertainment events that seeks to determine the profit maximizing tour among a fixed set of candidate locations over a fixed planning time. The profit contribution for each stop depends on a time-varying measure that accounts for the attraction of the event's location and the presence of events nearby, in location and time. We formulate an MIP model and develop two heuristics; local search and scatter search. The heuristics find optimal solutions for small test instances and for large instances, they provide a 32% improvement over the best feasible solution returned by a commercial solver.

5 - Demand-resilient Electric Vehicles Sharing System Design

Xin Wang, University of Wisconsin-Madison, 8916 Red Beryl Drive, Middleton, WI, 53562-4278, United States, xin.wang@wisc.edu, Yikang Hua, Dongfang Zhao, Xiaopeng Li

Electric vehicle sharing advances the green city development, but faces challenges in practical operations like infrastructure deployment and vehicle rebalancing. We build a multi-stage stochastic model to reduce the customer queueing under demand-shock scenarios. Our model incorporates uncertain customer demand arrival together with the daily fleet dispatch and rebalancing decisions.

New Directions for Product Assortment and Recommendation

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Clark C. Pixton, Massachusetts Institute of Technology, Massachusetts Institute of Technology, Cambridge, MA, 02139, United States, cpixton@mit.edu

1 - Long Tail or Blockbuster: Product Variety in Industries with Network Effects

Ming Hu, University of Toronto, Rotman School of Management, 105 St. George Street, Toronto, ON, M5S.3E6, Canada, ming.hu@rotman.utoronto.ca, Yinbo Feng

We provide a theory unifying the long tail theory and blockbuster phenomenon.

2 - Online Product Demand and Strategy in the Presence of Social Influence

Clark C. Pixton, Massachusetts Institute of Technology, 292 Vassar Street, Apt D-5, Cambridge, MA, 02139, United States, cpixton@mit.edu

We explore the demand patterns observed in product categories of online retailers, and add to the modeling literature explaining these effects. We provide managerial implications for new product introduction and demand estimation.

3 - Analytics for a Hotel Property: Demand Prediction and Optimization of Pricing and Capacity Allocation Decisions

Rui Sun, Massachusetts Institute of Technology, 77 Massachusetts Avenue, MIT.Bldg. E18-436, Cambridge, MA, 02139, United States, ruisun@mit.edu, Eduardo Candela, David Simchi-Levi

We present our work with a hotel company as an example of how machine learning techniques can be used to improve the demand predictions of a hotel property as well as its pricing and capacity allocation decisions. We first build a random forest model to predict the number of price-sensitive bookings and then feed these predictions into a mixed integer program to optimize prices and capacity allocations. We prove that the mixed integer program can be equivalently solved as a linear program. Finally, numerical results show that the optimized decisions are able to generate an increase in revenue compared to the historical policies.

4 - Assortment Optimization under a Mixture of Multinomial Logits with Nested and Interval Consideration Sets

Jacob Feldman, Olin Business School, United States, jbfeldman@wustl.edu, Huseyin Topaloglu

We study assortment problems when customers choose under the multinomial logit model with various consideration set structures. In this choice model, there are multiple customer types and a customer of a particular type is interested in purchasing only a particular subset of products. We use the term consideration set to refer to the subset of products that a customer of a particular type is interested in purchasing. We develop novel approximation schemes for the assortment problem under nested and interval consideration set structures.

Improving STEM Education

Sponsored: INFORMEd

Sponsored Session

Chair: Kingsley Anthony Reeves, University of South Florida, 4202 E Fowler Avenue, ENB118, Tampa, FL, 33620, United States, reeves@usf.edu

1 - Practices to Improve Engineering Engagement in Rising 9th Graders: A Case Study on Advanced Manufacturing

Justin Yates, Francis Marion University, Florence, SC, 29501, United States, jyates@fmarion.edu, Karen Fries, Meredith Love, Tracy Meetze-Holcombe, Matthew Nelson

This project is a collaboration among The School of Education, the Industrial Engineering Program, and the Center of Excellence for College and Career Readiness at Francis Marion University. Curriculum and student exercises were created for a one-day short course targeted at improving engagement in rising 9th graders with risk factors that inhibit their pursuit of college. We present pre and post data and discuss the short-term outcomes of this short course. We also discuss novel ways in which students from Industrial Engineering and the School of Education supported the planning and implementation of this short course.

2 - Teaching and Learning of Economic Decisions for Uncertain and Complex Projects

K. Jo Min, Iowa State University, 3004 Black Engineering, Department of Industrial &, Ames, IA, 50011-2164, United States, jomin@iastate.edu, John Jackman, Michelle Zugg

Economic decisions for projects that are complex and facing uncertainties are inherently difficult. In this paper, based on simple principles of stochastic optimal control, we show such subject can be taught and learned in an undergraduate course. Empirical statistical analysis of student learning outcomes as well as insights from experience will be presented.

3 - Fun and Innovative Ways to Teach Computer Programming Concepts

Stephany Coffman-Wolph, Lecturer, The University of Texas-Austin, 2880 Donnell Drive, Round Rock, TX, 78664, United States, scoffmanwolph@utexas.edu

Although most college students are familiar with computers, almost all stem majors must take one or more introductory computer courses. Teaching these classes can be challenging as students are unaware of what being a computer scientist really entails. The activities presented are designed to be extremely cost-effective, easily portable, require minimum preparation, and do not require a lab or prior computer experience. The end goal of these activities is to introduce various computer science topics using familiar everyday experiences and fun physical activities.

4 - Reimagining the Engineering Textbook: Learning-centered Textbook Design

Kingsley Anthony Reeves, Associate Professor, University of South Florida, 4202 E. Fowler Avenue, ENB118, Tampa, FL, 33620, United States, reeves@usf.edu, Grisselle Centeno, Garrett Bowleg, Brittany Clift

We present the initial results of a design effort to reimagine the engineering textbook. The goal was to develop a Probability and Statistics for Engineers textbook that was designed with the needs of instructors, the needs of students, and learning theory in mind. The resultant design features will be displayed along with their explicit connection to best practices as identified in the teaching and learning literature.

Joint Session SpORts/Practice: Sports Analytics IV

Sponsored: SpORts

Sponsored Session

Chair: Walter DeGrange, CANA Advisors, Chapel Hill, NC, 27517, United States, wdegrange@canallc.com

1 - Rank and Score: Athlete-event Assignment Optimization

Matthew Bailey, Bucknell University, Bucknell University, Taylor Hall, Lewisburg, PA, 17837, United States, matt.bailey@bucknell.edu, Maciek A.Nowak

With over 16,000 programs and one million secondary school athletes annually, track and field is second only to football in national participation. For coaches managing these large teams the focus is often solely on the training and development of athletes. As a result, coaches may overlook and underappreciate the competitive advantage of strategically assigning athletes to events to maximize their team's points in a meet. Building upon previous work, we present a generalization and extension of an assignment problem where we simultaneously assign, rank, and score athletes in events to maximize the expected total team points scored under a variety of scenarios, league rules, and preferences.

2 - Sports Analytics: Viable Career Path or Something Really Smart People Made up to Try to Get in the Game

Walter DeGrange, Cana Advisors, Chapel Hill, NC, 27517, United States, wdegrange@canallc.com, Jesse McNulty

With the recent success of sports teams heavily using analytics (Cubs, Patriots, Penguins, Warriors, Leicester City F.C.), does this mean that analytics has gained a foothold in the sports world? And if so, is there a career path that a high school student can use to become a sports analytics professional? This presentation attempts to answer both of these questions and summarizes all the areas of the application of analytics in sports.

3 - Predicting Collegiate Lacrosse Play Performance at the U.S. Major League Lacrosse Level

Walter DeGrange, CANA Advisors, 6727 Falconbridge Rd, Chapel Hill, NC, 27517, United States, wdegrange@canallc.com, Jesse McNulty, Harrison Schramm

Predicting the performance of amateur athletes at the professional level is challenging in any sport. Very few of the players get the opportunity to play professionally. In this presentation we will show the results of using machine learning and traditional techniques on a data set of over 45,000 collegiate lacrosse players that covers a three year period. The predictors are Major League Lacrosse shooting and defending data sets. Being able to connect data such as school, team strength of schedule, shooting, goal tending, and historical performance of professional players allows insight into the potential for a collegiate player's performance at an elite level.

4 - Using Machine Learning to Improve Football Play Calling Effectiveness

Jonathan David Lonski, Student, Clemson University, Clemson, SC, 29634, United States, jdlonsk@g.clemson.edu

Using past data from NCAA football games, we developed a tool that assists coaches with making in-game decisions regarding plays to call. Historical data describing the down, distance to gain a first down, field position, offensive formation, defensive front, and other key indicators. Our tool's objective is to recommend the play that has the highest expected average gain and the highest probability of achieving a first down, based on the situation and defensive formation being faced.

Developments in Bayesian Data Analysis

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Arman Sabbaghi, Purdue University, West Lafayette, IN, 47907, United States, sabbaghi@purdue.edu

1 - A Missing Data Perspective for Modeling Deformations in 3D Printed Products

Sobambo Sosina, PhD, Deloitte University, MD, United States, bambososina@gmail.com

In the past decade, additive manufacturing (AM), a layer-by-layer approach for printing 3D objects, has attracted a lot of attention from manufacturers. However, dimensional accuracy control currently poses a challenge in AM, often due to deformations resulting from phase changes in the printing material. Building on work done by Huang et al. (2015) on the minimization of deformations, we explore a missing data approach for understanding deformations, subsequently utilizing Bayesian models in the estimation of deformation, and compensation plan design for minimizing the deformation effect

2 - Designing for What's Important: Combining Bayesian and General Weighted Optimality Criteria

Jon Stallings, North Carolina State University, jwstalli@ncsu.edu

How one compares experimental designs depends heavily on the analysis goals (minimizing estimation variance, estimation bias, prediction variance, etc.). If one decides to focus on minimizing estimation variance, there is still the question of what has to be estimated and whether some effects are more important to estimate. DuMouchel and Jones (1994) tackled this issue with factorial experiments through a Bayesian framework assigning relative importance through prior variances. The Bayesian optimal design minimizes a summary of posterior variances and hence focuses on efficient estimation of effects with large prior variance. Stallings and Morgan (2015) introduced a class of general weighted optimality criteria that also allows the experimenter to assign relative importance to model effects through weighted variances. In this talk I compare the relative advantages and disadvantages of the two approaches in terms of their interpretability and utility for tailoring experiments to a researcher's goals. I then present a new criteria function that combines the two and demonstrate the resulting designs under multiple cases of different types of factorial experiments.

3 - A Bayesian Analysis of Communication Activity on Social Media Networks

Vinayak Rao, PhD, Purdue University, West Lafayette, IN, 47907, United States, varao@purdue.edu

Modeling communication activity among individuals on email, social media and citation networks is a topic of recent interest in statistics and machine learning. We examine such activity through the lens of two models: latent space models, where communication between individuals is determined by latent "interests", and reciprocal models, where this is a function of previous communication. We find both such models are inadequate for a variety of real-world communication data sets, and propose new models that address these limitations. Approaches we describe incorporate message content, include hierarchies of senders and receivers, and well as latent spaces that modulate reciprocal behavior.

4 - Automated Learning of Geometric Shape Deformation Models in Additive Manufacturing

Raquel Ferreira, Purdue University, West Lafayette, IN, 47907, United States, rdesouz@purdue.edu, Arman Sabbaghi, Qiang Huang

A major challenge in quality control for 3D printing is the specification of geometric shape deformation models. The current practice of constructing tailor-made deformation models for each combination of computer-aided design model, 3D printer, material, and machine setting, is impractical for general application. We propose an automated model building method based on extreme learning machines that does not require detailed knowledge of the underlying system. We illustrate promising benefits of our methodology for real-life case studies. Comparisons with current tailor-made models demonstrate the potential of our automated approach to yield similar results in a more systematic manner.

1 - Reliable Spatial Districting

Siyang Xie, U. of Illinois at Urbana-Champaign, 205 N Mathews Avenue, 3150 Newmark Lab, Urbana, IL, 61801, United States, sxie13@illinois.edu, Yanfeng Ouyang

Traditional districting problems focus on partitioning an area into districts under operational criteria, e.g., contiguity, compactness, workload balance, etc. In many real-world applications, each district is associated with a facility, thus involving additional location and assignment decisions. We develop a facility districting framework to combine the facility and districting considerations, with possible facility disruptions. We formulate the problem as a set-covering based reliable network partitioning model and design a column generation algorithm to effectively solve it. Numerical case studies are conducted to demonstrate the framework and to draw managerial insights.

2 - Electric Vehicle Routing Problem under the Limited Energy Supply

Shinichi Maeda, Osaka University, Suita, Japan, shinichi.maeda@ist.osaka-u.ac.jp, Hiroshi Morita

In recent years, the development and diffusion of Electric Vehicles have been advanced. For the delivery companies, electric vehicles are expected not only for means of transportation and delivery but also energy management systems by using vehicle storage batteries. Particularly, in cooperation with the smart grid or virtual power plant, which has recently undergone reforms, it is expected to minimize energy usage and reduce electricity bills. In this research, we will develop a delivery plan by electric vehicles according to changes in energy supply in future electric power systems.

3 - A Modern Optimization Approach for the Robust Airlift Planning Problem for the United States Transportation Command

Nishanth Mundru, Massachusetts Institute of Technology, Operations Research Center, E40, Cambridge, MA, 02139, United States, nmundru@mit.edu, Dimitris Bertsimas, Allison An Chang, Velibor Misic

The United States Transportation Command (USTRANSCOM) plans missions globally, the majority traveling by air. These missions are challenging to plan and are subject to uncertainty in travel times and cargo weights. We propose a solution approach based on local search methods, robust and mixed-integer optimization, and column generation, and show that it provides high quality solutions in practical times.

Supervised Learning Models and Applications

Sponsored: Data Mining

Sponsored Session

Chair: Ali Dag, Ali.Dag@usd.edu

1 - A Supervised Learning Approach for Matched Case-control Study

Nooshin Shomal Zadeh, Arizona State University, Tempe, AZ, United States, nshomalz@asu.edu, Sangdi Lin, George Runger

Matched case-control study is commonly used in the field of public health to detect important variables that affect an outcome. One of the challenges in this study is to determine the relationship between the variables and the outcome in the presence of large number of variables whose interactions can affect the outcome. Another challenge is that the relationships can be nonlinear and some are difficult to model by traditional approaches. In addition, handling both numerical and categorical variables remains an important and yet difficult problem. In this research, we propose a supervised learning approach which can address these challenges and handle both categorical and numerical variables.

2 - A Novel End-to-end Deep Learning Model for Time Series Classification

Sangdi Lin, Arizona State University, AZ, United States, Sangdi.Lin@asu.edu, George Runger

Time series classification is an important task in many domains such as manufacturing and finance. It is gaining more attention in health care as the wearable devices become popular, and more health-related time series data is recorded. In this presentation, we introduce a novel deep learning model which can be generally applied to time series classification tasks in various domains. The proposed deep learning model can be trained in an end-to-end fashion without the need of the traditional exhausting feature engineering step. Our deep learning model not only produces accurate classification results, but also obtains some insights and understanding about the time series data.

3 - Predicting the Survival of Breast Cancer Patients via Supervised Machine Learning Algorithms

Eyyub Kibis, PhD, The College of Saint Rose, Albany, NY, United States, eyyubyunus@gmail.com, Esra Buyuktahtakin, Ali Dag

Breast cancer is the second leading cause of death after lung cancer in the U.S. There are many reasons that impact the life time expectancy of patients. In this study, given a set of explanatory variables that include demographics, health conditions, and cancer treatment regimens of patients, our objective is to determine patient specific survival scores ten years after the initial breast cancer diagnosis. We use data mining methods and information fusion technique to determine the key features for breast cancer survivability as well as the patient specific survival score. Our results can help practitioners for adjusting the aggressiveness of treatments based on the survival scores of patients.

Chair: Hakan Yildiz, Michigan State University, Department of Supply Chain Management, 632 Bogue St., East Lansing, MI, 48824, United States, yildiz@msu.edu

1 - Reliable Synchromodal Transportation Networks

Rob A. Zuidwijk, Professor, Ports in Global Networks, Erasmus University-Rotterdam, RSM.Erasmus University, P.O. Box 1738, Rotterdam, 3000 DR, Netherlands, rzuidwijk@rsm.nl

This paper studies planning of container transport services on port hinterland networks where various transport resources are deployed in a flexible way. Two aspects receive particular attention. First, the sourcing of transport capacity to provide these services. Second, the reliability of the door-to-door services based on the reliability of the scheduled services of the various modes.

2 - Drone-assisted Delivery: A Practical Approach

Iman Dayarian, Georgia Institute of Technology, School of Industrial and Systems Engineering, 765 Ferst Dr NW, Atlanta, GA, 30318, United States, iman.dayarian@isye.gatech.edu, Martin W. P.Savelsbergh

Unmanned aerial vehicles, drones in particular, have recently seen an increased level of interest as their potential use in same-day home delivery has been promoted by large retailers and courier companies. We introduce the vehicle routing problem with drone resupply in which a delivery vehicle makes deliveries in a certain area and is regularly resupplied by a drone. Resupply can take place at specific meeting locations, where the drone will land on the roof of the delivery vehicle. We explore and compare different decision-making strategies and provide insights resulting from a comprehensive computational study.

3 - Transportation and Process Planning for Beverage Container Recycling

Hakan Yildiz, Michigan State University, Department of Supply Chain Management, 632 Bogue St., East Lansing, MI, 48824, United States, yildiz@msu.edu, Robert Wiedmer

Empty beverage containers are mostly returned to retail stores, which are then picked up and transported to processing facilities. The routes and schedules of pickup vehicles are mostly done based on forecasts, which makes this problem a variant of Vehicle Routing Problem with Stochastic Demand. We analyze data and develop methods to optimize the pick-up and processing operations.

4 - Routing and Scheduling Optimization in Road Transport Operations

Onur Can Saka, Optimization & Analytics Unit Manager, Borusan R&D, Istanbul, Turkey, osaka@borusan.com
Onur Can Saka, Optimization & Analytics Unit Manager, Koc University, Istanbul, Turkey, osaka@borusan.com, Sibel Salman

The aim of this study is to develop a methodology to optimize the daily planning of road transport operations of a third-party logistics provider. The problem is represented on a time-space network and time windows are imposed on both pick-ups and deliveries, while synchronization requirements arise at cross-docks. We propose a construction algorithm that generates routes considering predefined rules for distinct vehicle types. The resulting set of routes is then inserted into a comprehensive mixed-integer linear programming model to find the least-cost assignment of orders to routes and vehicles satisfying problem constraints. We test and validate our model using real-life data of the company.

Design and Analysis of Experiments with Heterogeneous and Functional Responses

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Lulu Kang, Illinois Institute of Technology, Chicago, IL, 60616, United States, lkang2@iit.edu

1 - A Sequential Split-conquer-combine Approach for Gaussian Process Modeling in Computer Experiments

Ying Hung, Rutgers State University of New Jersey, 110 Frelinghuysen Road, 501 Hill Center Busch Campus, Piscataway, NJ, 08854-8019, United States, yhung@stat.rutgers.edu

Gaussian process (GP) models are widely used in the analysis of computer experiments. However, two critical issues remain unresolved. One is the computational issue in GP estimation and prediction where intensive manipulations of an n-by-n correlation matrix are required and become infeasible for large sample size n. The other is how to improve the naive plug-in predictive distribution which is known to underestimate the uncertainty. In this talk, we introduce an unified framework that can tackle both issues simultaneously. The proposed framework is demonstrated by a data center example based on tens of thousands of computer experiments generated from a computational fluid dynamic simulator.

2 - An Empirical Adjustment of the Uncertainty Quantification in Gaussian Process Modeling

Ran Yang, Northwestern University, Dept. of Industrial Engineering, Rm C230, 21, Evanston, IL, 60208, United States, ranyang2011@u.northwestern.edu, Daniel Apley

Gaussian process (GP) models is the standard surrogate models for deterministic computer response surfaces, due in part to their built-in mechanism for providing uncertainty quantification (UQ) in the form of prediction intervals on the response. However, their parameter estimation methods tend to favor good prediction at the expense of poor UQ. We develop a post-processing method that takes a fitted GP model and its training data, and empirically adjusts the built-in GP UQ so that it is in better agreement with the actual uncertainty in the predictions. We show that it substantially improves the accuracy of the UQ, especially for nonstationary response surfaces that have more complex behaviors.

3 - Practical Heteroskedastic Gaussian Process Modeling and Design for Large Simulation Experiments

Mickaël Binois, University of Chicago, Chicago, IL, United States, mbinois@uchicago.edu, Robert B. Gramacy, Michael Ludkovski

We present a unified view of likelihood based Gaussian progress regression for simulation experiments exhibiting input-dependent noise. Replication plays a key role in that context as it allows to perform inference for all parameters, bypassing full-data sized calculations. We then borrow a latent-variable idea from machine learning to address heteroskedasticity, leveraging both the computational and statistical efficiency of designs with replication. We further propose to create and sequentially enrich designs with a tunable degree of replication.

Sponsored Session

Chair: Murat Caner Testik, Hacettepe University, Ankara, 06800, Turkey, mtestik@hacettepe.edu.tr

1 - An Economic Off-line Quality Control Approach for Unstable Production Processes

Rong Pan, Arizona State University, School of Computing Informatics & Decison Sys, P.O. Box 878809, Tempe, AZ, 85287-8809, United States, rong.pan@asu.edu, Zhenlu Chen, Lirong Cui

An economic off-line inspection/disposition approach is proposed, which incorporates manufacturing variation. This approach includes a new inspection algorithm for inspections based on cost minimization and utilizes a specified confidence level for identifying in-control items.

2 - A Discrete Spatial Model for Wafer Yield Prediction

Kaibo Wang, Tsinghua University, Department of Industrial Engineering, Tsinghua University, Beijing, 100084, China, kbwang@tsinghua.edu.cn

Yield analysis is one of the key concerns in the fabrication of semiconductor wafers. In this paper, we propose a novel discrete spatial model based on defect data on wafer maps for analyzing and predicting wafer yields at different chip locations. More specifically, based on a Bayesian framework, we propose a hierarchical generalized linear mixed model, which incorporates both global trends and spatially correlated effects to characterize wafer yields with clustered defects. Both real and simulated data are used to validate the performance of the proposed model.

3 - Charting Methods to Address Unknown Weights and Autocorrelation with Cyber Security Applications

Theodore T. Allen, Ohio State University, 210 Baker Systems, 1971 Neil Ave, Columbus, OH, 43210-1271, United States, allen.515@osu.edu

Literature relating to demerit and other multinomial charting methods is reviewed. A novel Bayesian charting method generalizing with convergence properties is introduced. Its applications to two problems in cyber security monitoring and addressing false positives are explored.

4 - ERLDAT2: X-bar Analysis Enhancements to the EWMA Run Length Distribution Analysis Tool

Hiram Moya, University of Texas, McAllen, TX, 78501, United States, hiram.moya@utrgv.edu, Douglas Timmer

ERLDAT provided quality practitioners an easy-to-use web-based tool to evaluate the on-target and off-target run length performance of the EWMA control chart. Performance metrics implement in ERLDAT included the average run length, variance of the run length and user-specified quantiles of the run length distribution. Seven options were provided to users to help design and evaluate EWMA control charts. ERLDAT2 extends the original ERLDAT application by providing the run length performance information for a comparable X-bar control chart versus EWMA control charts.

Data Mining

Contributed Session

Chair: Kyungduck Cha, SAS Institute Inc, Cary, NC, United States, Kyungduck.Cha@sas.com

1 - One-class Relaxed Support Vector Machines

Petros Xanthopoulos, Stetson University, 421 Woodland Blvd, DeLand, FL, 32723, United States, pxanthopoulos@stetson.edu, Orestis P. Panagopoulos, Athanasios A. Panagopoulos, Talayeh Razzaghi, Onur Seref

In this work, a new novelty detection method called One-Class Relaxed Support Vector Machines (ORSVMs) is proposed for datasets with outliers. ORSVMs are formulated using a quadratic loss function and are solved with sequential minimal optimization. Their performance is measured on several publicly available datasets and are compared to other state-of-the-art one-class classification methods.

2 - Lexicographic Multiobjective Programming (LMOP) Models for Feature Selection in LAD

Cui Guo, Associate Professor, Shantou University, 243 Da Xue Road,, Shantou, Guangdong Province, 515063, China, cguo@stu.edu.cn, Kedong Yan, Peihua Zhao

The bianrization step of Logical Analysis of Data(LAD) replaces each numerical attributes with a set of binary variables. This introduces large amount of binary features, which increases the complexity of subsequent pattern generation procedure. A feature selection method based on set covering was proposed to minimize the number of binary variables. In practice, however, it's also expected to reduce the number of real attributes. In this presention, we'll introduce LMOP models to select the optimal sets of variables w.r.t. to different lexicographic preferences. Theories and their proofs will be given. And the utilities of the propsed models will be demonstrated on various benchmark datasets.

3 - Classification of Intracardiac Electrogram During Atrial Fibrillation using Hidden Markov Models and Gaussian Mixture Models

Lianning Zhu, Texas Tech University, 2500 Broadway, Lubbock, TX, 79409, United States, lianning.zhu@ttu.edu, Dongping Du

This talk presents a new classification algorithm to identify electrical triggers in Atrial Fibrillation using hidden Markov models(HMM) and Gaussian mixture models(GMM). Activations of multi-lead Intracardiac Electrogram(IEGM) are detected based on the variance equality test. Wavelet transform is used to denoise and extract features to train HMMs. HMMs are developed for each lead of signal and used to calculate the log-likelihood of each activation in the IEGM. Computer simulation is performed to generate modeled IEGM for model testing and validation. The accuracy and sensitivity of this diagnosis system are relatively high.

4 - Robust Principal Component Analysis in Cloud-based Run-time Environment

Kyungduck Cha, SAS.Institute Inc, Sas Campus Drive, Cary, NC, 27513, United States, Kyungduck.Cha@sas.com, Seunghyun Kong, Zohreh Asqharzadeh, Arin Chaudhuri

Robust Principal Component Analysis (RPCA) is an enhanced statistical procedure to perform the principal component analysis in the presence of noisy data. Principal component analysis is widely used in data mining and machine learning. RPCA aims to recover a low rank matrix from grossly corrupted observations. RPCA has been applied in many areas, including image processing, latent semantic indexing, ranking and recommendations, and anomaly detection. The RPCA techniques have been implemented in SAS Viya platform, the cloud-based run-time environment for data management and analytics. We present the advantage of the distributed computing and how to use clients other than SAS, such as Python

5 - A Data Framework of Financial Deterioration Detection for Chinese Firms

Jun Huang, assistant professor, San Angelo State University, San Angelo, TX, United States, jun.huang@dusty.tamiu.edu, Haibo Wang

Firm level credit risk prediction, such as financial deterioration detection or financial distress prediction, is used to mitigate the risk of non-performing loans. The objectives of this study include: (1) Identify most efficient model in predicting the financial deterioration of Chinese firms based on different statistical and machine learning algorithms; (2) Use the model(s) to establish a warning mechanism to detect financial deterioration in an early stage; (3) Identify effective financial indicators for the prediction model by using a feature selection technique; (4) Test whether discretization of financial ratios improve the prediction performance of this classification problem.

Invited Session

1 - Building and Solving Optimization Models with SAS

Edward P. Hughes, SAS.Institute, Inc., Sas Campus Drive, Cary, NC, 27513, United States, ed.hughes@sas.com, Rob Pratt

SAS provides a broad and deep array of data and analytic capabilities, including data integration, statistics, data and text mining, econometrics and forecasting, and operations research. The SAS optimization, simulation, and scheduling features coordinate easily and fully with other SAS strengths in data handling, analytics, and reporting. OPTMODEL from SAS provides a powerful and intuitive algebraic optimization modeling language and unified support for building and solving LP, MILP, QP, NLP, CLP, and network-oriented models. And because the OPTMODEL optimization modeling language is contained within the OPTMODEL procedure, a SAS software module, it integrates seamlessly with the entire family of SAS functions, procedures, and macros. We'll demonstrate how you can use OPTMODEL to solve both basic and advanced problems, highlighting its newer capabilities and its support for both standard and customized solution strategies.

2 - JMP Pro: Top Features That Make You Say "Wow"!

Mia L. Stephens, SAS.Institute Inc, P.O. Box 290, York Harbor, ME, 03911, United States, mia.stephens@jmp.com

JMP is data visualization, analysis and modeling software from SAS for Mac or Windows. Come see the top 10 features in JMP Pro 13 that JMP users are raving about, including Text Explorer (for preparing and analyzing unstructured text data), the JMP Query Builder (for generating queries and writing SQL code directly in JMP), the Formula Depot (for comparing predictive models, scoring new data and generating C, Python, SAS, SQL and JavaScript code), dashboards, interactive web reports, and the latest visualization techniques in the drag-and-drop Graph Builder.

1 - Team Orienteering Problem with Stochastic Profits and Risk Constraints

Hadi Feyzollahi, SUNY University at Buffalo, Department of Industrial Eng., 316 Bell Hall, Buffalo, NY, 141260, United States, hadifeyz@buffalo.edu, Jose Luis Walteros

We proposed a dynamic programming approach to tackle the Team Orienteering Problem over graphs with stochastic profits and risk constraints. We study both discrete and continuous probability distributions to model the profits and test different approaches to compute their convolutions. We further presented a case study to illustrate the results.

2 - The Multiperiod Network Design Problem

Ioannis Fragkos, Rotterdam School of Management, Burg. Oudlaan 50, Rotterdam, 3062 PA, Netherlands, fragkos@rsm.nl, Jean-Francois Cordeau, Raf Jans

We devise decomposition methods to solve large-scale instances of multi-period network expansion problems. For capacitated networks, we devise a custom heuristic procedure combined with arc-based Lagrange relaxation. For uncapacitated networks, we employ Benders decomposition, where the subproblems are decomposable per period and per commodity. We formulate the problem of generating Pareto Optimal cuts, and based on structural properties of optimal solutions we devise an improve approach to solve it, thereby improving the original Benders cuts. Computational results demonstrate the efficiency of this approach.

3 - Self Charging Path Problem with Node Visiting

Dincer Konur, Missouri University of Science and Technology, 206 Emse, 600 W. 14th Street, Rolla, MO, 65409, United States, konurd@mst.edu

In this study, we analyze a shortest path problem with node visiting constraints such that the path should be self-charging. A self-charging path is defined as a path, on which the vehicle traveling charges the energy consumed on the path. This requires using wireless charging and we model integrated design and path decisions. The resulting model is a bi-objective mixed-integer programming model and we propose solution methods to generate Pareto efficient solutions after characterizing important properties of such solutions. A demonstration is also presented.

4 - A Sample Average Approximation Approach for a Network Evacuation Model with Joint Chance Constraints Considering Social Influence

Hyeong Suk Na, PhD Candidate, Pennsylvania State University, 234 Leonhard Building, University Park, PA, 16802, United States, hxn144@psu.edu, Necdet Serhat Aybat, Soundar Kumara

We consider a network evacuation problem with stochastic traffic demand, where the departure time decision-making behavior of evacuees is affected by social influence. Since it is difficult to characterize the departure behavior due to the inherent uncertainty, we study the evacuation process using the cell transmission model with joint chance constraints (JCCs). To resolve the intractability of JCCs, we adopt a sample average approximation method to handle JCCs. Numerical experiments are implemented to validate the performance of the proposed approximation method.

5 - Packages Delivery Optimization with On-demand Drivers

Farzad Daneshgar, University of Maryland, 4324 Rowalt Dr, 302, College Park, MD, 20740, United States, farzadd@umd.edu

Nowadays, purchases are made online more than ever and minimizing the delivery time is significantly essential to satisfy customers. Inspired by new innovations such as ride-hailing services, this research aims to develop a mathematical formulation to optimize packages delivery by on-demand drivers. We present a mixed-integer model to determine the scheduling for one-demand drivers by considering elements such as demand volume and operation costs.

6 - Parallel Benders Decomposition Method for Two-stage Stochastic Integer Programs

Ragheb Rahmaniani, Universite de Montreal, Pavillon Andre-Aisenst, CIRRELT, P.O. Box 6128, Montreal, QC, H3T.1J4, Canada, Ragheb.rahmaniani@gmail.com, Teodor Gabriel Crainic, Michel Gendreau, Walter Rei

In this talk, we discuss parallelization strategies for the Benders decomposition method. The existing parallel variants of the method rely heavily on the synchronization requirement between the master and subproblems. We describe an asynchronous parallel framework for this method. Relaxing the synchronization requirements, however, entails various theoretical and numerical difficulties that will be addressed in this presentation. We present numerical results and provide guidelines regarding how and when to use the proposed parallelization strategies and mention several fruitful research directions.

1 - Technology Opportunity Discovery through Extracting Opinion Trigger Based on Word2Vec and Natural Language Processing (NLP)

Taeyeoun Roh, First Author, Dongguk University, Seoul, Korea, Republic of, nty92@dongguk.edu, Yujin Jeong, Byungun Yoon

Some needs cannot be satisfied in technology same as needs due to there is no specify object that must be satisfied and some object is not related to their technology fields. To solve this problem, this research proposes an approach to discovering new technology opportunity related to opinion trigger(OT). OT is defined as object that users express a feeling. First, OT and their sentimental value are defined through natural language processing and naïve base classifier. Second, OTs and patent keywords which have similar meaning in context are clustered as needs and technology related to needs based on Word2Vec. Finally, technology which can be satisfied needs is derived as technology opportunity.

2 - Investigating Knowledge Management Enablers-a Case Study

Hamdy Elwany, Professor of Industrial Engineering and Operations, Alexandria University, 678 El Horreya Ave., Louran, Aexandria, 21532, Egypt, hamdy@elwany.com

This study investigates the relationship between Knowledge Management Enablers KMEs and Knowledge Management Success KMS in Middle East and North Africa region MENA industrial companies. Data was collected through an online self-administered questionnaire from 251 respondents in several industries/business sectors in MENA region. The findings of this research proved the existence of the relationship between KMEs and KMS. Also job satisfaction can be considered as KM enabler by having a positive impact on KMS. The organizational culture has a full mediating effect on the job satisfaction and KMS, and a partial mediating effect between organizational structure and IT support.

3 - Technology Adoption in Firm Networks

Wei Zhang, University of Hong Kong, Pokfulam Road, Hong Kong, 0050, Hong Kong, zhangw.03@gmail.com

We study how firms influence each other when adopting a new technology. Using real data from the semiconductor industry and survival analysis, we show that the chance of a firm adopting a new technology is a U-shaped function of the number of firms that have adopted the technology. In addition, the adoption decision of some firms would positively influence others while some firms would negatively influence others. We use the model to predict the demand of a new technology.

4 - Patent Technical Information Retrieval System Based on Natural Language Processing

Wan Wook Ki, Postech, Pohang, Korea, Republic of, wwki86@postech.ac.kr

With the development of text mining and natural language processing technology, it became possible to extract desired technical information from the each section of the patents. In this study, we developed a system that can semantically search technical information based on machine learning that can directly help technology planning such as technical function, context, components, purpose, and fusible technology in patents. This enables user to semi-automatically search and analyze patent information, which should have relied on the know-how of existing patent and technology domain experts.

5 - Optimization of Sustainable Capital Lifetime under Environmental Uncertainty

Yuri Yatsenko, Professor, Houston Baptist University, 7502 Fondren Road, Houston, TX, 77074, United States, yyatsenko@hbu.edu, Natali Hritonenko

Serial replacement of a single capital asset is analyzed under uncertain operating cost and uncertain technological improvements. A modification of classic Economic Life method is suggested and compared to popular asset replacement approach based on real options and dynamic programming. It is shown analytically and numerically that both techniques deliver similar results when the cost volatility is small. The constructed algorithm works equally well for any age-distribution of stochastic operating cost, while the real options technique is developed for geometric and linear cost age-profiles only. The algorithm is illustrated on replacement data for medical imaging devices.

1 - Modeling Cellular Metabolism as a Hypergraph Flow

Paul Brooks, Virginia Commonwealth Univ., Dept of Stat. Sci. and OR, P.O. Box 843083, Richmond, VA, 23284, United States, jpbrooks@vcu.edu

Optimization-based models of metabolism are a widely used tool in systems biology for generating predictions in medical and engineering applications. We explain how this modeling paradigm is essentially a study of flows in hypergraphs. We then demonstrate how optimal flux distributions can be decomposed into flows along pathways in a manner that enhances model interpretation. The method is applied to study the virulence of an infection-causing strain of Salmonella.

2 - Mixed-Integer Program and Heuristics for Monogamous Relationship Inference

Chun-An Chou, Northeastern University, Boston, MA, United States, ch.chou@northeastern.edu, Daehan Won, Tanja Berger-Wolf, W. Art Chaovalitwongse

In this study, we infer the relationships of parents and offspring in monogamous mating process. The inference of monogamous relationships is a NP-Hard combinatorial problem with the objective to minimize the number of parents, subject to the biological constraints (i.e., Mendelian laws). A heuristic approach is proposed to find the best monogamous parent information.

3 - Inferring New Protein Function with DEA

Allen Holder, Rose-Hulman Institute of Technology, Department of Mathematics, Terre Haute, IN, 47803, United States, holder@rose-hulman.edu

Proteins are classified into functionally similar classes called families. However, proteins probably don't have unique functionality, and hence, they likely share membership with families other than their original classification. We use a robust, inverse DEA model to help infer new functional relationships.

4 - New Density-based Optimization Formulations and Algorithms to Identify Fixations in Gaze Data

Wen Liu, Doctoral Student, Worcester Polytechnic Institute, 100 Institute Rd., Worcester, MA, 01609, United States, wliu3@wpi.edu, Andrew C.Trapp, Soussan Djamasbi

Eye tracking is an increasingly common technology with a variety of practical uses. Gaze data can be categorized into two main events: fixations, which represent attention, and saccades, which occur between fixations. We develop new optimization formulations to recover densest fixations, extending earlier work that identifies fixations using a novel density metric. We discuss related complexity results and demonstrate a polynomial-time algorithm exists if the number of fixations is apriori fixed, and very small. We conclude with encouraging computational results and insights on real data sets.

1 - Optimal Design of Efficient Rooftop Photovoltaic Arrays

Madeleine Udell, Cornell University, 207 Hoy Road, Ithaca, NY, 14850, United States, udell@cornell.edu, Alp Yurtsever, Joel Tropp, Volkan Cevher

In this talk, we consider a fundamental class of convex matrix optimization problems with low-rank solutions. We show it is possible to solve these problem using far less memory than the natural size of the decision variable when the problem data has a concise representation. Our proposed method, SketchyCGM, is the first algorithm to offer provable convergence to an optimal point with an optimal memory footprint.

2 - Large Gaps Between Cyclic Coordinate Descent and Randomized Versions

Ruoyu Sun, UIUC, 104 S Mathew Ave, Urbana, IL, 61801, United States, ruoyus@illinois.edu

A simple idea for solving large-scale computational problems is to iteratively solve smaller subproblems, which appeared in, e.g., Gauss-Seidel (G-S), Kaczmarz, coordinate descent (CD). We prove that for all these methods, there are large gaps between the deterministic cyclic versions and the randomized versions. In fact, we show an (up to) O(n^2) gap in the convergence rate for CD/G-S/Kaczmarz methods. There are examples showing cyclic CD (C-CD) can be much slower than randomized coordinate descent (R-CD), but there also exist practical examples where C-CD is faster. We show that C-CD indeed can be O(n^2) slower than R-CD in the worst case, by establishing a lower bound that matches the upper bound.

3 - Surpassing Gradient Descent Provably: A Cyclic Incremental Method with Linear Convergence Rate

Aryan Mokthari, University of Pennsylvania, 220 South 33rd Street, 107 Towne Building, Philadelphia, PA, 19104, United States, aryanm@seas.upenn.edu

The coordinate descent (CD) methods have seen a resurgence of recent interest because of their applicability in machine learning as well as large scale data analysis and superior empirical performance. CD methods have two variants, cyclic coordinate descent (CCD) and randomized coordinate descent (RCD) which are deterministic and randomized versions of the CD methods. In light of the recent results in the literature, there is the common perception that RCD always dominates CCD in terms of performance. In this paper, we provide problem classes for which CCD (or CD with any deterministic order) is provably faster than RCD in terms of asymptotic worst-case convergence.

4 - When Cyclic Coordinate Descent Beats Randomized Coordinate Descent

Mert Gurbuzbalaban, Researcher/Postdoctoral Associate, Rutgers University, Cambridge, MA, 02139, United States, mg1366@business.rutgers.edu

The coordinate descent (CD) methods have seen a resurgence of recent interest because of their applicability in machine learning as well as large scale data analysis and superior empirical performance. CD methods have two variants, cyclic coordinate descent (CCD) and randomized coordinate descent (RCD) which are deterministic and randomized versions of the CD methods. In light of the recent results in the literature, there is the common perception that RCD always dominates CCD in terms of performance. In this paper, we provide problem classes for which CCD (or CD with any deterministic order) is provably faster than RCD in terms of asymptotic worst-case convergence.

1 - Chance Constrained Combinatorial Optimization with a Probability Oracle

Hao-Hsiang Wu, University of Washington, Seattle, WA, United States, hhwu2@uw.edu, Simge Kucukyavuz

A chance-constrained combinatorial optimization problem (CCOP) aims to find a minimum cost selection of binary decisions, which satisfies a constraint with high probability. Suppose that we have an oracle that can compute the probability of satisfying the constraint exactly. Using this oracle, we propose a general method for solving CCOP exactly. In addition, if CCOP is solved by a sampling-based approach, the oracle can be used as a tool for checking and fixing the feasibility of the resulting solution. To demonstrate the effectiveness of the proposed methods, we apply them to an NP-hard probabilistic set covering problem, which admits a polynomial-time exact probability oracle.

2 - Preventive Maintenance Scheduling with Shared Set-ups

Eric C. Blair, University of Florida, 25 SW 5th Terrace, Apt. 4506, Gainesville, FL, 32601, United States, ecblair@ufl.edu, Yongpei Guan

We present a formulation of a preventive maintenance scheduling problem with shared set-ups. Maintenance jobs have a time-variant interval which they must be performed within, and some jobs share set-ups, so scheduling these jobs together can reduce set-up costs. The problem is modeled as an integer program, and can be relaxed to a linear program without sacrificing integrality when excluding complicating capacity constraints. We explore and discuss approaches that can be used to generate solutions for large-scale instances of the problem with all constraints included.

3 - On Knapsack Problems Over Time

Yuri Faenza, Assistant Professor, Columbia University, 500 West 120th Street, New York, NY, 10025, United States, yf2414@columbia.edu, Igor Malinovic

The time-Invariant Incremental Knapsack problem (IIK) has been introduced by Bienstock et al. [2013] as a generalization of the classical Maximum Knapsack to a discrete multi-period setting. At each time, the capacity increases and items can be added, but not removed, from the knapsack. The goal is to maximize the sum of profits of items over all times. IIK naturally models scenarios where resources (e.g. money, labor force) augment over time in a predictable way, allowing an expansion of our portfolio. In this talk, we give algorithmic and structural results on this and, if time permits, on related problems.

4 - A Regularized Cutting Plane Algorithm for Inverse Mixed Integer Programming Problems

Vishnu Vijayaraghavan, Texas A.& M.University, 400 Nagle Street, College Station, TX, 77840, United States, vishnunitr@tamu.edu, Kiavah Kianfar, Andrew J.Schaefer

An inverse optimization problem is to minimally perturb the cost function of an optimization problem with respect to some Lp-norm, so as to make a given feasible solution the optimal one. Inverse optimization for mixed integer problems is particularly challenging. Wang (2009) proposed a cutting plane algorithm to solve inverse mixed integer problems under a weighted norm. We present an improved version of this cutting plane algorithm by regularizing the addition of more effective cutting planes. Our computational results demonstrate significant gains over the previous approach, more profoundly for problems in large dimensions.

1 - Bundle Pricing and Inventory Planning for a Multi Products Newsvendor Problem

Nooshin Hamidian, University of Tennessee-Knoxville, 5 11Q John D. Tickle Engineering Building, 851 Neyland Dr, Apt A5, Knoxville, TN, 37996, United States, nhamidia@vols.utk.edu, Rupy Sawhney

The multi-product newsvendor problem is studied. The objective is to maximize expected revenue while both the selling prices and ordering quantities are decision variables. The demand for all products and bundles are additive stochastic and cross-elastic. The mathematical model for the problem is developed. A two-stage algorithm is proposed in order to solve the mathematical model. The proposed algorithm is based on multi-directional search and Nest Partitioning algorithm and has both methods' advantageous. Sensitivity analysis is presented to obtain managerial insights.

2 - Biased Random-key Genetic Algorithm for Balanced Edge Partitioning

Larissa P.G. Petroianu, PhD Student, University of Washington, 3900 E Stevens Way NE, Mechanical Engineering Building, Seattle, WA, 98195, United States, lpetroia@uw.edu, Mauricio G.C. Resende, Wanpracha Art Chaovalitwongse

Vertex partitioning in graphs has received more attention in the literature than edge partitioning. In this talk, we consider an edge-partitioning problem with applications in page-rank computation and delivery routing. We develop a Biased Random-Key Genetic Algorithm (BRKGA) that finds optimal or near-optimal solutions to this problem. We present experimental results, comparing our algorithm with other approaches.

3 - Automatic Design of Algorithms for Knapsack Problems

Victor Parada, Dr Sc, Universidad de Santiago de Chile, Av. Ecuador 3659, Departamento de Ingeniería Informática, Santiago, Chile, victor.parada@usach.cl

Automatic design of algorithms for combinatorial optimization problems can generate new procedures from existing heuristics. We generated algorithms for the 0-1 binary knapsack and for the multidimensional knapsack problems that efficiently and competitively solve a set of typical problem instances. The automatically constructed algorithms are generated by genetic programming as a result of exploring the heuristic combinations space.

4 - Unmanned Aircraft System Path Planning for Inspecting Electric Transmission Towers

Hyeoncheol Baik, Auburn University, 3331 Shelby Center, Auburn, AL, 36849, United States, hbaik@auburn.edu, Jorge F.Valenzuela

Electric utilities inspect transmission towers by dispatching line crews and helicopters. This method has high operation costs and safety concerns. To mitigate these issues, the utilities are using unmanned aircraft system to accomplish this task. We have developed a particle swarm optimization based algorithm to find an efficient flight route for a UAS to inspect a transmission tower. The proposed model contains three sub-objectives: to minimize the total flight distance, maximize the inspection coverage, and maximize the image resolution. We have tested our model and make recommendations for the actual use of a UAS in the field.

Market-based Management of Future Electricity Grids

Sponsored: Energy, Natural Res & the Environment Electricity

Sponsored Session

Chair: Wolfgang Ketter, University of Cologne, Cologne, Germany, ketter@wiso.uni-koeln.de

1 - Pricing Mechanisms to Coordinate EV Charging: A Variable Charging Speed Approach

Konstantina Valogianni, Assistant Professor, IE Business School, VAT.# ES.B-82334319, Maria de Molina 13, Madrid, 28006, Spain, konstantina.valogianni@ie.edu, Wolfgang Ketter, John Collins, Gediminas Adomavicius

We present a decision support system (DSS) that coordinates electric vehicle (EV) charging. It combines the benefits of a decentralized decision making approach with a top-down control mechanism. This hybrid approach creates a less volatile aggregate power demand curve, and therefore a better match between the output of renewable energy sources and overall demand. Our mechanism is based on price signals to individual EV owners. We prove that are sufficient to motivate self-interested EV owners to approach a desired profile, given a range of user preferences. We prove the analytical properties of the mechanism in order to induce desired charging profiles and evaluate its outcome on real-world data.

2 - Risk-neutral and Risk-averse Methods for Bidding in the Energy Market

Daniel Jiang, University of Pittsburgh, Pittsburgh, PA, 15261, United States, drjiang@pitt.edu, Warren B. Powell

The talk is centered on developing optimal trading/bidding policies for the energy market in the presence of storage. In the context of this application, we describe two general methodological contributions: approximate dynamic programming for monotone value functions and for risk-averse sequential problems.

3 - Implement Real-time Pricing with Regret-based Learning Games

Zibo Zhao, PhD Candidate, Purdue University, West Lafayette, Grissom Hall, 315 N Grant Street, West Lafayette, IN, 47907, United States, zhao438@purdue.edu

The situation where price-responsive consumers determine what to do in the near future (such as when to charge their PEVs) forms a dynamic and incomplete-information game, in which the consumers' collective actions will impact electricity prices, which in turn affect their payoffs. We propose a multi-armed bandit (MAB) game framework in which each consumer plays an MAB problem to minimize the cumulative regret, as opposed to naively responding to day-ahead prices. Numerical results show very fast convergence to a steady-state of the MAB game with much reduced price volatility than the naïve-response case.

1 - Generating Large Size Social Networks

Xu Dong, Research Assistant, University of Miami, 1251 Memorial Drive, Coral Gables, FL, 33145, United States, x.dong3@umiami.edu, Nazrul I.Shaikh

Researchers conduct various tests on simulated social networks, because of the infeasibility of testing certain conditions (e.g. node removal, link adding, etc.) and processes (e.g. spread of diseases, opinions, influence, etc.) that take place in real-world social networks. However, the existing social network models are only able to recover small social networks with few members in it. In this work, we focus on generating large-scale networks with desired social network topologies, such that they can serve as the test beds for modeling specified social processes and activities.

2 - Blockchain for Security of Cyber Physical Systems

Leili Soltanisehat, Research Assistant, Old Dominion University, Norfolk, VA, United States, lsolt001@odu.edu

In recent decades, along with various cyber attacks to some important settings, security of cyber-physical systems (CPS) has become a challenging issue. In this paper, we are analyzing the implications of Blockchain Technology in boosting the security of CPS. General idea is that CPS will be more secure and resilient if both information and physical security are controlled. Using the concept of cryptography and decentralization, Blockchain technology enables the cyber system with a very high degree of certainty and reliability. Certainty and reliability ensure the integrity and accuracy of information.

3 - Analyzing the Economic and Environmental Impacts of Cloud Computing

Chialin Chen, Professor, National Taiwan University, College of Management, National Taiwan University, Taipei, Taiwan, cchen026@ntu.edu.tw, Xiaodan Pan

Cloud computing has fundamentally changed the way today's companies use information technology. We use Systems Dynamics to construct a simulation model to analyze the economic and environmental impacts of cloud computing. On the demand sides, we classify customers in different market segments for cloud computing, and then characterize their specific demand patterns and preferences. On the supply side, we identify different infrastructure and network costs as well as different sources of energy consumption associated with cloud computing. By observing the dynamic systems behaviors, we identify the key determinants of the economic and environmental risks and benefits of cloud computing.

4 - A Decision-theoretic Approach to Verification in Systems Engineering

Aditya Umesh Kulkarni, Virginia Tech, 250 Durham Hall, 1145 Perry Street, Blacksburg, VA, 24061, United States, aditya88@vt.edu, Christian Wernz, Alejandro Salado

Verification is a key step in the development of a complex system. Multiple decision-making agents across multiple firms are involved in verification activities. A comprehensive and rigorous mathematical framework for computing optimal verification strategies in this multi-agent and multi-firm environment has not yet been developed. We propose a new approach that builds upon principal-agent modeling, partially observable Markov decision processes and multiscale decision theory. Using this new approach, we identify incentive and information exchange mechanisms that allow for better verification at lower cost.

Urban Operations: Towards Livable Cities

Sponsored: Energy, Natural Res & the Environment, Energy

Sponsored Session

Chair: Tim Williams, University of Michigan, Ann Arbor, MI, 48104, United States, tgw@umich.edu

Co-Chair: Tom M. Logan, University of Michigan, Ann Arbor, MI, 48109, United States, tomlogan@umich.edu

1 - The Role of Behaviour in Undermining the Effectiveness of Adaptive Measures in Reducing Long-term Vulnerability to Natural Hazards

Tom M. Logan, Industrial and Operations Engineering, University of Michigan, Ann Arbor, MI, 48104, United States, tomlogan@umich.edu, Seth Guikema, Jeremy Bricker

How to defend the world's cities from natural hazards is the subject of intense debate. Allegedly, some adaptive measures increase vulnerability to unforeseen events. Here, we develop a cellular automaton model to quantitatively examine the effect of alternative adaptive strategies in reducing a community's risk over time when subject to repeated natural hazards (tsunamis). We find that while hard measures (sea walls) protect against expected events, they increase vulnerability to future, larger events. Actions to avert development from risk zones appear more effective. These results demonstrate hard-adaptive measures can result in maladaptation, thus challenging current practice.

2 - How Accessible Are Our Cities? A Cross-sectional Analysis of Access to Green Space

Tim G. Williams, Industrial and Operations Engineering, University of Michigan, Ann Arbor, MI, 48104, United States, tgw@umich.edu, Tom Logan, Connie Zuo, Kevin Liberman, Seth Guikema

Adapting our cities requires us to resolve the contentious issue of social justice in service access. Green spaces provide a wide range of benefits, and their access has been subject to much analysis. However, the generalizability of many existing conclusions is limited by both scope and resolution of analysis. Here, we evaluate access to green space in multiple US cities to: a) Investigate whether systemic inequity exists across US cities; and b) Assess the sensitivity of these conclusions to measures of amenity quality. This large-scale, fine-resolution analysis incorporates uncertainty and enables us to draw enhanced insights to answer these questions, essential to designing livable cities.

3 - Using Machine Learning to Predict Building Level Waste Generation and Recycling Rates

Constantine Kontokosta, ckontokosta@nyu.edu, Boyeong Hong

New York City generates approximately 3.2 million tons of waste each year at a cost of over $1.5 billion. This paper develops a machine learning model to predict building-level waste generation at daily and weekly timescales for over 800,000 residential properties, and uses the results to evaluate the impact of incentive and regulatory measures designed to change household behavior. We use NYC Department of Sanitation daily waste collection data over eight years at the individual truck level, which account for more than 5,000,000 observations, and integrate these with weather, socioeconomic, and land use characteristics. We apply multiple approaches to validate our model output.

4 - Urban Analytics: A Case Study in Philadelphia

Shane Jensen, Wharton School, University of Pennsylvania, Philadelphia, PA, United States, stjensen@wharton.upenn.edu

Urban data analysis has been recently improved through publicly available high resolution data, allowing us to empirically investigate urban design principles of the past half century. We are currently using safety as a measure of the health of a neighborhood and exploring how it relates to local neighborhood features, including land use zoning, business locations and activity as well as economic measures and population density. I will discuss matching analyses of the relationship between vibrancy and safety and spatial modeling of the change in safety over the past decade. Philadelphia is an interesting case study for this work with its recent population growth and substantial urban development.

1 - Improvement of Linear Decision Rules in Robust Optimization by Lifted Uncertainty Sets

Frans de Ruiter, Tilburg University, H.R.Holststraat 48, Tilburg, 4103 VB, Netherlands, f.j.c.t.deruiter@uvt.nl

We design a new class of nonlinear decision rules for robust optimization and approximate this class of decision rules using lifted uncertainty sets. The new decision rules on the lifted uncertainty set are linear again and strictly improve on the classical linear decision rules and existing lifting methods. We show that the resulting model with our new decision rules on the lifted uncertainty set are not more difficult from a computational standpoint than the models that use classical linear decision rules. The power of our new decision rules is shown on existing applications taken from the literature on adjustable robust optimization.

2 - Stochastic Dynamic Programming using Optimal Quantizers
Anna Timonina-Farkas, Postdoctoral Researcher, EPFL, RAO, Rue Saint-Laurent 33, Lausanne, Switzerland, anna.farkas@epfl.ch

Multi-stage stochastic optimization is a well-known quantitative tool for decision-making under uncertainty. Theoretical solution of stochastic programs can be found explicitly only in very exceptional cases due to the problems complexity. Therefore, the necessity of numerical solution arises. In this work, we deal with numerical approximation methods for the solution of multi-stage optimization problems, which enhance both accuracy and efficiency of the solution. We preserve accuracy of the estimation by the use of optimal distribution discretization techniques on scenario trees, as well as we enhance efficiency of numerical algorithms by the combination with the dynamic programming.

3 - On the Optimality of Affine Policies for Budget of Uncertainty Sets
Omar El Housni, oe2148@columbia.edu, Vineet Goiyal

The performance of affine policies for two-stage adjustable robust optimization problem under a budget of uncertainty set. This important class of uncertainty sets provide the flexibility to adjust the level of conservatism in terms of probabilistic bounds on constraint violations. The two-stage adjustable robust optimization problem is hard to approximate within a factor better than $\Omega(\log n)$ even for budget of uncertainty sets where n is the number of decision variables. We show affine policies provide the best possible approximation of $O(\log n)$ for budget of uncertainty sets. We discuss performance of affine when the uncertainty set is given by intersection of budget constraints.

Recent Advances in Risk Averse Optimization

Sponsored: Optimization, Optimization Under Uncertainty

Sponsored Session

Chair: Gabor Rudolf, Koc University, Koc University, Istanbul, 34450, Turkey, grudolf@ku.edu.tr

1 - Optimization with Incomplete Information About Risk Measures
Jonathan Yu-Meng Li, Telfer School of Management, University of Ottawa, 55 Laurier Avenue East, Ottawa, ON, K1N 6N5, Canada, jonathan.li@telfer.uottawa.ca, Erick Delage

New risk theories have been developed recently that formalize measures that reasonably capture ones' risk preferences. The problem, however, of applying these theories is that in reality only limited information about ones' risk preferences is available. In this talk, we present a unified framework, preference robust optimization, that allows one to apply principles established by the latest risk theory to measure risk even when the preference information is incomplete and to generate solutions that are robust in terms of one's true risk preferences. Our main result is to show that most optimization problems under uncertainty can be tractably solved even with incomplete preference information.

2 - Acceptability Pricing of Contingent Claims under Model Ambiguity using Stochastic Optimization
Martin Glanzer, PhD Student, University of Vienna, Oskar-Morgenstern-Platz 1, Vienna, 1090, Austria, martin.glanzer@univie.ac.at, Georg Ch. Pflug

Optimal bid and ask prices for contingent claims can be found by mathematical optimization. The traditional strategies find the optimal prices under the constraint that all risks are shifted to the resp. counterparty. We weaken this assumption by introducing risk (acceptability) functionals in the stochastic optimization framework. Moreover, we consider the associated ambiguity problem, where we replace the single probability model by a nonparametric set of models. We show that weakening the acceptability constraint leads to a shrinking bid-ask spread while considering model ambiguity makes it even larger. We discuss algorithmic solution methods and present some illustrative examples.

3 - A Decomposition Algorithm for ASD Risk Measure for Stochastic Programs with 0-1 Variables
Saravanan Venkatachalam, Wayne State University, 4815 Fourth St., Detroit, MI, 48377, United States, saravanan.v@wayne.edu, Lewis Ntaimo

Due to the lack of block-angular structure, stochastic programs with ASD risk measure pose computational challenges. In this talk, we propose a decomposition algorithm to ASD risk-measure and computational results are presented for a supply chain application.

4 - Optimization with Stochastic Preferences Based on a General Class of Scalarization Functions
Gabor Rudolf, Koc University, Koc University, Istanbul, 34450, Turkey, grudolf@ku.edu.tr, Nilay Noyan

We consider problems where a decision leads to multiple uncertain outcomes, and decision makers' preferences are incorporated via risk measures or via dominance constraints. Scalarization functions are a common tool to combine multiple outcomes. While the stochastic multi-objective literature largely relies on linear scalarization, a variety of other functions are used in deterministic settings. We incorporate a general class of scalarizations into multi-criteria decision models with stochastic preference constraints, and develop a theoretical background along with tractable solution methods.

Optimization, Robust

Contributed Session

Chair: Shunichi Ohmori, Waseda University, Tokyo, Japan, ohmori0406@gmail.com

1 - A Robust Optimization Approach in Dynamic Pricing with Online Demand Learning
Maryam Zokaeinikoo, Graduate Research Assistant, Pennsylvania State University, Department of Industrial and Manufacturing Engineering, 364 Leonhard Building, University Park, State College, PA, 16802, United States, mzz30@psu.edu, Janis Terpenny, Tao Yao, Xue Wang

We consider dynamic pricing problem in revenue management where the goal is to maximize revenue from multiple products with limited inventory over a finite time horizon. The demand function is unknown and should be learned from the sales data. We can formulate this problem as a multi-armed bandit problem to address the challenge of exploration-exploitation tradeoff. Through exploration, the retailer attempts to learn the demand at different prices and set a price that maximizes revenue over the remainder of the selling season (exploitation). We use robust optimization in this problem and show that the regret bound achieves near optimal performance compared to an oracle that knows all the parameters.

2 - Many-objective Evolutionary Approach to Scenario-based Optimization Problems
Hayrullah Mert Sahinkoc, Bogazici University, Istanbul, Turkey, hmertsahinkoc@gmail.com, Umit Bilge

We propose to approach optimization problems under scenario-based uncertainty by transforming them into multi-objective optimization problems where each scenario is considered as a separate objective. Solving the multi-objective counterpart provides optimal solutions with respect to different robust performance measures in a Pareto optimal set. To overcome the challenges posed by more than three scenarios, we resort to an emerging research area called many-objective optimization. The proposed many-objective evolutionary algorithm strategically combines several features and yields promising results on scenario-based 0-1 Knapsack problem compared to a set of existing algorithms.

3 - Optimization Problem for the Most Robust Preference
Jian Hu, Assistant Professor, University of Michigan-Dearborn, 4901 Evergreen Rd., Dept. of IMSE,, Dearborn, MI, 48128, United States, jianhu@umich.edu

We propose an optimal model with most robust preference. This problem is to seek a valid option most robustly preferable to benchmark. We develop an approximation approach based on Bernstein polynomials, and a cut-generation algorithm to solve the approximation problem. A financial portfolio investment problem has been used to illustrate the effectiveness of this model.

4 - A Heuristic Method for Stochastic Optimization
Shunichi Ohmori, Assistant Professor, Waseda University, Room 0903A, Okubo 3-4-1, Shinjuku, Tokyo, Japan, ohmori0406@gmail.com

We studied stochastic non-convex optimization problem. We proposed an analysis framework using stochastic dynamical system and analyze stability of algorithm. By doing so, we can adjust the balance between diversification and convergence.

Keynote: Optimization and Analytics Applications in the Oil and Gas Industry

Invited: Keynote

Invited Session

1 - Optimization and Analytics Applications in the Oil and Gas Industry

Cassandra McZeal, Exxon-Mobil

The oil and gas industry is going through transformational times as reflected in the shale revolution, the gradual increase of the use of non-renewables, the recent drop in the oil prices, and the increasing efficiency in energy uses. With such changes, the industry is faced with several challenges in achieving its goals of efficient and environmentally responsible operations, production optimization, and capital cost reduction. The oil and gas industry is often divided into three sectors: upstream, midstream and downstream. The upstream is mainly focused on activities related to the exploration and production of hydrocarbons. Such activities include searching for subsurface accumulation of hydrocarbons, drilling wells, and the production of those resources. On the other hand, the downstream sector is mainly concerned with the conversion of produced raw hydrocarbons into useful and useable products. Downstream activities include refining of petroleum crude oil, the processing of natural gas, and the distribution of refined products, such as gasoline, jet fuel, diesel oil, heating oil, fuel oils, lubricants, and many other petrochemicals products. The midstream sector comprises the transportation, storage, and marketing of crude oil, refined petroleum products, natural gas and petrochemicals. Transportation and logistics for the various products are carried out through a variety of modes including pipelines, rail, barges, oil tankers and trucks. Optimization and analytics technologies are currently playing a vital role in enabling the oil and gas industry to achieve the above objectives. In this talk, I will review selective applications of optimization technology in the Oil and Gas Sector with focus on problem modeling and algorithmic development in all three sectors.

Judgments and Forecasting

Sponsored: Decision Analysis

Sponsored Session

Chair: Kenneth Nguyen, University of Southern California, 8211 Somers Drive, Anaheim, CA, 92841, United States, hoangdun@usc.edu

1 - Comparing Verbal and Numeric Forecasts: New Findings and Implications

Kenneth Nguyen, University of Southern California, 8211 Somers Drive, Anaheim, CA, 92804, United States, hoangdun@usc.edu, Richard S.John

This research compares verbal and numeric forecasts of subjective probability estimates. A sample of 118 NFL football experts was recruited to participate in the study. The experts were randomized into one of the two experimental conditions that differ in the modes of the response scale. Verbal responses were later transformed into numbers using a method based on Savage's conceptualization of subjective probabilities. Results showed that verbal forecasts were not statistically significant from numerical predictions in terms of the overall accuracy. However, numerical judgments were more discriminatory and more biased than verbal judgments.

2 - Quantifying the Accuracy of Subjective Probability Estimates: A Meta-analysis

Kenneth Nguyen, University of Southern California, 8211 Somers Drive, Anaheim, CA, 92804, United States, hoangdun@usc.edu, Matthew Baucum, Richard S. John

We attempted to address the question whether subjective probability estimates are actually better than random guesses, and explored the effects of various methodological and substantive factors. A comprehensive database search returned 466 records, and 84 of these met the study's inclusion criteria. Preliminary data analyses suggest that subjective probability estimates were better than chance. In addition, experts' judgments were significantly better than laypeople's judgments. Yet, there was remained large heterogeneity in the effect size, suggesting the roles of other moderators beyond expertise. Data analyses are ongoing, and a full report is expected by September.

3 - The One Man Show: the Connection Between Overconfidence and Joint Decision-making

Dominik Piehlmaier, Doctoral Student, University of Wisconsin-Madison, 1300 Linden Dr, Madison, WI, 53706, United States, piehlmaier@wisc.edu, Dee Warmath, Cliff Robb

Verbal and nonverbal interactions as well as social networks enable humans to profit from the knowledge and skills of others (Harvey and Fischer, 1997). Advice seeking and taking are integral parts of such interactions and help to increase calibration in one's decision-making process (See et al., 2011). This study explores the connection between shared decision-making and overconfidence. We draw from a dataset of 2,000 investors (45 % female) and find that individuals who include household members and/or financial advisors in their investment decisions are significantly more calibrated in their financial judgments and less overconfident in terms of monetary expectations towards future growth.

4 - Judgement Error in Lottery Play: When the Hot Hand Meets the Gambler's Fallacy

Qingxia Kong, Assistant Professor, Erasmus University, Rotterdam, Netherlands, q.kong@rsm.nl, Chung-Piaw Teo, Nicolas Lambert

We use two sets of naturally occurred data to show that both the gambler's fallacy and hot-hand fallacy can exist in lottery games. The existence of hot-hand fallacy is surprising, as previous works have documented instead the presence of an opposite effect, the gambler's fallacy, in the US lottery market. Some literature also suggest that gambler's fallacy prevails when random numbers are generated by mechanical devices such as in lottery games. We show that our empirical findings are consistent with the classical optimal Bayesian learning model, which allows us to investigate some conditions in the lottery game design that determine which phenomenon will dominate.

Chair: Jun Zhuang, University at Buffalo, SUNY, Buffalo, NY, 14260, United States, jzhuang@buffalo.edu

1 - Mapping Terrorist Networks with Graphical Databases

Alexander Gutfraind, Uptake, Inc., 600 W. Chicago Avenue, Chicago, IN, 60654, United States, sasha.gutfraind@uptake.com

Open datasets about terrorist networks are scarce, small, and frequently suffer from incomplete data. To address this problem, we developed a system for recording data on terrorist events based on open media sources using graphical databases, and applied it to ISIS networks in Europe. We found robust differences between covert ISIS networks and Al-Qaida's networks from the earlier generation of Islamist terrorism. We suggest that graphical databases promise to enable more robust and reproducible analysis of covert networks.

2 - Evaluating the Resilience of Subway Systems under Simulated Attacks

Jose Emmanuel Ramirez-Marquez, Stevens Institute of Technology, Castle Point on Hudson, School of Systems & Enterprises, Hoboken, NJ, 07030, United States, jmarquez@stevens.edu, Gabriela Noemi Gongora Svartzman

After the attacks on 9/11 the government of USA took extra effort into tracking potential terrorist threats to their country. Around the world public transportation systems have been a popular target for terrorists. This work shows the effect of a possible attack on the subway system of NYC, measuring alternatives and resilience of the system itself. The stages of resilience measured include the reliability of the system before an attack, the vulnerability and adaptability after an event. The data is drawn from daily crimes reported at subway stations, inflows and outflows, and census data. A discrete event simulation of the subway system is modeled and used to evaluate an attack on the subway.

3 - Decision Analytic Techniques in Practice for Homeland Security Problems

Julia A. Phillips, Argonne National Laboratory, Oswego, IL, United States, phillipsj@anl.gov

This discussion presents an overview of decision analytic techniques that have been deployed for use in the homeland security and resilience operational space. This dialogue will also cover several tools that are currently in use based off these decision analytic techniques.

4 - Deductible-based Public Assistance Program

Allison C. Reilly, Assistant Professor, University of Maryland, College Park, MD, United States, areilly2@umd.edu, Gina Tonn, Seth Guikema, Hamed Ghaedi

Recently, FEMA proposed establishing a deductible-based approach for its Public Assistance (PA) Program. The new rule is designed to encourage States to engage in pre-disaster planning and mitigation by offering targeted reductions to their deductible. This change represents a seismic shift in how post-disaster money is allocated and has the potential to change the hazard environment. This talk will review the proposed rule and discuss how States should best respond given different objectives.

5 - Staying Ahead of the Game: Adaptive Robust Optimization for Dynamic Allocation of Threat Screening Resources

Sara McCarthy, University of Southern California, Los Angeles, CA, United States, saramarm@usc.edu, Phebe T. Vayanos, Milind Tambe

We consider the problem of dynamically allocating screening resources at checkpoints to successfully avert an attack. Previous work in this area operates under the unrealistic assumption that screenee arrival times are perfectly known. We thus propose a novel framework that explicitly accounts for uncertainty in arrival times. We model the problem as a multistage robust optimization problem and propose a tractable solution approach using compact linear decision rules combined with robust reformulation and constraint randomization. We show that our approach is scalable and outperforms previous state of the art in terms of both feasibility and optimality.

Competition in Multi-Echelon Systems

Invited: Tutorial

Invited Session

1 - Competition in Multi-Echelon Systems

Awi Federgruen, Columbia University, New York, NY, United States, af7@gsb.columbia.edu

Around the start of this new millennium, scholars in the operations management/operations research field started to make important contributions to the study of price competition models. In this tutorial, we review these contributions, and partition them into five broad areas. Most of the tutorial is devoted to the last and most recent category: price competition models for multi-echelon supply chains with an arbitrary number of competing firms and products at each echelon.

Joint Session APS/SIM:Simulation and Applied Probability

Sponsored: Applied Probability

Sponsored Session

Chair: Shane Henderson, Cornell University, Ithaca, NY, 14853, United States, sgh9@cornell.edu

1 - High Volume Traffic Modeling: Simulation and Statistics

Zeyu Zheng, Stanford University, 94 Thoburn Ct. 110#, Stanford, CA, 94305, United States, zyzheng@stanford.edu, Peter W. Glynn

Many service system applications require the ability to adequately model and statistically characterize high volume traffic. Most prior work with focus at the inter-arrival time scale may fail to identify non-stationarities, correlations and non-Poisson behavior that may only manifest over longer time scales. Existing limit theory shows that system performance is primarily affected by arrival behavior over time scales that are at the order of service time. We develop a "top-down" modeling toolbox to capture the statistical characteristics of incoming traffic that have a primary impact on performance. This talk describes our modeling perspectives and tools. This work is joint with Peter Glynn.

2 - Robust Multivariate Extreme Event Analysis

Xinyu Zhang, Columbia University, New York, NY, United States, xz2691@columbia.edu, Henry Lam

We discuss an approach to estimate extremal quantities from data under multivariate settings, based on estimated marginal information such as density estimates and tail probability masses, and conjectured geometric constraints such as monotonicity and convexity that aim to reduce estimation conservativeness. The approach utilizes optimization over probability distributions to obtain extremal bounds with statistical confidence guarantees. We discuss our solution techniques that generalize some classical mixture representations for convex sets of probability measures, and the implications of our results in rare-event simulation.

3 - Combined Acceptance-rejection and Importance Sampling Methodologies for Perfect Sampling from Gibbs Point Processes

Sarat B. Moka, Visiting Fellow, Tata Institute of Fundamental Research, HB Raod, Colaba, Mumbai, 400005, India, sarathmoka@gmail.com, Sandeep Juneja, Michel Mandjes

We consider generating perfect samples from spatial Gibbs processes and associated unbiased estimation problem. Traditionally, the former problem is addressed using coupling from the past based methods. We focus on acceptance-rejection with and without importance sampling for generating perfect samples. We illustrate the efficacy of proposed methods relative to existing ones in a simpler setting of hard sphere models that we analyze in asymptotic regime where the number of spheres generated increases to infinity while the sphere radius decreases to zero at varying rates. Our analysis identifies the large deviations rates of no overlap probability of spheres when centers form a Poisson process.

4 - Estimating the Probability that a Function Observed with (simulation) Noise is Convex

Shane Henderson, Cornell University, School of ORIE 230 Rhodes Hall, Cornell University, Ithaca, NY, 14853, United States, sgh9@cornell.edu, Nanjing Jian

Consider a real-valued function that can only be observed with stochastic simulation noise at a finite set of design points. We wish to determine whether there exists a convex function that goes through the true function values at the design points. We develop an asymptotically consistent Bayesian sequential sampling procedure that estimates the posterior probability of this being true. In each iteration, the posterior probability of convexity is estimated using Monte Carlo simulation. Of 3 variance reduction methods — change of measure, acceptance-rejection, and conditional Monte Carlo, numerical experiments suggest that conditional Monte Carlo should be preferred.

Choice Models and Assortments

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Sumit Kunnumkal, Indian School of Business, Hyderabad, 500032, India, sumit_kunnumkal@isb.edu

1 - Learning to Rank an Assortment of Products

Kris Johnson Ferreira, Harvard Business School, Morgan Hall 492, Boston, MA, 02163, United States, kferreira@hbs.edu, Shreyas Sekar

A large product variety makes it impractical for consumers to browse all products before purchasing, making product ranking an important decision. Best practice is to rank products in decreasing order of popularity. However, its optimality assumes that consumers know their expected utility for all products a priori. When this assumption does not hold, consumers must form an expectation of their utility of unseen products. We identify the optimal product ranking in light of this and propose and test an online algorithm that learns consumer preferences and converges to the optimal ranking.

2 - Relating the Fixed Cost and Space Constrained Assortment Problems

Jacob Feldman, Olin Business School, United States, jbfeldman@wustl.edu, Alice J.Paul

In the assortment optimization problem, a retailer seeks the revenue maximizing set of products to offer to each arriving customer. In effort to make the problem more realistic, there have been a number of extensions to this classic version. For example, the space constrained assortment problem places a limit on the total space consumed by the set of offered products. The fixed cost assortment problem associates a stocking cost with each offered product. Combinatorially, the two problems are drastically different, however, in both problems, there is a "penalty" of sorts for offering a product. The goal of this research is to link the two problems.

3 - Assortment Optimization with Product Costs and Constraints

Sumit Kunnumkal, Queen's University, 465 Goodes Hall, Kingston, ON, K7L2G8, Canada, sk162@queensu.ca, Victor Martinez de Albeniz

We consider the assortment optimization problem under the MNL model with product fixed costs and constraints. We propose a new method to obtain an upper bound on the optimal expected profit. We show that our method is tractable and has provable performance guarantees for some common types of assortment constraints.

Empirical Operations Management

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Eduard Calvo, ecalvo@iese.edu

Co-Chair: Weiming Zhu, IESE Business School, Avenida Pearson 21, Barcelona, 08034, Spain, zhuwm923@gmail.com

1 - The Incentive Game under Target Effects: Evidence from the Ride Sharing Market

Liu Ming, University of Maryland, 9530 Baltimore Avenue, Apt 603B, College Park, MD, 20740, United States, mldshg@gmail.com, Xirong Chen, Zheng Li, Weiming Zhu

Ride sharing platforms usually provide monetary incentives to keep registered drivers active. To theoretically and empirically analyze the incentive game under target effect, we model platform's bonus scheme and driver's working hours at equilibrium. We derive theoretically how driver's target effects shape their willingness to drive. We then structurally probe the existence of target effect and derive the optimal bonus strategy.

2 - A Computer Plays the Beer Game: A Deep Reinforcement Learning Algorithm for Inventory Optimization

Lawrence V. Snyder, Lehigh University, Mohler Lab 200 West Packer Avenue, Bethlehem, PA, 18015-1582, United States, lvs2@lehigh.edu, Afshin Oroojlooy Jadid, Mohammadreza Nazari, Martin Takac

We propose an algorithm to play the beer game with "teammates" that are humans or other algorithms. The beer game is a multi-agent serial supply chain in which agents attempt to minimize network cost while each agent only observes its local information. We develop a Deep Q-Network algorithm to solve this problem. We show that our algorithm outperforms approaches from literature and unlike the majority of them does not impose restrictions on the problem parameters, and also provides good solutions even if other agents do not follow rational policies. The algorithm can be extended to any decentralized multi-agent cooperative game with partial information, which is a common situation in supply chains.

3 - Stress on Operational Risk: Empirical Evidence from Commercial Bank

Yuqian Xu, University of Illinois at Urbana-Champaign, Champaign, IL, United States, lillian.xyq@gmail.com, Fangyun Tan, Serguei Netessine

Operational risk is now one of the three most important risks in the financial services industry. This paper studies how workload affects bank operational risk events frequency and severity. To achieve this goal, we use a unique operational risk event data set from a commercial bank that contains 1441 operational risk events in two years. We find that workload has a U-shape impact on operational risk frequency. We then proceed to discuss bank capital allocation on staffing level among branches so as to reduce operational risk losses. We compare our optimal staffing policy with bank's original policy with both in-sample and out-of-sample studies.

Renewable Energy and Energy Efficiency

Sponsored: Manufacturing & Service Oper Mgmt, Sustainable Operations

Sponsored Session

Chair: afak Yücel, safak.yucel@georgetown.edu

1 - Business Models for Off-Grid Energy Access at theBottom of the Pyramid

Bhavani Shanker Uppari, INSEAD, 1 Ayer Rajah Avenue, Singapore, 138676, Singapore, BhavaniShanker.Uppari@insead.edu, Ioana Popescu, Serguei Netessine

One in every five people people does not have access to electricity, relying mostly on kerosene for light. Solar technologies are healthier and offer greater value, yet they require significant one-time investments which are not affordable to people living on 2 USD per day. Even though cheaper rechargeable lighting technologies are available, their adoption is low and some consumers still use kerosene. We develop a consumer behavior model that accounts for income variability and liquidity constraints specific to impoverished markets, and investigate alternative business models, based on a case study in Rwanda.

2 - Investments in Renewable and Conventional Sources: The Role of Operational Flexibility

Safak Yucel, Georgetown University, Georgetown University, 3700 O St. NW, 523 Hariri Building, Washington, DC, 20057, United States, safak.yucel@georgetown.edu, Gurhan Kok, Kevin Shang

We study capacity investments of a utility firm in renewable and conventional energy sources with different levels of operational flexibility, i.e., the ability to quickly ramp up or down the output of a generator. We consider supply characteristics of conventional and renewable sources and derive the optimal capacity investment portfolio. We find that inflexible sources (e.g., nuclear energy) and renewables are substitutes; flexible sources (e.g., natural gas) and renewables are complements.

3 - Utility Ownership of Decentralized Combined Heat and Power

Eric Webb, PhD Student, Indiana University, 2915 W. Winterberry Ct., Bloomington, IN, 47404, United States, eric.michael.webb@gmail.com, Owen Wu, Gilvan Souza

Combined heat and power (CHP) plants generate electricity and capture excess heat for space heating, water heating, or industrial processes. CHP plants reach 70-80% efficiency, improving on the 40-50% efficiency of natural gas combined cycle or the 30-35% efficiency of coal. A CHP plant, located at a firm with large heating needs, may provide reliability benefits by continuing to operate during a grid outage. Despite these benefits, CHP plants are rarely owned by utilities in the United States. We study the economics of utility ownership of CHP, determining when it is valuable to the utility, to the on-site firm, and to society. We examine which regulatory policies encourage CHP ownership by utilities.

4 - Strategic Forward Trading and Technology

Heikki Peura, Imperial College Business School, South Kensington Campus, London, SW7 2AZ, United Kingdom, h.peura@imperial.ac.uk, Derek W. Bunn

Motivated by the electricity industry's transition towards renewable power, we analyze how operational factors of production, such as its flexibility and reliability, can influence market prices indirectly through altering the balance of spot and forward trading. We show, for example, that increasing the capacity of intermittent renewable electricity generation, despite its lower marginal production cost, may not necessarily reduce power prices.

Data-Driven and Dynamic Decision-Making for Healthcare Policies

Sponsored: Health Applications

Sponsored Session

Chair: Alireza Boloori, Arizona State University, Tempe, AZ, 85283, United States, aboloori@asu.edu

1 - Optimal Scheduling of Medical Diagnostics

Arkajyoti Roy, Northwestern University, Evanston, IL, 60208-3119, United States, aroy@bgsu.edu, Omid Nohadani

In medical decision making, clinical information on patient is collected from a history or physical examinations. To refine and to track the progression of care, often one or more diagnostic tests are conducted during the treatment. The timing of these tests affects the understanding and influences the efficacy of decisions. In this work, we provide a framework for optimal schedules via robust optimization by modeling an evolving uncertainty set in time. We apply the approach to cancer radiation therapy. The findings are general and relevant to a broad range of applications, e.g., maintenance scheduling.

2 - Using a Branch-and-bound Scheme with Multi-fidelity Models to Optimize Hepatitis C Screening and Treatment Policies under a Budget Constraint

TingYu Ho, University of Washington, Industrial and Systems Engineering, Box 352650, Seattle, WA, 98195-2650, United States, tyhotw@uw.edu, Shan Liu, Zelda B.Zabinsky

We propose an efficient algorithm for Hepatitis C (HCV) screening and treatment allocation problem with disease progression, budget constraint, and population evolution. We first present a low fidelity model by approximating future disease progression with a stationary Markov model. We then design a combined rollout algorithm embedding the low fidelity model into a high fidelity model with disease progression to efficiently identify a good incumbent policy. Lastly, we incorporate the incumbent and a theoretical upper bound into a branch-and-bound scheme.

3 - Optimal Breast Cancer Diagnostic Decisions Based on Disease Subtypes to Reduce Overdiagnosis

Sait Tunc, University of Chicago, Chicago, IL, United States, sait.tunc@chicagobooth.edu, Oguzhan Alagoz, Elizabeth S. Burnside

Mammography, which reduces breast cancer mortality, has several negative effects such as overdiagnosis. Overdiagnosis may be reduced if indolent breast cancer subtypes can be identified and followed with noninvasive imaging. We develop a large-scale MDP to optimize the post-mammography diagnostic decisions based on disease subtypes. We present an efficient and easily implementable algorithm to find the exact optimal solution. We reduce the computational complexity of the algorithm by obtaining feasible upper bounds for the optimal decision thresholds using dimension reduction.

4 - Operational Policy Recommendations for Treatment Protocol Restrictions at a County Hospital: A Process-based Case Study

Olga Bountali, Southern Methodist University, 4210 Fairmount Street, Apartment 3063, Dallas, TX, 75219, United States, obountali@smu.edu, Farnaz Nourbakhsh, Sila Cetinkaya, Vishal Ahuja

County hospitals serving the indigent are subject to treatment protocol restrictions under which the uninsured are admitted only if the patient's clinical condition is evaluated as life threatening. The underlying goal of such restrictions is improved oversight and efficiency. Motivated by clinical observations, we present a process-based case study and offer analytical and numerical results for a comparative analysis of the impact of protocol restrictions on patient- and systems-level metrics. Counterintuitive to the common belief, protocol restrictions may be myopic.

5 - Data-driven Management of Post-transplant Medications: An APOMDP Approach

Alireza Boloori, Arizona State University, 505 W. Baseline Rd, Apt 2158, Tempe, AZ, 85283, United States, aboloori@asu.edu, Soroush Saghafian, Harini A. Chakkera, Curtiss B. Cook

Patients after organ transplantations receive high amounts of immunosuppressive drugs (e.g., tacrolimus) to reduce the risk of organ rejection. However, this practice has been shown to increase the risk of New-Onset Diabetes After Transplantation (NODAT). We propose an ambiguous POMDP framework to generate effective medication management strategies for tacrolimus and insulin. Our approach increases the patient's quality of life while reducing the effect of transition probability estimation errors. We also provide several managerial and medical implications for policy makers and physicians.

Kidney Exchange

Sponsored: Health Applications

Sponsored Session

Chair: Burhaneddin Sandikci, University of Chicago, Chicago, IL, 60637, United States, burhan@chicagobooth.edu

1 - Incentives in Kidney Exchange

Itai Ashlagi, Stanford University, Department of Management Sci. and Engr., Stanford, CA, 94305, United States, iashlagi@stanford.edu

We provide empirical evidence for the inefficiency resulting in the current kidney exchange marketplace in the US and propose a novel mechanism that can implement the first best in equilibrium.

2 - Operation Frames and Clubs in Kidney Exchange

Tuomas W. Sandholm, Carnegie Mellon University, Gates Center for Computer Science, Pittsburgh, PA, 15213, United States, sandholm@cs.cmu.edu, Gabriele Farina, John Dickerson

Kidney exchanges use 2-cycles, 3-cycles, and chains. We propose generalizations. We allow more than one donation in exchange for an organ. We also support a donor willing to donate if any of a number of patients receive organs. We generalize these notions to organ clubs that are willing to donate outside if the club receives organs from outside according to specifications. We introduce operation frames for sequencing operations across batches. We present IP formulations for the clearing problems for these exchanges. Experimentally, in the single-donation setting, operation frames improve planning by 34%-51%. Allowing up to two donors to donate in exchange for an organ increases welfare further.

3 - A Non-asymptotic Approach to Analyzing Kidney Exchange Graphs

Christopher Ryan, University of Chicago, 5807 S Woodlawn Ave, Chicago, IL, 60637, United States, chris.ryan@chicagobooth.edu, Yichuan Ding, Dongdong Ge, Simai He

We propose a novel methodology to study kidney exchange. Taking the random graph model of kidney exchange introduced in Ashlagi, Gamarnik, Rees and Roth (2012), we propose a non-asymptotic approach based on a two-phase procedure where random walks are used to allocate chains, followed by allocation in cycles. Random walks preserve the probabilistic structure of residual graphs, greatly facilitating analysis. Our results complement previous findings in large (limit) graphs and also shows how prioritizing chains over easy-to-transplant cycles improves performance and we provide analytical bounds on the associated benefits.

4 - Matching and Thickness in Dynamic Markets

Maximilien Burq, Massachusetts Institute of Technology, 77 Massachusetts Avenue, Cambridge, MA, 02139, United States, mburq@mit.edu, Vahideh Manshadi, Itai Ashlagi, Patrick Jaillet

We study dynamic matching in an infinite-horizon stochastic networked market, in which some agents are a priori more difficult to match than others. Agents can match either bilaterally or indirectly through chains. We study the effect of varying the composition of the market. Counter-intuitively, we show that increasing the market size does not always result in less waiting for hard-to-match agents. We also provide precise bounds that allow us to theoretically and numerically compare different matching policies and priority schemes.

Personalized Medical Decision-Making

Sponsored: Health Applications

Sponsored Session

Chair: Gian Gabriel P. Garcia, University of Michigan, Ann Arbor, MI, 48105, United States, garciagg@umich.edu

1 - Mobile Health for Chronic Disease Management: A Change Point Detection Approach

Anthony Bonifonte, Georgia Institute of Technology, 5940 Water Oaks Dr, Austell, GA, 30106, United States, ABonifon@gatech.edu

Wearables and other mobile health devices have the potential to revolutionize the management of chronic disease. We present a Bayesian changepoint detection algorithm that indicates when a health characteristic has exceeded a threshold value. We demonstrate the performance of this algorithm on realistically simulated blood pressure data, and show improvement over baseline policies and simpler, more general changepoint procedures. This work demonstrates the enormous improvement in chronic disease screening and monitoring that can be achieved using data from mobile health technologies.

2 - Designing Personalized Weight Loss Interventions with Behavioral Analytics

Yonatan Mintz, UC Berkeley, 1822 Francisco St., Apt 10, Berkeley, CA, 94703, United States, ymintz@berkeley.edu, Anil Aswani, Philip Kaminsky, Elena Flowers, Yoshimi Fukuoka

In this talk, we develop a behavioral analytics framework which uses patient data to effectively design personalized weight loss interventions. Our framework utilizes a utility maximization model for patient behavior which combined with integer programming and Bayesian prediction allows us to create several personalized interventions, as well as aggregate these interventions into a cohort weight loss program. We then present simulation results which show that our method maintains efficacy while potentially reducing the associated person hours and cost of the intervention.

3 - A Stochastic Programming Approach to Determine Decision Boundaries for Medical Diagnosis

Gian Gabriel P. Garcia, University of Michigan, 1823 Pointe Crossing Street, Apt 204, Ann Arbor, MI, 48105, United States, garciagg@umich.edu, Mariel Sofia Lavieri, Ruiwei Jiang, Steven P. Broglio, Michael McCrea, Thomas W. McAllister

We use stochastic programming to determine decision thresholds for medical diagnosis risk models under uncertain data samples from a fixed population. These thresholds maximize sensitivity and specificity under constrained false positive and false negative rates. We show that sample average approximation solutions for these models are consistent estimators. We apply our method to concussion assessment and show that our thresholds dominate single decision thresholds under multi-criteria evaluation.

4 - Value and Design of Clinical Decision Support Systems in the Presence of Bias in Imaging-based Decisions

Mehmet U.S. Ayvaci, University of Texas at Dallas, 800 W. Campbell Rd, Sm33, Richardson, TX, 75080-3021, United States, mehmet.ayvaci@utdallas.edu, Mehmet Eren Ahsen, Srinivasan Raghunathan

A patient's clinical risk information could bias a radiologist's assessment of a mammogram. We examine the design and value of a clinical decision support system (CDSS) in the breast cancer diagnosis context. The CDSS assists a caring physician in her follow-up recommendation to a patient based on the radiologist's assessment. We show that the CDSS can eliminate the adverse impact of bias if there is no variability associated with the bias-induced error in radiologist's assessment. Using point estimates based on mammography practice and the medical literature, we show that a bias-aware CDSS can significantly improve the expected patient life years or the accuracy of decisions based on mammography.

Disaster and Emergency Management

Contributed Session

Chair: Sandeep Grover, YMCA University of Science & Technology, Faridabad, India, groversandeep@hotmail.com

1 - Optimal Recovery Strategy for the Power Grid after a Cascading Failure

Yan-Fu Li, Tsinghua University, N410, Shunde Building, Haidian District, Beijing, 100084, China, liyanfu@tsinghua.edu.cn, Yi-Fei Yuan

Although heavily protected, electric power grids fail more frequent than expected. Severe failures, e.g. cascading failure, often result to significant damages to our society. Therefore it is of great importance to quickly repair the damaged power grid in the immediate aftermath of such failures. Whereas, the repair actions are cost-associated. In this study, we formulate an optimization problem for repair activity planning with the objective to minimize the total cost during recovery process, which includes the expense of repair actions and the economic loss due to load shedding. The proposed model is demonstrated on a Chinese provincial power grid.

2 - Network Planning Model for Food Aid Distribution During Chennai Floods: A Big Data Analytic Approach

Ravi Shankar, Indian Institute of Technology Delhi, Department of Management Studies, Vishwakarma Bhavan, Shaheed Jeet Singh Marg, New Delhi, 110016, India, ravi1@dms.iitd.ac.in, Ashish Kumar Kaushal

In this paper we design an effective last-mile food aid distribution network using big data analytics. We present location models to determine a set of distribution centres, where the food is directly distributed to the beneficiaries, during Chennai floods, 2015 in India. Our models take into account the consideration of all key stakeholders involved in the response system.

3 - Understanding Strategies Governing the Use of Social Data in a Disaster Response Operation

Justin Taylor, University of Arkansas, 4207 Bell Engineering Center, 1 University of Arkansas, Fayetteville, AR, 72701, United States, jlt025@email.uark.edu, Ashlea Bennett Milburn

The use of social data during disaster response has the ability to provide more information to emergency responders quickly, however the data is not guaranteed to be accurate. As such, responders are likely to have concern over the incorporation of social data and may limit the use of it by organizational policies or personal preferences. The research aims to help define what the current social data collection strategies are through interviews with emergency managers, as well as characterize the social data that are used during a disaster response operation.

4 - A Decision Support System for Location of Warehouses During the Preparedness Phase

Ravi Shankar, Indian Institute of Technology Delhi, Delhi, India, ashishkiitd89@gmail.com, Ashish Kumar Kaushal

This study integrates the fuzzy DEMATEL and goal programming model for solving the warehouse location problem during preparedness phase for effective disaster response. The managerial usefulness of this proposed method is that it allows decision makers to set multiple aspiration levels for the decision criteria.

5 - Early Forecasting of Flood Response Requirements for American Red Cross Mass Care Services

Sanjeev Goyal, Assistant Professor, YMCA University of Science & Technology (Faridabad, India), NH-2, Sector 6, Mathura Road, Faridabad, 121006, India, goyalsanjeev@pitt.edu, Kiatikun Louis Luangkesorn, Sandeep Grover

In the United States, after a disaster resources are sent based on needs assessed at the local level. However, this local assessment can take time while local resources are preoccupied with immediate response activities. This delays the mobilization of personnel, resources, and supplies into the disaster area. We develop a machine learning method to estimate the required American Red Cross sheltering and feeding resources using data that would be readily available to disaster response managers on the first day of a flood. This enables more rapid mobilization and deployment and more effective provision of services to those affected by disaster.

Machine Learning in Healthcare

Sponsored: Health Applications

Sponsored Session

Chair: Yingfei Wang, Princeton University, Princeton, NJ, 08540-5233, United States, yingfei@princeton.edu

1 - The Behavior of Value of Information Policies in the Presence of a Locally Quadratic Belief Model

Nana Kwabena Aboagye, Princeton University, Sherrerd Hall, Charlton Street, Apartment A, Princeton, NJ, 08544, United States, aboagye@princeton.edu, Warren B.Powell

We study the problem of learning the unknown parameters of an expensive function where the true underlying surface can be well-approximated by a quadratic polynomial. We demonstrate that the well-known behavior of many learning policies for lookup table belief models no longer apply, and that the behavior when using a quadratic belief model exhibits a very special structure. This is the first paper to identify and exploit the behavior of learning policies in the presence of parametric belief models. We derive a simple rule that is much simpler to compute than a knowledge gradient policy that maximizes the one-step value of information and demonstrate its performance empirically.

2 - Machine Learning in Healthcare

Nilakantan Sundara Raman Narasinganallur, K.J. Somaiya Institute of Management Studies & Research, B.602 Tulip Rachna Garden, Mulund Colony, Mumbai, 400082, India, nilakantan@somaiya.edu

Healthcare is one of the new areas with potential for data analytics. With the generation of voluminous data, the use of big data analytics is essential for reaching useful conclusions in medical research. While past efforts in data analytics have been more in the area of statistical methods based on assumptions of linear data structures, machine learning provides an alternate basis to analyse for nonlinear relationships. The presentation will provide an overview of the use of machine learning in healthcare.

3 - Estimating the Cost-savings of Preventive Dental Services by Unsupervised Learning

Ilbin Lee, Assistant Professor, University of Alberta, 3-23 Business Building, Edmonton, AB, T6G 2R6, Canada, ilee79@gatech.edu, Sean Monahan, Nicoleta Serban, Paul Griffin, Scott L. Tomar

Dental caries is the most common chronic disease among U.S. children. Preventive services have been shown to be effective in preventing caries, but little is known about how the use of preventive services affects downstream care expenditures. We followed dental care utilization of nearly a million Medicaid children for 7 years and classified them using an unsupervised clustering algorithm. The results showed that expenditures were much lower for children who received preventive care than those who did not, and thus, preventive dental care can have substantial return on investments while also improving oral health outcomes.

4 - Adapting Kernel Mean Matching to Balance Observational Data in Health Care

Martin Cousineau, PhD Candidate, McGill University, 1001 Sherbrooke St W, Montreal, QC, H3A 1G5, Canada, martin.cousineau@mail.mcgill.ca, Susan A. Murphy, Joelle Pineau, Vedat Verter, Gustavo Turecki

We propose the use of kernel mean matching to compute a causal effect from observational data. We also propose an improved tuning procedure for kernel mean matching.

5 - Approximation Methods for Markov Decision Processes with Application to Clinical Trial Design

Vishal Ahuja, Southern Methodist University, Cox School of Business, P.O. Box 750333, Dallas, TX, 75275, United States, vahuja@smu.edu, John R. Birge

Multi-armed bandit problems, typically modeled as Markov decision processes (MDPs), exemplify the exploration vs. exploitation tradeoff. For many practical problems of interest, the state space is intractably large, rendering exact approaches to solving MDPs impractical. We propose a novel approximation approach that combines the strengths of multiple methods - grid-based state discretization, methods to improve approximation accuracy, and simulation, to obtain near-optimal policies for large scale MDPs with minimal added computational burden. Our numerical analysis shows our design to be almost as good as a fully optimal design and superior to existing heuristics.

New Trends in Pricing and Revenue Optimization

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Gustavo Jose Vulcano, Universidad Torucato di Tella, New York University, New York, NY, 10012, United States, gvulcano@stern.nyu.edu

1 - Large-scale Bundle Size Pricing: A Theoretical Analysis

Tarek Abdallah, New York University, Stern School of Business, New York, NY, United States, tabdalla@stern.nyu.edu, Arash Asadpour, Joshua Reed

Bundle size pricing (BSP) is a multi-dimensional selling mechanism where the firm prices the size of the bundle rather than the different possible combinations of bundles. In BSP, the firm offers the customer a menu of different sizes and prices. The customer then chooses the size that maximizes his surplus and customizes his bundle given his chosen size. In this talk, we provide a simple and tractable theoretical framework to analyze the large-scale BSP problem. Solving the BSP problem is in general hard, however we show that for large numbers of products, the BSP problem transforms from a hard multi-dimensional problem to a simple multi-unit pricing problem.

2 - Randomized Pricing, Fulfillment, and Product Ranking for Ecommerce Retailers

Stefanus Jasin, University of Michigan, 2836 Barclay Way, Ann Arbor, MI, 48105, United States, sjasin@umich.edu, Yanzhe Lei, Joline Uichanco, Andrew Vakhutinsky

We consider an etailer selling multiple products to customers from multiple regions. Products are stored at multiple warehouses and the decisions are price, fulfillment (i.e., from which warehouse to ship the request), and products display ranking (i.e., how we should order the products—ordering affects product visibility, which in turn affects purchase probability). The deterministic version of the problem can be solved as an MILP, however it may have a large number of binary variables. We propose a different approach: We first relax the problem (turning the MILP into an LP) and then we construct a randomization strategy that guarantees the optimal performance under the relaxed LP in expectation.

3 - Demand Learning and Earning with Online Bundle Recommendations

Anna M. Papush, Massachusetts Institute of Technology-ORC, 411 Norfolk Street, Apt 2C, Somerville, MA, 02143, United States, apapush@mit.edu, Pavithra Harsha, Georgia Perakis, Divya Singhvi

Product recommendation systems have grown to become a necessity in the vast majority of online retail businesses. However, most existing literature focuses on efficient design under the assumption that consumer demand is known. In this work we propose and discuss an approach for online pricing and recommendation of product bundles that makes strategic offers in order to learn consumer demand efficiently over time while maximizing profits and balancing inventory. We test our algorithm's performance and provide theoretical guarantees against optimal offline approaches with known demand.

4 - Customized Individual Promotions: Model, Optimization, and Prediction

Dmitry Mitrofanov, NYU. Stern, 44 West 4th Street, 8th Floor, New York, NY, 10012, United States, dm3537@stern.nyu.edu, Srikanth Jagabathula, Gustavo Jose Vulcano

We consider the problem of predicting individual responses to a product promotion using historical transaction data, tagged by customer ID. In our proposal, we model each individual through a partial-order that embeds promotion information. Then, we calibrate a multinomial logit model over the partial orders and quantify their prediction power on out-of-sample transactions. Then, we use this information to optimize personalized promotions, obtaining a remarkable performance.

Co-Chair: Wei Qi, McGill University, Montreal, QC, 1, Canada, qiwei@berkeley.edu

1 - Zoning for Last Mile Delivery: A Data-driven Approach

Sheng Liu, University of California, Berkeley, 2249 Bonar Street, Unit C, Berkeley, CA, 94702, United States, lius10@berkeley.edu, Long He, Zuo-Jun Max Shen

In this study, we propose a data-driven approach for strategic zoning planning in last mile delivery services. Using historical data to calibrate driver behaviors, we construct a practical routing distance prediction model. We then develop a mixed integer linear program as a sample average approximation model and show significant delay reductions from the benchmark model in numerical studies.

2 - Efficiency-fairness Trade-offs: the Case of the Federated Locker System

Guodong Lyu, National University of Singapore, 1 Business Link, BIZ2 Building, Singapore, 117592, Singapore, guodong.lyu@u.nus.edu, Chung-Piaw Teo

We study the efficiency-fairness trade-offs in a class of last mile delivery problems, using automated parcel lockers. We show that the concerns on reduction in efficiency can be mitigated with the proper choice of the scale of the system. To see this, we develop a locker choice model and calibrate the parameters to predict the volume of parcels that the system can attract based on location decisions. Contrary to conventional wisdom, our model does not place lockers near areas with peak usage because of endogeneity issues in existing demand data.

3 - Managing a Portfolio of Self-scheduling Workers

Kaitlin Daniels, Olin Business School, Washington University in St. Louis, Saint Louis, MO, United States, k.daniels@wustl.edu

Self-scheduling workers value their ability to decide for themselves how much they work. However, granting this flexibility costs the coordinating platform its ability to directly control its capacity. We study a system of heterogeneous workers who decide how much to work in response to incentives offered by a platform. In this setting, the platform may elect to place restrictions on a worker's decision. We study how the resulting portfolio of working-behaviors changes as workers make costly demands of the firm (e.g. expense reimbursement, overtime pay, minimum wages), like those made by Uber drivers in recent lawsuits.

4 - Shared Mobility for Last-mile Delivery: Design, Operational Prescriptions and Environmental Impact

Wei Qi, McGill University, Montreal, QC, Canada, qiwei.0216@gmail.com, Lefei Li, Sheng Liu, Zuo-Jun Max Shen

We evaluate the prospect where shared mobility of passenger cars prevails throughout urban areas for home delivery services. We develop logistics planning models that characterize drivers' responses to wages, optimal open-loop routes, interactions with the ride-sharing market and service zone design. Then we prescribe several scenarios where this business model is economically and environmentally favorable.

Models for Evolving Public Transportation Systems

Sponsored: Transportation Science & Logistics

Sponsored Session

Chair: Nicholas E. Lownes, University of Connecticut, 261 Glenbrook Road, Unit 3037, Storrs, CT, 06269-3037, United States, nlownes@engr.uconn.edu

1 - Research on Integrated Development Plan for the Urban Rail Transit Station with the Concept of Linkage Development of Station and City

Xinmei Chen, Southwest Jiaotong University, Chengdu, China, siyu.tao@okstate.edu

Xinmei Chen, National United Engineering Laboratory of Integrated and Intelligent Transportation, Chengdu, China, siyu.tao@okstate.edu, Qiyuan Peng, Siyu Tao, Yida Li

Expanding the city function blindly around the transit stations led to the contradiction between the traffic jams and land use. For linkage development of the urban rail station and city, multi-goal programming model was used to determine the final integrated development plan of the station and land, considering the investment risk, economic benefit, traffic impact of real estate for the layout of the connection channel between the station and city.

2 - On-demand Public Bus Service on a Multimodal Travel Corridor
Jie Zhang, PhD Student, Nanyang Technological University, N1-B4-B06, 50 Nanyang Avenue, Singapore 639798, Singapore, 639798, Singapore, jzhang049@e.ntu.edu.sg, Zhiwei Wang

On-demand Public Bus (ODPB) service, a new type of public transport service, has emerged in many big cities. This study analyzes the provision of ODPB by applying analytical approaches based on demand analysis and network modeling. Several alternative travel modes are considered. The choices of mode and route/service are taken into account simultaneously in logit-type formula. The resultant traffic equilibrium condition is expressed as a variational inequality (VI) problem. Numerical analysis from one idealized corridor indicates that the introduction of ODPB service could effectively bring a significant impact on mode shift, especially for the long distance trip.

3 - Design Optimal Strategy of On-demand Mobility Allowance Shuttle Transit (MAST) Service
Dahye Lee, Texas A&M.University, 3135 TAMU, College Station, TX, 77843-3135, United States, dahyelee1991@tamu.edu, Luca Quadrifoglio, Kai Yin

We adopt the Markov Decision Process (MDP) with empirical dynamic programming algorithms to design optimal strategies for Mobility Allowance Shuttle Transit (MAST) service with demand uncertainties. The MAST allows vehicles to deviate from fixed routes to serve customers at their desired pick-up and drop-off locations within the service area. The main objective of this study is to then obtain the optimal policy of vehicle routing strategy that minimizes the total cost subject to the vehicle distance traveled and the number of served customers, and evaluate the quality of solutions with numerical studies.

4 - Bus Fleet Turnover Strategies to Optimize Life-cycle Costs and Carbon Emission Reductions
Nicholas E. Lownes, University of Connecticut, 261 Glenbrook Road, Unit 3037, Storrs, CT, 06269-3037, United States, nicholas.lownes@uconn.edu, Adrita Islam

The increasing competitiveness of battery electric bus (BEB) technology is prompting transit agencies across the globe to consider a transition to a BEB fleet. In most cases, this transition will occur over a number of years, depending on the age composition of the bus fleet. BEB stand to generate substantial mobile GHG savings and are seen as increasingly cost competitive with standard diesel hybrid buses, with cost parity anticipated to occur sometime within the next decade. This paper presents a fleet turnover optimization model that considers life-cycle costs and potential GHG reductions. An application on the Connecticut bus fleet is presented to illustrate results of the model.

1 - An Integrated Feedback and Optimization Approach for Healthcare Services
Soumyajyoti Datta, Indian Institute of Management Indore, Indore, India, f14soumyajyotid@iimidr.ac.in, Rohit Kapoor

This work addresses an integrated service quality and multi objective optimization problem in the context of healthcare delivery. Feedback on the experience in the hospitals concerning the clinical and process parameters have been collected. Machine learning techniques have been applied to recommend a healthcare delivery. Moreover, we feel that an integrated approach involving feedback and healthcare operational process parameters more scientifically reflect the quality of care. Hence an optimization problem involving the operational parameters has been studied using evolutionary intelligence.

2 - An Analysis of Pricing Models Between Online Medical Service and Traditional Hospital
Donghui Yang, Southeast University, Sipailou 2, Nanjing, 210096, China, dhyang@seu.edu.cn

With new developments related to online technologies and environments, medical online is much more a feasible venue for physicians and patients. In this work, three scenarios (online consulting, see a doctor online or in a hospital, see a doctor online or in a hospital with drug purchasing option) are compared to help a patient to make a good decision. Meanwhile, a game between online medical and a hospital is constructed to optimize their profits.

3 - Approximation of Max Min Fairness of Bandwidth Allocation in Multicommodity Flow Networks
Hamoud S. Bin Obaid, PhD candidate, University of Oklahoma, 1526 E.Lindsey Street, Apt I, Norman, OK, 73071, United States, hsbinobaid@ou.edu, Theodore B.Trafalis

A bi-objective LP model to find the max min fair flow vector in multicommodity flow networks is proposed. The overall throughput is maximized in the first objective, and the sum of absolute deviations among commodities is minimized in the second objective. The model is capable of solving large-scale networks with low computational time producing a quality solution. The model is tested on real and random networks.

4 - RISKMETER: An Interactive Tool for Integrating Public Preferences into Long-range Electricity Supply Planning
Georgios Xexakis, ETH Zurich, Universitatstrasse 22, K76.1, Zurich, CH-8092, Switzerland, georgios.xexakis@usys.ethz.ch, Sandra Volken, Evelina Trutnevyte

Finding consensus pathways for transforming national electricity supply systems is a challenge due to multi-dimensional policy priorities and complexity of public preferences. We use a linear optimization model EXPANSE with Modeling to Generate Alternatives (MGA) to quantify 500 electricity supply scenarios for Switzerland in 2035. We then assess the scenarios in terms of health, safety, built and natural environment impacts and use an interactive tool RISKMETER to visualize the impact tradeoffs. Ultimately, we conduct an online survey (N=200) with non-experts to empirically evaluate the RISKMETER's usability, collect public preferences, and integrate these with the EXPANSE scenarios.

5 - Modelling and Analyzing Stabilities and Equilibrium Strengths of Strategic Non-cooperative Conflicts using the Constrained Rationality Framework
Majed Al-Shawa, Strategic Actions, Waterloo, ON, N2V 2V8, Canada, malshawa@strategic-actions.com

We discuss the theory of moves and counter-moves of decision making agents that Constrained Rationality proposes for strategic multi-agent non-cooperative conflicts, and define four different stability and equilibrium solution concepts to analyze such conflicts. These concepts will guide the stability analysis of the conflict's states, for each agent. Then, we define the stability strength for each solution concept and the strength of the equilibrium that could result from it. To demonstrate the effectiveness of the framework, we model and analyze the Cuban Missile Crisis, and show why the sequence of events observed in reality was the most rational sequence of events for the conflict to take.

Modeling to Improve Healthcare System Performance

Sponsored: Manufacturing & Service Oper Mgmt, Healthcare Operations

Sponsored Session

Chair: Bryan A. Norman, University of Pittsburgh, University of Pittsburgh, Pittsburgh, PA, 15261, United States, banorman@pitt.edu

1 - A Technical Note on (r,s,q) Inventory Control Systems in Hospitals
Bryan A. Norman, University of Pittsburgh, Department of Industrial Engineering, 1006 Benedum Hall, Pittsburgh, PA, 15261, United States, banorman@pitt.edu, Nazanin Esmaili, Jayant Rajgopal

We develop discrete time Markov chain models of (R,s,Q) inventory control systems which are used at Point of Use Locations (POU) in hospitals and characterized by limited storage capacity, stochastic demand, periodic reviews with fractional lead times, expedited delivery when stocking out, and very high service level requirements. We present a novel approach that locally decomposes the state space for this specific class of inventory systems and use this to reduce the number of equations that must be solved by at least a factor of two. The result is that the overall computational effort required for finding the optimal replenishment policy parameters is significantly reduced.

2 - Wait Time Announcements at Hospital Emergency Departments
Marco Bijvank, University of Calgary, 2500 University Dr. NW, Calgary, AB, T2N.1N4, Canada, marco.bijvank@haskayne.ucalgary.ca, Zhankun Sun

A number of Canadian hospitals have started publishing live emergency department (ED) wait times online in an effort to provide patients with expectations on how long they will have to wait to be seen for non-urgent care after initial assessment by a triage nurse. We accurately predict the state-dependent wait times at emergency departments based on a busy-period analysis for a multi-class, multi-server priority queue with delayed feedback. We illustrate the robustness and impact of the predictor on patient flow and patient care with a case study at four major hospitals in the Calgary area.

3 - Predicting Patient Treatment Deferrals/no-shows to Improve Chemotherapy Pre-Mix Policies

Donald B. Richardson, University of Michigan, 2753 IOE Building, 1205 Beal, Ann Arbor, MI, 48109-2117, United States, donalric@umich.edu, Amy Cohn

In collaboration with the University of Michigan Comprehensive Cancer Center, we have developed a predictive model to determine the probability that a patient will not show for or defer treatment on a given day. This information can then be used in our proposed expected drug waste cost functions to aid outpatient chemotherapy centers in deciding which drug to make-ahead. We test a wide range of predictive models including Generalized Linear models (GLM), tree-based methods, Neural Networks, and various Ensemble models. This work complements our optimization model which determines the superior set of drugs to make ahead to reduce patient waiting time in the outpatient cancer center.

4 - Sequencing Patients for Ancillary Service in an Inpatient Unit

Pratik Parikh, Associate Professor, Wright State University, Dayton, OH, 45435, United States, pratik.parikh@wright.edu, Nicholas Ballester, Nan Kong, Jordan Peck

Ancillary service providers on an inpatient unit, such as social workers, care managers, and physical and occupational therapists, play crucial roles in the inpatient discharge process. However, these providers are also responsible for other patients besides those to be discharged. There is a paucity of research suggesting an optimal patient sequencing strategy for these providers. We model this problem similar to a stochastic single machine sequencing problem with side constraints. Using a simulation-optimization approach, we derive near-optimal policies and benchmark industry practice.

Sustainable Supply Chains

Sponsored: Manufacturing & Service Oper Mgmt, Supply Chain

Sponsored Session

Chair: Basak Kalkanci, Georgia Institute of Technology, Atlanta, GA, 30339, United States, basak.kalkanci@scheller.gatech.edu

1 - Voluntary vs. Compulsory Supplier Sustainability Assessments in Supplier Selection

Karca Duru Aral, Assistant Professor, Syracuse University, 721 University Avenue, Syracuse, NY, 13244, United States, kdaralwa@syr.edu

In order to make an informed supplier selection during a total-cost procurement auction, the buyer can choose to make sustainability assessments compulsory for the competing suppliers. However, this would negatively affect competition as some suppliers can drop out of the auction given the assessment costs. The buyer can instead make assessments voluntary - but would then risk making a less informed selection. We analyze this trade-off and identify how the buyer should set her assessment policy.

2 - Worker Flexibility Training and Production Autonomy

Evan Barlow, Weber State University, Goddard School of Business & Economics, 1337 Edvalson St, Ogden, UT, 84408, United States, evanbarlow@weber.edu, Gad Allon, Achal Bassamboo

We explore the interaction between worker production autonomy and workers' decisions on training to become flexible resources. Research on flexible resources is prevalent in the operations management literature. Human resources, however, are decision makers and have rights to decide on their own training levels. Many firms, however, have also given workers some production autonomy. We show how workers' training decisions are affected by the identity of the production decision maker.

3 - When to Source from a Competitor?

Eda Kemahlioglu Ziya, North Carolina State, Poole College of Management, Campus Box 7229, Raleigh, NC, 27695-7229, United States, ekemahl@ncsu.edu, Olga Perdikaki

We study the outsourcing decisions of an original equipment manufacturer (OEM). One option is to source from an independent supplier and the other is to source from an integrated firm who is also a competitor of the OEM in the consumer market. However, the advantage of the latter option is that the independent supplier can achieve lower production cost by exploiting the manufacturing synergies between the two products. We also study how/if the OEM's decision is impacted by the type of contract between the OEM and it's supplier.

4 - Selling Off-grid Light to Liquidity Constrained Consumers

Bhavani Shanker Uppari, INSEAD, 1 Ayer Rajah Avenue, Singapore, 138676, Singapore, BhavaniShanker.UPPARI@insead.edu, Ioana Popescu, Serguei Netessine

A large proportion of the world's population has no access to electricity and so relies on noxious kerosene for their lighting needs. As an alternative, there are business models relying on rechargeable light bulbs that are sold at a subsidized price (which renders them affordable) and require regular micropayments for recharges (which eases liquidity constraints). These bulbs provide a cheaper and healthier light source than kerosene, yet their adoption is lower than expected and some consumers continue to use kerosene. This paper explores the potential drivers of such preferences and proposes strategies to alter them.

Chair: Xiaojing Feng, Shanghai Jiao Tong University, Shanghai, China, fengxj89@sjtu.edu.cn

1 - How Market Power Impacts Invest in Supply Chain

Jingjie Su, University of Texas at Arlington, 2508 Mustang Drive, Arlington, TX, 76001, United States, jingjie.su@mavs.uta.edu

Consider a supply chain network with two players, one is original equipment manufacturers and another is contract manufactures.. OEM and CM have relationships both as downstream supplier and competitor in the market. In this supply chain network, when OEM is deciding about making an investment to lower the cost of the product, based on different investment cost and market power, the Nash Equilibrium theory predicts the different decision. We conduct a series of experiments, varying the investment cost and market power, and find out that the experiment data varies from theory. We then apply behavior models to explain these difference.

2 - Prescriptive Analytics for Optimizing the Scheduling of Maintenance Operations

Stefan Feuerriegel, University of Freiburg, Platz der alten Synagoge, Freiburg, 79098, Germany, stefan.feuerriegel@is.uni-freiburg.de, Niklas Goby, Dirk G. Neumann

Maintenance of industrial components frequently occurs upon failure, thereby incurring costs from down-times. A remedy is given by preventive maintenance, for which we propose a prescriptive methodology that schedules maintenance events in order to minimize the service-related costs. This approach consists of two stages: first, we predict the time-to-service of machines based on sensor data using machine learning. In the second stage, we identify the optimal timing of maintenance operations. Here the key ingredient of this work is the fusion of prediction and optimization. We demonstrate the effectiveness of our approach in a case study with real-world data from a large wind park operator.

3 - An Investigation of the Impacts of Nurse Slack on Care Quality and Operating Costs

Xiaosong (David) Peng, Associate Professor, University of Houston, 511 Somerset Dr, Sugarland, TX, 77479, United States, xpeng@bauer.uh.edu, Yuan Ye, Xin Ding

As value-based purchasing (VBP) and patient-centered care take the center stage in today's healthcare environment, healthcare organizations including hospitals are in an ongoing quest to improve both clinical quality and (patient) experience quality while containing rapidly rising costs. To improve and control clinical quality and experiential quality, hospitals must carefully determine the level of nurse slack, defined as the amount of nurse capacity relative to the amount of work performed. This research seeks to identify the fine-grained relationships between nurse slack and clinical quality, experiential quality, and operating costs.

4 - In-house vs Outsourcing: the Effect of Volume-based Learning on Quality Competition

Yanni Ping, PhD Candidate, Drexel University, 3220 Market Street, Philadelphia, PA, 19104, United States, yp86@drexel.edu, Seung-Lae Kim

This paper considers an original equipment manufacturer (OEM) who outsources finished products from an contract manufacturer (CM) where the CM, by adopting existing technology, achieves cost reduction and quality improvement through learning-by-doing. Besides the role of upstream partner, the CM also acts like a downstream competitor. We study the OEM's outsourcing strategy dynamically when competition exists and does not exist. We construct a two-period model and explore the interplay of learning, quality and cost and identify the condition under which pure outsourcing, partial outsourcing or non-outsourcing outplays the others.

5 - Decision Conflict in the Newsvendor Game
Ilkka Leppanen, Dr, Loughborough University School of Business and Economics, Epinal Way, Loughborough, LE11 4NZ, United Kingdom, i.leppanen@lboro.ac.uk

We argue that decision conflict between the pecuniary motive of profit maximization and the nonpecuniary motive of satisfying demand is the driving force behind non-normative behavior in the newsvendor game. We find in behavioral experiments that the previous round situation affects current round decision time such that "intermediate" situations where demand was not satisfied and the decision was not normative produce more decision conflict and deliberation in the current round than "extreme" situations where either demand was satisfied or/and the decision was normative. We demonstrate that decision conflict between pecuniary and nonpecuniary motives can affect newsvendor behavior.

6 - Is the Optimal Suggestion the Best for Managerial Decision Making? A Laboratory Investigation of the Newsvendor Problem
Xiaojing Feng, PhD Candidate, Shanghai Jiao Tong University, 2nd Yanjiusheng Building 1519, Huashan Road 1954, Shanghai, 200031, China, fengxj89@sjtu.edu.cn, Ying Rong, Tianjun Feng

Decision makers often tend to choose the inferior humans' forecasts rather than the superior algorithms' forecasts, although algorithms outperform humans in most cases. So, how to design an efficient decision support system (DSS) that helps people to make better forecasts and decisions becomes our concern. We investigate how the suggestions of different DSSs affect humans' order decisions in the classical newsvendor settings. Through laboratory experiments, we find that the introduction of DSS induces human newsvendors to exhibit algorithm aversion and regret aversion. We identify the most efficient DSS which eliminates human newsvendors' pull-to-center bias.

Service Systems in Applied Probability

Sponsored: Applied Probability

Sponsored Session

Chair: Jing Dong, Northwestern University, Evanston, IL, 60208, United States, jing.dong@northwestern.edu

1 - A Fluid Model for Service Systems with Dependent Service and Waiting Times
Chenguang Allen Wu, Northwestern University, Evanston, IL, United States, allenwu@u.northwestern.edu, Ohad Perry, Achal Bassamboo

We consider a large service system in which the service time of each customer depends on his waiting time. Specifically, there can be two types of dependence: either a customer's patience depends on his individual service requirement, or the actual service requirement changes in response to the delay in queue. To study the two cases, we develop a unified fluid model that captures those two types of dependencies, and demonstrate its accuracy via simulations. We prove qualitative results for the stationary and transient behavior of the fluid model, which reveal the fundamental differences between the two dependence structures.

2 - Multi Queue Service Systems with Dynamic Customer Choice
Yichuan Ding, University of British Columbia, University of British Columbia, 6333 Larkin Drive, Vancouver, BC, V6T.1C3, Canada, daniel.ding@sauder.ubc.ca, Mahesh Nagarajan, Zhe Zhang

We study a stochastic service system with multiple servers and dynamic consumer choice., where service providers of heterogeneous quality are distributed at different locations. An arriving customer chooses a service provider to obtain service by observing the service reward and length of each queue. Many real life queueing systems can be accommodated by this model. We study this system using both fluid and diffusion approximations. We prove the existence of the unique equilibrium customer queue-length vector of the service providers.We show that the system can be approximated by a multi-dimensional reflected Ornstein-Uhlenbeck process centered at that equilibrium.

3 - Central Limit Theorems for Bike-sharing Networks
Jamol Pender, Cornell University, jjp274@cornell.edu

Bike-sharing is an emerging mode of eco friendly transportation in many cities. In this talk, we prove central limit theorems for a bike-sharing stochastic model. These central limit theorems allow us to move beyond mean field behavior and describe the fluctuations around the mean field limit. Moreover, we are able to derive new Gaussian approximations for various performance measures such as the probability that a station has no bikes or is at capacity.

4 - Optimal Policy in Single-server Multi-class Queuing Systems with Abandonment
Sina Ansari, Northwestern University, Evanston, IL, United States, SinaAnsari2013@u.northwestern.edu, Seyed Iravani, Laurens G. Debo

We study a multi-class queuing system with a single server and customer abandonment. We fully characterize the structure of the server's optimal scheduling policy that minimizes the total average customer abandonment cost.

Queueing Systems and Approximations

Sponsored: Applied Probability

Sponsored Session

Chair: John Hasenbein, University of Texas-Austin, Austin, TX, 78712-0292, United States, jhas@mail.utexas.edu

1 - An Asymptotically Optimal Control Policy for a Multiclass Many Server Queue with General Reneging Distributions
Amy R. Ward, University of Southern California, Marshall School of Business, Bridge Hall BRI 401H, Los Angeles, CA, 90089-0809, United States, amyward@marshall.usc.edu, Amber L. Puha

We consider a multiclass many-server queue with general interarrival, service, and reneging distributions. For reneging distributions with bounded, nonincreasing hazard rates, we find that static priority may not be asymptotically optimal on fluid scale. We propose a new class of policies, called Random Buffer Selection, and prove their asymptotic optimality. We further identify the fluid approximation to the limiting cost as the optimal value of a certain optimization problem.

2 - Operational Benefits of Free Trials in Large Scale Service Systems
Yasar Levent Kocaga, Sy Syms School of Business, Belfer Hall Room # 403/A, 2495 Amsterdam Ave, New York, NY, 10033, United States, kocaga@yu.edu, Chihoon Lee

We consider a firm that is serving price and delay sensitive customers and that has the option of offering a free trial service to a new market of customers. We first show that it is optimal for the revenue maximizing firm to operate in the QED heavy traffic regime and provide tractable and accurate expressions for the optimal price and revenue. Then, we use these expressions to identify conditions under which offering free trials is beneficial to the firm.

3 - Stability and Tail Asymptotics in a Multiclass Queue with State-dependent Arrival Rates
John Hasenbein, University of Texas-Austin, 1 University Station Stop C2200, Department of Mechanical Engineering, Austin, TX, 78712-0292, United States, jhas@mail.utexas.edu, Philip Ernst, Soren Asmussen

We analyze a multiclass single-server queueing system in which the arrival rates depend on the current job in service. The system is characterized by a matrix of arrival rates. Using fluid models, we obtain the necessary and sufficient conditions for stability. Utilizing the natural connection with the multitype Galton-Watson processes, we derive the Laplace-Stieltjes transform of busy periods. We conclude with tail asymptotics for the busy period for heavy-tailed service time distributions for the regularly varying case.

4 - Naor's Model with Heterogeneous Customers and Arrival Rate Uncertainty
Chengcheng Liu, 2815 Rio Grande Street, Austin, TX, 78705, United States, liuchengcheng2011@gmail.com, John Hasenbein

This research examines extensions of Naor's queueing model in which the arrival rate is not known with certainty by either customers or system managers. The arrival rate is considered as a non-degenerate random variable. In view of a social optimizer and a revenue maximizer, we investigate both static and state-dependent pricing policies in the presence of customer heterogeneity in their economic characteristics. Two cases are considered: the observable case and the unobservable case. This work is also an extension of the study of Chen and Hasenbein on a related model in that their model only considers homoge- neous customer populations.

1 - Minimizing the Warehouse Order Picking Costs Considering Probabilistic Risk

Atieh Madani, University at Buffalo (SUNY), 308 Bell Hall, Buffalo, NY, 14260, United States, atiehmad@buffalo.edu, Rajan Batta, Mark Henry Karwan

The expansion of online shopping and supply chain in today's world makes the warehouses as one of the main element of trading network. In this research first we give a brief review on different aspects of warehousing and in continue we present the order picking as one of the most common problems in this area. In our research we have focused on the problem of minimizing order lateness and picking cost by deciding on the number of pickers and the probabilistic risk of batching. This cost includes customer loyalty, internal transportation, and etc. We have used queuing theory to create an algorithm in order to produce an optimal or near optimal decision for batching and workforce level.

2 - A Comparison of Construction Productivity Ratings

Mostafa Ghandehari, Senior Lecturer, University of Texas-Arlington, Civil Engineering, Univ. of Texas at Arlington, Arlington, TX, 76019, United States, ghandeha@uta.edu

Labor utilization rating model is used to calculate labor rating factor. Chi-square distribution is used to compare productivity ratings of three or more construction crews. Statistical test of hypothesis for proportions is utilized to decide if proportions of productive times between crews are equal or not.

3 - Reducing Manufacturing Electricity Costs by Controlling Dependence Between Production Parameters

Hyun Woo Jeon, Assistant Professor, Louisiana State University, 3272X Patrick F. Taylor Hall, Mechanical and Industrial Engineering, Baton Rouge, LA, 70803, United States, hwjeon@lsu.edu

Manufacturing electricity costs are charged for energy consumption (EC in kWh) and peak demand (PD in kW). To model the costs accurately, EC and PD need to be considered together, but a model investigating the two factors has not been thoroughly studied. This study introduces a novel approach to estimating and reducing the costs by applying a multivariate probability model. The proposed model as a joint probability distribution characterizes important production parameters, and then EC and PD are evaluated from the model. From various examples, the proposed model provides a strategy to reduce the costs (EC + PD) by adjusting the production parameters and their dependence.

4 - An Active Learning Approach for Gaussian Processes

Rajitha Meka, Graduate Student, University of Texas at San Antonio, 15801 Chase Hill Blvd, Apt 104, San Antonio, TX, 78256, United States, rajitha.meka@utsa.edu, Adel Alaeddini

Gaussian process regression is a well-known non-parametric regression method that provides the estimate of uncertainty along with the predictions. Having the initial fit of the model with the points observed, active learning method helps to choose a promising point that improves the Gaussian process model. For the design space with large number of unobserved points, the main aim is to provide a good model with less number of evaluations by learning information about the design space at each evaluation.

1 - Exploring the Affect of Idea Sources on the Successful Evaluation of Ideas

Nilam Kaushik, University College-London, London, United Kingdom, nilam.kaushik.13@ucl.ac.uk, Bilal Gokpinar

In this project we explore the factors affecting the successful evaluation of ideas on a crowdsourcing platform. In particular we are interested in understanding how the diversity, semantic distance of source ideas from the problem domain and the ways in which sources recombine affect the likelihood of idea success. In this work, we leverage text mining techniques and information retrieval methods to understand the recombination process.

2 - Structural Anatomy and Evolution of Supply Networks: A Multi-method Approach

Hyunwoo Park, The Ohio State University, Columbus, OH, 43210, United States, park.2706@osu.edu, Marcus A. Bellamy, Rahul C. Basole

We investigate the evolutionary dynamics of supply networks with a focus on the influence of structural, firm-, and industry-specific mechanisms. We characterize the dynamic relationship between the structural mechanisms on a longitudinal dataset of 2,221 unique firms and 13,668 firm-year observations. We find empirical support for negative crossover effects between two key structural mechanisms inherent in supply networks, a positive moderation of a firm's absorptive capacity and a negative moderation of industry growth on the structural reinforcement.

3 - Engaged Scholarship and Co-Creating Knowledge: A Design Science Approach to Operations Management Research

Aravind Chandrasekaran, Associate Professor, The Ohio State University, 600 Fisher Hall, 2100 Neil Avenue, Columbus, OH, 43210, United States, chandrasekaran.24@osu.edu, Joan Ernst Van Aken, Bradley R. Staats, Andrew H. Van de Ven

We question whether the decline in business education is partly due to the research approach adopted by operations management scholars. We show how co-creating knowledge with practice through a design science approach can derive dual benefit of relevance and rigor through several examples. We also offer suggestions on when and how to use this research approach.

4 - Unpacking the Value of Novelty in Design

Tian Chan, Emory University's Goizueta Business School, 1300 Clifton Road, Atlanta, GA, 30322, United States, tian.chan@emory.edu

We study how novelty in product form influences its economic value. We exploit a confidentiality feature specific to the design patent and use stock market reactions in the days subsequent to patent grant to estimate the private value of individual design patents granted to firms publicly listed in the US. We use the construct of styles—categories of product designs that are similar in form—to build various measures of novelty relative to designs of the same style, thus taking into account the context in which novelty is perceived. We show how different kinds of novelty positively or negatively affect value. Our results have implications on how firms should rely on novelty to seek value.

1 - Sourcing Uncertain Product Quality: Competition, Learning, and Volume Postponement

Alexander Rothkopf, Julius-Maximilians-University Wuerzburg, Carla-Henius-Straße 9, Wuerzburg, 97070, Germany, alexander.rothkopf@uni-wuerzburg.de, Felix Lauton

Global-health buyers seek to introduce competition by incenting new generics suppliers with uncertain performance/quality to enter the market. We investigate the benefits of postponing a portion of the procurement volume to learn entrant's performance and how the dynamics of learning and competition depend on the size of the postponed volume.

2 - A Method for Location, Allocation and Distribution of Critical Supplies After a Natural Disaster

Ricardo Giesen, Associate Professor, Pontificia Universidad Catolica de Chile, Vicuna Mackenna 4860 Macul, Casilla 306 Cod. 105, Santiago, 7820436, Chile, giesen@ing.puc.cl
Ricardo Giesen, Associate Professor, CIGIDEN, Santiago, 7820436, Chile, giesen@ing.puc.cl, José Ignacio Olave, Juan Carlos Herrera

Humanitarian logistics after a natural disaster is normally characterized by lack of coordination, material convergence and shortage of critical supplies. This work proposes a mathematical programming method for location, allocation and distribution of critical supplies considering demand forecasting per item, operational costs and social costs including deprivation costs. Different scenarios are compared in terms of costs, considering water, food and shelter items.

3 - Resource Allocation Decisions to Manage Material Convergence
Merve Ozen, Research Assistant, University of Wisconsin-Madison, 1513 University Avenue, Madison, WI, 53706, United States, mozen@wisc.edu, Ananth Krishnamurthy

The large flow of donated items, both solicited and unsolicited, immediately after a major disaster, lead to the material convergence problem. Inefficient resource allocation can cause significant wastage of donated goods as well as deprivation of critical items for victims affected by the disaster. Using transient queuing models, we model this phenomenon to quantify material convergence and assess the impact of staffing strategies that improve efficiency.

4 - A Preposition and Allocation Model for Disaster Relief Inventories with Explicitly Considering Demand Risk
Feng Li, PhD, University of Science and Technology of China, NO. 96, JinZhai Road, Baohe District, Hefei, Anhui Province, 230026, China, lfeng90@mail.ustc.edu.cn

In humanitarian operations management, the relief organizations always have incomplete information on the beneficiaries. As a result, there would exist an estimation error between the estimated demand and real demand for relief supplies. In this paper, we propose a preposition-allocation model for disaster relief inventories by considering a demand risk parameter. We will investigate the impacts of demand risk on decisions of humanitarian logistics and human sufferings of beneficiaries. A cooperative strategy is also developed to cover the demand risk and to reduce human sufferings. Further, the proposed model will be demonstrated using the real case of Rammasun Typhoon in Hainan Island.

Novel RM Models for Loyalty Programs

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Ang Li, PROS, Inc., Houston, TX, 77002, United States, ali@pros.com

1 - Allocation Priority Tiebreakers for Frequent Flyer Seat Allocation Optimization
Shigeru Tsubakitani, PROS, Inc., 43360 Hillpark Street, South Riding, VA, 20152-2597, United States, stsubakitani@pros.com

Three approaches for breaking ties of alternative solutions for a frequent flyer seat allocation optimization model are discussed. The tiebreakers help generate solutions more desirable for airline companies by eliminating randomness and allocating frequent flyer seats more evenly among flights when there are many $0 bids exist in a market.

2 - Which Customers are More Valuable in a Dynamic Pricing Situation?
Anton Ovchinnikov, Queen's School of Business, 143 Union Street, Kingston, ON, K7L.3N6, Canada, ao37@queensu.ca, Jue Wang

We consider a firm that dynamically price its inventory and examine whether customers who purchase at higher prices indeed add higher marginal value to the firm. We present modeling and computational results which are calibrated on a unique data set from a major airline. We show that in some situations a customer's value can be independent of the price paid.

3 - Predicting Customer Retention using Cart Models
Pratik Mital, Senior Consultant, Operations Research, Revenue Analytics, Inc., 300 Galleria Parkway, Suite 1900, Atlanta, GA, 30339, United States, pmital@revenueanalytics.com

Predicting customer retention is an important problem in airlines, cruise lines, and any other industry where demand has a tendency to go higher than capacity. This allows the planners to optimally book more than the capacity, depending upon how many customers are expected to cancel. The margin for error in predicting customer retention can be quite low, since a wrong prediction can lead to either a denied boarding or an empty seat cost. The following are the key areas that will be covered during the talk: 1. Overview of customer retention and CART models 2. Customer attributes that can be utilized in the models 3. A real-world example 4. Accuracy metrics to evaluate the accuracy of the models

Joint Session RMP/APS: Data-driven Revenue Management

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Will Ma, willma353@gmail.com

Co-Chair: David Simchi-Levi, Massachusetts Institute of Technology, Cambridge, MA, 02139, United States, Dslevi@mit.edu

1 - Data-driven Dynamic Pricing with Model Misspecification and Endogeneity Effect
He Wang, Georgia Institute of Technology, Atlanta, GA, 30332-0205, United States, he.wang@isye.gatech.edu, Milashini Nambiar, David Simchi-Levi

We study a dynamic pricing problem with contextual information where the seller may assume an incorrect demand model. The seller sequentially observes demand, estimates model parameters, and then chooses price. In this setting, model misspecification can cause price endogeneity, which in turn leads to inconsistent estimation of price elasticity and bad pricing decisions, a phenomenon known as the "spiral-down effect" in revenue management. To address the endogeneity effect we propose a "Random Price Shock" algorithm that dynamically generates independent price shocks to estimate price elasticity while maximizing revenue.

2 - Learning with Abandonment
Sven Peter Schmit, Stanford University, 729 Escondido Rd, Apt 224, Stanford, CA, 94305, United States, schmit@stanford.edu, Ramesh Johari

Consider a seller that repeatedly sets a price for a subscription product to the same customer. The seller would like to raise the price to the maximum the customer is willing to pay, but if it exceeds this value the customer abandons forever. Therefore, the learner has to be conservative in its policy.We propose a general thresholded learning problem that models such scenarios. The goal is to maximize the sum of discounted rewards based on a activity level set at discrete times. However, the process stops if the activity level exceeds an unknown threshold. We show that simple policies perform well under fairly general conditions.

3 - Data-driven Promotion Planning with Multiple Forms of Cannibalization
Hanwei Li, MIT, Cambridge, MA, United States, hanweili@mit.edu, Will Ma, David Simchi-Levi, Jinglong Zhao

We study the problem of promotion planning given data from a distributor which sells multiple products through multiple retailers. While planning these promotions, three cannibalization effects must be taken into consideration: across products, across retailers, and across time. We also analyze the effects of competing SKU's from other distributors.

4 - Continuous Assortment Optimization with Incomplete Information
Arnoud den Boer, University of Amsterdam, Postbus 94248, Room Number F3.33, Amsterdam, 1090 GE, Netherlands, A.V.denBoer@uva.nl

We study the classical assortment optimization problem with multinomial-logit type choice probabilities and finite capacity, but with a continuous instead of discrete set of products. We discuss how to determine an optimal assortment, how to estimate the choice probabilities from data, and how to apply these in an online-learning setting.

Topics in Revenue Management, Choice Modeling and Assortment Optimization

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Vineet Goyal, Columbia University, Columbia University, New York, NY, 10027, United States, vgoyal@ieor.columbia.edu

1 - Revenue Management with Dynamic Customer and Assortment Selection
Adam Elmachtoub, Columbia University, 500 W. 120th St., New York, NY, 10027, United States, adam@ieor.columbia.edu, Vineet Goyal, Roger D. Lederman

We provide algorithms that select customers dynamically, each with their own choice model, in order to maximize revenue from a limited supply of inventory. We propose constant factor approximations when assortments may be chosen dynamically, and for a constrained setting where the set of offered products can only decrease over time.

2 - A Dynamic Learning Approach to Assortment Selection
Vashist Avadhanula, Columbia University, 3022 Broadway, 4th Floor West, New York, NY, 10027, United States, vavadhanula18@gsb.columbia.edu, Shipra Agrawal, Vineet Goyal, Assaf Zeevi

We consider a dynamic assortment selection problem where customers choose according to a multinomial logit (MNL) choice model. The retailer observes this choice and the objective is to dynamically learn the model parameters, while optimizing cumulative revenues over a selling horizon of length T. We present an efficient algorithm that simultaneously explores and exploits, achieving performance independent of the underlying parameters. The algorithm can be implemented in a fully online manner, without knowledge of the horizon length T. Furthermore, the algorithm is adaptive in the sense that its performance is near-optimal in both the "well separated" case and the general parameter setting.

3 - The Limit of Rationality in Choice Modeling: formulation, Computation, and Implications
Srikanth Jagabathula, NYU. Stern School of Business, 44 W. 4th St, Kmc Rm 8-74, New York, NY, 10012, United States, sjagabat@stern.nyu.edu, Paat Rusmevichientong

We focus on quantifying the limit of rationality (LoR) in choice modeling applications, defined as the "cost" of approximating the observed choice fractions from a collection of offer sets with those from the best fitting probability distribution over rankings. Computing LoR is intractable in the worst case. We express the complexity in terms of structural properties of an appropriately defined graph and exploit the graph structure to compute LoR efficiently for a large class of applications. Using real-world grocery sales data, we identify product categories for which going beyond rational choice models is necessary to obtain acceptable performance.

1 - How do IT Infrastructure and Human Resources Impact Operational Adjustment Agility
Peiran Gao, Huazhong University of Science and Technology, 1037 Luoyu Road, Wuhan, China, gaopeiran@hust.edu.cn, Jinlong Zhang, Yeming Gong, Shan Liu

This study proposes that two types of IT resource(i.e, IT infrastructure and human resources) enhance operational adjustment agility by facilitating structural IT capabilities, and that the magnitude of facilitation depends on the level of CEO support of IT. We test these relationships based on data from a multi-industry survey. Our results demonstrate that IT infrastructure and human resources do enhance operational adjustment agility through the mediated effects of structural IT capabilities, and that CEO support of IT differentially affects these relationships.

2 - Spatial Patterns and Socioeconomic Dimensions of Shared Accommodations: the Case of Airbnb in Los Angeles
Avijit Sarkar, Professor, University of Redlands, 1200 E.Colton Avenue, Redlands, CA, 92373, United States, avijit_sarkar@redlands.edu, Mehrdad Koohikamali, James B. Pick

This study examines spatiotemporal aspects and socioeconomic dimensions of shared accommodations within the broader context of the sharing economy. Specifically, we examine how socioeconomic attributes of Airbnb hosts moderated by hosts' attitudes towards trust and greener consumption influence participation in the sharing economy. Spatial bias in sharing economy participation rates is examined and policy implications for the supply side of shared accommodations are discussed along with generalizability of results.

3 - A Study of Mixed Reality Feature Utilization within Social Networking Applications
Alsius David, Doctoral Student in IT, University of North Texas, 1155 Union Circle #311277, Denton, TX, 76203, United States, alsiusdavid@my.unt.edu, Daniel A.Peak

Mixed reality (MR), where both real and virtual worlds are mixed, has been trending in social networking applications. MR enhances communication by integrating a virtual experience into the users' current environment. Taking the user's perspective, this study identifies whether personality, quality, and environmental characteristics influence feature utilization on the reality-virtuality continuum employed by SnapChat and Facebook Messenger.

4 - The Effect of Emotional Support by Conversational Assistants on Information Disclosure by Users
Kambiz Saffarizadeh, Georgia State University, 35 Broad Street, Suite 900, Atlanta, GA, 30303, United States, ksaffarizadeh1@gsu.edu, Maheshwar Boodraj, Tawfiq Alashoor

The main objective of this research is to investigate interaction behaviors between CAs and users. Specifically, we will examine how CA-based emotional support can influence users' satisfaction and disclosure behavior. We will draw upon interpersonal communication theories to develop and test a research framework in an experimental setting using a conversational assistant. We are interested in examining how CA-based emotional support can facilitate higher trust and lower privacy concern toward sharing personal information, which in turn influence the relationship between the user and CA in terms of service satisfaction and users' disclosure behavior.

5 - A Duopoly Model of Competition in Cloud Computing Services
Pelin Atahan, Assistant Professor, Ozyegin University, Nisantepe Mah Orman Sok Cekmekoy, Istanbul, 34794, Turkey, pelin.atahan@ozyegin.edu.tr, Basak Altan, Okan Orsan Ozener

In this paper, we investigate the price, quality of service and capacity decisions of 'Cloud Computing' service providers. We present a model where customers vary in their valuation of quality and in the quantity they demand. We study a duopolistic market, where the incumbent firm enjoys lower costs in later periods as a result of learning. We study how the service offerings change and how the entrant firm positions itself under two scenarios. In the first case, the incumbent firm does not consider future competition, whereas, in the second case, the incumbent firm anticipates future competition and acts strategically to deter entry in the first period.

Cyber Analytics and Optimization

Sponsored: Social Media Analytics

Sponsored Session

Chair: Les Servi, The MITRE Corporation, The MITRE Corporation, Bedford, MA, 01730-1420, United States, lservi@mitre.org

1 - Multifirm Models of Cybersecurity Investment and Competition vs. Cooperation and Network Vulnerability
Anna B. Nagurney, University of Massachusetts Amherst, Isenberg School of Management, Dept of Operations & Information Mgmt, Amherst, MA, 01003, United States, nagurney@isenberg.umass.edu, Shivani G. Shukla

We develop and compare three distinct models for cybersecurity investment in competitive and cooperative situations to safeguard against potential and ongoing threats. We utilize game theory and optimization theory. We then apply the framework to two case studies on retailer and financial services and recommend a course of action.

2 - Scheduling and Training Multi-skilled Analysts under Uncertainty
Doug Altner, MITRE Corporation, 7515 Colshire Drive, M/S.H617, McLean, VA, 22102, United States, daltner@mitre.org, Erica Mason, Les Servi

This talk introduces a shift scheduling problem with unknown demand, multiple job types, and multi-skilled employees who can be trained to complete additional jobs. We provide a stochastic integer programming formulation of this problem and demonstrate that this formulation can be directly fed into Gurobi to solve instances with as many as 50 employees and 50 scenarios per day without any decomposition techniques. Finally, we present a local search heuristic that consistently produces good solutions for instances that are too large for a direct feed into a commercial solver.

3 - A Methodology to Measure and Monitor Level of Operational Effectiveness of a Cybersecurity Operations Center (CSOC)
Rajesh Ganesan, George Mason University, Fairfax, VA, United States, rganesan@gmu.edu, Ankit Shah, Sushil Jajodia, Hasan Cam

There are a number of disruptive factors that can adversely impact the normal operating conditions of a cybersecurity operations center (CSOC) such as 1) higher alert generation rates from a few IDSs, 2) new alert patterns that decreases the throughput of the alert analysis process, and 3) analyst absenteeism. The impact of all the above factors is that the alerts wait for a long duration before being analyzed, which impacts the readiness of the CSOC. It is imperative that the readiness of the CSOC be quantified and measures taken to maintain it, which in this talk is defined as the Level of Operational Effectiveness (LOE) of a CSOC.

4 - Deriving Global Criticality Conditions from Local Dependencies
Les Servi, The MITRE Corporation, M/S.M230, 202 Burlington Road, Bedford, MA, 01730-1420, United States, lservi@mitre.org, Paul R. Garvey

To assure greater resilience in a richly connected cyber network from exploited vulnerabilities, it is necessary to identify critical nodes and links that, without which, could compromise the ability of the system to operate as required. This talk provides a new near linear time way to find the globally critical nodes and links from local dependencies between elements that comprise the system.

Social Media Analytics III

Invited: Social Media Analytics

Invited Session

Chair: Sriram Somanchi, University of Notre Dame, Notre Dame, IN, 46556, United States, somanchi.1@nd.edu

1 - Apply Text Mining Technology to Assist Design of Mobile Game Pokémon Go
Shih-Hsien Tseng, Chung Yuan Christian University, 200 Chung Pei Road, Chung Li District, Taoyuan City, 32023, Taiwan, tsengsh@mail2000.com.tw, Hsiao-Ying Chen, Chung-Yu Lao

With the prevalence of Mobile Games, numbers of Games Developers and the players are growing significantly. Many players like to discuss experiences and suggestions at the forum, and therefore online reviews from users become an important source of information for the game developer. In this research, we apply LDA Topic Model to analyze the opinions from users of Mobile Game Pokémon Go on PTT which is the largest forum in Taiwan to help game developers enhance the design quality.

2 - Opinion Dynamics with Bounded Openness to Ideas
Youzong Xu, Xi'an Jiaotong-Liverpool University, 111 Ren'ai Road, Business Building 423B, Suzhou, 215123, China, xu.youzong@wustl.edu, Bo Li

We study opinion dynamics with agents who have bounded openness to ideas. We characterize necessary and sufficient conditions under which agents with bounded openness to ideas can reach a consensus, or become segregated groups that never listen to each other. We then apply our findings to show why, when social media is providing a platform that people can easily be connected with each other, social media may lead to segregation and even polarization of people's opinions.

3 - Exploring the Social Media Prevalence and Consequence of "Sharing without Reading"
Frank Zheng, Doctoral Student, UT-Austin, Austin, TX, United States, jianqing.zheng@mccombs.utexas.edu

Extant research on social contagion assumes that information spreads as sharers deliberately process external information, then decide whether or not to share it; as each sharer processes this information, s/he is "infected" with new knowledge. However, emerging evidence suggests that this is not always the case; for example, 16.2% of shared links on Twitter have more retweets than clicks (Zarrella, 2013). We propose that "sharing without reading" represents a distinct phenomenon in which information "carriers" spread content without being infected by it. Evidence from four studies suggests that sharing without reading leads to increases in subjective, but not objective, knowledge.

4 - Exploring Social Influence from Social Opinion to Social Network
Shu-Ping Tsai, Graduate Student, National Sun Yat-Sen University, No. 70, Lienhai Rd., Kaohsiung, 80424, Taiwan, Kaohsiung, Taiwan, m054020017@Student.nsysu.edu.tw

With the rapid development of social Web and electronic commerce, the potential consumers seek for product-related information before making a purchase decision from various online resources. Among all kinds of online resources, customer review provides critical product features and discussion posts play a vital role for peer communication. However, there is a lack of integration of these rich online resources. This study particularly investigates customer review and interpersonal information from discussion boards and explores how these two social resources associated with each other to improve the insight into each user's preference with a social role they act.

Mechanism Design and Pricing

Invited: Auctions

Invited Session

Chair: Gabriel Weintraub, Stanford Graduate School of Business, Stanford, CA, 94304, United States, gweintra@stanford.edu

1 - Evaluating Strategic Forecasters
Rahul Deb, University of Toronto, 150 St George Street, Toronto, ON, M5S.3G7, Canada, rahul.deb@utoronto.ca

Motivated by the question of how one should evaluate professional election forecasters, we study a novel dynamic mechanism design problem without transfers. A principal who wishes to hire only high quality forecasters is faced with an agent of unknown quality. The agent privately observes signals about a publicly observable future event, and may strategically misrepresent information to inflate the principal's perception of his quality. We show that the optimal deterministic mechanism is simple and easy to implement in practice: it evaluates a single, optimally timed prediction. We study the generality of this result and its robustness to randomization and noncommitment.

2 - The Scope of Sequential Screening with Ex-post Participation Constraints
Gabriel Weintraub, Stanford Graduate School of Business, Knight Management Center, Stanford University, 655 Knight Way, E364, Stanford, CA, 94304, United States, gweintra@stanford.edu, Dirk P. Bergemann, Francisco Javier Castro

We study the classic sequential screening problem with the additional constraint that the seller is required to satisfy the buyer's ex-post participation constraints. This setting arises in several practical applications, such as the market for display advertising. First, we provide a necessary and sufficient condition under which the static contract (buyers are not sequentially screened) is optimal for general distributions. When this condition fails, we fully characterize the optimal dynamic contract, which randomizes the low type buyer and exhibits other novel properties.

3 - Understanding and Pricing on a Network with Latent Agents
Alexandre Belloni, Duke University, Fuqua School of Business, 100 Fuqua Drive, Durham, NC, 27708, United States, abn5@duke.edu, Baris Ata, Ozan Candogan

A recent literature on social networks has focused on understanding how a seller can use the available social network information to improve decisions. This paper investigates how a seller estimates the impact of the social network on agents' consumption and makes pricing decisions when there are additional latent agents which are not observed by the seller. These latent agents can purchase the same product from a different channel and can influence the agents in the observable part of the network. We establish structural results, compute optimal pricing rules based on observable quantities, and estimate the effective latent network.. Variants with and without random shocks are considered.

4 - Local Computation Mechanism Design
Shai Vardi, California Institute of Technology, Pasadena, CA, United States, svardi@caltech.edu

Local computation mechanisms (LCMs) are game theoretic mechanisms that produce small parts of a solution extremely quickly, without any pre-processing. LCMs reply to queries in time sub-linear in the input size, so that the replies to different queries are consistent with a single global solution that satisfies some required game-theoretic properties. LCMs are useful in scenarios when the market is so big that mechanisms that require access to all of the input and produce the entire output are impractical. We design local computation mechanisms for several classical game-theoretical problems: stable matching, job scheduling and unit-demand combinatorial auctions.

1 - Measuring Large-scale Market Responses from Aggregated Sales: Regression for High-dimensional Sparse Data

Nobuhiko Terui, Professor, Tohoku University, Kawauchi Aoba-Ku, Sendai, 980-8576, Japan, terui@econ.tohoku.ac.jp

We propose a regression model for high-dimensional sparse data from store-level aggregated sales. The modeling comprises two sub-models—topic model and hierarchical factor regression model—that are applied sequentially not only for accommodating high dimensionality and sparseness but also for managerial interpretation. First, the topic model is applied unusually to aggregated data to decompose the aggregated sales volume of a product into sub-sales for several topics by allocating each unit sale in a day into one of topics based on joint purchase information. Then, we construct a topic-wise market response function by hierarchical factor regression based on canonical correlation analysis.

2 - In Store Customer Experience Creation in the Retail Industry

Trisha D. Anderson, Texas Wesleyan University, 1201 Wesleyan Street, Fort Worth, TX, 76105, United States, trdanderson@txwes.edu

This paper examines the impact of the right mix of atmospheric factors used to create the in-store customer experience in a retail market that includes ambience factors (volume of music, type and strength of aroma, level of lighting), interaction with sales people, and store display, on the in-store customer experience, the customer's emotional state, and customer shopping behavior.

3 - Do Marketing Talents Matters its Relationship to Marketing Capability and Performance

YiChun Liu, National Taiwan University, Room 1116, No 30, Sec 3, Taipei, 10668, Taiwan, d02724003@ntu.edu.tw

The discussion of marketing capability on firms' performance has been well documented for the last two decades. Most of the previous studies regarding the measurement of marketing capability are based solitary on the attitude of top managers. However, employees' marketing talents are rarely discussed. This study investigates a new construct of marketing capability and the measurement of individual employee's marketing talents. A preliminary questionnaire was developed to conduct an empirical study, of which over 2,000 employees were surveyed. This study identified the positive impact of employee marketing talent and managerial marketing capability to organizational performance.

4 - Peer Effects in the Adoption of a New Social Program

Claudio Mora, Pontificia Universidad Javeriana, Carrera 7 #40b-36, Piso 4, Bogota, Colombia, claudio_mora@javeriana.edu.co

Launching a new program is challenging for organizations because their potential clients have to learn its unknown quality. This is the first paper to empirically study how adoption by high school classmates and coworkers affects each peer's adoption of a new employment subsidy during implementation stages. Identification comes from a discontinuity in the subsidy assignment rule inducing exogenous variation in a neighborhood around the worker's wage eligibility cutoff. Using a unique set of administrative records, we find that: coworkers strongly influence one's adoption, classmates do not; peer effects decrease over time. Hence, information diffusion can explain adoption in the short run.

5 - The Power of Social Networks in Predicting Noncontractual Customer Activity Evidence from Venmo

Pantelis Loupos, PhD Candidate, Kellogg, Northwestern University, 2800 N Lakeshore Dr, Apt 2913, Chicago, IL, 60657, United States, louposp@gmail.com

There is a shift away from the subscription-based business model to on-demand (OD) services. We focus on predicting customer activity (CA) in OD settings in the presence of social network (SN) data. Data comes from Venmo, a P2P payment application. We: 1) Conduct a dynamic analysis to quantify the effect of user and SN metrics on CA and find that SN metrics help achieve a significant increase in predictive accuracy during the beginning of a customer's lifetime. 2) Evaluate our models in the task of CA-based customer segmentation and find that we can identify customers segments with high accuracy. 3) Identify structural differences among the different customer segments.

6 - Controlling Endogeneity in Event Studies: Valuing Movie Product Placements using Prediction Market Data

David Richardson, Assistant Professor of Marketing, Illinois Institute of Technology, Chicago, IL, 60605, United States, david.richardson@stuart.iit.edu

Abstract: Event studies are widely used in marketing to value intangible investments using abnormal returns as measured by equity markets. Two objections; omitted variables which are endogenously related to event timing may bias estimates, and researcher flexibility in choosing the event window allows for cherry picking results. We use data from the Hollywood Stock exchange (HSX) to control for these effects in a study of product placement of automobiles in films. We evaluate individual placements using regression on panel data and compare the results with the conclusions from a standard event study approach to shed light on potential endogeneity bias in such studies.

1 - Analyst Coverage, Board Monitoring, and Firm Value. Evidence from a Natural Experiment

Torsten Twardawski, University of Konstanz, Universitaetsstr. 10, Konstanz, 78467, Germany, Torsten.twardawski@uni-konstanz.de, Iana Zborshchyk

In this paper, we estimate a causal impact of analyst coverage on the long-term value of a company. Using two established quasi-natural experiments, we find that exogeneous coverage reductions decrease long-term firm value. We show that the reduction in firm value is linked to a decline in fundamental value and stronger if a board has weak monitoring power. Conditional on their initial internal monitoring quality, firms try to offset the negative effect by improving their internal governance mainly through getting more independent boards. Overall, our results confirm that analysts create value through their governance role, which interacts with preexisting internal monitoring.

2 - The Role of Sentiment-driven Institutional Investors in IPO Pricing

Bo Liu, University of Electronic Science and Technology of China, No. 2006, Xiyuan Ave, West Hi-Tech Zone, Chengdu, 611731, China, b.liu07@fulbrightmail.org, Jingbin He

In this paper, we take advantage of the unique setting and big data of Chinese auction-based IPO process to examine the role that sentiment institutions play in the pricing of newly listed stocks. We find that underwriters may "strategically" use positive/negative language to manipulate the writing style in the premarket Valuation Report to influence bidder's pricing and hence the final offer prices of IPO. This is one type of "agency problem", which leads to substantial losses of both retail and institutional investors and more volatile post-IPO stock prices. The results suggest that sentiment institutional investors deteriorate the pricing of newly listed stocks.

3 - Financial Assets and Demand Estimation

Murat Tiniç, PhD Candidate, Bilkent University, Ankara, Turkey, tinic@bilkent.edu.tr

In this study, I propose to model the investment decisions of an investor as a discrete choice action, and estimate the demand for a financial asset through the underlying structure of the investor's utility.

4 - The Impact of a CEO's Status as High Quality Board Director , on Personal and Organizational Outcomes: Evidence fro CEO Awards

Nadja Younes, University of Konstanz, Universitaetsstr. 10, Konstanz, 78467, Germany, nadja.younes@uni-konstanz.de, Torsten Twardawski

In this paper we examine the extent to which a CEO's status as high quality board director impacts economic outcomes. We use a unique data set of CEO awards to measure positive second-order status shocks to CEOs, who serve on an award-winning CEO's board. Around the awarding, we find negative and significant stock-price reactions for the CEOs' focal firms. We show that affected CEOs accept more board positions and receive higher compensation. Corporate governance has a moderating effect on the investigated outcomes. Our findings suggest that CEOs with reputable board positions become busy with firm-unrelated activities, dedicate less time and effort to their firms, and destroy shareholder wealth.

1 - Dynamic Pricing Competition of Fresh Produces under Vertical Product Differentiation

Chang Xu, East China University of Science and Technology, Shanghai, China, 947319206@qq.com

This paper study the dynamic pricing competition between two firms respectively offering vertically differentiated fresh produces of which freshness is decrease over time without considering fresh-keeping effort. Then, through taking into account the freshness-keeping effort, we deepen the analysis of the problem. We show that the retailer would mark down its price when its decay rate promote comparing to its rival and , accordingly, its accumulated discount income would decline. And we also find it would be profitable for the retailer to trade off between the gains from the depressing the decay rate and the losses from rising the price for the compensation of the cost of freshness-keeping effort.

2 - Cost of Information Sharing in Group Purchasing

Gilles Merckx, University of Namur, Rempart de la Vierge, 8, Namur, 5000, Belgium, gilles.merckx@unamur.be, Wenli Peng, Aadhaar Chaturvedi, Philippe Chevalier

We investigate through a Cournot model whether group purchasing could be attractive for competing firms, when the next period market demand and firms' product quality are uncertain. In this context, group purchasing offers the firms a higher negotiation power with the supplier, but also requires to reveal some sensitive information to the competitor, as the quantity desired (which is a signal of a firm's product quality and market demand estimation), in order to negotiate as a single buyer with the supplier. Hence it is not clear whether firms should agree on doing group purchasing. We find that different types of uncertainty can lead the firms to select opposite purchasing strategies.

3 - Price Competition and Quality Competition: National Brand vs. Store Brand

Tulika Chakraborty, Research Associate, John Molson School of Business, 1450 Rue Guy, Montreal, QC, H3H2L5, Canada, jum.tulika@gmail.com, Satyaveer S. Chauhan, Xiao Huang

We consider a supply chain in a market segment where a national brand competes with a retailer's private label product with respect to not only price but also quality. We use the game theoretic model to focus the impact of different channel leadership of quality-setting stage on optimal decisions.

4 - Strategic Timing of New Product Release with Information Leakage under Competition

Huajiang LUO, PhD Student, Lingnan University, Hong Kong, Hong Kong, huajiangluo@ln.edu.hk, Tian Li, Weixin Shang

We consider a model in which two firms plan to sell substitutable new products to a uncertain market. Each firm makes two decisions (release timing decision and quantity decision) based on its private information. The late firm can infer the early one's information via its quantity. We find that the late firm will commit a higher quantity, and hence early releasing doesn't necessarily translate into a bigger market share. When the competition is not intense, the equilibrium is that the more-informed firm releases later than the less-informed one. With private information, sequentially releasing new product dampens the quantity competition, and firms benefit from the differentiation of release time.

From the Center to the Terminal: Methods for Managing Airspace and Airport Operations

Sponsored: Aviation Applications

Sponsored Session

Chair: James Calvin Jones, University of Maryland, College Park, MD, United States, jonesjc1@gmail.com

1 - An Optimization Framework for Trajectory Based Operations in Air Traffic Flow Management

Guglielmo Lulli, Lancaster University, Lancaster, LA1 4YX, United Kingdom, g.lulli@lancaster.ac.uk, Veronica Dal Sasso, Franklin Djeumou Fomeni, Giuseppe Murgese, Konstantinos G. Zografos

In this talk, we present a mathematical framework - developed within the activities of the SESAR ER project OptiFrame - to optimally configure and assess the performance of the Trajectory Based Operation (TBO) concept. The existence of multiple and sometimes conflicting objectives, reflecting the views and expectations of the different airspace stakeholders, naturally lead to multi-objective optimization. To evaluate the tractability of the proposed model, a computational performance analysis on a set of realistic instances will be presented.

2 - Capacity Scenarios for Multiple Airport Regions and their Application for Regional Air Traffic Management

Ang Li, angli@berkeley.edu, Mark M. Hansen

We identify multiple airport regions (MARs) in the United States based on the temporal distance between airports. Clustering analysis is implemented to identify daily capacity scenarios in 2015 for the airports for the New York MAR. Using the scenarios, we formulate a mixed-integer linear programming model to reschedule and reassign flights into the New York MAR to minimize the total cost of delay and inter-airport flight shifting.

3 - Evaluating Capacities of New York-area Airports Combining Empirical Data with Enveloping Methods

Jeremy Eckhause, RAND Corporation, 1200 S. Hayes St., Arlington, VA, 22202, United States, eckhause@rand.org, Kenneth Kuhn, Candice Miller

We present a capacity estimation method that combines large amounts of ASPM data with published capacity studies and methods in the literature for estimating capacity envelopes at the three New York-area airports. Based on this approach, will illustrate how existing capacity values may not provide sufficient flexibility tradeoff in off-nominal conditions. As a result, we provide suggested alternative capacities to reflect those additional data points, to provide inputs into models that assess the delay performance under certain GDP procedures.

4 - Models for Setting Airport Capacities

James Calvin Jones, University of Maryland-College Park, 223 Concord Turnpike, Apt 206, Cambridge, MA, 02140, United States, jonesjc1@gmail.com

In this presentation we propose a supervised learning method for predicting airport capacity as well as the uncertainty associated with those predictions. We also discuss a chance-constrained programming model that leverages the uncertainty from these predictions to select the planned airport capacity.

Supply Chain Optimization

Contributed Session

Chair: Ziyu Zhai, Huazhong University of Science and Technology, Wuhan, China, zhaiziyu000@126.com

1 - An Analytical Model for Low Carbon Supplier Development

Chiranjit Das, Indian Institute of Management Rohtak, MD University Campus, Rohtak, Haryana, Rohtak, 124001, India, fpm02.003@iimrohtak.ac.in, Sanjay Jharkharia

This paper deduces a set of association rules of firm's investment and collaboration decisions for low carbon supplier development through fuzzy-c-means (FCM) clustering algorithm and fuzzy formal concept analysis. Firstly, suppliers are classified based on carbon performances through FCM algorithm and finally fuzzy formal concept lattice structure and implication rules for relative investment and collaboration decisions are deduced through the help of next closure algorithm and implication operator. Lastly, the model is illustrated through a case study of an Indian apparel manufacturing firm.

3 - EU Effect and the Adoption of Environmental Practices Among Apparel and Textile Firms in Developing Economies

J. Shubham, Indian Institute of Management Raipur, GEC Campus, Raipur, 492015, India, shubham.1913@gmail.com, L.S. Murty

This paper analyses the linkage between international trade and environmental issues. We examine how the commitments of Annexe I countries to Kyoto Protocol has impacted the reduction in carbon dioxide emission(CO_2) levels of top apparel and textile exporting developing countries? We found that trade with the European Union has helped in significantly reducing emissionCO_2 levels among developing countries. Thus, this paper acknowledges the strength of European Union as a formidable trade power and presence of "EU-effect" in the area of environmental governance.

2 - The Impact of Buyer Pressure on Supplier Transparency
Suvrat Dhanorkar, Assistant Professor, Pennsylvania State University, 466 Business Building, University Park, PA, 16802, United States, ssd14@psu.edu, Veronica H.Villena

We explore conditions under which buyer pressure may succeed or fail to drive greater supplier transparency. To test the hypotheses, we combine data from the Carbon Disclosure Project's (CDP) supply chain program and ASSET 4 on a sample of 700+ suppliers over the 2013-2015 period. The results show that the degree of influence exerted by buyer pressure is significantly lower when suppliers have in place internal environmental structures (i.e., an environmental strategy, a dedicated board representative and managerial incentives).

4 - The Optimal Incentive Supervision Contract for Ewaste Recycling with Retailers Self Interest Behavior
Ziyu Zhai, Huazhong University of Science and Technology, Wuhan, China, zhaiziyu000@126.com

We adopted the principal agent theory to explain this phenomenon and study the impact of incentive supervision contract on the self-interest behavior of retailers. Pure supervision and penalty on retailers does not always avoid the self-interest behavior of retailers, even when the revenue from selling recycled E-waste to individual is low and the producers have ability to control the recycling market; the hidden number of retailers recycling is weakly correlated with the supervision level and penalty degree, furthermore only the supervision level and penalty degree reach to be a certain threshold, self-interest behavior of retailers can be effectively avoided;

Modeling to Inform Science Policy

Sponsored: Service Science

Sponsored Session

Chair: Maryam Alsadat Andalib, Virginia Institute of Technology, Virginia Institute of Technology, Blacksburg, VA, 24060, United States, maryam7@vt.edu

1 - System Dynamics and Operations Research: A New Synergy for Policy Modeling
Richard C. Larson, Massachusetts Institute of Technology, E40-233, Cambridge, MA, 02139, United States, rclarson@mit.edu, Navid Ghaffarzadegan

We offer a methodological hypothesis that many traditional OR models can be modified with SD feedback loops driven by forces outside of the traditional OR modeler's universe. We argue that such models, even if simple and approximate, will be powerful and effective for policy modeling. We present examples of our recent models. These cases benefit from both schools of modeling. We think the fields of SD and OR can significantly benefit from collaboration. We further discuss the first steps towards integration of queueing models and feedback loop models: endogenous queueing models.

2 - The Network of Cross-disciplinary Research in Health: Neuroscience Bridging Scientific Disciplines
Ran Xu, Virginia Tech, Blacksburg, VA, 24060, United States, ranxu@vt.edu, Navid Ghaffarzadegan

We map the progression of cross-disciplinary research studies in biological and health sciences by examining the topics of doctoral dissertations from US institutions. Examining dissertations from the past two decades, we analyze the changes in frequency of subjects that appear in each discipline, as well as how subjects co-appear in the same dissertations. We further conduct a topic-network analysis of the dissertations and examine emerging topics and links between the topics. Results show that behavioral sciences and engineering fields are playing an increasingly important role in biological and health sciences research. There are also important new bridges emerging around neuroscience.

3 - Modeling Long-term Success and Innovation in Career of Scientists in Academia
Arash Baghaei Lakeh, Virginia Tech, 1145 Perry Street, 250 Durham Hall (0118), Blacksburg, VA, 24061, United States, arashb@vt.edu, Navid Ghaffarzadegan

Success and innovation in a scientist's career depend on multiple organizational factors such as availability of funding, resource allocation, capacity development, and learning through exploration. In this project, we investigate the dynamics of innovation and success in a scientist's career through a system dynamics model. By capturing the important feedback mechanisms in the process of science production and modeling the stochastic nature of scientific inquiry, we study the conditions under which scientists can be successful and follow innovative projects in their careers.

Multi-Objective Methods for Infrastructure Analysis

Sponsored: Multiple Criteria Decision Making

Sponsored Session

Chair: Kash Barker, University of Oklahoma, Norman, OK, 73019, United States, kashbarker@ou.edu

1 - Vehicle Routing Formulation for Infrastructure Network Recovery
Nazanin Morshedlou, University of Oklahoma, 1135 E.Brooks Street, Apt 2, Norman, OK, 73071, United States, nazanin.morshedlou@ou.edu

This research proposes an extension of the vehicle routing problem with a comprehensive formulation that accounts for scheduling work crews to recover an infrastructure network after a disruptive event. In this problem, work crews are routed from depots to disrupted network components to maximize the cumulative flow in the network in a desired time horizon. As disrupted network components possess different characteristics (e.g., level of disruption, the rate of recovery), we develop the formulation to address (i) different levels of requirements for disrupted components and (ii) the possibility of assigning more than one work crew to a single link to change its recovery rate.

2 - Integrated Performance Modeling of Water and Transportation Infrastructures with Physical-socioeconomic Interdependencies
Shima Mohebbi, University of Oklahoma, Norman, OK, United States, mohebbi@ou.edu, Mingyang Li, Qiong Zhang, Qing Lu, E. Christian Wells

This study develops an integrated performance modeling and decision framework to maintain and improve the operations of water and transportation infrastructures by considering their physical-socioeconomic interdependencies. We first develop system level performance measures to evaluate the vulnerability. Based on failure scenarios heuristically simulated, we then examine their consequences on system performances and characterize the degree of interdependency. A two-stage stochastic mathematical model is further developed to investigate the cost-effective maintenance and rehabilitation decisions. A case study will be demonstrated in the City of Tampa, FL.

3 - Optimizing Interdependent Infrastructure Resilience under the Dynamics of Individuals and Organizations
Andres David Gonzalez, The University of Oklahoma, Norman, OK, United States, andres.gonzalez@ou.edu, Camilo Gómez-Castro, Hiba Baroud

Most research on infrastructure resilience assumes a centralized decision maker with a single well-defined objective function. In this work, we propose a model that incorporates a multi-objective societal layer to analyze and optimize the resilience of interdependent infrastructure networks. The proposed approach enables modeling how human and organizational aspects (e.g., biases, risk preferences, multiple interests, and decentralization, among others) influence infrastructure risk and resilience management decisions on the stakeholders involved in their use and operation, and how these impact the overall performance and resilience of infrastructure systems.

4 - Resilience-based Freight Transportation Infrastructure Network Design

Mohamad Darayi, Pennsylvania State University-Great Valley, 201-F Wadsack Dr., Malvern, PA, United States, mud415@psu.edu, Nazanin Morshedlou, Kash Barker

Improving freight transportation infrastructure network design (i) by the addition of capacitated links/nodes or (ii) by increasing the capacity of current network components are explored as options to strengthen the functionality of the network and its effect on the multiple industries relying upon it. Considering different disruption scenarios, this research addresses a network completion decision making problem with respect to the network resilience, as well as multi-industry impacts.

The Analytics of Modern Political Campaigning

Sponsored: The INFORMS Section on Practice

Sponsored Session

Chair: Douglas Alan Samuelson, InfoLogix, Inc., Annandale, VA, 22003-3807, United States, samuelsondoug@yahoo.com

1 - Polling, Psychology and Propaganda in Forecasting Electoral Outcomes

Dimitris Vayenas, Metapoll, London, United Kingdom, dimitris@metapoll.co.uk

Having predicted the outcomes of recent elections the session addresses the underlying theories that are calling for a re-evaluation of political campaigning. By utilising formal models developed to quantify transparency in many-to-many communications, accurate forecasting is attainable based on the motives of the population as addressed by the campaigns; in the case of Brexit with a 0.1% deviation one month before the elections. The shortcomings of polling methodologies and how analytics can help mitigate the impact of unreliable responses are also addressed. Models of human socialty and motivators are employed in the mapping of quantifiable sentiments and reactions to propaganda.

2 - Voting Access and Delay

Theodore T. Allen, Ohio State University, 210 Baker Systems, 1971 Neil Ave, Columbus, OH, 43210-1271, United States, allen.515@osu.edu

Election officials are often poor users of waiting line analyses including simulations. As a result, they often fail to account for longer ballots in certain locations requiring more resources. Also, they can fail to provision enough ballots so that lines are uniform and minimal. Evidence from elections in New Mexico and North Carolina is discussed. In both cases, there is evidence that one party in power used lines (with somewhat unclear intentionality) to improve its own election results likely, for some elections, changing the outcomes.

3 - Targeting and Virtual Tribalism

Douglas Alan Samuelson, InfoLogix, Inc., 8711 Chippendale Court, Annandale, VA, 22003-3807, United States, samuelsondoug@yahoo.com

Recent US elections and marketing data indicate that the country is evolving toward a form of virtual tribalism. Virtual tribes are defined by shared values and perceptions rather than kinship, but they work the same way: mutual reinforcement of information and opinions, excluding outsiders. Several political campaigns have exploited this tribal structure to target selected groups of voters with focused messages, especially via non-traditional media. We review these methods and phenomena and discuss some of their implications.

Operations/Finance Interface

Contributed Session

Chair: Haitao Li, Univ of Missouri-St Louis, St Louis, MO, United States, lihait@umsl.edu

1 - Bank's Effect on Entry of Capital-constrained Firm

Guanmei Liu, PhD, Shanghai Jiao Tong University, 1954 Huashan Roda, Shanghai, 200030, China, lgmei2006@sjtu.edu.cn

This paper studies the effect of finance on new entry in industry market, when an entrant and an incumbent both need to borrow money from a common bank. We derive two firms' optimal production quantities and bank's optimal interest rate in two scenarios: monopoly without entry and competition with entry. We find that bank may not deter entry in one of three cases: 1)two firms are symmetric, 2)incumbent only has advantage in working capital, 3)incumbent has advantage in market size or production cost or both but with more working capital. Interestingly, only when incumbent has no or a little working capital, his larger market size or lower production cost advantage could make bank deter entrant.

2 - The Newsvendor with Uncertain Accounts Receivable

Emre Berk, Bilkent University, Faculty of Business Administration, Ankara, 06800, Turkey, eberk@bilkent.edu.tr

I revisit the classical newsvendor with different customer segments having different likelihoods of not being able to pay for the purchases they have already made. Under various collection scenarios, analytical results are obtained on the optimal production, marketing (promotion) and financial (collection) decisions. Basic trade-offs are discussed via illustrative examples.

3 - Effects of Overconfident Coos on Inventories.

Jaeseok Na, KAIST, Seoul, Seoul, 082, Korea, Republic of, jsna@kaist.ac.kr, Bowon Kim, Jeong Eun Sim

This study investigates the effects of overconfident Chief Operating Officers (COO) on the corporate inventory strategy of a large number of U.S. manufacturing companies. Overconfident managers tend to overestimate future outcomes; thus we hypothesize that overconfident COOs set their operational strategy more aggressively expecting to increase their sales. Using option-based proxies for the overconfidence, we find that such firms fail to maintain lean strategy. In addition, we suggest the relationship is moderated by market structure. We therefore conclude that understanding the behavioral aspects of managers provides valuable insights in managing inventories.

4 - Optimal Supply Chain Financing Strategies with Loss Aversions: Financing vs. Investment

Ye Liu, Central University of Finance and Economics, Beijing, China, yeliuaug@gmail.com, Nina Yan

This paper designs two supply chain financing schemes for the capital-constrained retailer, namely, supplier financing and supplier investment. Considering the retailer's loss aversions, we comparatively analyze the optimal strategies for all participants under these two schemes and investigate the optimal financing choices for the retailer in different cases.

5 - Optimal Commodity Selling using Spot and Forward Markets

Behzad Ghafouri, Graduate Research Assistant, University of Western Ontario, 1151 Richmond Street, Western Science Centre, Room 262, London, ON, N6A 5B7, Canada, b.ghafouri@gmail.com, Matt Davison, Somayeh Moazeni

During contango oil markets, the offshore crude oil storage trade in which cheaper spot oil is purchased for higher forward sale is popular. The optimal sale of a commodity stored in a rental tanker over a finite horizon is studied. At each time step, the quantity of inventory sold at spot and the forward contract maturity for the remaining inventory are decided. Using the short/long-term Schwartz-Smith price model, the problem is formulated and analyzed as a Markov Decision problem. Approximate dynamic programming policies are investigated. The value of dynamic selling in the forward market and adaptively adjusting the forward maturities are compared to initial spot selling.

6 - A Bilevel Programming Approach to Optimize Credit Term Decisions in Supply Chains

Haitao Li, Univ of Missouri-St Louis, College of Business Administration, 229 Express Script Hall, St. Louis, MO, 63121-4400, United States, lihait@umsl.edu

We present a new game-theoretic framework to model the problem of optimizing credit-term in a supplier-buyer supply chain. The interaction between supplier's credit term decision and buyer's order decision is captured in a Stackelberg game, where the supplier is the leader who determines credit terms for the transaction anticipating certain order quantities from the buyer; then the buyer reacts with its order quantity decision as a follower. A real world case study is presented to show benefit of our optimal credit term solution comparing with two fixed heuristic solutions.

Health Care, Other

Contributed Session

Chair: Anna Paula Galvão Scheidegger, Texas A&M University, College Station, TX, United States, apscheidegger@tamu.edu

1 - Preliminary Integrated Approach to Modeling the Prescription and Illicit Opioid Epidemic

Jacqueline Garrahan, Healthcare Systems Engineering Institute, Northeastern University, Boston, MA, 02115, United States, j.garrahan@northeastern.edu, Iulian Ilies, James C. Benneyan

We formulated a differential equations model of the prescription and illicit opioid co-epidemic and parametrized this model for Massachusetts aggregate and county-level populations as case studies. We optimized parameter values to reproduce historic overdoses by using a grid search approach, identified a prior systemic change leading to increased prevalence, and simulated the consequences of potential interventions. Results identified chronic prescribing and the prescription-to-illicit use pipeline as major drivers of epidemic growth, providing avenues for future research and model expansion.

2 - Maximizing Social Welfare in Vaccine Procurement for Multiple International Group Buying Entities with or with out Cooperation

Bruno Alves Maciel, Rochester Institute of Technology, 5000 Nathaniel Rochester Hall 248, Rochester, NY, 14623, United States, ba8641@rit.edu, Kushal Mehta, Ruben Proano

This study models the global vaccine market for a set of antigen bundles from different manufacturers. Those are sold to international group-buying entities (GAVI, PAHO, etc.) and/or individual countries organized as markets that may or may not cooperate. Through a sequence of optimization problems, vaccine prices and allocations are compared in different scenarios of cooperation to maximize social welfare and ensure profit for the manufacturers.

3 - Assessing Decisions in Medical Referral Networks from Empirical Data

Mojtaba Araghi, Wilfrid Laurier University, 438 King Street W, Apt 1208, Toronto, ON, M5V. 3T9, Canada, maraghi@wlu.ca, Michael Pavlin

Informal referral networks are central to the allocation of medical resources in many healthcare systems. In this paper we assess decisions in a cataract surgery referral network. The system is modeled as a bipartite queueing network and empirical techniques are developed to estimate decision making parameters from aggregate data.

4 - Application of Kolmogorov-sinai Entropy for Estimating Uncertainty in Infectious Disease Spread Model

Anna Paula Galvão Scheidegger, Texas A&M.University, College Station, TX, 77843-3131, United States, apscheidegger@tamu.edu, Amarnath Banerjee

Kolmogorov-Sinai (KS) entropy has been widely applied for image texture and biological signal analyses. Consequently, it has been proposed as an alternative tool to diagnose chronic diseases such as epilepsy and Parkinson. Despite the similarities between chronic and infectious diseases with respect to complexity, uncertainty and dynamic components, to the best of our knowledge KS entropy has not yet been applied to infectious diseases. Therefore, the goal of this study is to use KS entropy to investigate whether infectious disease spread models are sensitive to initial conditions and to quantify the average amount of uncertainty in the model.

Chair: Tulay Flamand, Colorado School of Mines, Division of Economics and Business, Engineering Hall 816 15th Street, Room 313, Golden, CO, 80401, United States, tulayvarol@gmail.com

1 - Distinguishing Temporal Associations from Coincidences

Thomas R.Willemain, Senior VP, Smart Software, Inc., 4 Hill Road, Belmont, MA, 02478, United States, tomw@smartcorp.com

Consider two binary time series. In some time periods, both series will be "on" simultaneously. How do we use this type of data to distinguish between associations and mere coincidences? The answer has operational significance in logistics and other military functions. We review several alternative technical approaches to this problem and outline an application to spare part logistics.

2 - Social Networks and Life Satisfaction: the Interplay of Cultural Orientation and Network Density

Jacob Do-Hyung Cha, Seoul National University, Room 204, 935-Dong, Family Housing, SNU, Seoul, 150-742, Korea, Republic of, research.dohyung@gmail.com, Yun Ha Cho

We present that an individual's cultural orientation moderates the influence of social network density on life satisfaction. Study 1 demonstrates that high collectivism effectiveness participants report higher life satisfaction when embedded in a high-density network, whereas high individualism effectiveness participants report lower life satisfaction in the same condition. Study 2 elaborates the underlying mechanism; a high-density network facilitates interdependent self-oriented goals pursuits while it hampers independent self-oriented goals pursuits. We discuss the implications for studying the interplay among social networks, cultural psychology, and positive psychology.

3 - A Branch-and-price Algorithm for the Optimal Deployment Problem

Tulay Flamand, Colorado School of Mines, Division of Economics and Business, Engineering Hall 816 15th Street, Room 313, Golden, CO, 80401, United States, tflamand@mines.edu, Mohamed Haouari, Ghaith Rabadi

We address the problem of deploying multiple types of commodities or assets from various origins to various destinations across a network of multiple modes of transportation. Applications of this problem exist in military, commercial and humanitarian contexts. A B&P algorithm is proposed for this hard problem to minimize the total travel time.

Proactive Planning Against Natural Disasters

Sponsored: Public Sector OR

Sponsored Session

Chair: Ozlem Ergun, Northeastern University, Boston, MA, 02115, United States, o.ergun@neu.edu

Co-Chair: Mahsa Ghanbarpour, mahsa.ghanbarpour@gmail.com

1 - Considering Disaster Volunteer Behavior in Management Decisions During Relief Events: A Simulation Approach

Abdelwahab Alwahishie, Clemson University, Clemson, SC, United States, aalwahi@g.clemson.edu, Kevin M. Taaffe

Following disasters, non-governmental organizations (NGOs) rely heavily on their volunteers to provide assistance to the impacted communities. While their main goal is to serve community needs, NGOs should not ignore disaster volunteer's dissatisfaction and intention to quit. We propose a simulation that models a volunteer's behavior and a manager's decisions through the effects of job mismatch, workload and group conflict. Embedding a volunteer's in the NGO's decisions can reduce volunteer dissatisfaction and intention to quit while not negatively impacting the level of unmet community needs. The model information is based on survey data from two relief organizations in the US.

2 - A Robust Chance Constraint Programming Approach for Evacuation Planning under Uncertain Demand Distribution

Ayda Darvishan, University of Houston, Houston, TX, United States, ayda.darvishan@gmail.com, Gino Lim, Mukesh Rungta, Mohammad Reza baharnemati@gmail.com

We consider an evacuation planning problem where the demand (the number of evacuees) is uncertain and use a chance-constrained model to ensure a reliable evacuation plan. In the context of mass evacuation, we make the assumption that only partial information of the demand distribution, such as moment, support, or symmetry information is known. A distributionally robust chance-constrained model is proposed that ensures the demand constraints are satisfied for any probability distribution consistent with the known properties of the underlying unknown demand. Numerical experiments suggest that our model provides excellent results in terms of solution feasibility and robustness.

3 - Evaluating the Hurricane Decision Simulator

Cameron MacKenzie, Iowa State University, 3029 Black Engineering, Ames, IA, 50014, United States, camacken@iastate.edu, Eva D.Regnier, Anna Prisacari, Sophia Hetherington

We previously developed the Hurricane Decision Simulator to help the U.S. Marine Forces Reserve in New Orleans train to make decisions in advance of a hurricane. In the simulation, a user must decide when and which preparatory decisions to make (e.g., evacuating the headquarters). This presentation will provide the results of a behavioral study in which college students trained using the simulation. We assess how their decisions change after practicing with the simulation. Users believe their decisions improve after practicing with the simulation, and training on the simulation makes users more likely to wait to evacuate.

4 - Proactive Surgery Cancellation Based on Weather Forecasts

Mahsa Ghanbarpour, Northeastern University, Boston, MA, 02115, United States, ghanbarpourmamagh.m@husky.neu.edu, Ozlem Ergun

Severe weather such as hurricanes and snowstorms can dramatically disrupt the delivery of many essential services within a community, including healthcare services. This study introduces proactive surgery cancellation planning due to impending snowstorms and considers weather forecast updates as time progresses. Since weather events can be predicted more accurately closer to the event, the framework we develop is a decision support system for the evaluation of the tradeoff between making better decisions later due to more accurate forecasts and the increased cost of cancellations as the event gets closer. This tradeoff is captured by a dynamic planning approach over particular time horizons.

5 - Cooperative Strategies for Emergency Services under Resource Constrained Settings

Lavanya Marla, University of Illinois, Urbana, IL, lavanyam@illinois.edu, Jungeun Shin

We consider a case where emergency medical services compete as well as collaborate to serve a population. Settings like these are inspired from the cases of mutual aid between neighboring counties, and from emerging economies, where multiple EMSs have to interact strategically and tactically. We aim to understand the cooperative and competitive impacts when EMS agencies interact and share resources or information. We embed simulation-optimization frameworks into game-theoretic settings to understand the impact of such cooperative and competitive interactions.

1 - Competitive Equilibria in Product Plus Service Solutions with Customer Self Selection and Taste Heterogeneity

Arvind Sainathan, Nanyang Business School, S3-B2a-03, Nanyang Business School, 50 Nanyang Avenue, Ntu, Singapore, 639798, Singapore, Asainathan@ntu.edu.sg

Many firms do not just sell products or services but solutions, integrated combinations of products and services. We analyze the competition between two solution providers (SPs) who sell to taste-heterogeneous customers. Type 1 customers are solution-based and consider the entire solution. Type 2 (Type 3) customers are product-first (service-first) and are primarily concerned about product component(s) (service component(s)). We first model customer self-selection in a novel way through an optimization problem. We then characterize different types of competitive equilibria between the SPs. We find that customer composition plays an integral role in determining the nature of equilibrium.

2 - Component Procurement Contract for an Assembly System with Random Capacity

Xinyan Cao, University of Wisconsin-Milwaukee, 3202 Maryland Ave, Milwaukee, WI, 53202, United States, xinyan@uwm.edu, Xiang Fang

We study a decentralized assembly supply chain under supply uncertainty. In the decentralized assembly supply chain, one assembler assembles a set of components each produced by a different supplier into a final product to meet an uncertain market demand. Each supplier faces an uncertain production capacity. The assembler and the suppliers adopt a so-called Vendor-Managed-Consigned-Inventory contract. We formulate the problem as a two-stage sequential game. We analytically characterize the equilibrium of this game, based on which we obtain several interesting managerial insights.

3 - Dynamic Production and Pricing Decisions in the Presence of Snob Effect

Keita Sogo, Keio University, Yokohama, Japan, k.sogu92@gmail.com, Nobuo Matsubayashi

Snob effect is a phenomenon where the more it is difficult to obtain a product, the higher its utility will be. "Hunger-marketing" is known as a marketing strategy utilizing this effect, in which a firm strategically makes a product shortage. Analyzing a monopoly model to determine price and output levels over multiple periods in the presence of snob effect, we derive the condition under which this type of strategy becomes optimal.

4 - Allocation and Sizing of Fast Charging Station in High-way Network

Yue Wang, Dr., National University of Defence Technology, NVDT, Kaifu Area, Changsha, China, wangyy0115@hotmail.com, Jianmai Shi, Yajie Liu

Adequate charging station distribution is the necessary part to promote Electric Vehicles(EV). Different with refuel stations, the infrastructure is costly with limited service capacity because of the long charging time. Meanwhile, in optimization of location and scale of the charging station, the limited range of EVs and the selection process of drivers must be taken into account. This paper described the behavior of driver and station to illustrate how the demand distribute in road network. Then developed a heuristic algorithm to optimize the location and size of charging stations . A practical case of Hebei highway network in China is also studied to test the efficiency of algorithm.

5 - The Adoption Time of Production Commonality and Consumer Deliberation

Pin Zhou, School of Management,HUST, Wuhan, China, zhoupin@hust.edu.cn, He Xu

We study the impact of commonality strategy and consumer deliberation on the optimal product line design in multiple quality attributes. When the firm adopts the commonality strategy to maximize the profits ,there is a trade off between cost savings and product differentiation(i.e.cost-reduction effect and cannibalization effect).Compared with the quality, profit and consumer surplus in two different scenarios(with and without the commonality strategy),we find that (1)quality dispersion of the customized attribute is always larger with the commonality strategy;(2)the firm prefers the commonality strategy only when the cost reduction effect is strong.

Retail Management

Contributed Session

Chair: Miguel Ruiz, University of Puerto Rico at Mayaguez, Mayaguez, PR, United States, miguel.ruiz6@upr.edu

1 - Extreme Scale Resource Allocation Problem Involving Billion Variables

Kalyanmoy Deb, Porfessor, Michigan State University, Electrical & Computer Engineering, 428 S Shaw Lane, East Lansing, MI, 48824, United States, kdeb@egr.msu.edu

Many resource allocation problems in practice involve extremely large number of variables. Such problems give rise to an integer linear program, for which scalable algorithms are not possible due to the exponential nature of associated branch-and-bound approach. In this presentation, we consider a casting scheduling problem (similar to a cutting stock problem) and propose a metaheuristics based optimization method for finding near-optimal solutions involving as large as Billion variables.

2 - A Column Generation Based Distributed Scheduling Algorithm in Manufacturing Supply Chains

Changchun Liu, Dr., Tsinghua University, Hai Dian, Beijing, Beijing, 100084, China, liucc15@mails.tsinghua.edu.cn

This paper considers a resource constrained scheduling problem with a single shared resource. In this model, there are multiple processors who need to complete jobs with a certain amount of shared resource. The resource is of limited supply and must be shared between processors. We propose a column generation based distributed scheduling algorithm and compare the proposed method with other methods. Computational results prove our proposed method has an advantage both in objective value and CPU time to solve this problem.

3 - Simultaneous Matching Mechanisms for On-Demand Markets with Limited Resources

Seyed Shahab Mofidi, Rensselaer Polytechnic Institute (RPI), 110 8th Street, CII 5107, Troy, NY, 12180, United States, mofids@rpi.edu, Jennifer A.Pazour

In sharing economy applications, a central mechanism (CM) is vital to efficiently facilitate matches between decentralized utilitarian agents and finite available alternatives. The CM makes personalized recommendations, from which myopic independent agents select with full discretion, and CM collects benefit from the matches. However, the alternatives have limited capacity, which creates interdependencies among selections of agents. Thus, personalized recommendations need to be considered holistically and in conjunction with the system's and agents' preferences. A bilevel optimization framework and specialized solution approaches are developed to solve this large scale problem.

4 - Effect of Time Pressure and Individual Learning in the Worker Task Assignment

Yaileen M. Mendez Vazquez, Oregon State University (School of Mechanical, Industrial and Manufacturing Engineering), Corvallis, OR, 97331, United States, mendezvy@oregonstate.edu, David A. Nembhard

This work addresses the worker-task assignment problem when the effect of time pressure and workers learning capacity are considered on the individual worker performance. Previous works related to worker-task assignment does not consider the effect of time pressure and individual learning capacity simultaneously. However, literature states the impact of learning by repeatedly perform a task in the improvement of worker's performance, and as well of time pressure in the individual diligence to perform a specific task. A mathematical model is proposed to incorporate these two factors in the estimation of individual worker performance and investigate its effect for the worker-task assignment.

5 - Optimal Cash Rationing Strategy under Different Product Priority Classes

Youssef Boulaksil, Assistant Professor, United Arab Emirates University, P.O. Box 15551, Building H3, Office 2055, Al Ain, United Arab Emirates, youssef.boulaksil@gmail.com

We consider small, traditional retailers (nanostores) that are widely present in developing countries. They operate under very limited cash availability. Therefore, nanostores categorize their assortment into different (product) priority classes, and consequently, more cash is allocated to replenish a higher priority product. In this paper, we develop a mathematical model and present the optimal cash rationing strategy for the nanostore who faces uncertain demand and uncertain cash position. We also show how this strategy affects the suppliers' distribution process towards the nanostores. An extensive numerical experiment reveals several interesting insights.

6 - Assignment Model Solution for Common Challenges in Complex Service Systems

Miguel A.Ruiz, Student, University of Puerto Rico at Mayaguez, Mayaguez, PR, United States, miguel.ruiz6@upr.edu, Betzabe Rodriguez

Our research tailors the assignment model to account for common challenges faced by service organizations such as detrimental benefit of fulfilling tasks with unfit resources, myriad of tasks and diverse personnel profile. The proposed model uses as a test bed the Puerto Rico Agricultural Extension Service.

Recent Advances in Energy Storage and Others

Invited: Energy Systems Management

Invited Session

Chair: Xiaojie Wang, University of Florida, UFL, Gainesville, FL, 4, United States, xwang828@ufl.edu

1 - Optimal Battery Charging in Smart Grids with Price Forecasts

Sandjai Bhulai, Vrije Universiteit Amsterdam, Department of Mathematics, De Boelelaan 1081a, Amsterdam, 1081 HV, Netherlands, s.bhulai@vu.nl, Sven van der Kooij, Pia Kempker, Hans van den Berg

We consider a residential cluster in which some of the households own home batteries. The battery owners have forecasts of future prices for optimally utilizing the long-term flexibility of the battery. These forecasts become increasingly uncertain the further we look into the future. The home batteries are individually too small to influence prices; collectively however, they have enough capacity to have an influence. We formulate an algorithm based on stochastic dynamic programming to optimize individual/collective/cluster profits. Through simulation, we find that this solution performs well when incentives are put in place to promote the right use of storage in the future grid.

2 - Valuation of Oil Tank in Combustion Turbine under Uncertain Gas Network

Shu Tu, Lehigh University, 200 West Packer Avenue, Bethlehem, PA, 18015, United States, sht213@lehigh.edu

The interdependency of gas and electricity is very high as 83% of electricity produced in 2005 is from gas and that percentage will still be over 70% in 2020. This fact brings a potential threat to the safety of the electricity network. In order to satisfy the electricity network security constraints, fuel flexibility is a good choice. In this paper, we consider the valuation of a combustion turbine which can use both natural gas and oil to produce power under a vulnerable gas network assumption. We solve this problem by developing a finite horizon Markov Decision Process model to determine the optimal policy of generating power with two kinds of fuels and provide reasonable results to support adding oil tank.

3 - Robust Optimal Control of Wind Farm with PHEVS Participating in Energy Market

Xiaojie Wang, University of Florida, Gainesville, FL, 32603, Gainesville, FL, 32603, United States, United States, xwang828@ufl.edu

We consider a wind farm with plug-in hybrid electric vehicles as storage devices participating an energy market by submitting their commitments. This new model gives a robust solution considering price and renewable generation uncertainties. Our numerical results show the advantages of our proposed model.

4 - Strong Formulation for Unit Commitment Considering Storage

Yanan Yu, University of Florida, 321 University Village, Apt 3, Gainesville, FL, 32603, United States, yuyn@ufl.edu, Kai Pan, Yongpei Guan

In this talk, we present a polyhedral structure of integrated minimum-up/-down time and ramping polytope, considering the storage characteristics in the traditional Unit Commitment problems. By exploring its specialized structures, we derive strong valid inequalities and convex hull description. The computational studies show the effectiveness of the proposed strong valid inequalities.

Behavioral Issues in Supply Chains

Sponsored: Behavioral Operations Management

Sponsored Session

Chair: Mirko Kremer, Frankfurt School of Finance and Management gGmbh, Frankfurt, 60314, Germany, m.kremer@fs.de

1 - Increasing Retailer Preferences for New Products with Buyback Contracts

Anna Devlin, Assistant Professor, University of Alabama, Huntsville, 301 Sparkman Drive NW, Huntsville, AL, 35801, United States, anna.g.devlin@gmail.com, Wedad Jasmine Elmaghraby, Rebecca Hamilton

We study the ability of buyback contacts to increase retailer preferences for new products in a series of laboratory studies. New products are shrouded with demand uncertainty, decreasing the likelihood they gain market entry. We find that buyback contracts decrease an individual's level of ambiguity aversion and increase preferences for new products in a one time period game. In an extended game, we find that because buyback contracts encourage earlier experimentation with the new product, participants learn faster and converge to selecting the most profitable product faster when offered a buyback back contract rather than a wholesale price contract.

2 - Inventory Decisions in the Presence of Strategic Customers: Theory and Behavioral Evidence

Benny Mantin, University of Luxembourg, 162A, Avenue de la Faïencerie, Luxembourg City, L-1511, Luxembourg, benny.mantin@uni.lu, Yang Zhang, Yaozhong Wu

We study the inventory decisions of a retailer facing a mix of myopic and strategic consumers in a two-period selling horizon with pre-announced markdowns. Testing our theoretical model via lab experiments, we find that while retailer subjects exhibit the pull-to-center bias, as observed in standard newsvendor experiments, their orders may be pulled below the mean demand in the presence of strategic customers (referred to as pull-below-center bias). We develop a behavioral model based on reference dependence and fit it to our data, which explains the pull-below-center phenomenon, as well as the presence and asymmetry of the generalized pull-to-center effect observed in our experiment.

3 - An Experimental Investigation of Transshipment and Local Decision Making

Kay-Yut Chen, University of Texas at Arlington, 511 Pine Island Circle, Mansfield, TX, 76063, United States, kychen@uta.edu, Shan Li

When a retailer has surplus stock and another has a supply shortage, it is desirable to transfer surplus stock from the former to the latter. We experimentally examine how transshipments between two independent retailers affect local decisions of inventory and transfer price. We found that transfer prices and inventory decisions are dependent on whether the prices are set before or after inventory decisions and the realization of the demand. We construct a behavioral model, incorporating bounded rationality, fairness and psychological pain of excess supply to explain the findings.

4 - Trusting the Forecast: the Role of Numeracy

Tobias Stangl, University of Cologne, Cologne, 50923, Germany, tobias.stangl@uni-koeln.de, Gary Bolton, Elena Katok

In a controlled study of decision making in a simple take-the-risk or take-the-cost decision game, we examine compliance rates (trust) for forecast guidance provided as probabilities as well as recommendations. Most strikingly, and contrary to our initial expectation, low numerate subjects exhibit less trust in recommendation forecasts than do high numerates. While we find a positive relationship between subject numeracy and trust in probability forecasts, this relationship is overshadowed by the fact that even high numerate subjects use the probabilities inefficiently.

Practice/Healthcare III

Contributed Session

Chair: Najibe Sadatijafarkalaei, Wayne State University, 4815 Fourth Street, Detroit, MI, 48202, United States, fv0017@wayne.edu

1 - Managing Appointment Scheduling with Walk-ins under Two-agent Perspective

Shenghai Zhou, Shanghai Jiao Tong University, Shanghai, China, zshsjtu2014@sjtu.edu.cn, Guohua Wan

Consider the healthcare appointment system with walk-ins, we develop a two-agent optimization model to determine the optimal template. We demonstrate that, under a mild assumption, the optimal structures are fundamentally different from those existing literature which does not consider two-agent. For the general case, the problem can be formulated as a two stage stochastic optimization model. Numerical analysis is also used to demonstrated the effectiveness of the proposed method.

2 - Managing Operational Efficiency & Health Outcomes at Outpatient OB/GYN Clinics through Effective Scheduling

Samira Fazel Anvaryazdi, PhD Candidate, Wayne State University, Detroit, MI, United States, samira.fazel@wayne.edu, Saravanan Venkatachalam, Ratna Babu Chinnam

We discuss methods for improving flow at outpatient clinics through effective appointment scheduling policies by applying two-stage stochastic programming approach. The aim is to increase throughput per session while providing timely care, continuity of care, and overall patient satisfaction as well as equity of resource utilization.

3 - Fair Allocation of Donor Hearts for Transplantation

Farhad Hasankhani Kohneh Shahri, PhD Student, Clemson University, 278 Freeman Hall, Clemson, SC, 29634, United States, fhasank@clemson.edu, Amin Khademi

The optimal allocation of limited donated hearts to patients on the waiting list is one of the top priorities in heart transplantation management. In order to design an efficient and fair system for allocating donor hearts to patients waiting for transplantation, we model the problem as a constrained stochastic dynamic program to maximize total quality-adjusted life years (QALYs) of the population. Because solving the optimality equation is intractable in our setting, we use fluid approximation, which is an optimal control problem, to produce allocation rules. We assess the quality of any allocation rule by providing an upper bound to the optimal value function.

4 - Optimization of Inventory for Hip and Knee Joint Operations via Multistage Stochastic Programming

Mohammad Pirhooshyaran, Lehigh University, 7 Duh Drive Apt.113, Bethlehem, PA, 18015, United States, mop216@lehigh.edu, Lawrence V. Snyder

Knee and hip joint replacements are among the most common orthopedic operations. Supplying hospitals with prosthetic implants is difficult because the supply is limited, the demand is stochastic. Often the supply logistics fall to the manufacturer or a distributor. We present a multi-stage stochastic optimization model to optimize the distribution of implants from a central depot to hospitals. We find that our model can reduce costs and improve service compared to how our industry partner currently distributes implants.

5 - Interaction between Operational Efficiency and Doctor Incentives in Outpatient Services

Xiaofang Wang, Renmin University of China, Mingshang Building, Room 1023, Beijing, 100872, China, xiaofang.wang@gmail.com, Guoming Lai

This paper studies the interaction between a doctor and a population of patients in a congested health service delivery system. The doctor's prescribing decisions depend on her diagnostic/treatment ability, level of altruism and the institutional framework. Some patients are strategic and decide to see this doctor based on perceived quality, congestion and monetary costs. Within such a setting, we study the socially optimal decisions and provide policy insights.

6 - Perspectives on Real Time Orchestration of Operations in Health Systems

Najibe Sadatijafarkalaei, Wayne State University, 4815 Fourth Street, Detroit, MI, 48202, United States, fv0017@wayne.edu, Ratna Babu Chinnam, Alper E.Murat

Most hospital systems in the U.S. have employed some form of an EHR system in recent years to improve health outcomes. While EHR systems form a critical data backbone for improving operational efficiencies, there is a need for platforms that can promote situational awareness, predictive operational intelligence, and eventually coordinated orchestration. We present findings from the literature and observations derived from major healthcare systems in SE-Michigan.

Autonomous Systems Optimization II

Sponsored: TSL, Urban Transportation

Sponsored Session

Chair: Jian Wang, Purdue University, 4550, West Lafayette, IN, United States, wang2084@purdue.edu

1 - Stable User Matching for Autonomous Vehicle Co-Ownership Problem

Anpeng Zhang, University at Buffalo, Buffalo, NY, 14228, United States, anpengzh@buffalo.edu

We develop a user matching for autonomous vehicle co-ownership programs based on stable matching and single-vehicle Dial-A-Ride Problem (DARP). The optimization model will determine the optimal schedule of trips in the same car sharing group as well as a fair match for all participants in the program. Our model also utilizes nash bargaining game to consider the utility balance between the members in the same group. A case study based on the travel activity dataset of households in California will be present to show the matching performance.

2 - Commute Ridesharing with Autonomous Vehicles Considering Work End Time Uncertainty

Yan Zhao, University of Michigan, Ann Arbor, MI, 48109, United States, zhaoyann@umich.edu, Xiaolei Guo, Henry Liu

Uncertainty of work end time can prevent ridesharing between two people with identical home and work locations. When two people share a ride from home to work, if the realized work end time results in a long wait between the two, with traditional cars, one has to either bear the long wait or call expensive taxi service. We demonstrate that autonomous vehicles (AV) can increase ridesharing in the context of commute bottleneck congestion with random work end time, where one can share ride from home to work in the morning, and either share ride or call AV to pick her up from work to home in the afternoon, depending on the realized work end time.

3 - Exploring Braess's Paradox for Congested Pedestrian Crowd in Continuous Space

Zhaodong Wang, University of Illinois, Urbana, IL, United States, zwang137@illinois.edu, Yanfeng Ouyang

This paper explains continuous Braess's Paradox under congestion by proposing a continuous user equilibrium model describing the steady state of pedestrian flow. Moreover, the exact overall performance improvement can be quantitatively obtained by our framework, which enables us to develop an optimization-based approach seeking optimal infrastructural design.

4 - Optimal Deployment of Autonomous Vehicle Lanes under Network Equilibrium

Jian Wang, Purdue University, West Lafayette, IL, United States, wang2084@purdue.edu, Srinivas Peeta, Sean X He

This study develops a bi-level program to facilitate the deployment of autonomous vehicle (AV) lanes. The upper-level program seeks to reduce the total travel time, while the lower-level program formulates the network equilibrium with the mixed traffic of AVs and non-AVs. Numerical examples are used to investigate the optimal deployment of AV lanes that provides insights into network design to better accommodate AV-based trips.

■ TE51

361D

Telecommunications

Contributed Session

Chair: Dawoon Jung, Korea University, Seoul, United States, bogsil@korea.ac.kr

1 - Evaluating Antecedents and Consequences of Telemedicine Adoption in Clinics

Xiaojin Liu, University of Virginia, 100 Darden Blvd, Charlottesville, VA, 22903, United States, liux@darden.virginia.edu, Susan Goldstein, Karen Soderberg, Kingshuk K.Sinha

Telemedicine, the technology-enabled remote delivery of clinical care, is one potential means to improve patient access to health care services. We investigate how socioeconomic, geographical, and organizational characteristics determine telemedicine adoption in clinics, and examine how telemedicine interacts with technological characteristics on health care delivery effectiveness.

2 - Technological Discontinuity and Market Competition in the Mobile Service Industry

Xiahua Wei, University of Washington, Bothell School of Business, 18115 Campus Way NE, Box 358584, Bothell, WA, 98011, United States, xhwei@uw.edu

We study how technological discontinuity contributes to market competition in the mobile service industry. Based on a firm-level panel dataset, we examine whether the ability of new entrants to disrupt incumbents depends on the responsiveness of incumbents to new technologies, and whether technological discontinuities by incumbents can delay industry shakeouts.

3 - Cross-culture Collaboration and Research Citation Impact

Xiaopeng Wang, Xi'an Jiaotong University, Xi'an, Shaanxi, 710049, China, Archy714@126.com, Jun Lin, Cui Wentian

This research investigated how national cultural difference among scientific teams affect research citation impact. We classified national culture into 5 culture clusters base on Hofstede's five cultural indicators. The results from the bibliometric analysis showed that articles written by authors from at least two culture clusters has a higher citation impact. Furthermore, we demonstrated a positive moderating effect of focal author's prestige and a negative moderating effect of discipline difference on the relation mentioned above. We also found that increasing the culture diversity (amount of culture clusters involved) of teams has an inverted-U shaped relation with impact.

4 - Optimal Two-period Response Strategy To New Technology

Xiaoxi Liu, Korea University, Seoul, Korea, Republic of, polar1018@korea.ac.kr, Byungcho Kim

Technology develops so rapidly, thus when a new technology appears, innovative firms face a dilemma of whether to keep an old technology along with a new one, or drop it. In reality, many industries show the co-existence of both technologies despite the cost of maintaining two product lines. This paper introduces a two-period decision model that examines a firm's response strategy to the emergence of new technology. In the first period, the firm decides whether to keep the old product line, and in the second period, it chooses whether to improve old version's quality. The equilibrium price and quality levels are investigated and the impact of market share and marginal cost are further discussed.

5 - A Bibliometric Analysis on Human Reliability Analysis

Yangyang Chang, Tsinghua University, ZJ.17#, Tsinghua University, Haidian, Beijing, 100084, China, changyy15@mails.tsinghua.edu.cn, Pingke Li

This study investigates the development and longitudinal trends in human reliability analysis (HRA) during 1986-2015 through the bibliometric analysis on a data set of 4695 publication records retrieved from Web of Science and Ei Compendex. The number of the HRA documents is used as the performance indicator and examined through both the temporal and geographical perspectives. To reveal the conceptual evolutions of HRA research, the three decades are divided into four consecutive periods (1986-1999, 2000-2006, 2007-2011, 2012-2015), and the research fronts in each period are investigated through SciMAT.

6 - Entering Convergent Product Market

Dawoon Jung, PhD Candidate, Korea University, Business School, LG-Posco Hall, # 408, Seoul, 02841, Korea, Republic of, bogsil@korea.ac.kr, Byung Cho Kim, Bosung Kim

Technological convergence is an attempt to integrate disparate technologies across the conventional boundaries and its outcome is convergent product which often exhibits irreplaceable synergetic advantages. This paper examines a firm's strategic choice that confronts the technological convergence with the view of targeting the growing demand and the synergy from convergence.

Robust and Data-Driven Optimization

Sponsored: Optimization, Optimization Under Uncertainty

Sponsored Session

Chair: Phebe Vayanos, University of Southern California, Los Angeles, CA, 90089, United States, phebe.vayanos@usc.edu

1 - Small Data Linear Optimization

Vishal Gupta, University of Southern California, Marshall School of Business, 3670 Trousdale Parkway, Los Angeles, CA, 90026, United States, guptavis@usc.edu, Paat Rusmevichientong

Optimization problems frequently depend on a huge number of uncertain parameters, but the amount of data per parameter is small. We propose a framework for optimization in this small-data/high dimensional regime. We combine ideas from empirical bayes and compound decision problems to 1) pool information across parameters and 2) exploit optimization structure. We prove our approach is never worse than, and often better than, "estimate-then-optimize," sample average approximation, and conventional high-dimensional statistics techniques. As the number of uncertain parameters grows and the amount of data per parameter is fixed, our approach performs comparably to the best-in-class estimator.

2 - Applications of the Wasserstein Metric in Robust Transportation Problem

John Gunnar Carlsson, University of Southern California, 3750 McClintock Avenue, Los Angeles, 90089, United States, jcarlsso@usc.edu

Recent research on the robust and stochastic travelling salesman problem and the vehicle routing problem has seen many different approaches for describing the region of ambiguity, such as taking convex combinations of observed demand vectors or imposing constraints on the moments of the spatial demand distribution. One approach that has been used outside the transportation sector is the use of statistical metrics that describe a distance function between two probability distributions.

3 - Robust Multiclass Queuing Theory for Wait Time Estimation in Resource Allocation Systems

Phebe T. Vayanos, University of Southern California, OHE 310L, University Park, USC, Viterbi School of Engineering, Los Angeles, CA, 90089, United States, phebe.vayanos@usc.edu, Chaithanya Bandi, Nikolaos Trichakis

We present a data-driven optimization approach to estimate wait times for individual patients in the U.S. Kidney Allocation System, based on the very limited system information that they possess in practice. To deal with this information incompleteness, we develop a novel robust optimization analytical framework for wait time estimation in multiclass, multiserver queuing systems. We calibrate our model with highly detailed historical data and illustrate how it can be used to inform medical decision making and improve patient welfare.

Behavioral Operations

Contributed Session

Chair: Abhishek Sharma, Indian Institute of Management-Rohtak, Rohtak, India, aabhishek sharma01@gmail.com

1 - A Cooperative Game with Envy

Ziteng Wang, Assistant Professor, Northern Illinois Universtiy, 590 Garden Road, EB 240, DeKalb, IL, 60115, United States, zwang3@niu.edu

This research proposes an envy-incorporated cooperative game model and investigates the envy effects on players' coalition-forming and payoff-allocating decisions. A player's utility depends on her/his own payoff and the envy toward other players, inside and outside the same coalition, with higher payoffs. Envy core is defined to characterize stable coalition structures and payoff allocations of this new game. Conditions for the envy core to be nonempty are provided. The relative significance of in-coalition envy and out-coalition envy is shown to be a key factor to the form of the envy core. Application to a simple gameshows that envy may significantly change players' decisions.

2 - Anchoring and Demand Chasing in Stockout Avoidance Decision Making

Shivom Aggarwal, IE Business School, IE University, Instututo de Empresa S.L., CIF: B82334319, Calle de Maria de Molina, 12 Bajo, Madrid, 28006, Spain, saggarwal@faculty.ie.edu, Antti Tenhiala

Even though, virtually every major supermarket chain uses an automatic store replenishment (ASR) system to optimize replenishment timing and order quantities; stock-outs (SO) still cost retailers billions of dollars every year in lost sales. In this study we focus on SO avoidance and argue that (i) augmentations of ASR proposals are driven by anchoring and demand chasing, and (ii) deviations triggered by these two biases are generally unsuccessful in avoiding stock-outs, leading to unnecessary inventory inflation. We test our hypotheses with proprietary data from a European high-end supermarket chain. Our study highlights the consideration of biases as critical and distinct from other drivers.

3 - A Summary and Comparison of Common Methods Variance Techniques

Xiaotong Liu, University of North Texas, 2411 S Interstate 35 E, Apt 1218, Denton, TX, 75010, United States, xiaotong.liu@unt.edu, Victor R. Prybutok

In most empirical studies, the existence of common methods variance (CMV) is consideration for which the data should be tested. However, some challenges exist about which technique researchers should use to test CMV for data from a single instrument. This research uses examples to summarize and compare several tests related to CMV.

4 - A Study on Prospect Theory and the Newsvendor Problem
Abhishek Sharma, PhD Scholar, Indian Institute of Management Rohtak, Indian Institute of Management, MDU Campus, Rohtak, Haryana, Rohtak, 124001, India, aabhisheksharma01@gmail.com, Sanjay Jharkharia

It is identified from the experimental studies on newsvendor problem that decision makers do not choose theoretical optimal order quantities, while using some heuristics to take their decisions. Prospect theory, as a theory for decision framing under uncertainty, has been used in literature to explain such preferences of decision makers. The recent literature shows that how these empirical findings can be explained through original prospect theory (OPT), when the reference point differs from the status quo. In this paper, we further study this argument and apply cumulative prospect theory (CPT) that accounts for the better modeling of psychological phenomenon of diminishing sensitivity.

Economics

Contributed Session

Chair: Jing Xu, University of Pennsylvania, Philadelphia, PA, United States, xjing@sas.upenn.edu

1 - Moral Perceptions of Advised Actions
Alexander Gotthard Real, Assistant Professor, Pontificia Universidad Javeriana, Calle 59 # 3A - 24 Apt 504, Bogota, Colombia, agotthard@javeriana.edu.co

Can an organization avoid some blame for an unpopular action by hiring an adviser to advise them to do it? We present experimental evidence suggesting this is the case advice to be selfish substantially decreases punishment of being selfish. Further, this result is true despite advisers conflicts of interest, known to all: Through a relational contract, advisers are motivated to tell the principals what they want to hear. In follow-up treatments, we show advice does not decrease punishment solely by affecting beliefs of how necessary the selfish action was. Finally, when advisers are available, selfish principals act more selfishly.

2 - Surfing or Working? Productivity Responses to Changes in Workload
Erina Ytsma, Post-doctoral Associate, Massachusetts Institute of Technology, MIT IDE, 77 Massachusetts. Avenue, Cambridge, MA, 02139-4301, United States, eytsma@mit.edu, George F. Westerman

We study the effect of workload on productivity, hours worked and internet use while at work using big data on insurance claims examiners. We find that, for every 1% increase in workload, productivity increases by 0.3% to 0.4%, tardiness decreases by 0.06 to 0.13 percentage points, and quality does not falter. Hours worked increase slightly, but extra work time can explain at most 10% of the increase in productivity. Non-productive internet use decreases with workload, while productive uses of internet increase. These findings are consistent with the presence of slack and an increase in efficiency in response to workload surges.

3 - Bargain Network and the Matchmaker
Jing Xu, University of Pennsylvania, 209 S.33rd Street, Math Dept, Philadelphia, PA, 19104, United States, xjing@sas.upenn.edu

I study a dynamic market with an intermediary that matches participants connected in a network to bargain over prices of heterogeneous goods. Players who reach an agreement pay a commission fee to the intermediary and exist from the network without replacement. The intermediary can choose its favorite matching pair each time before participants make the bargain. I establish the existence of Markov perfect equilibria (MPEs) of the infinite horizon game and illustrate the equilibrium matching probabilistic distributions adopted by the middleman. Moreover, when payoffs are homogeneous, any MPE achieves constrained efficiency.

Quantitative Methods in Financial Engineering

Sponsored: Financial Services

Sponsored Session

Chair: Ning Cai, Hong Kong University of Science & Technology, Kowloon, Hong Kong, Hong Kong, ningcai@ust.hk

1 - Recursive Method for Static Options Replication of Complex Structured Products
Kyoung-Kuk Kim, Associate Professor, KAIST, Dept of Industrial & Systems Engineering, 291 Daehak-Ro, Daejeon, 34141, Korea, Republic of, catenoid@kaist.edu, Dong-Young Lim

This study aims to extend static options replication of financial derivatives to complex products with autocallable features and barrier features. The key idea is based on the combination of calendar-spread approach and strike-spread approach in a recursive manner. Such replicating strategies are exact, and we utilize the theory of integral equations. Our numerical examples include complex equity-linked structured products traded in Europe, US, and Korea.

2 - Investment Decisions and Falling Cost of Data Analytics
Jussi Keppo, National University of Singapore, Mochtar Riady Building, BIZ 1 8-69, 15 Kent Ridge Drive, Singapore, 119245, Singapore, keppo@nus.edu.sg, Hong Ming Tan, Chao Zhou

We study how the cost of data analytics and the characteristics of investors and investment opportunities affect investment decisions and their data analytics. We show that the falling cost of the data analytics raises investors' leverage, financially constrained or highly risk-averse investors use less data analytics, the quantity of data analytics is highest with mediocre investment opportunities and it is lowest with a high expected return or a low risk opportunities. Due to the increased leverage, the falling cost of data analytics may lead to more frequent crises or higher losses during the crises.

3 - Susceptibility and Predictability in the NASDAQ Order Book
James Primbs, California State University Fullerton, Fullerton, CA, United States, jprimbs@exchange.fullerton.edu, B. Ross Barmish, Sean Warnick, Scott Condi

In this work, we analyze the structure and predictability of the NASDAQ order book based on ITCH transaction level data. Specifically, we explore the shape of the bid and ask sides of the order book over time, and apply various statistical and machine learning related tools to address questions of predictability and susceptibility to manipulation by adverse agents.

4 - A Structural Model for Liquidity Risk
Ning Cai, Hong Kong University of Science & Technology, Room 5559D, Industrial Engineering, and Logistics Management, Kowloon, Hong Kong, Hong Kong, ningcai@ust.hk

In this paper, we develop a structural model for liquidity risk and credit risk. Empirical studies illustrate that our model captures the features of the market observed credit spreads quite well.

Logistics

Contributed Session

Chair: Satya Malladi, Georgia Institute of Technology, Atlanta, GA, United States, mss@gatech.edu

1 - Tracking Technologies for the Efficient Operations of Distribution Center
Yong-Hong Kuo, Assistant Professor, The University of Hong Kong, Department of Industrial and Manufacturing Systems Engineering, The University of Hong Kong, Pokfulam Road, Hong Kong, yhkuo@hku.hk, Chun Hung Cheng, Matthew Petering

Our work was motivated by a real-world problem in a large air mail centre. We have developed an RFID-based location-positioning platform for the application.The RFID-tag attachments to carts and reader mounts at the top of the building allow the facility operators to locate target carts quickly. We have also conducted an initial analysis of data collected using this technological infrastructure to understand issues on cart movements and operational efficiency.

2 - Analyzing the Benefits of Optimal Dispatching in Shipment Consolidation
Benhur Satir, Assistant Professor, Dr., Çankaya University, Etimesgut, Ankara, 06790, Turkey, benhur@cankaya.edu.tr, F. Safa Erenay, James H. Bookbinder

In practice, most logistics providers dispatch consolidated loads at pre-planned periods, i.e. using a time policy. In this study, we investigate the relative benefit and conditions leading to it when the optimal policy is used instead. The benefit is measured in terms of expected discounted total cost. We model the problem as a Continuous Time Markov Decision Process, and assume compound Poisson arrivals of two customer types, viz. expedited and regular. We prove the existence of quantity-based optimal threshold policies under particular conditions, and develop an efficient solution approach for large problem instances. We provide numerical studies using two industrial cases.

3 - New Insights into Sharing Warehouse Markets in Beijing Metropolitan Area: Scraping and Analyzing Web Rental Listings

Yixuan Ma, Beijing Jiaotong University, Beijing, China, mayixuan@bjtu.edu.cn
Yixuan Ma, University of California-Irvine, Irvine, CA, United States, mayixuan@bjtu.edu.cn, Zhenji Zhang, Baoxiang Pan

Open warehouse marketplace is of fundamental importance for pivoting the accelerating supply chain. Existed warehouse storage trading platforms focus on clients' trading activities, missing the potential to bring the full scope of logistics storage marketplace into light. Given this, we collected, cleaned, analyzed, mapped, and visualized 20,000 real-time web sharing warehouses listings from different platforms for the Beijing Metropolitan Area, one of the most busy logistic districts in the world today. The data revealed fine patterns of warehouse distribution, acreage and price through putting the real-time accumulating database to the urban development background.

4 - A Hybrid Simulation-based Location-allocation Approach of Biofuel Warehouses

Sojung Kim, Assistant Professor, Texas A&M.University-Commerce, P.O. Box 3011, Commerce, TX, 75429-3011, United States, sojung.kim@tamuc.edu, Su Min Kim, James R. Kiniry

The goal of this study is to propose a hybrid simulation-based location-allocation approach of Biofuel Warehouses in order to minimize operational cost of the biofuel supply chain. The proposed approach consists two simulation methodologies: (1) ALMANAC® for estimating production of ethanol based on crop yields and (a) AnyLogic® for finding the best locations of biofuel warehouses with the minimum operational cost regarding supply variability (e.g., seasonality) of crop yields. The proposed approach is demonstrated with real crop yield data in Southern Great Plains, USA.

5 - Transporting Capacity vs. Transshipping Inventory under Nonstationarity

Satya Sarvani Malladi, PhD Candidate, Georgia Institute of Technology, 2209 Briarcliff Rd NE, Apt 17, Atlanta, GA, 30329, United States, mss@gatech.edu, Alan Erera, Chelsea C. White

We study a production-inventory system in which capacity and/or inventory can be moved between locations under nonstationary demands affected by a partially observed underlying state of the world. We seek to determine when moving production capacity is more beneficial than transshipping inventory between locations.

Scheduling

Contributed Session

Chair: Trung Le, International University, Ho Chi Minh, Viet Nam, trung.le@hcmiu.edu.vn

1 - Nonlinear Dynamics Forecasting of Obstructive Sleep Apnea Onsets

Trung Le, International University, Linh Trung Thu Duc, Ho Chi Minh, Viet Nam, trung.le@hcmiu.edu.vn

This paper reports an investigation into heart rate dynamics aiming to predict in real time the onsets of OSA episode before the clinical symptoms appear. A prognosis method based on a nonparametric statistical Dirichlet-Process Mixture-Gaussian-Process (DPMG) model to estimate the transition from normal states to an anomalous (apnea) state is utilized to estimate the remaining time until the onset of an impending OSA episode. Validation tests suggest that the model can be used to track the time until the onset of an OSA episode with the likelihood of correctly predicting apnea onset in 1 min to 5 mins ahead is 83.6 ± 9.3%, 80 ± 8.1%, 76.2 ± 13.3%, 66.9 ± 15.4%, and 61.1 ± 16.7%, respectively.

2 - An ABM Framework to Analyze the Region's Resilience Evolving under Repeated Hazards

Chengwei Zhai, University of Michigan, 1837 McIntyre Drive, Ann Arbor, MI, 48105, United States, cwzhai@umich.edu, Seth Guikema, Allison C. Reilly

Understanding human behavior under repeated hazards is essential in reducing damage from hazards, promoting wise decisions, and providing insights into how community resilience evolves. This talk summarizes an Agent Based Model that can be applied to analyze how decision makers adapt to repeated hazards and different policies and how this influences the evolution of regional vulnerability over time. It introduces modeling different hazard scenarios, agent learning and decision making processes, collective action, and government policies. A case study using open-source data in Maryland is presented to show how this region's vulnerability evolves under repeated hazards.

3 - Risk-based Path Optimization for Unmanned Aerial Systems

Jeffrey W. Herrmann, Professor, University of Maryland-College Park, Department of Mechanical Engineering, College Park, MD, 20742, United States, jwh2@umd.edu, Shapour Azarm

Flying an unmanned aerial system (UAS) over inhabited areas creates a risk to persons on the ground. UAS operators thus need low-risk flight paths, but the lowest-risk flight paths could be excessively long. We present a risk assessment technique and a bi-objective optimization method to find low-risk and time solutions to this problem. We used computational experiments to evaluate the methods' computation time and solution quality. The most promising method constructs a graph for the problem, generates an initial solution using the graph, and improves that solution with a local search.

4 - Innovation and Information Privacy

Gwendolyn K.Lee, Chester C. Holloway Professor, University of Florida, Gainesville, FL, 32611, United States, gwendolyn.lee@warrington.ufl.edu, Ye Xia

Do firms converge or diverge in choosing how much personally identifiable information (PII) to collect when consumers have heterogeneous attitudes about privacy risk and when companies interact competitively in the market? In our model, firms choose their strategies with respect to how much PII they collect from consumers. Based on our game-theoretical analysis, we find that, at the competitive equilibrium, rational firms choose to collect different amounts of PII, thus spreading apart in the space of strategies. Such a finding is by no means obvious. We show exactly how far apart the firms will spread out and explain why firms don't converge to the same strategy, such as collecting the maximum amount.

5 - Developing a Risk Index for Sustainable Freight Transportation

Ravi Shankar, Professor, Indian Institute of Technology Delhi, New Delhi, India, r.s.research@gmail.com, Divya Choudhary

This research introduces an innovative concept of risk index for sustainability (RIS) to evaluate the risk exposure of sustainable freight transportation (SFT). Interval 2-tuple and digraph matrix approaches have been used to model this problem. Different SFT systems are analyzed and managerial implications are drawn.

Layout and Location

Sponsored: TSL, Facility Logistics

Sponsored Session

Chair: Ardavan Asef-Vaziri, College of Business and Economics, Dept of Systems and Operations MGMT, 18111 Nordhoff Street, Northridge, CA, 91330-8378, United States, aa2035@csun.edu

1 - A Multiple Allocation P-hub Location Problem with Third-party Operated Vehicles

Armin Lüer-Villagra, Universidad Andres Bello, Antonio Varas 880, Providencia, Santiago, 7501085, Chile, armin.luer@unab.cl, Vladimir Marianov, German Paredes-Belmar

Hub and spoke networks are very common in the postal, airline, and parcel delivery industries. Hubs are facilities used to sort, consolidate and transfer flows from multiple origins and destinations. We formulate a multiple allocation p-hub location problem when a third party operate the vehicles and offer volume discount to the operating company. We perform extensive computational experience, noting differences in the solutions obtained.

2 - A Dynamic Data Driven Adaptive Simulation Based Optimization Framework for Layout and Resource Allocation in Horticultural Grafting Nurseries

Sara Masoud, University of Arizona, 1300 E.Fort Lowell Road, # A214, Tucson, AZ, 85719, United States, saramasoud@email.arizona.edu, Bijoy Dripta Barua Chowdhury, Young-Jun Son, Chieri Kubota, Russell Tronstad

Resource allocation and layout design are critical decisions in designing/operating grafting nurseries; yet, their concurrent optimization is challenging due to the dynamics of workers' performance, resource availability, and demands. We propose a dynamic data driven adaptive simulation based optimization framework to optimize layout design and resource allocation by using data gloves to evaluate the workers' performance at a micro level, and radio frequency identification system to study the motion of the workers and material flow at a macro level. The effectiveness of the proposed framework will be demonstrated via a case study in finding the optimal layout design and resource allocation.

3 - The Optimization of a Municipal Solid Waste Management System
Yan Zhang, Associate professor, Dalian Maritime University, No.1 Lingshui Road, Dalian, 116023, China, yan.zhang@dlmu.edu.cn, Hualong Yang

In a waste management system, the location of proper facilities for treating waste is a sensitive issue that has often caused political and social tension. We study the problem of simultaneous design of a distribution network with central treatment facilities, transfer stations and sanitary landfills, and the coordination of waste flows within this network. In order to determine the number, sizes and locations of the solid waste management facilities, we formulate a mathematical model for the problem and propose a heuristic to solve large problems efficiently. Finally, we apply these models and algorithms for the development of a solid waste management system for a specific region in Dalian.

4 - Covering and Connectivity Constraints in the Block Layout Shortest Loop Design Problem
Ardavan Asef-Vaziri, Professor, College of Business and Economics, Dept of Systems and Operations MGMT, 18111 Nordhoff Street, Northridge, CA, 91330-8378, United States, aa2035@csun.edu, Morteza Kazemi

The shortest loop covering at least one edge of each workcenter in a facility layout is an instance of the GTSP. The optimal solution to this problem is a promising design for non-vehicle-based material handling. This formulation is usually embedded within the problem of the concurrent design of the loop and the I/O stations for vehicle-based material handling. The shortest loop provides an effective heuristic scheme to achieve prosperous and robust solutions for the design of the loop and stations. We review and compare covering constraints formulations, provide new insight into connectivity constraints, improve the model formulation and solution procedure, and report computational results.

Chair: Ilgin Acar, Anadolu University, Eskisehir, Turkey, ipoyraz@anadolu.edu.tr

1 - Filling Current Healthcare Gaps: Thoughtful Application of Robust Parameter Design with Conditions-based Selection of Regression Estimators
Kathryn Pegues, Student, Clemson University, 104 Hyde Lane, Clemson, SC, 29631, United States, kpegues@gmail.com

Underlying assumptions for RPD modeling and process conditions should be taken into account when selecting a regression estimator for developing fitted models. If these assumptions are incorrect, then a direct use of estimates obtained has the potential to be problematic, and the results may be potentially catastrophic, particularly when applied to the healthcare field. This paper examines alternative approaches to regression estimation when the process data indicates that asymmetry or a high degree of process variability exists. The performance of select alternative regression methods is compared using Monte Carlo simulation and numerical analysis.

2 - How Does Government's Willingness to Fund Influence the Level of Health Prepayment
Ying Zhang, Southeast University, Nanjing, China, yingzhang@seu.edu.cn

Significant prepayment is a crucial factor to ensure that all individuals have access to effective health care at affordable prices. The research question we address here is, does government's willingness to spend more on health means higher prepayment rates in the health financing system? These questions are addressed in 34 OECD members over the 1995-2013 period. Our findings show that government's willingness to pay on health increases both the level of total prepaid expenditure and public prepayment [social health insurance, tax-financed]. Our research also highlights that government's willingness to fund is not systematically crowding out private prepaid plans.

3 - Developing an HPV Infection Risk Prediction Model and Self-assessment Tool for Young Adult Females
Rachel Holmer, University of Arkansas, 4207 Bell Engineering Center, Fayetteville, AR, 72701, United States, reholmer@uark.edu, Shengfan Zhang

According to the Centers for Disease and Control Prevention (CDC), nearly one in four people are currently infected with Human Papillomavirus (HPV) in the United States. Although most people with HPV never experience symptoms, there is a risk of developing different types of HPV-related cancers after infection. These cancers and other related diseases result in almost $8 billion spent annually for treatment. This research seeks to create a risk prediction model with a focus on young adult females that will assist these individuals to estimate the risk of HPV infection based on demographic, life style, and sexual behavior factors.

4 - Blockchain Application in Healthcare Supply Chain for Effective Recall and Outdates Management
Raja Jayaraman, Khalifa University of Science and Technology, PO Box 127788, Abu Dhabi, United Arab Emirates, raja.jayaraman@kustar.ac.ae, Nelson King

Product Lifecycle Management in healthcare is a complex process due to significant factors such as volume, variety, information inaccuracy on procurement, trends in consumption, poor data quality. In this presentation, we explore the role and use of blockchain technology in integrating critical product information across various processes in healthcare supply chain.

5 - Risk Factors Affecting Work Related Musculoskeletal Disorders in a Manufacturing Company
Ilgin Acar, Anadolu University, Ikieylul Campus, Faculty of Engineering, Eskisehir, 26555, Turkey, ipoyraz@anadolu.edu.tr, Nihal Erginel, Sura Toptanci

Various risk factors including individual factors such as personal and anthropometric variables, physical work and psychosocial factors are used as predictors of Work-related musculoskeletal disorders (WMSDs). The aim of this study is to build fuzzy regression models to understand the relationship between WMSDs and risk factors, to estimate the injuries, and to assess individual's risk levels. A designed survey is used to collect data in a manufacturing company and to measure the influences of risk factors on the musculoskeletal symptoms. As the risk factors can be defined by fuzzy regression models, it may be easy to minimize the effect of risk factors to prevent WMSDs to provide safe environments.

1 - The Urban and Rural Income Gap in China Based on the Opportunity Inequality
Xiufan Zhang, Harbin Engineering University, Harbin, China, zhangxiufan@hrbeu.edu.cn

With the continuous improvement of economic, China's income increases fast, but the income gap between urban and rural areas is grim. Gini-coefficient is widely used to measure inequality in the distribution. But the deeper consequences behind inequality are ignored, including policy, institutional and social and cultural opportunities,making the income gap last for long. The paper summarizes various indicators of income inequality,calculates the income gap between urban and rural areas in China and analye the specific influencing factors of opportunity inequality on income inequality.The paper finally put forwards some Countermeasures of Urban - rural Income Gap.

2 - Re-engineering Agricultural Extension Services: Perceptions' Intrinsic Role in the Design Process
Elizabeth Ayala-Medina, Graduate Student, University of Puerto Rico-Mayagüez, Mayagüez, Puerto Rico, elizabeth.ayala@upr.edu, Betzabé Rodriguez

Yearning to uphold a service of quality and excellence that meets the needs of farmers, this study pretends to expand on the intrinsic nature of perceptions throughout the design process. Furthermore, validate the assertiveness of integrating farmers' perception in the development of a tool that aids in their learning process.

3 - Optimizing Performance Pay in K-12 Education
Vanitha Virudachalam, Doctoral Candidate, The Wharton School, 3730 Walnut Street, 500 Jon M. Huntsman Hall, Philadelphia, PA, 19104, United States, vanitha@wharton.upenn.edu, Sergei Savin, Matthew Steinberg

We study performance-based contracts in a K-12 educational setting, where a local school district (the principal) contracts with teachers (the agents) to meet student performance goals. Teachers' wages are partly determined by student performance on the end-of-the-year state achievement test. The level of student knowledge is not perfectly known prior to this test; the district may choose to reduce this uncertainty by administering an interim assessment at a cost. We model this setting using a dynamic principal-agent model with partially hidden states. We determine the optimal performance-based contract and testing schedule the school district should offer teachers.

Finance, Portfolio Analysis

Contributed Session

Chair: Aloagbaye Momodu, University of Toronto, Toronto, ON, Canada, aimomodu@mie.utoronto.ca

1 - Portfolio Construction using Gerber Statistics Based Risk Parity Model

Ravi Shankar, Indian Institute of Technology Delhi, New Delhi, India, ravi@dms.iitd.ac.in, Dhanya Jothimani, Surendra S. Yadav

In this research, we use Hierarchical Risk Parity model for portfolio optimization, where covariance of stocks are clustered. Covariance of the stocks is obtained using Gerber statistics. Sample consisted of firms listed on National Stock Exchange during the period 2008-2016. We find that the performance of the proposed model was better than Global Minimum Variance model. The contributions are two-fold: first, the model helps to avoid errors arising from estimation of returns and second, it avoids the need for inversion of covariance matrix.

2 - Identifying Robust Diversified Portfolios with Second Order Stochastic Dominance Constraints

Peng Xu, PhD Candidate, Aalto University School of Business, Runeberginkatu 22-24, Helsinki, FIN-00100, Finland, peng.xu@aalto.fi

Identifying Second-order Stochastic Dominance (SSD)-efficient portfolios is of great interest to finance research where investors are routinely assumed to be rationally risk-averse in making financial decisions. This paper seeks to (i) evaluate some most recent SSD approaches and their out-of-sample performance in portfolio diversification, and (ii) examine if robust optimization improves the out-of-sample performance of these approaches. We report the results from an empirical application analyzing how robust optimization based diversification among industry portfolios increases the likelihood of obtaining out-of-sample SSD over the market portfolio.

3 - Solving Cardinality Constrained Mean – Variance Portfolio Optimization using Message Passing Algorithms

Alexia Yeo, University of Toronto, Toronto, ON, Canada, ayeo@mie.utoronto.ca

The cardinality constrained mean-variance optimization problem has the advantage of reducing transaction costs and the complexity of asset management. It may be see as a special case of the quadratic knapsack problem. We approach this problem by using probabilistic inference in a graphical model to estimate portfolio selections. Message passing is a class of inference algorithms that utilizes the factorization and decomposition properties of the problem's graphical model to efficiently estimate the value of unknown parameters. We evaluate the performance of the message passing algorithms MPLP and TRW against branch-and-cut algorithms. Contributors: Alexia Yeo, Dr. Roy Kwon

4 - Multiasset Game Contingent Claims Valuation using a Projected Successive Over Relaxation Algorithm

Aloagbaye Momodu, University of Toronto, 121, Wolseley Street, Toronto, ON, M6J.1K1, Canada, aimomodu@mie.utoronto.ca, Chi-Guhn Lee

Game contingent claims (Israeli options) are generalizations of American contingent claims in which the writer (seller) has the right to cancel the contract before maturity subject to the payment of a prespecified penalty. This added feature leads to complexities in the valuation with no analytical solution in the literature for finite maturity game contingent claims. In this paper, we value multi-asset game contingent claims in a standard Black-Scholes framework by solving finite difference discretization of the Black-Scholes partial differential equation using a projected successive over relaxation algorithm.

1 - Simulation-based Optimization of Prognostics and Health Management Enabled Condition-based Maintenance Policy

Taiwo Joel Omoleye, Mr, City University of Hong Kong, Tat Chee Avenue, Kowloon Tong, Kowloon, Hong Kong, jtomoleye3-c@my.cityu.edu.hk, Kwok Leung Tsui

The practical implementation of condition-based maintenance (CBM) is trailing behind the widespread theoretical benefits in the literature. This necessitates the growing concern about the effectiveness of CBM policy in industries implementing CBM. To overcome this, research is focusing on the value of Prognostics and Health Management (PHM) information in CBM policy. In this paper, simulation-based optimization is used to assess the benefits of PHM-enabled CBM policy under resource dependence. Also, a framework is developed, numerically illustrated, and compared with classic CBM, and traditional maintenance policies using ARENA-based discrete event simulation model.

2 - Resilience of Core-periphery Networks

Babak Heydari, Assistant Professor, Stevens Institute of Technology, 1 Castle Point, Babbio Center, Hoboken, NJ, 07030, United States, babak.heydari@stevens.edu

We discuss conditions for resilience of core-periphery networks, an important class of complex systems. A successful model that captures resilience needs to model the extent of performance loss due to disruption, the post-recovery performance level, and the relative speed of recovery. We present a network model that incorporate connection costs and direct and indirect benefits of connection, assumes efficiency at both pre-disruption and steady-state post disruption systems, and focuses on core-periphery structures. We investigate conditions under which core-periphery structures increase the overall resilience of the network.

3 - Optimal Selective Maintenance for Networked Infrastructure Systems

Wanshan Li, Tsinghua University, Beijing, 100084, China, liws16@mails.tsinghua.edu.cn, Chi Zhang

Networked infrastructures, such as electricity, telecommunication and transportation, are considered critical for both economic development and social wellbeing of modern societies. To ensure their continued effective performance, cost-effective maintenance without interrupting their operation is necessary. This research proposes a new selective maintenance approach that can help determine optimal maintenance strategies for networked critical infrastructures with general structures. Our approach can also ensure an infrastructure's ability of satisfying the customers' demand continuously, even during the process of maintenance.

4 - Economic Design of Repetitive Inspection Plan with Testing Errors

Young H.Chun, Louisiana State University, 2211 Business Education Complex, Baton Rouge, LA, 70803-6316, United States, prof@drchun.net

Inspection has been widely used as an important tool for quality improvement in manufacturing and service industries. However, inspection errors are inevitable during a screening process of manufactured items such as computer chips; some of the defective items are tested negative and other non-defective items are tested positive erroneously. To improve the outgoing quality, each item is often tested more than once. Based on the test results, we can estimate the defective rate and the inspector's type I and II errors via the method of maximum likelihood. We also propose various types of repetitive inspection plans and compare their performances in a simulation study.

Chair: Ashutosh Nayak, Purdue University, West Lafayette, IN, United States, nayak2@purdue.edu

1 - A Decomposition Method for the Two Stage Staffing Problem in Multiskills Call Centers under Arrival Rate Uncertainty

Thuy Anh Ta, University of Montreal, CP 6128 Succursale Centre-Ville, Montreal, QC, H3W1C5, Canada, tathuyanh1989@gmail.com, Wyean Chan, Fabian Bastin, Pierre l'Ecuyer

We consider a stochastic staffing problem with uncertain arrival rates. The objective is to minimize the total cost of agents under some chance constraints, defined over the randomness of the service level in a given time period. In the first stage, an initial staffing must be determined in advance. At a later time, when the forecast becomes more accurate, this staffing can be corrected with recourse actions by adding or removing agents. We propose a decomposition algorithm based on simulation, cut generation and stochastic programming to solve the problem in reasonable computational time.

2 - Selecting Good Enough Designs using Optimal Computing Budget Allocation

Fei Gao, City University of Hong Kong, 83 Tat Chee Avenue, Kowloon, Hong Kong, feigao9-c@my.cityu.edu.hk, Siyang Gao

We study the problem of selecting a subset of good designs from a finite set of simulated designs. We develop an approach to select r good enough designs instead of the exact top r designs, where good enough designs are defined as the top g designs ($r \leq g$). Using the optimal computing budget allocation framework, we formulate the problem as that of maximizing the probability of correctly selecting r good enough designs under a simulation budget constraint. Based on the approximate measure of the probability of correct selection, we derive an asymptotically optimal selection procedure for selecting good enough designs. The proposed method shows good performance on some typical selection problems.

3 - Adaptive Secant Tangents Averaged Stochastic Approximation
Marie Chau, Virginia Commonwealth University, 1015 Floyd Avenue, Richmond, VA, 23220, United States, mchau@vcu.edu, Jong J. Lee, Michael C. Fu

We introduce Adaptive Secant Tangents AveRaged SPSA (aSTAR-SPSA) for multivariate stochastic optimization problems. Under the setting, where direct and indirect gradients are available, aSTAR-SPSA employs a hybrid Hessian, which is a weighted combination of gradient-free (GF) and gradient-based (GB) Hessians. GF consists of symmetric finite differences (SFD) of SPSA gradients, and the SFD of the associated direct gradients generate GB. We propose weights to minimize two criteria under the Frobenius norm. We prove convergence, establish asymptotic normality, and investigate the empirical performance of aSTAR-SPSA against second-order SA methods through numerical experiments.

4 - Integrating Lyapunov Optimization with Monte Carlo Simulation for Online Decisions
Ashutosh Nayak, PhD Candidate, Purdue University, 45 N Salisbury Street, Apt 9, West Lafayette, IN, 47906, United States, nayak2@purdue.edu, Seokcheon Lee

With the explosion of real-time information, online decision making is increasingly gaining popularity in different applications. Smart Microgrids receive dynamic load requests from consumers and time-varying electricity from renewables. The stochastic nature of demand and supply makes online load scheduling decisions in Microgrid imperative. Lyapunov optimization is an elegant and simple stochastic dual-gradient method that does not consider estimation of future information. In this work, we integrate Lyapunov optimization with Monte Carlo simulation to construct an online algorithm for dynamic load scheduling decisions based on historical decisions and future estimation.

1 - Manufacturing Functional Data Analysis
Ran Jin, Virginia Tech, 1145 Perry Street, Durham Hall, Room 250 (0118), Blacksburg, VA, 24061, United States, jran5@vt.edu, Hongyue Sun

Modern manufacturing system generates spatially and temporally dense data sets. This talk focuses on manufacturing modeling problems with functional data, where the models will be used in data-driven decision making in smart manufacturing. Examples in functional variable selections, in situ process modeling, and data interpretation from natural language processing perspective will be discussed.

2 - Monitoring for Changes in the Nature of Stochastic Textured Surfaces
Anh Tuan Bui, Northwestern University, Technological Institute 2145 Sheridan Road, Room C210, Evanston, IL, 60208, United States, atbui@u.northwestern.edu, Daniel Apley

This work aims to monitor for global changes in the nature of stochastic textured surfaces, which are fundamentally different than the profiles and images that are the focus of most prior profile monitoring works. We represent normal in-control behavior by using supervised learning models to implicitly characterize the joint distribution of the surface image pixels. Based on this characterization, we develop a monitoring statistic using likelihood-ratio principles to detect changes in the surface nature, relative to the in-control nature. Our approach can detect general surface changes with no prior knowledge of the changes. We demonstrate the approach with a textile example.

3 - Early Detection Vessel Delays using Combined Historical and Real-time Information
Sungil Kim, Assistant Professor, UNIST, Ulsan, Korea, Republic of, sungil.kim@unist.ac.kr

Detecting vessel delays in advance or in real time is important in order to fulfill the expectations of customers and to help customers reduce delay costs. However, the early detection of vessel delays faces the challenges of numerous uncertainties, including weather conditions, port congestion, booking issues, and route selection. This paper proposes a data-driven method for the early detection of vessel delays: in our new framework of refined case-based reasoning, real-time S-AIS vessel tracking data are utilized in combination with historical shipping data. Real data examples from a logistics company demonstrate the effectiveness of the proposed method.

4 - A Generic Multisensor-based Degradation Model
Changyue Song, University of Wisconsin-Madison, Rm 3221, Mechanical Engineering Building, 1513 University Ave, Madison, WI, 53715, United States, csong39@wisc.edu, Kaibo Liu

Nowadays multiple sensors have been widely used to monitor the degradation status of a unit simultaneously, which enables an unprecedented opportunity for condition-based monitoring and maintenance. However, most of the existing studies focus on the modeling and prognosis based on a single signal. Other studies either analyze each signal separately, or fuse multiple signals into a composite index. This paper proposes a generic multisensor degradation model which can capture the correlation among sensors and learn the failure mechanism of units directly from multiple signals. As a result, the proposed method is more flexible and achieves better prognostic performance.

Vehicle Routing

Sponsored: TSL, Freight Transportation & Logistics

Sponsored Session

Chair: Justin Goodson, Saint Louis University, St. Louis, MO, 63108, United States, goodson@slu.edu

1 - Generic Branch-and-Bound Schemes for Time Window Assignment Vehicle Routing Problems
Anirudh Subramanyam, Carnegie Mellon University, DH3122, 5000 Forbes Ave., Pittsburgh, PA, 15213, United States, asubramanyam@cmu.edu, Chrysanthos Gounaris

We study the allocation of long term delivery time windows to customers in the context of VRPs. Once a time window has been assigned, the operator must strive to meet it on a daily basis as well as possible. Since operational parameters such as customer demands or travel times vary from day to day, the aim is to assign time windows in a way that minimizes the expected routing cost. In this work, we show that this problem can be reduced to a variant of the Consistent VRP and adapt an algorithm we developed for the latter problem to solve to exact optimality instances of the former. Our approach is highly competitive and can address uncertainty in a wider class of parameters when compared to the previous state of the art.

2 - A Branch-Price-and-Cut Approach for Robust Vehicle Routing
Akang Wang, Carnegie Mellon University, Pittsburgh, PA, 15213, United States, akangw@andrew.cmu.edu, Chrysanthos Gounaris

We present a Branch-Price-and-Cut approach for tackling the Vehicle Routing Problem (VRP) under demand uncertainty. We utilize Limited-Memory Subset Row Cuts and robust Rounded Capacity Inequalities to strengthen the linear relaxation at every node. We use a Tabu Search heuristic to generate columns with negative reduced cost, and we resort to exact pricing via Dynamic Programming only if the former fails to identify such columns. Computational studies are performed on VRP benchmark instances stemming from multiple variants.

3 - Travel Time Correlation in Vehicle Routing
Iurii Bakach, Graduate Student, University of Iowa, 2119 Keokuk Street, Apt 9, Iowa City, IA, 52240, United States, iurii-bakach@uiowa.edu, Ann Melissa Campbell, Jan Fabian Ehmke, Timothy Urban

Due to the complexity of the problem, the majority of routing models consider arc costs to be deterministic and independent. However, in reality, arc costs are often correlated, for instance, when they reflect travel times in urban areas. We examine a routing problem with a min-max objective with both stochastic and correlated travel times. We develop a method using extreme-value theory to estimate the expected makespan and embed this within a routing heuristic. We present results that demonstrate the impact of different correlation patterns and levels of correlation on route planning.

4 - Route-Based Markov Decision Processes for Dynamic Vehicle Routing Problems
Justin Goodson, Saint Louis University, John Cook School of Business, Davis-Shaughnessy Hall, St. Louis, MO, 63108, United States, goodson@slu.edu, Marlin Wolf Ulmer, Dirk C. Mattfeld, Barrett Thomas

We propose a model for dynamic routing problems (DRPs) that extends the conventional Markov decision process (MDP) model for dynamic and stochastic optimization problems to more closely align with route-based solution methodologies in the DRP literature. We construct route-based MDPs by redefining the action space to operate on sets of planned routes. We generalize the state to include route plans and redefine the current-period reward/cost to be the marginal change in value associated with an update to a route plan. We show route-based MDPs are equivalent to the conventional MDP model.

Analysis of Shared Mobility Systems

Sponsored: Transportation Science & Logistics

Sponsored Session

Chair: Mustafa Lokhandwala, Purdue University, 241 Sheetz Street, Apt 14, West Lafayette, IN, 47906, United States, mlokhand@purdue.edu

1 - A Study on the Phenomenon of E-hailing Taxi Order Discard Based on Customer Impatience and Arrival Time Fluctuation Analysis

zhuying Jiang, Sparkzone Research Group, Beijing, China, 2579658790@qq.com, Yu Xin, Yinghao Jia, Yinghao Jia

E-hailing applications are commonly believed to improve the traveling efficiency and service quality by increasing transport supply to meet customers' demand. However, customers may discard the E-hailing taxi and take the cruising taxi instead to minimize the waiting time, depending on fluctuation of arrival time and individual patience. Based on data-driven approaches and human factor analysis, we propose an analytical framework to study the competition of E-hailing and cruising taxis by quantitatively evaluating the extent of reduced efficiency, thus optimizing the balance between system efficiency and service quality.

2 - Modeling Users' Memory in Shared Bike Systems

Dmitry Gimon, Assistant Professor, Fort Hays State University, 600 Park Street, Hays, KS, 67601, United States, dmitrygimon@gmail.com

Shared resources, such as car or bicycle rental systems, have become a norm of life in cities. Since transportation patterns vary during the day, the key problem of these systems is network balance, which affects systems reliability and users satisfaction. We propose to model user satisfaction as a function of relevant concessions that this particular user or other users have made in deciding to use different drop-off/pickup sites. We compare existing and theoretical incentive models and users' strategies to find the one that will result in the most balanced network or the one with the most satisfied users. This study contributes to the area of shared vehicle design and operations.

3 - Ride Sharing a Case Study of Shared Taxis in New York City

Mustafa Lokhandwala, Graduate Student Purdue University, Purdue University, 235 Littleton Street, Apt 15, West Lafayette, IN, 47906, United States, mlokhand@purdue.edu, Hua Cai

This study uses simulation to analyze the benefit of Taxi Sharing using agent-based modeling. The focus of our study is to build an agent-based simulation model using \color{red} real world \color{black}trip data obtained from the New York Taxi and Limousine Commission, model the decision making methodologies of the agents (the taxis and the riders) in a taxi sharing scenario and run this model using the most recent trip data within the GIS setting of New York City. The end result from this experiment is to optimize the number of taxis operating on the streets of New York City and also quantify the economic and environmental benefits of the same.

Sponsored Session

Chair: Jing Li, Arizona State University, Tempe, AZ, 85287-8809, United States, jing.li.8@asu.edu

1 - Multilinear Principal Component Analysis for Statistical Modeling of Cylindrical Surfaces: A Case Study

Bianca Colosimo, Politecnico di Milano, Milan, Italy, biancamaria.colosimo@polimi.it, Massimo Pacella

The work focuses the problem of modeling manufactured surfaces for statistical process control. The application of Multilinear principal component analysis (MPCA) is discussed. A real case study concerning cylindrical surfaces obtained by a lathe-turning process is taken as reference. The measurements related to a specific surface are stored in a matrix addressed by 2 index variables, while the observed data set related to several surfaces is stored in a 3rd- order tensor addressed by 3 indexes. Any 2.5- dimensional surface (i.e. where scalar measurements are sampled for each item by using a fixed grid of two spatial index variables) can be modeled with the proposed MPCA-based approach.

2 - Monitoring Communications: Aiming to Identify Periods of Unusually Increased Communications between Parties of Interest

Ross Sparks, CSIRO.Computational Informatics, North Ryde, NSW, Australia, Ross.Sparks@data61.csiro.au

Communication monitoring of large networks with aim of detecting unusually increased communications is a challenging task. This talk will cover some of the challenges when firstly the target sub-group of the network with potentially increased communications is known and changes in size over time; and secondly when the sub-group is unknown and needs to be found. The unknown sub-group case will be carried out under two situations. Firstly when the sub-group has a dominant leader and communication sparsity in the sub-group can be exploited. Secondly when sub-group has a collaborative leader and no communication sparsity generally exists in the sub-group.

3 - Two-sided Tolerance Intervals for Members of the (Log)-location-scale Family of Distributions

Yili Hong, Virginia Polytechnic Institute, 213 Hutcheson Hall, Department of Statistics, Blacksburg, VA, 24061, United States, yilihong@vt.edu

In this paper, we propose methods to calculate exact factors for two-sided control-the-centre and control-both-tails tolerance intervals for the (log)-location-scale family of distributions, based on complete or Type II censored data. With Type I censored data, exact factors do not exist. For this case, we developed an algorithm to compute approximate factors. Our approaches are based on Monte Carlo simulations. We also provide algorithms for computing TIs that control the probability in both tails of a distribution.

Sustainable and Responsible Supply Chain Management

Sponsored: Energy, Natural Res & the Environment Environment & Sustainability

Sponsored Session

Chair: Jose Cruz, jose.m.cruz@uconn.edu

1 - Revenue and Demand Management of Smart Cities

Shivani Shukla, PhD, University of Massachusets, Amherst, MA, United States, sshukla@som.umass.edu

A smart city concept encompasses enhancement of transportation to support growth initiatives, environmental review to sustain modernization, and sustainable travel. Multiple public and private entities cooperate to share information and resources for collective efforts driven to achieve sustainability. This work focuses on measuring the effectiveness of such cooperative enterprises in the realm of demand management through the intended shift from the typical travel practices to more reliable alternatives.

2 - Supply Chain Sustainability through Risk Sharing Contracts

Jose Cruz, University of Connecticut, School of Business, 2100 Hillside Road, Storrs, CT, 06269-1041, United States, jose.m.cruz@uconn.edu

In this paper, we develop a framework that captures sustainability trough d risk-sharing contracts in supply chain networks. Risk-sharing contracts specify who needs to incur the costs when supply chain disruptions occur. We present the behavior of the various decision-makers, derive the governing equilibrium conditions, establish the finite-dimensional variational inequality formulation, and present numerical examples.

3 - Supply Chain Network Competition and Sustainable Environmental Policies

Min Yu, PhD, University of Portland, Portland, OR, United States, yu@up.edu, Jose Cruz, Dong Li

We first develop a competitive supply chain network model consisting of a finite number of firms competing in an oligopolistic manner. We investigate the problem with progressive emission taxes, in which the emission tax function is a piecewise-defined function of the total emission. Second, we extend the single period model to a multiperiod model to study the firm's long-term investment strategy on the sustainable energy-efficient technologies to take advantage of tax incentives while maximizing the net present value (NPV) of the investment.

4 - A Competitive Multiperiod Supply Chain Network Model with Freight Carriers and Green Technology Investment Option

Sara Saberi, Worcester Polytechnic Institute (WPI), Washburn Rm 217, Foisie School of Business, Worcester, MA, 01609, United States, ssaberi@wpi.edu, Jose Cruz, Anna B. Nagurney

This paper presents a multiperiod supply chain with freight carriers model. Manufacturers, retailers, and carriers maximize the net present value of their investments in technology. Future production, inventory, transaction, and transportation costs savings are used to help fund investments. The environmental impact of the costs are all integrated. The tradeoff between the initial technology investment and its ecological footprint effect are considered. We provide variational inequality formulations of the equilibrium conditions and propose the modified projection method. Numerical examples are examined with an analysis of the effects of technology investments on supply chain network.

5 - Polling, Psychology and Propaganda in Forecasting Electoral Outcomes

Dimitris Vayenas, Metapoll, London, United Kingdom, dimitris@metapoll.co.uk

Having predicted the outcomes of recent elections the session addresses the underlying theories that are calling for a re-evaluation of political campaigning. By utilising formal models developed to quantify transparency in many-to-many communications, accurate forecasting is attainable based on the motives of the population as addressed by the campaigns; in the case of Brexit with a 0.1% deviation one month before the elections. The shortcomings of polling methodologies and how analytics can help mitigate the impact of unreliable responses are also addressed. Models of human socialty and motivators are employed in the mapping of quantifiable sentiments and reactions to propaganda.

6 - Optimization of Feedstock Blending for Biochemical Conversion

Mohammad Sadekuzzaman Roni, Idaho National Laboratory, 21 T. Wallace Circle, Starkville, MS, 39759, United States, msr131@gmail.com

Identifying a least cost blend is challenging, especially when decisions about feedstock blending must be based on a number of criteria. This study developed an optimization framework to identify optimal blending of feedstock to meet biochemical conversion specifications. Results reveal the tradeoff among blend components in the least cost blend based on biomass resource availability, quality requirement and logistics cost.

1 - Mathematical Programming Approaches and Data Representations for Multiple Instance Learning

Emel Seyma Kucukasci, Istanbul Commerce University, Kucukyali E5 Kavsagi Inonu Cad No 4, Istanbul, 34840, Turkey, emelseyma@gmail.com
Emel Seyma Kucukasci, Boaziçi University, Istanbul, Turkey, emelseyma@gmail.com, Mustafa Gokce Baydogan, Z. Caner Ta kın

We propose a multiple instance learning framework including new mathematical models of multiple instance classification and enhanced data representations. We efficiently solve MIL problem without imposing strict assumptions on object descriptions. Our approach embeds instance relationships via inputting various data representations and determines class memberships of the objects. We compare our learning procedure with state-of-the-art MIL methods on a wide range of machine learning datasets to highlight the classification success on different application domains.

2 - Forecasting Gathering Events through Continuous Destination Prediction on Big Trajectory Data

Amin Vahedian Khezerlou, University of Iowa, S283 Pappajohn Business Building, Iowa City, IA, 52242, United States, amin-vahediankhezerlou@uiowa.edu, Xun Zhou

Gathering Event Forecasting (GEF) in urban areas is the problem of forecasting unexpectedly high number of arrivals in an urban region. In this work, we propose a trajectory-based approach to forecast the gathering events by predicting the destinations of incomplete trip trajectories at a given time. To the best of our knowledge, this method is the first to adopt this approach to GEF. This method includes a novel destination prediction model, which is superior to the models in the literature in terms of accuracy and computational cost (both running time and memory). We show through experiments that our method successfully forecasts real events.

3 - Discovering Urban Typologies for Future Mobility Scenarios in Prototype Cities

Jimi Oke, Postdoctoral Associate, Massachusetts Institute of Technology, 77 Massachusetts Avenue, Building 1-178, Cambridge, MA, 02139, United States, oke@mit.edu, Yafei Han, Sean Hua, Carlos L. Azevedo, P. Christopher Zegras, Moshe E. Ben-Akiva

Ongoing trends in the development of vehicle fuels and technologies along with potential environmental and policy regulations will produce a complex space of futures of mobility outcomes in urban areas. We gather the most recent land-use, economic, environmental and mobility data from over 331 cities. We extract the key factors and then cluster the cities to find the prevailing urban typologies. Further, we estimate a latent class choice model for mobility responses based on 43000 individual observations from a global sample, thus confirming our typology classes. In a novel effort, we will then generate new representative prototype cities in order to model various urban mobility scenarios.

Modeling and Analysis of Power System Expansion Planning

Sponsored: Energy, Natural Res & the Environment Electricity

Sponsored Session

Chair: Enzo E Sauma, PhD, Pontificia Universidad Catolica de Chile, Pontificia Universidad Catolica de Chile, Santiago, Chile, esauma@ing.puc.cl

1 - Quantifying the Effect of Head-sensitive Hydropower Approximations on Investments and Operations

Francisco Munoz, Universidad Adolfo Ibáñez, Santiago, Chile, fdmunoz@uai.cl, Gonzalo Ramírez

Planning for new generation infrastructure in hydrothermal power systems requires consideration of a series of nonlinearities that are often ignored in capacity-planning models. In this article we use three different capacity-planning models, with different degrees of complexity and accuracy, to quantify the impact of simplifying the head dependency of hydropower generation on investments in thermal units and system operations. We find that simplified investment models can bias the optimal generation portfolios significantly and increase system costs compared to more detailed nonlinear models.

2 - Joint Expansion Planning of Distribution Networks, EV Charging Stations and Wind Power Generation under Uncertainty

Javier Contreras, Univ de Castilla-La Mancha, E.T.S.de Ingenieros Industriales, Campus Universitario s/n, Ciudad Real, 13071, Spain, Javier.Contreras@uclm.es, Pilar Meneses de Quevedo, Gregorio Muñoz-Delgado

This paper describes the consideration of uncertainty in distribution system expansion planning (DSEP) including electric vehicles (EV) and the possibility of joint investment in EV charging stations (EVCS) and wind power generators. The charging demand necessary for EVs transportation is performed using a vehicle decision model based on travel patterns. The problem is defined as a stochastic-programming-based model driven by the minimization of the annualized investment, maintenance, production, losses and non-supplied energy costs. A 24-bus system case study is provided illustrating the results of the proposed approach.

3 - Transmission Expansion Planning: A Distributionally Robust Optimization Approach

David Pozo, Skolkovo Institute of Science and Technology, Mosco, Russian Federation, davidpozocamara@gmail.com, Alexandre Street, Alexandre Velloso

Investment decisions on power systems should be robust among all (infinite) possible future scenarios. This talk addresses the transmission expansion planning (TEP) problem where decisions have to be optimized given that the future is uncertain, there are several scales of uncertain parameters, and there is no knowledge of the true probabilities. A Distributionally Robust Optimization framework is proposed. Numerical test results are reported in comparison with the conventional approaches such as two-stage stochastic optimization and adaptive robust optimization.

4 - Interrelationship Between the Impending Major Energy Transitions and Pollutant Emissions

Daniela Quiroga, Pontificia Universidad Catolica de Chile, Santiago, Chile, diquiroga@uc.cl, Enzo Sauma, David Pozo

Energy sector is facing important transitions motivated by the strong incentives for encouraging renewable energy production and the adoption of energy efficiency measures. We study the interrelationship between the impending energy transitions over the coming decade and local and global pollutant emissions, in the context of the Chilean power system. In particular, we develop and analyze policy-relevant scenarios describing the energy transitions facing Chile over the coming decades and identify the key factors of the power sector contributing to pollutant emissions. We then identify some regulations in the Chilean power sector and study the general and distributional effects on emissions.

1 - Solving Uncapacitated Facility Location and Network Design Problems with Disaggregagted Benders Decomposition

Robin Pearce, University of Queensland, School of Mathematics and Physics, Mathematics Department, St Lucia, 4068, Australia, r.pearce2@uq.edu.au

Numerous problems fall under the category of facility location and network design problems, most of which can be effectively solved using Benders decomposition. In this talk we list a number of these problems, present the general problem and show how to apply disaggregated Benders decomposition these problems. In particular, we look at potential improvements that can be applied to improve time to solution, such as Pareto-optimal analytically-derived Benders cuts or tighter feasibility cuts. We will conclude with computational results to demonstrate the effectiveness of this approach.

2 - Robust Optimization to One-way Electric Vehicles Sharing System Considering Uncertain Travel Time

zihao jiao, Beijing Institute of Technology, Beijing, China, zihaobit@163.com

As operators' concern, the main problems of Electric vehicles sharing service such as charging demand and range anxiety, impact operation process and generate several secondary problems. Another unnoticeable aspect of operation is uncertainty, a general issue in engineering systems. We propose a robust model to handle with perturbed data, taking location and layout into consideration as well. Then we use a two-stages algorithm to solve the model. The results of case study show that uncertainty of travel time makes an unstable fleet size each depot, increasing optimal cost and worse cost management ability. Besides, we appraise environment benefits by evaluate the CO2 saving by EVs sharing.

3 - A New Lagrangian Relaxation for Multicommodity Capacitated Network Design Problem

Mohammad Rahim Akhavan Kazemzadeh, Universite de Montreal (DIRO), 5775 ave Wilderton, Montreal, QC, H3S2V7, Canada, akhavanm@iro.umontreal.ca, Teodor Gabriel Crainic, Bernard Gendron

The usual Lagrangian relaxations for multicommodity capacitated network design are the so-called shortest path and knapsack relaxations, which are obtained, respectively, by relaxing linking constraints and flow conservation equations. We present a new reformulation and Lagrangian relaxation for the problem. We show that the Lagrangian dual bound improves upon the so-called strong LP bound (known to be equal to the Lagrangian dual bounds of the shortest path and knapsack relaxations).

4 - The Constrained Covering Tour Problem

Sanaz Goldani, PhD Student, North Carolina State University, 3610 Detrick Drive, Apt 321, Raleigh, NC, 27609, United States, sgoldan@ncsu.edu, Yahya Fathi

The Constrained Covering Tour Problem (CCTP) is an integer programming (IP) problem that arises in the context of solving the Bi-objective Maximal-covering Minimal-tour Problem (BCTP) via the -constraint method. We introduce a family of valid inequalities and propose a branch-and-cut algorithm for solving this IP problem. We also present the results of a computational experiment to assess the effectiveness of this algorithm. We then employ this algorithm to obtain the non-dominated frontier of the corresponding bi-objective optimization problem.

5 - Slim Branch and Price Method for Combinatorial Optimization Problems

Ahmed M. Marzouk, Southern Methodist University, Lyle School of Engineering, Southern Methodist University, Dallas, TX, 75275-0123, United States, ambadr@email.tamu.edu, Erick Moreno-Centeno, Halit Uster

The Slim Branch and Price (SBP) method is a new optimization method that can be described as a framework that borrows ideas from general branch-and-price and cutting plane frameworks. We describe a specific implementation of the SBP algorithm and illustrate its effectiveness in a generalized traveling salesperson problem known as the Hamiltonian p-Median Problem.

Parallel Algorithms in Optimization

Sponsored: Computing

Sponsored Session

Chair: Oleg Shylo, University of Tennessee, Knoxville, TN, 37996, United States, oshylo@utk.edu

1 - Parallel Branch and Bound Algorithms for Rectangular Maximum Agreement

Jonathan Eckstein, Rutgers University, 100 Rockafeller Road, Room 5145, Piscataway, NJ, 08854, United States, jeckstei@rci.rutgers.edu, Ai Kagawa

Rectangular maximum agreement (RMA) in an NP-hard combinatorial problem arising as a subproblem in various machine learning contexts. We show how the problem arises and discuss its solution using the PEBBL parallel branch-and-bound framework. We discuss various possible branching strategies and the specialized data structures that facilitate them. We give parallel performance results on problem instances derived from real datasets, and may also discuss restricted versions on the problem intended to be easier to solve.

2 - A Flocking-based Approach for Distributed Stochastic Optimization

Shi Pu, University of Florida, Gainesville, FL, United States, sp3dw@virginia.edu, Alfredo Garcia

We consider a distributed asynchronous computing scheme for stochastic optimization with modest communication amongst processors. Specifically, we analyze a scheme with $N > 1$ independent threads implementing each a stochastic gradient algorithm. The threads are coupled via a perturbation of the gradient (with attractive and repulsive forces) in a similar manner to mathematical models of flocking found in nature. We show a flocking-like approach provides a noise reduction effect similar to that of a centralized algorithm. Moreover, when the overhead related to the time needed to gather N samples and synchronization is not negligible, the flocking implementation outperforms a centralized one.

3 - Boosting Performance via Communication in Concurrent Algorithms

Oleg Shylo, University of Tennessee, 523 John D. Tickle Engineering Building, 851 Neyland Drive, Knoxville, TN, 37996, United States, oshylo@utk.edu, Andrii Berdnikov

We discuss a theoretical framework that captures communication in concurrent optimization algorithms, and use the proposed model to streamline parallel communication. In particular, the focus is on communicative algorithm portfolios, where a group of optimization algorithms works in parallel and shares information about the search process to boost performance. Discussion of the structure and content of scalable communication for a class of scheduling algorithms is provided.

4 - Asynchronous Parallel Stochastic Global Optimization using Radial Basis Functions

David Eriksson, Cornell University, 136 Hoy Road, Rhodes Hall 657, Ithaca, NY, 14853, United States, dme65@cornell.edu

We propose an asynchronous parallel surrogate optimization algorithm for global optimization of computationally expensive black-box objective functions. Our algorithm uses a radial basis function surrogate and doesn't require gradient information. We compare our algorithm to a synchronous implementation on several test problems and analyze how the performance depends on the distribution of the objective function evaluation times. Based on our experimental results we propose an empirical method to predict when asynchronous parallel is expected to outperform synchronous parallel.

1 - Taming Nonconvexity with Data

Zhaoran Wang, Princeton University, Apt 302, 13 Lawrence Drive, Princeton, NJ, 08540, United States, zhaoran@princeton.edu

In this talk, I will illustrate how statistical thinking enables us to harness the power of nonconvex optimization. In specific, I will present an algorithmic framework for exploiting the latent geometry induced by the randomness of data. By integrating three new global exploration meta-algorithms — namely, homotopy continuation, tightening after relaxation, and noise regularization — with local search heuristics — such as the variants of gradient descent — this unified framework leads to new nonconvex optimization algorithms for a broad variety of challenging learning problems.

2 - SARAH: Stochastic Recursive Gradient Algorithm

Lam Minh Nguyen, Lehigh University, 200 West Packer Avenue, Room 362, Bethlehem, PA, 18015, United States, lmn214@lehigh.edu, Jie Liu, Katya Scheinberg, Martin Takac

We propose a StochAstic Recursive grAdient algoritHm (SARAH), as well as its practical variant SARAH+, as a novel approach to the finite-sum minimization problems. Different from the vanilla SGD and other modern stochastic methods such as SVRG, S2GD, SAG and SAGA, SARAH admits a simple recursive framework for updating stochastic gradient estimates; when comparing to SAG/SAGA, SARAH does not require a storage of past gradients. The linear convergence rate of SARAH is proven under strong convexity assumption. We also prove a linear convergence rate in the strongly convex case for an inner loop of SARAH, the property that SVRG does not possess. Numerical experiments show the efficiency of our algorithm.

3 - Optimal Generalizability in Parametric Learning

Meisam Razaviyayn, University of Southern California, Los Angeles, CA, United States, razaviya@usc.edu, Ahmad Beirami

Cross-validation is the most popular approach for measuring the predictive performance of a statistical model. This procedure requires solving multiple optimization problems which is computationally expensive in practice. In this work, we first propose a computationally efficient surrogate for the cross-validation and provide theoretical guarantees for its performance. Then we use the proposed surrogate to provide an optimization algorithm for finding the optimal regularizer in the empirical risk minimization framework. In our numerical experiments, we illustrate the accuracy and efficiency of of our proposed surrogate as well as our proposed framework for the optimal regularizer.

4 - Iteration-complexity of Linearized Proximal Multiblock ADMMs for Solving Linearly Constrained Nonconvex Optimization Problems

Renato Monteiro, School of ISyE, Georgia Tech, Atlanta, GA, 30332, United States, monteiro@isye.gatech.edu

This talk discusses iteration-complexity of linearized proximal multiblock alternating direction methods of multipliers (ADMM) for solving linearly constrained nonconvex optimization problems. The subproblems are obtained by partially or fully linearizing the augmented Lagrangian with respect to the corresponding minimizing block variables. Complexity bounds are obtained for any choice of a relaxation parameter in the interval (0, 2).

1 - Stronger Polyhedral Relaxations for Polynomial Optimization Problems

Aida Khajavirad, Carnegie Mellon University, 5000 Forbes Ave, Pittsburgh, PA, 15232, Pittsburgh, PA, 15213, United States, aida@cmu.edu, Alberto Del Pia

We consider the Multilinear set defined by a collection of multilinear terms over the unit hypercube. Such sets appear in factorable reformulations of many types of mixed-integer nonlinear programs including polynomial optimization problems. Utilizing an equivalent hypergraph representation for the Multilinear set, we derive various types of facet defining inequalities for its polyhedral convex hull and present a number of tightness results based on the acyclicity degree of the underlying hypergraph. Subsequently, we detail on the implementation of the proposed cutting planes in the branch-and-cut based global solver BARON. Extensive computational results will be presented.

2 - Global Optimization of Power Systems Problems

Burak Kocuk, Sabanci University, Istanbul, Turkey, burakkocuk@sabanciuniv.edu, Santanu Subhas Dey, Andy Sun

In this talk, we consider polynomial optimization problems form power systems. Due to nonlinearity induced by alternating current power flow equations, these two optimization problems are nonconvex and require efficient global optimization methods. We make effective use of several different strategies to handle nonconvexity, including conic relaxations, envelopes, disjunctive extended formulations, cutting planes, variable bound tightening techniques and feasibility heuristics. Our approaches scale well to large power systems problems and provide provably good solutions in time compatible with the needs of the system operators.

3 - Deriving the Convex Hull Form of a Symmetric Multilinear Polynomial

Yibo Xu, Clemson University, 110 Martin Hall, Box 340975, Clemson, SC, 29634, United States, yibox@clemson.edu

We generate all the facets of the convex hull of a symmetric multilinear polynomial (SMP) that is constrained over a symmetric box. Our approach exploits the problem symmetry to: define a "core" family of facets that motivates all remaining facets, develop necessary and sufficient conditions for establishing that a valid inequality is a facet, and use our conditions to derive all "core" facets. We propose algorithms that generate all the facets, and also provide a facet-certification algorithm. Our algorithms run successfully in MATLAB, one of which employs PORTA. The computational results provide insight into the complexity of the convex hull generation of a SMP.

4 - Disjunctive Cuts for Bilinear Programming

Akshay Gupte, Clemson University, Dept. of Mathematical Sciences, O-321 Martin Hall, Clemson, SC, 29634-0975, United States, agupte@clemson.edu, Michael Glen Eldredge

Consider the problem of optimizing a bilinear function x'Qy + cx + dy over the feasible set given by x \in X, y \in Y, where X and Y are two polyhedral sets. This problem is NP-hard in general, and appears either as is in applications or can be extracted as a relaxation of another problem. We borrow the disjunctive programming paradigm from integer programming to derive strong cutting planes for bilinear optimization. We discuss when the proposed valid inequalities generate the underlying convex hull and how many rounds of these cuts are required to achieve this. Computational results on test instances will be presented.

1 - Alternative Modelings for the Hub Location Problem with Discrete Transportation Cost

Milad Keshvari Fard, ESSEC Business School, 3 Avenue Bernard Hirsch, Cergy, 95021, France, milad.keshvarifard@essec.edu, Laurent Alfandari

In many real world problems, the transportation cost is better approximated as a function of the number of vehicles required, than a linear function of load. In this research we study the Hub Location Problem with discrete costs and show that the location/allocation decisions found under a linear cost function could be significantly different than those found with a discrete cost function. We analyze the resulting optimality gap if a linear cost is used. We show that by choosing a proper linear cost function specific to the problem's data, we can obtain solutions close to those found by a discrete cost function, while avoiding the higher computational complexity.

2 - Relaxations of Discrete Sets with Semicontinuous Variables

Gustavo Angulo, Assistant Professor, Pontificia Universidad Católica de Chile, Avenida Vicuña Mackenna 4860, Macul, Santiago, 7820436, Chile, gangulo@ing.puc.cl

A variable is said semicontinuous if its domain is given by the union of two disjoint nonempty closed intervals. As such, they can be regarded as relaxations of binary or integrality constraints appearing in combinatorial optimization problems. For knapsacks and a class of single-node flow sets, we consider relaxations involving unbounded semicontinuous variables. We analyze the complexity of linear optimization over such relaxations and provide descriptions of their convex hulls in terms of linear inequalities and extended formulations.

3 - Complete Efficient Frontier of Multi-objective Multi-constrained Separable Nonlinear Optimization Problems

Yoshiko.Hanada, Ms., Kansai University, 3-3-35, Yamate-cho, Suita, Osaka, 564-8680, Japan, hanada@kansai-u.ac.jp, Yuji Nakagawa, Chanaka Edirisinghe

Improved Surrogate Constraint (ISC) Method is an enumeration technique to find an exact optimal solution of separable discrete optimization problems with multiple constraints, referred to as a multidimensional nonlinear knapsack (MNK) problem. We introduce a new technique based on the ISC method for finding all efficient solutions for the multi-objective case. Our computational experiments demonstrate the superiority of the proposed method relative to existing algorithms in both speed and accuracy. Also, an application in financial engineering is reported.

4 - First Responder Planning under Hypercube Queuing Equilibrium, Disruption and Cooperation

Han Liu, Ph.D Visiting Student, UIUC, 205 Mathew, Champaign, IL, 61801, United States, 407049583@qq.com, Jian Wang, Yanfeng Ouyang

This talk presents a mixed-integer non-linear program (MINLP) model that integrates hypercube queuing equilibrium, probabilities service disruptions and responder cooperation. Numerical experiments and an empirical case study show applicability of the proposed models. It is shown that cooperative dispatch of responders can potentially reduce expected system-wide costs.

Green Technology Development & Adoption: Environmental Regulation, Competition and Green Consumerism

Sponsored: Energy, Natural Res & the Environment Environment & Sustainability

Sponsored Session

Chair: Arda Yenipazarli, ayenipazarli@georgiasouthern.edu

1 - The Impact of Environmental Regulations on Facilities Decisions: When to Invest in Green Technology and End-of-pipe Abatement

Nazli Turken, Cleveland State University, 1860 East 18th St. BU 544, Cleveland, OH, 44117, United States, n.turken@csuohio.edu, Vedat Verter, Janice E.Carrillo

We analyze the effect of different environmental regulations such as emissions tax, emissions trading, and command-and-control, on the facilities, green technology, and end-of-pipe emissions abatement investment decisions of a company. We find the scenarios when green technologies are preferred over end-of-pipe abatement solutions by firms and vice versa. We identify the regulation parameters that minimize local and global emissions.

2 - Environmental Taxes and Green Technology Choice: The Impact of Competition and Consumer Awareness

Arda Yenipazarli, Assistant Professor of Operations Management, Georgia Southern University, 2224 College Of Business Administration, Statesboro, GA, 30460, United States, ayenipazarli@georgiasouthern.edu

There are many situations where policy makers would like to induce firms to make a major discrete conversion in production technology to reduce emissions intensity of their production processes. We study the impact of emissions tax on the choice of abatement technology in a competitive market, where two profit-maximizing firms facing price- and emissions intensity-dependent demand decide on whether to convert to a pollution-abatement technology and price in response to the tax set by the regulator. On the demand side, customers exhibit horizontal differentiation for product feature and vertical differentiation for emissions intensity reductions achieved by abatement technology adoption.

Use and Enhance Energy Models to Get Insightful Results

Sponsored: Energy, Natural Res & the Environment, Energy

Sponsored Session

Chair: Denis Lavigne, PhD, Royal Military College Saint-Jean, 29, rue Louis-Frechette, St-Jean-sur-Richelieu, QC, J2W 1E9, Canada, denis.lavigne@cmrsj-rmcsj.ca

1 - An Ensemble Approach to Forecast Electricity Day Ahead Auction Prices: Experiences from the Turkish Market

Ezgi Avci-Surucu, Rotterdam School of Management, Technology and Operations, Management Department, Rotterdam, 3062 PA, Netherlands, avcisurucu@rsm.nl, Wolfgang Ketter, Eric Van Heck

Despite the great diversity of electricity price forecasting methods, there are still many forecasting challenges that a bidder has to take into account, such as whether to use individual models on their own, rather than in ensemble, the multi-seasonality problem and how to select appropriate exogenous variables. We address these challenges by using a detailed market-level data from the Turkish electricity day-ahead auctions, which is an interesting research setting in that it presents a number of challenges for forecasters. We examine the key distinguishing features of this market which then allows us to propose individual and ensemble forecasting models that are particularly well suited to it.

2 - Energy Development Pathways to Reach Mexico's Climate Change Goals

Rodrigo Mercado Fernandez, University of Massachusetts Amherst, 65 McClellan Street, Amherst, MA, 01002, United States, rodmerfdez@gmail.com

This paper examines the generation expansion planning (GEP) problem in the Mexican Electrical Grid while considering long term national emissions goals. We will compare results from high level top-down studies, produced by Integrated Assessment Models, with more detailed bottom-up approaches, to inform the feasibility and the requirements for the development of Mexico's electricity portfolio. We will identify the common characteristics for development of the different portfolios, be it generation technologies, critical areas of infrastructure development and investment, or policy measures.

3 - Advances in Modeling Increasingly Integrated North American Natural Gas and Power Markets

Robert Brooks, President, RBAC Inc, 4020 Magnolia, Suite B, Burbank, CA, 91505, United States, robert.brooks@rbac.com

In addition to growth of wind and solar in the generation mix, abundant supplies of low cost natural gas have begun to supplant coal as North American electricity generation's primary fuel source. Yet there are numerous challenges involved in the integration of these disparate technologies and markets. Computer modeling tools have been around for decades to assist understanding the natural gas and power markets. However, these models focus on their own respective markets using simplistic assumptions about the other. My presentation will show techniques my colleagues and I have developed for more realistic combined modeling of increasingly integrated North American natural gas and power markets.

4 - Expanding a Bottom-up Energy Model into a General-equilibrium Model: Rationale, Formulation and Implementation for Saudi Arabia

Hossa Almutairi, Sr. Research Associate, King Abdullah Petroleum Studies & Research Center, Airport Road, Riyadh, 11672, Saudi Arabia, hossa.mutairi@kapsarc.org, Frederic H. Murphy, Axel Pierru, Shreekar Pradhan

We represent the Saudi economy using an applied general equilibrium framework, which combines a bottom-up technology-rich representation of energy-related sectors with a standard top-down CGE representation of the rest of the economy. This work is motivated by the large size of energy and energy-intensive sectors in the Saudi economy and the structural changes that these sectors will experience in the coming years. Our approach can serve as a general template for expanding any bottom-up model into a general equilibrium. To illustrate the capabilities of the model, we applied the energy price reform implemented in 2016 to the static version of the model calibrated to 2013 data.

5 - Osemosys Energy Model: Introducing Elasticity

Denis Lavigne, Professor, Royal Military College Saint-Jean, 29, rue Louis-Frechette, Saint-Jean-sur-Richelieu, QC, J2W. 1E9, Canada, denis.lavigne@cmrsj-rmcsj.ca

The OSeMOSYS project proposes an open-access energy modeling tool for a wide audience. Its relative simplicity makes it appealing for academic researchers and governmental organizations to study the impacts of policy decisions on an energy system in the context of possible severe greenhouse gases emissions limitations. This paper presents how an elasticity of demand capability can be embedded in an OSeMOSYS analysis, allowing leaders to get insightful results on which end-use demands are sensible to such limitations. A detailed description of the approach will be presented.

Multistage Stochastic Programming

Sponsored: Optimization, Optimization Under Uncertainty

Sponsored Session

Chair: Anthony Downward, University of Auckland, Auckland, 1024, New Zealand, a.downward@auckland.ac.nz

1 - A Deterministic Decomposition Algorithm to Solve Multistage Stochastic Programmes

Regan Baucke, University of Auckland, 70 Symonds Street, Auckland, 1010, New Zealand, rbau155@aucklanduni.ac.nz

Stochastic dual dynamic programmes are an important class of optimisation problems, especially in energy planning and scheduling. Because of the large scenario trees that these problems induce, current solution methods use random sampling of the tree in order to build a policy. Candidate policies are evaluated using Monte Carlo simulation; convergence of a given policy requires a statistical test at a given level of confidence. In this paper, we present a deterministic algorithm to solve these problems. The main feature of this algorithm is a deterministic path sampling scheme during the forward pass phase of the algorithm. This precludes the use of Monte Carlo simulation, increasing performance.

2 - Multi-period Adaptive Fleet Planning Problem

Bruno F. Santos, Assistant Professor, TU. Delft, Kluyverweg 1, Faculty of Aerospace Engineering, Delft, 2629 HS, Netherlands, b.f.santos@tudelft.nl, Laura Requeno Garcia

This works presents a stochastic modelling approach to the multi-period airline fleet planning problem. Approximate Dynamic Programming (ADP) is used to model the impact of demand uncertainty on fleet decisions. The proposed ADP algorithm applies local value function approximations resulting from Gaussian kernel regressions to estimate future airline operating profits. A case study is used to show the effectiveness and practicability of the proposed approach. Optimal solutions are achieved for the deterministic case of the problem, while obtained policies excel the most-likely deterministic solution on stochastic versions.

3 - Investments for Disaster Mitigation Given the Uncertain Effects of Climate Change

Anthony Downward, University of Auckland, Level 3, 70 Symonds Street, Auckland CBD, Auckland, 1024, New Zealand, a.downward@auckland.ac.nz

Climate change is said to be responsible for increases in extreme weather events, however, the exact impact on the frequency or damage of such events is unknown. In this presentation we discuss a multi-criteria multi-stage stochastic programming model for disaster mitigation. In each period, a risk-averse central planner decides on investments that should be made so as to minimize future negative effects on the economy, environment and the society. This is modelled using stochastic dual dynamic programming, with the climate modelled as a Markov chain.

Risk Management in Stochastic Optimization and Machine Learning

Sponsored: Optimization, Optimization Under Uncertainty

Sponsored Session

Chair: Giorgi Pertaia, gpertaia@ufl.edu

1 - Risky Robust Optimization and Sparsity

Matthew Norton, University of Florida, Gainesville, FL, United States, mdnorton@ufl.edu

Robust Optimization has proven to be an intuitive and fruitful framework for optimization under uncertainty. Typically, Robust Optimization approaches view uncertainty from a pessimistic, or worst-case, viewpoint and thus can be overly restrictive. We diverge from this tradition, and show that an optimistic, or best-case, viewpoint of uncertainty should not be ignored. We show that this viewpoint can help improve the profitability of robust policies without sacrificing significant robustness properties. In addition, we show that this notion provides new insight into the recently popularized non-convex regularization schemes in machine learning that induce sparsity.

2 - Risk Management with POE, VaR, CVaR, and bPOE

Stan Uryasev, University of Florida-Gainesville, AOD, 303 Weilhall, Gainesville, FL, 32611, United States, uryasev@ufl.edu

This paper compares four closely related probabilistic measures: Probability of Exceedance (POE), Value-at-Risk (VaR) which is a quantile, Conditional Value-at-Risk which is a Superquantile, and Buffered Probability of Exceedance (bPOE). We discuss basic properties and relations of these functions. We show equivalence of constraints for POE and VaR and for bPOE and CVaR.

3 - Finite Mixtures with CVaR Constraints

Giorgi Pertaia, 1221 South West 21st Avenue, Gainesville, FL, 32601, United States, gpertaia@ufl.edu

Normal mixtures models are used in financial applications dealing with heavy tail distributions. We have suggested a new CVaR distance between distributions. The CVaR distance is a convex function w.r.t. weights. Weights of normal mixture are found by minimizing CVaR distance between the mixture and the target distribution. We suggested convex constraints on the weights assuring that tail of mixture is as fat as the original distribution. We have conducted a case study demonstrating efficiency of the suggested approach.

1 - The Trimmed Lasso: Sparsity and Robustness

Martin S. Copenhaver, Massachusetts Institute of Technology, Cambridge, MA, 02139, United States, mcopen@mit.edu, Dimitris Bertsimas, Rahul Mazumder

Nonconvex penalty methods for variable selection in linear regression have been a topic of fervent interest in recent years. In this talk we introduce a continuous family of nonconvex penalty functions that we call the trimmed Lasso. We show that this family of penalties is an exact method for variable selection with direct control over the desired level of sparsity. In analyzing the properties of the trimmed Lasso, we highlight its connection to existing nonconvex approaches as well as its algorithmic implications.

2 - Generalized Affine Decision Rules for Mixed Integer Linear, Quadratic and Nonlinear Adjustable Robust Optimization Problems by Multiparametric Programming

Efstratios N. Pistikopoulos, Texas A&M.Energy Institute, College Station, TX, United States, stratos@tamu.edu, Styliani Avraamidou, Styliani Avraamidou, Chao Ning, Nikolaos A. Diangelakis, Fengqi You

We propose a novel method for the derivation of generalized affine decision rules for linear/quadratic/nonlinear and mixed-integer ARO problems through multi-parametric programming. The problem is treated as a multi-level programming problem that is then solved using M-POP, a novel algorithm for the exact and global solution of multi-level mixed-integer programming problems. The main idea behind the proposed approach is to solve the lower optimization level of the problem parametrically. This will result in a set of affine decision rules optimal for the entire feasible space. A set of illustrative numerical examples are provided to demonstrate the potential of the proposed novel approach.

3 - Integrated Optimization of Proactive and Reactive Project Scheduling to Minimize Uncertain Cost

Yanting Wang, Xi'an Jiaotong University, Xi'an, China, wangyt.66@163.com

In this paper, we present an integrated proactive-reactive model to investigate the optimal fashion of integrating the two scheduling methods under the objective of minimizing the total cost. In proactive phase, resource occupation cost is incurred through inserting buffers to protect potential disruptions and adjustment cost is generated to re-optimize the schedule when disruption occurs. An improved hybrid algorithm that combines a variable neighborhood search and a probabilistic tabu search is developed. Detailed computational experiments are presented to evaluate the improvement strategies and to prove the efficiency of the hybrid algorithm.

1 - Determinants of Meaningful Usage of Health Information Technology

Jingyun Li, California State University Stanislaus, Turlock, CA, United States, jli9@csustan.edu, Indranil Bardhan

As Meaningful Use Stage 2 has been rolling out since 2014, a large portion of U.S. hospitals have finished or are undergoing the transition from paper-based medical records to electronic ones and use certified health information technology to improve healthcare quality, safety, and efficiency. Drawing on data from AHA Annual Survey Information Technology Supplement Survey and other databases, we study the characteristics of hospitals that are likely to achieve MU.

2 - Socio-emotional Support in Online Healthcare Q&A Community

Zhe Shan, University of Cincinnati, 2925 Campus Green Dr (Linder Hall) Rm 509, Cincinnati, OH, 45221, United States, zhe.shan@uc.edu, Xin Xu

In online health Q&A platforms, to be selected as best answer is not only about the quality of the response itself, but also affected by other factors such as social-emotional support. In this study, we collected data from "Yahoo! Answers" specifically in the allergies, autism, cancer and diabetes areas, and then used content analysis to encode the questions and their answers respectively. Based on the correlation analysis between different evaluation criteria for information quality, we explored whether socio-emotional support is an important factor in best answer selection.

3 - Accreditation Regime Change: Does "Announcing the Visit" Matter?

Sehwon Kang, University of Minnesota, 321 Nineteenth Avenue South, Suite 3-150, Minneapolis, MN, 55455, United States, kangx584@umn.edu

While accrediting agencies have changed their on-site accreditation survey visits from preannounced to unannounced, little extant literature has empirically examined the impact of this regime change on quality. We examine this impact on the relationship between accreditation and quality performance in US hospitals.

4 - Risk Assessment of Cyber Threats in Healthcare Devices

Arik Sadeh, HIT Holon Institute of Technology, 52 Golomb St., Holon, 58102, Israel, sadeh@hit.ac.il

A treat in a medical device may lead to various damages that can be categorized into two groups: damages to information systems and physical damages to patients. Damages may occur in different level of severity. This research is aimed to explore the importance of 60 cyber threats in healthcare devices. Data about 60 threats was collected from 30 expert respondents. Each threat was analyzed with respect to three information technology dimensions and two healthcare dimensions. The chance for occurrence of that threat was also considered. The concept of winning combinations using the algorithm of Quine-McClusky is used to determine the most important and serious threats.

1 - Weak Convergence Approach to the Multi Arm Bandit Problem

Yilun Chen, Georgia Institute of Technology, 755 Ferst Drive NW, Atlanta, GA, 30332-0205, United States, ylchen@gatech.edu

For the Bayesian multi-arm bandit problem, the optimal policy is known to be the so-called Gittins index policy. However, this policy is essentially a "black box", and it is apriori unclear how such a policy behaves, i.e. what an observer would actually see if a decision-maker implemented this policy. Using the framework of weak convergence, we shed light onto this question and the behavior of several associated stochastic processes. Time permitting, we will also discuss some related results for Thompson sampling.

2 - Optimal Solution to the Multinomial Selection Problem for Two Alternatives

Timur Tankayev, Georgia Institute of Technology, Atlanta, GA, United States, timur.tankayev@gatech.edu, Craig Aaron Tovey

The multinomial selection problem is to find a stopping policy for repeated independent trials, each of which reports a winner among competing alternatives, that has low expected cost and high probability of correct selection (PCS) of the best alternative. In 1959, Bechhofer, Elmaghraby and Morse formulated the problem as minimizing the worst case expected number of trials, subject to a lower bound on PCS and upper bound on the maximum number of trials, over all probability vectors outside an indifference zone. For the case of two alternatives, we prove that if one employs a particular probability vector known as the slippage configuration, then a linear program always finds an optimal stopping policy.

3 - Adaptive Learning with Robust Generalization Guarantees

Rachel Cummings, California Institute of Technology, 1200 E California Boulevard, MC 305-16, Pasadena, CA, 91125, United States, racheladcummings@gmail.com
Rachel Cummings, Georgia Institute of Technology, Atlanta, GA, United States, racheladcummings@gmail.com, Katrina A. Ligett, Kobbi Nissim, Aaron Roth, Steven Zhiwei Wu

The traditional notion of generalization – i.e., learning a hypothesis whose empirical error is close to its true erro – is surprisingly brittle. As has recently been noted, even if several algorithms have this guarantee in isolation, the guarantee need not hold if the algorithms are composed adaptively. In this talk, we study three notions of generalization – increasing in strength – that are robust to postprocessing and amenable to adaptive composition, and examine the relationships between them.

4 - Learning via Distributionally Robust Optimization with Optimal Transport Costs

Karthyek Murthy, Columbia University, New York, NY, United States, karthyek@gmail.com, Jose Blanchet, Yang Kang, Fan Zhang

The idea of distributionally robust optimization (DRO) has been of active research recently in Operations Research to help beat "optimizer's curse" when performing optimization under uncertainty. In this talk, we shall discuss how various machine learning estimators such as generalized Lasso estimator for linear regression, regularized logistic regression, support vector machines, etc. can be viewed under the unifying lens of DRO using optimal transport costs. In addition, for a larger class of useful models, we shall see that these DRO problems can be solved almost as fast, and in some cases even faster than, the respective traditional empirical risk minimization schemes.

1 - Upstream Versus Downstream Experience in Crowdsourcing Platforms with Interdependent Problem Domains: An Empirical Investigation

Anant Mishra, George Mason University, Fairfax, VA, 22030, United States, amishra6@gmu.edu, Nirup M.Menon, Shun Ye

Using detailed archival data from TopCoder, a crowdsourcing platform that hosts contests across software development problem domains (e.g., architecture, design, testing), we use a classification scheme to represent a contestant's experience in related problem domains on the crowdsourcing platform and examine how it impacts her performance in a contest.

2 - Revisiting the Role of Collaboration in Creating Breakthrough Inventions

Tian Chan, Assistant Professor, Emory University's Goizueta Business School, 1300 Clifton Road, Atlanta, GA, 30322, United States, tian.chan@emory.edu, Jurgen Mihm, Manuel Sosa

Using utility and design patents, we compare the effects of working alone (vs. teams) on the probability of creating breakthrough inventions. Working alone lowers performance, consistent with literature. But we also find that this performance disadvantage disappears for design. We find empirical support that the difference is due to the holisticness of design. Finally, we show that lone inventors with a large number of past collaborators significantly improve their propensity to create breakthrough innovations to the point that they outperform teams for holistic inventions.

3 - Employee Mobility and Process Innovation in Manufacturing

Philipp Cornelius, UCL.School of Management, London, United Kingdom, philipp.cornelius.12@ucl.ac.uk, Bilal Gokpinar, Fabian J. Sting

Regular employees can be a good source of innovative ideas to improve operational efficiency. We empirically investigate how mobility affects the innovation value created by the employees. We examine the immediate and long term (static and dynamic) implications as well as the role of direction of employee moves on innovation outcomes.

4 - Help or Hindrance? the Role of Familiarity in Collaborative Product Development

Murat Unal, Georgia Institute of Technology, Scheller College of Business, 800 West Peachtree Street, Atlanta, GA, 30308, United States, Murat.Unal@scheller.gatech.edu, Karthik Ramachandran, Necati Tereyagoglu

We study whether the impact of team familiarity on the outcome of a creative process differs when individuals have design and managerial roles in a video game development setting based on data of the complete careers of 13,230 individuals and 752 different video games. We find that familiarity among individuals who perform design tasks has a detrimental effect on the final performance, while higher familiarity among producers (managers) strengthens the final performance. We also analyze the impact when the source of familiarity is different from or similar to the members' current roles.

Chair: Xi Chen, University of Michigan-Dearborn, Dearborn, MI, 48128, United States, xichenxi@umich.edu

1 - Green Technology Development and Adoption: Competition, Regulation, and Uncertainty - A Global Game Approach

Xin Wang, Hong Kong University of Science and Technology, Kowloon, Hong Kong, xinwang@ust.hk, Soo-Haeng Cho, Alan Scheller-Wolf

When a government is considering tightening a standard on a pollutant, their decision often is influenced by the number of firms being able to meet the tightened standard, because a higher number indicates a more feasible standard. We study how such regulation may affect a firm's incentive to develop a new technology to reduce a pollutant. To analyze this problem, we use the global game framework recently developed in economics. We find that regulation that considers industry capability, compared with regulation that ignores it, can more effectively motivate development of a new green technology. Surprisingly, uncertainty in the payoff can also help promote development of a new green technology.

2 - Does Supply Chain Visibility Affect Operating Performance? Evidence from Conflict Minerals Disclosures

Caroline Swift, Pennsylvania State University, University Park, PA, United States, cas669@smeal.psu.edu, Suresh Muthulingam, V. Daniel Guide

Firms face the challenge of identifying and monitoring members across their supply chains because they are increasingly held responsible for their supply chain partners' actions. Consequently, supply chain visibility (SCV) is essential to mitigate risks in supply chains. We use data from the U.S. conflict mineral disclosure legislation to assess the extent of firms' visibility across their supply chains. Then, we compare the operating performance of firms with high SCV against those with low SCV. We find that firms with higher SCV benefit from improved profitability, productivity, and sales.

3 - Green Sourcing: the Role of Premium Sharing and Consulting Services

Xi Chen, University of Michigan-Dearborn, 2290 Engineering Complex, 4901 Evergreen Rd, Dearborn, MI, 48128, United States, xichenxi@umich.edu, Niyazi Taneri, Saif Benjaafar

Certified sustainable products often times enjoy a significant green premium in the retail market. In this paper, we study a retailer's use of premium sharing and consulting service offers to incentivize suppliers to exert greening efforts, which improve the chances of receiving certification and in turn capture the green premium. We also examine the case where the retailer has incomplete information about the supplier's cost of greening efforts.

4 - Compete Versus Cooperate? A Strategic Game Behind the EV Standards War

Ni Fang, University of Cologne, Cologne, Germany, fang@wiso.uni-koeln.de, Emmanuel Dechenaux, Marco Ceccagnoli

This paper studies the strategic choice facing two EV manufacturers in light of the standards war currently staged in the EV industry on whether to compete or cooperate in the development and deployment of an extensive EV charging network (a key complementary asset that helps mitigate EV range anxiety). We show that the strategic choice of standardizing EV charging systems has the offsetting effects on EV production volumes and profits. The degree of product differentiation in the EV is the key driver of the private incentives to cooperate in the provision of the complement as well as overall industry diffusion of the EV.

1 - Bayesian Fall Risk Assessment for Older Adults in Assisted Living Facilities

Suiyao Chen, University of South Florida, 5017 Patricia Court, Apt 237, Tampa, FL, 33617, United States, suiyaochen@mail.usf.edu, William D. Kearns, James L. Fozard, Mingyang Li

Fall is a devastating critical event with high incidence and mortality rate among older adults in USA. Existing approaches mainly focused on population-level modeling and evaluated average fall frequency in a certain time period. To account for individual heterogeneity of fall occurrences and provide instantaneous assessment of fall risk over time, this paper proposes a personalized fall risk assessment model using Bayesian approaches. Different performance indices are presented to evaluate fall characteristics of individuals. A real case study based on fall records from Florida assisted living facilities is provided to illustrate the proposed work and demonstrate its effectiveness.

2 - Individualized Prediction of Chronic Disease Occurrence
Qingpeng Zhang, City University of Hong Kong, Kowloon, Hong Kong, qingpeng.zhang@cityu.edu.hk, Haolin Wang, Eman Leung, Frank Y. Chen

This research proposes a tensor factorization based model to predict the onset of chronic diseases and the co-occurrence of chronic and acute diseases using patients' EHR record. With 2 year-worth of hospitalization records in a major hospital in Hong Kong, we demonstrate that the proposed model is able to predict the occurrence of new chronic diseases at individual level with superior accuracy.

3 - Two-stage Stochastic Programming Model for Resource Planning in Patient Centered Medical Homes
Mohammad Hessam Olya, Wayne State University, 71 W. Hancock St, Apt 4, Detroit, MI, 48201, United States, mhmdhesam@gmail.com, Kai Yang

One of the biggest challenges in PCMH healthcare delivery system is to find an efficient mechanism to design PCP patient panel where there is a portfolio of healthcare providers. Since the demand is unknown, a framework that incorporates workload prediction model into stochastic allocation is needed. In this study using a novel patient workload prediction model for generating different demand scenarios called multivariate hierarchical structured additive regression, a two-stage stochastic integer programming with integer recourse model for patient allocation is presented for assisting decision makers while minimizing the total cost of patient assignment to care providers at a given time.

4 - Analysis of the Infection Time from a Potential H7N9 Influenza Pandemic Outbreak
Walter A.Silva Sotillo, University of South Florida, 4202 E Fowler Ave, Tampa, FL, 33620, United States, silvasotillo@mail.usf.edu, Mingyang Li, Tapas K. Das

Avian influenza viruses have been affecting human populations for a long time. Since then, other mutations and reassortments of the influenza viruses have emerged causing pandemics. Researchers have developed early estimates of some of the epidemiological parameters to characterize H7N9 virus in China but infected persons appear everyday. In this research we analyzed the distribution that follows the infection time from a potential H7N9 influenza pandemic outbreak using an agent-based (AB) simulation model. We analyzed some continuous probability distributions and conclude that the lognormal distribution provides a better fit estimate to the time to be infected.

5 - A Multi-state Semi-Markov Model of Patient Flow in Long-term Care Network
Hambisa Keno, BAE Systems, Burlington, MA, United States, hambisa.keno@gmail.com, Nan Kong, Steven Landry, Christopher M. Callahan

Long-term care (LTC) represents an expensive segment of the healthcare system. It is essential to carefully characterize patient flow in the LTC network, with implications on model-based policy evaluation. We extend a length of stay based model to characterize patient flow across the network via an multi-state semi-Markov (MSSM) model. We investigate the order of the embedded Markov chain that best characterizes patient transition data. We limit the regression parameters in the model to casual variables through Bayesian network structure learning on care transitions. We diagnose sensitivity of the model parameters and compare goodness-of-fit of the model for different embedded Markov chains.

1 - Using Inverse Optimization to Evaluate Knowledge-based Planning Methods for Oropharyngeal Cancer
Aaron Babier, University of Toronto, 153 Robert Street, Unit 2B, Toronto, ON, M5S.2K6, Canada, ababier@mie.utoronto.ca, Justin James Boutilier, Andrea L. McNiven, Timothy Chan

Knowledge based planning (KBP) is often used to predict clinically acceptable dose volume histogram (DVHs), however the predictions may be undeliverable. We develop two KBP methods to predict DVHs for over 200 oropharyngeal cancer patients, and use an inverse optimization model to reverse engineer fluence deliverable maps from the predictions. To illustrate the impact that a prediction has on our pipeline, we compare the plans that were reverse engineered from each KBP method. Each plan is also compared to a clinical plan to validate our fluence maps and demonstrate the role inverse optimization can play in an automated planning pipeline.

2 - Robust Hypoxia-based Radiation Plan Optimization
Arkajyoti Roy, Bowling Green State University, 349 Business Administration Building, Applied Statistics and Operations Research, Bowling Green, OH, 43403, United States, aroy@bgsu.edu, Omid Nohadani

Low oxygen concentration reduces radiosensitivity of tumor cells, adversely affecting radiation treatments. Reoxygenation leads to uncertain temporal changes in cell oxygenation, ranging from short-term fluctuations due to perfusion to gradual changes from angiogenesis. In this work, a time-dependent uncertainty set is employed to model the reoxygenation progression. A robust optimization model incorporating the uncertainty set is solved for a set of clinically realistic reoxygenation scenarios. The proposed method is evaluated in comparison to current clinical practice using a prostate case.

3 - Spatioteporally Integrated Radiotherapy with Treatment Length Update
Ali Ajdari, University of Washington, Seattle, WA, 98199, United States, ajdari@u.washington.edu, Archis Ghate

In a typical formulation of the spatiotemporally integrated radiotherapy, the number of treatment sessions (N) has to be decided prior to the beginning of the actual treatment. However, taking advantage of the new imaging techniques, a more dynamic treatment planning can adapt to the tumor's response thoughout the treatment course and determine N on the fly. In this study, we propose a method to dynamically determine the optimal number of remaining sessions, and reoptimize the treatment plan in each session accordingly. Solutions obtained in this manner have more flexibility to the tumor's evolution and could potentially result in higher biological effective dose.

4 - Optimization of Radiation Therapy Fractionation Dose Considering the Biological Effects
Azin Khabazian, University of Houston, 5465 Braesvalley Dr. Apt 566, Houston, TX, 77096, United States, akhabazian@uh.edu, Gino J. Lim

The goal in fractionation radiation therapy is to maximize tumor-damage while limiting toxic effects of radiation on nearby healthy anatomies. This is achieved through a sequential radiation treatment process in which the treatment plan can be modified using a regular feedback of measurements. In this study, we develop a chance-constrained programming (CCP) framework under a probabilistic description of dose delivery to optimize the fractionation dose by adjusting to tumor response in each fraction of treatment planning. We evaluate the model in the context of tumor coverage and normal tissue sparing and numerically demonstrate its superiority over the traditional treatment planning.

Nonprofit Operations

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Milind Sohoni, Indian School of Business, Hyderabad, 500032, India, milind_sohoni@isb.edu

1 - Improving Societal Outcomes in the Organ Donation Value Chain
Priyank Arora, Georgia Institute of Technology, 800 W. Peachtree Street NW, Atlanta, GA, 30308, United States, priyank.arora@scheller.gatech.edu, Ravi Subramanian

We examine a principal-agent problem in the cadaver organ donation value chain (ODVC) where the principal in our case is a social planner that has an overall quality-adjusted-life-year improvement objective. The agents include a non-profit organ procurement organization (OPO) with a volume-of-care objective and a profit-maximizing hospital (trauma center). While the majority of the healthcare operations management literature focuses on the demand side of the ODVC, we develop an analytical model to study the effects of contextual parameters and operational decisions of the supply-side entities (OPO and hospital) on their respective payoffs and on societal outcomes.

2 - Payment for Results - Funding Non-profit Operations
Sripad K. Devalkar, Indian School of Business, Ac3 L1 Room 3114, Hyderabad, 500032, India, sripad_devalkar@isb.edu, Milind Sohoni, Neha Sharma

Payment for results (PfR), with funding contingent on actual results delivered, has been proposed as a mechanism that allows donors to channel funds to more efficient NPOs. However, many NPOs are financially constrained and need an intermediary to provide the funds required to implement the project upfront. We compare the performance of a PfR mechanism involving a social planner, intermediary and NPO, with that of a traditional upfront funding mechanism involving only the social planner and NPO. For risky projects, we find that the social planner's expected utility under traditional funding can be higher compared to when using PfR.

3 - Supply Constrained Location-distribution Problems in Public and Nonprofit Settings: A Fractional Programming Approach

Chong Hyun Park, Southern New Hampshire University, Manchester, NH, United States, c.park1@snhu.edu, Gemma Berenguer

There is a need to design location-distribution problems in public and nonprofit contexts where limited resources have to be allocated to different demand regions and, thus, a combination of efficiency and equity goals can rightfully be considered. We propose the use of a new inequity measure related to Gini coefficient that is based on the relative utility obtained by each demand region given a certain supply allocation. We suggest a novel bi-objective integer linear fractional programming approach to solve the suggested supply constrained location-distribution models and show the suggested algorithm can solve the problems in polynomial time. A food crisis in Angola is presented as a case study.

Auctions/Mechanism Design

Contributed Session

Chair: Rad Niazadeh, Stanford University, Palo Alto, CA, United States, radniazadeh@gmail.com

1 - Combinatorial Auction Mechanism for Freight Information Platform with Quoted Price Uncertainty

Yuting Zheng, Huazhong University of Science and Technology (HUST), Wuhan, China, ytzheng@hust.edu.cn, Jianbin Li, Peng Hu

We consider a combinatorial auction mechanism for O2O freight information platform with quoted price uncertainty. This research question derived from a O2O freight platform we field investigated for half a year. Meanwhile, a series of numerical examples with real data are enumerated in this paper with the different approaches to cope with the uncertainty of carriers' quoted price which may enlighten the managers in related industry.

2 - Optimal Allocation of Budget for Incentive Structure Design in a Resource Sharing Network

Pu Yang, Cornell university, 292 Rhodes Hall, Ithaca, NY, 14850, United States, py75@cornell.edu, Peter Frazier, Krishnamurthy Iyer

We propose a spatial temporal model for network economic settings with heterogeneous locations, and characterize a mean field equilibrium in this system. We study the problem of how to optimally allocate a budget of incentives to maximize a system level objective, by alternating the equilibrium behavior of agents in the system through subsidies or penalties. We show that the intractable problem of finding the optimal payment structure can be reduced to a problem of finding the optimal equilibrium strategy achievable with the budget, and the latter problem is a standard constrained optimization problem with a low dimension domain that could be solved via mainstream constrained optimization methods.

3 - Preferences and Decision Support in Competitive Bidding

Philippe Gillen, Center for European Economics (ZEW), L7,1, Mannheim, 68161, Germany, gillen@zew.de, Nicolas Fugger, Alexander Rasch, Christopher Zeppenfeld

We examine bidding behavior in first-price sealed-bid and Dutch auctions, which are strategically equivalent under standard preferences. We investigate whether the empirical breakdown of this equivalence is due to non-standard preferences or due to the different complexity of the two formats (i.e. different levels of math./individual sophistication). We elicit measures of individual preferences and then manipulate complexity by offering various levels of decision support. Our results show that the strategic equivalence only breaks down in the absence of decision support. This indicates that the empirical breakdown is caused by differing complexity rather than non-standard preferences.

4 - Bernoulli Factories and Blackbox Reductions in Mechanism Design

Rad Niazadeh, Postdoctoral Researcher, Stanford University, Palo Alto, CA, United States, radniazadeh@gmail.com, Shaddin Dughmi, Jason Hartline, Robert Kleinberg

We provide a polynomial time reduction from Bayesian incentive compatible mechanism design to Bayesian algorithm design for welfare maximization problems. Unlike prior results, our reduction achieves exact incentive compatibility for problems with multi-dimensional and continuous type spaces. The key technical barrier preventing this in prior black-box reductions is that repairing violations of incentive constraints requires understanding the distribution of the mechanism's output. We overcome this barrier by employing and generalizing a computational model in the literature called "Bernoulli Factories", which is about simulating a new coin from old ones by only sampling.

5 - Ants for Auctions – Solving the Winner Determination Problem using Ant Colonies

Abhishek Ray, PhD Scholar, Purdue University, 401 S Grant Street, West Lafayette, IN, 47907, United States, ray52@purdue.edu, Mario Ventresca

At the fundamental level, any combinatorial auction can be treated as an efficient allocation problem widely studied in integer programming. Determining winner in such auctions is demonstrably NP-Complete. Previous work in estimating a winner in combinatorial auctions employs a depth-first branch and bound approach that imposes upper bounds on contribution of unallocated items to the maximum revenue for the auctioneer. Our approach differs drastically since we employ a probabilistic nature-inspired search heuristic that uses the concept of stigmergy to explore and exploit the search landscape.

6 - Online Auctions and Multiscale Learning

Rad Niazadeh, Postdoctoral Researcher, Stanford University, Palo Alto, CA, United States, radniazadeh@gmail.com, Sebastien Bubeck, Nikhil Devanur, Zhiyi Huang

We consider revenue maximization in online auctions and pricing. A seller sells an identical item in each period to a new buyer, or a new set of buyers. For the online posted pricing problem, we show regret bounds that scale with the best fixed price, rather than the range of the values. We also show regret bounds that are scale free, and match the offline sample complexity, when comparing to a benchmark that requires a lower bound on the market share. To obtain this, we generalize the learning from experts and multi-armed bandit problems to their "multi-scale" versions, where the reward of each action is in a different range, and the regret w.r.t. a given action scales with its own range, rather than the maximum.

Incentives in Queueing and Sharing Platforms II

Sponsored: Manufacturing & Service Oper Mgmt, Service Operations

Sponsored Session

Chair: Rouba Ibrahim, University College London, London, WC1E 6BT, United Kingdom, rouba.ibrahim@ucl.ac.uk

Co-Chair: Amy R Ward, University of Southern California, Los Angeles, CA, 90089-0809, United States, amyward@marshall.usc.edu

1 - Labor Platforms for On-demand Services

Saif Benjaafar, University of Minnesota, 111 Church Street SE, Department of Industrial and Systems Engr, Minneapolis, MN, 55419, United States, saif@umn.edu, Jian-Ya Ding, Guangwen Kong, Terry Taylor

We study consumer and labor welfare in on-demand service platforms that rely on self-scheduled workers. The platform decides on wages and prices knowing that customers are price- and delay- sensitive and agents have reservation wage rates that depend on their availability.

2 - Designing Efficient Budget-constrained Incentive Schemes: To Compete or to Cooperate?

Ragavendran Gopalakrishnan, Research Scientist, Conduent Labs India, Etamin Block, 4th Floor, Wing-A, Prestige Technology Park II, Bangalore, 560103, India, ragavendran.gopalakrishnan@conduent.com, Sabitha Devarajulu, Rahul Ghosh

We study the design of real-world performance-based incentive schemes, which are necessarily budget-constrained, must be simple to understand and implement, and satisfy some fairness criteria. The resulting competition among agents for incentives is modeled as a noncooperative game. We characterize budget-constrained performance maximizing incentive schemes, and find that the maximum performance is a concave function of the available budget. We also study competitive vs. cooperative fairness among high and low performing agents to quantify the efficiency loss in moving from Nash to dominant strategy equilibrium. We conclude with additional insights obtained from numerical experiments.

3 - Pricing in a Two-sided Market with Time-sensitive Customers and Suppliers

Philipp Afeche, University of Toronto, Rotman School of Management, 105 St. George Street, Toronto, ON, M5S.3E6, Canada, afeche@rotman.utoronto.ca, Mustafa Akan

We consider a firm that matches stochastically arriving and time-sensitive customers and suppliers. Agents are rational and choose whether to enter the market upon arrival. Customers and suppliers differ in their arrivals rates, rewards from matching, and waiting costs. The matching is instantaneous and frictionless. We characterize the structure and performance of the profit-maximizing and socially optimal pricing policies.

4 - Independent Contractors or Full-time Employees? On Staffing a Blended Workforce.
Rouba Ibrahim, University College London, MS& I Department, UCL, Gower Street, London, WC1E 6BT, United Kingdom, rouba.ibrahim@ucl.ac.uk, Jing Dong

The rise of the blended workforce is identified as one of the top workplace trends in 2017. A blended workforce melds independent contractors or freelancers with permanent employees. We study optimal sta ng decisions in service systems with a blended workforce, and characterize the pertinent trade-offs.

Simulation and Optimization

Contributed Session

Chair: Keli Feng, South Carolina State University, Orangeburg, SC, United States, kfeng1@scsu.edu

1 - A State Dependent Inventory Policy for Multi Period, Multi Stage Systems
Anna-Lena Sachs, Professor, University of Cologne, Albertus-Magnus-Platz, Cologne, 50923, Germany, anna-lena.sachs@uni-koeln.de, Stewart Liu, Stefan Minner, Philip Kaminsky

Inventory management for perishable products such as fruit and vegetables is a challenging task for retail managers. We investigate a retail chain that owns several stores and keeps inventory both at the stores and at a central warehouse. We determine the optimal inventory policy as a function of external variables such as price, weekday and weather. By integrating forecasting and inventory optimization using robust optimization and a gradient-search algorithm, we are able to solve this complex problem for a large number of stores and variables

2 - Multiperiod Inventory Management with Advance Supply Contracts
Sercan Demir, Teaching/Research Assistant, University of Miami, 1251 Memorial Drive #268, Department of Industrial Engineering, Coral Gables, FL, 33146, United States, s.demir@umiami.edu, Mazhar Arikan, Murat Erkoc

We study a multi-period inventory control problem of a seasonal product where the demand for the product is stochastic and non-stationary across periods. The demand distribution across the planning horizon is shaped by a market signal that is random at the beginning of the planning horizon. The firm has the option of contracting its supplies before the realization of the market signal to benefit from price discounts. It is also possible for the firm to replenish its inventories during the selling season by paying higher spot market prices. Our research is motivated by applications in cruise line industry where contracts are made before the final number of bookings is realized.

3 - A Two-phase Derivative-free Optimization Algorithm for a Process Governed by Non-linear Algebraic Partial Differential Equations
Ishan Bajaj, Texas A&M.University, 503 Cherry St., College Station, TX, 77840, United States, ishan.bajaj@tamu.edu, Shachit S. Iyer, Priyadarshini Balasubramanian, Faruque Hasan

A data-driven two-phase trust-region based optimization algorithm is proposed to solve problems where the constraints and objective function cannot be expressed analytically in terms of decision variables. In the first phase of the algorithm, a feasible point is obtained and in the second phase, the objective function is decreased while maintaining feasibility. The algorithm is applied to optimize the design and operating conditions of an integrated carbon capture and conversion process such that constraints related to product quality and emissions are satisfied and cost is minimized.

4 - Continuous Inspections Assessing Economic Feasibility of Strategies under a Changing Demand Distribution
Anh Ta, University of North Texas, Denton, TX, 76201, United States, Anh.Ta@unt.edu, Robert Pavur

Continuous inspections is an essential part of many processes. Minimizing the long run cost is an important criterion in selecting a strategy. This research assesses proposed continuous auditing methodologies by using a Monte Carlo Simulation approach under conditions that may be changing over time. Estimating the parameters for the rate of occurrences is an important step in using effective continuous inspection techniques. Applications to using this methodology in supply chain inspections are examined.

5 - Bayesian Optimization with Gradients
Matthias Poloczek, Cornell University, 272 Rhodes Hall, 136 Hoy Road, Ithaca, NY, 14853, United States, poloczek@cornell.edu, Jian Wu, Andrew Wilson, Peter Frazier

Bayesian optimization has proven successful for global optimization of expensive-to-evaluate, multimodal functions. However, it typically does not use derivative information. In this talk, we show how Bayesian optimization can exploit derivative information to decrease the number of objective function evaluations required for good performance. In particular, we develop a novel algorithm, the derivative-enabled knowledge-gradient, that provides state-of-the-art performance compared to a wide range of optimization procedures with and without gradients, on benchmarks including logistic regression, kernel learning, and k-nearest neighbors.

6 - Performance Comparison under Two Replenishment Policies in Master Production Scheduling with Demand Uncertainty
Keli Feng, Associate Professor, South Carolina State University, 300 College Street NE, Department of Business Administration, Orangeburg, SC, 29117, United States, kfeng1@scsu.edu

We study a single end-product master production scheduling problem with supply capacity limits and dynamic stochastic demand. Our replenishment options include using an order quantity vector or using order-up-to levels. The performance measures we consider include service levels, average cost, standard deviation of cost, expected upside risk, "cost-at-risk", and probability of exceeding a target cost. Using simulation-based optimization method, we perform a computational experimental design to explore the impact of parameters on performance measures under both replenishment policies.

Decision Support Systems

Contributed Session

Chair: Gizem Erdinç, erciyes university, kayseri, Turkey, gizemerdincc@gmail.com

1 - Using a Moving Reference Approach for Measuring Balance in Resource Allocation Problems
Hale Erkan, Bilkent University, Bilkent University, Engineering Department, Ankara, 06800, Turkey, hale.erkan@bilkent.edu.tr, Ozlem Karsu

We consider a resource allocation settings where there are several categories of projects, each with uncertain cost and benefit values. The decision maker (DM) tries to determine the projects to fund given a limited budget. The two objectives are maximizing efficiency and balance among categories. Balance is measured with respect to a reference distribution (RD), which changes as used budget changes. We propose a biobjective robust optimization model and find Pareto solutions using the E-constraint method. Our results show that considering balance explicitly provides useful insights to the DM.

2 - Context-aware Process and Organization Analytics: Extending Business Analytics Towards More Effective and Flexible Organization
Seunghoon Lee, PhD Candidate, POSTECH, 77, Cheongam-ro Dept. of Industrial and Management Engineering, Pohang, 37673, Korea, Republic of, frhyme@postech.ac.kr, Injun Choi

Recently, as related technologies such as machine learning has been advanced rapidly, interest in business analytics (BA) has been significantly increased in academia and industry. However, existing BA approaches only consider organization from limited perspective thus fail to improve the actual performance of organization from holistic view point. Thus, we propose a new BA paradigm by developing the Context-aware Process and Organization Analytics to flexibly cope with various contextual changes in the complex environment. In particular, we define an ontology that can represent situational knowledge of the organization by identifying the relationships among organizational elements.

3 - Fuzzy Risk Analysis for Construction Projects
Gizem Erdinç, Erciyes University, Kayseri, Turkey, gizemerdincc@gmail.com, Feyza Gurbuz

The construction industry serves humanity in a subjective and risky environment in comparison with other industries. In contrast to automation, almost every processes are done by human. Therefore, project managers should overcome much more uncertainties and probability in solving management problems of construction projects. A risk analysis was presented while adopting some criteria were affect the outcome performance of project such as cost, time quality, performance and safety. The impact levels of criteria and emergence ratings were calculated using Fuzzy Sets and ranked. In this way, decision makers who work in management level in companies can make better and more accurate decisions.

Data-driven Research of Hospital Workflow and Performance

Sponsored: Manufacturing & Service Oper Mgmt, Healthcare Operations

Sponsored Session

Chair: Jonas Oddur Jonasson, MIT Sloan School of Management, MIT Sloan School of Management, Cambridge, MA, 02142, United States, joj@mit.edu

1 - Staff Planning for Anesthesiologists

Sandeep Rath, University of North Carolina at Chapel Hill, CB #3490, McColl Building, McColl 4705, Chapel Hill, NC, 27599, United States, sandeep@unc.edu, Kumar Rajaram

Staff planning for human resources like anesthesiologists at hospitals takes place sequentially, where planning is done for regular staffing as well as reserve capacity. The staff planners balance the expected overtime, under-utilization costs as well as the cost of keeping staff on reserve. Some of these costs are not explicitly known. We employ a structural estimation model to infer these implicit costs and subsequently find heuristic solution for the medium term staff planning. We apply this approach to staff planning for anesthesiologists.

2 - Proactive Customer Service

Kraig Delana, London Business School, PhD Program Office, London, NW1 4SA, United Kingdom, kdelana@london.edu, Nicos Savva, Tolga Tezcan

We study a service setting where the provider may learn about customers' future service needs and initiate service for these customers proactively if they are flexible with respect to the timing of service delivery. Utilizing both exact and asymptotic analysis, we find that proactive service can generate significant reduction of delays for customers. Despite this, we find that customers are less willing to be flexible compared to social optimum because of a positive externality - flexible customers benefit not only themselves but inflexible customers as well. Hence to achieve the benefits of proactive service, providers may have to incentivize customers to overcome this economic friction.

3 - Hospital Finances and Operations

Christopher J. Chen, London Business School, Regent's Park, London, NW14SA, United Kingdom, cchen@london.edu, Nicos Savva

We analyze how changes in hospital spending affects readmissions and mortality, and lay the foundation for studying the impact of funding cuts on operational decisions such as staffing levels and mix. Combining non-profit tax filings with data from the Centers for Medicare & Medicaid Services (CMS) on hospital characteristics and patient outcomes, and using instrumental variable estimation to address endogeneity in hospital spending, we find that increases in spending per patient in select cost centers have a positive impact on aggregate outcomes. Our findings indicate a potential mechanism through which spending cuts impact patients and sets up further tests on the resource pecking order.

4 - Data Analytics on the Operations of a Radiology Workflow Platform

Gonzalo Romero, University of Toronto, Toronto, ON, Canada, gonzalo.romero@rotman.utoronto.ca, Timothy Chan, Nicholas Howard, Saman Lagzi

Most hospitals in the U.S. follow an unstructured process for assigning images to radiologists, where each doctor has ample freedom to select the next image to work on out of a common pool. This can result in long processing times and sub-optimal use of the specialists' time. A centralized workflow platform can address this problem by routing the right image to the right doctor at the right time. Motivated by our ongoing collaboration, we analyze a large and unique dataset from the operations of a radiology workflow platform, providing interesting and novel clinical findings.

Optimization Modeling in Supply Chains

Sponsored: Manufacturing & Service Oper Mgmt, Supply Chain

Sponsored Session

Chair: Joel Goh, Harvard Business School, Boston, MA, 02163, United States, jgoh@hbs.edu

1 - Retailing with 3D Printing

Yao Cui, Cornell University, Ithaca, NY, United States, yao.cui@cornell.edu, Li Chen, Hau Leung Lee

We consider a firm that produces and sells products in two channels, an online store and a traditional store. The firm may use the traditional production technology or adopt the 3D printing technology in the online channel or in both channels. We study 3D printing's impacts on the firm's product offering and pricing decisions, as well as the firm's supply chain operations.

2 - Inventory Optimization for Fulfillment Integration in Omnichannel Retailing

Aravind Govindarajan, Ross School of Business, University of Michigan, 645 Hidden Valley Club Drive, Apt. 303, Ann Arbor, MI, 48104, United States, arav@umich.edu, Amitabh Sinha, Joline Uichanco

Omnichannel refers to the seamless integration of a retailer's channels such as brick-and-mortar and e-commerce. Using analytical models, we study three basic omnichannel fulfillment systems varying in the level of integration between in-store and online demands, and obtain optimal order quantities for the single period, two-store case. We extend our analyses to a network of stores and fulfillment centers, developing an asymptotically near-optimal heuristic which provides significant cost savings over naive strategies. Finally, we discuss extensions to the multi-period case under lost sales.

3 - Optimal Control and Value of Reverse Logistics in Supply Chains with Multiple Flows of Product

Ozalp Ozer, The University of Texas at Dallas, 800 West Campbell Road, Sm30, Richardson, TX, 75080-3021, United States, oozer@utdallas.edu, Alexandar Angelus

We formulate and solve a finite-horizon, multiechelon inventory model to jointly optimize regular ordering, expedited ordering and reverse-ordering decisions. We identify the structure of the optimal policy that achieves the decomposition of the objective cost function into a sequence of single-dimensional subproblems. We generalize our results to settings when excess inventory can be sold off to secondary markets at each stage. Our results allow us to quantify the value of reverse logistics under a variety of supply chain structures, and establish that reverse logistics and expediting can be either complements or substitutes depending on other elements of the supply chain.

4 - Intermediation in the Supply of Agricultural Products in Developing Economies

Ehsan Valavi, Harvard Business School, 114 Western Avenue 2203C, Boston, MA, 02134, United States, evalavi@hbs.edu, Kris Johnson Ferreira, Joel Goh

The agricultural industry has been growing in developing economies, yet farmers continue to struggle. One reason for this is that farmers bear the risk of mismatched supply and demand, since farmers must make planting and harvesting decisions prior to knowing the price they can get for their crop at an auction. Recently, e-intermediaries have emerged as an alternative channel to the auction for which farmers can sell their crop; e-intermediaries use technology to inform farmers about a fixed crop price prior to harvest. We study the impact that e-intermediaries have on the supply chain.

Operations Management

Contributed Session

Chair: Yuqiao Cheng, University of Houston, Houston, TX, United States, chengyuqiao126@gmail.com

1 - The Operational Implications of Introducing New Products into Consumer Packaged Goods Supply Chains: the Case of a Spanish Manufacturer

Leonardo Laranjeira Gomes, PhD Candidate, MIT-Zaragoza International Logistics Program, Calle Bari 55, Edificio Nayade 5, Zaragoza, 50197, Spain, leogomes@mit.edu, Rafael Diaz

We analyze and measure the operational impact of introducing new products into the supply chain of a consumer packaged goods manufacturer. By conducting an in-depth statistical analysis of a Spanish poultry products company, we identified factors that impact its operational performance and should be considered when analyzing exploration versus exploitation trade-offs.

2 - Selecting Procurement Auction Mechanisms

Andreas Gernert, EBS.University, Burgstr. 5, Oestrich-Winkel, Germany, andreas.gernert@ebs.edu, David Wuttke, H. Sebastian Heese

We compare two procurement auction mechanisms for innovative products. We examine when buyers should first invite multiple suppliers to engage simultaneously in R&D before selecting the winner as opposed to selecting first one supplier who then engages with higher effort in R&D.

3 - Capacity Expansion Strategies in Cloud Computing Environment
Mohammad Ebrahim Arbabian, PhD Student, University of Washington, 4120 Brooklyn Ave NE unit 503, # 4, Seattle, WA, 98105, United States, arbabian@uw.edu, Shi Chen, Kamran MoeinZadeh

We study the problem of deploying new servers in a cloud company. We consider a continuous review system and present the optimal policy which minimizes the total discounted cost rate in finite and infinite horizon settings. Moreover, the optimal server specifications to be ordered each cycle given the current servers are derived.

4 - Managing Innovation Pipeline by Small Firm Researchers
Mengyang Pan, Southwest University of Finance and Economics, 692 Riverview Drive, Apt 128, Columbus, OH, 43202, United States, pan.295@osu.edu, Aravind Chandrasekaran

Small firm researchers may have multiple R&D projects in their pipeline, that are in various development stages and may or may not have substantial external collaborations. This research intends to explore the challenges for them induced by limited time and resources, as well as IP protection risks. Our analyses of longitudinal data suggest the timing and extent of external collaboration in a portfolio of projects can be an important decision for success.

5 - Dynamic Task Allocation with Learning and Forgetting
Thomas Vossen, University of Colorado-Boulder, Leeds School of Business, UCB419, Boulder, CO, 80309, United States, thomas.vossen@colorado.edu, Peter Letmathe

We consider a setting where tasks arrive randomly over time for possible processing. Incoming tasks can be allocated to (human) resources, whose productivity depends on the number of tasks processed by the resource before (learning) and is impacted by changes in the workforce over time (forgetting). We formulate the task allocation problem as a weakly coupled stochastic dynamic programming problem, and use a Lagrangian Relaxation approach to derive heuristic allocation policies. We evaluate the flexibility and resilience that emerge from these policies, and analyze how various environmental factors impact performance.

6 - Linking Operations Characteristics to Operations Strategy in Hospital Merger and Acquisitions
Yuqiao Cheng, University of Houston, 4800 Calhoun Rd, Houston, TX, 77004, United States, chengyuqiao126@gmail.com, Xiaosong David Peng

We present research examining the impact of hospital M&A at the operational level. The impact may stem from similarities in operational characteristics and a more focused operations strategy. We analyze archival data from various sources using Difference in Differences analysis and conduct case studies to present our findings.

Big Data and Queueing Networks

Sponsored: Applied Probability

Sponsored Session

Chair: Cathy Honghui Xia, Ohio State University, Ohio State University, Columbus, OH, 43210, United States, xia.52@osu.edu

1 - Queueing-theoretic Models for Data Center Performance
Mor Harchol-Balter, Carnegie Mellon University, 5000 Forbes Avenue, Computer Science Dept, Pittsburgh, PA, 15213, United States, harchol@cs.cmu.edu

Data Centers are a never-ending source of interesting performance problems for queueing theorists. In this talk we will introduce problems ranging from Job Replication to Hadoop Scheduling to Optimizing Parallelism. For each problem, we will propose queueing-theoretic models (and some solutions), with an emphasis on realistic assumptions. This talk is meant to bridge Computer Systems optimization and OR modeling/analysis.

2 - Queueing Control using Learning Based Semi-online Algorithms
Jin Xu, Texas A&M.University, 3120 Texas A&M.University, College Station, TX, 77840, United States, jinxu@tamu.edu, Natarajan Gautam

Motivated by applications in smart reconfigurable manufacturing, we consider queueing systems where workload is revealed before service with the help of IoT. The objective is to minimize sojourn time for jobs under constraints of order of service and server conditions. We propose a learning-based semi-online algorithm to solve the problem and demonstrate its performance.

3 - Throughput Scalability of Large Parallel and Distributed Processing Systems with Advancing Capabilities
Yun Zeng, The Ohio State University, Columbus, OH, United States, zeng.153@buckeyemail.osu.edu, Cathy Honghui Xia

Parallel and distributed processing systems have expanded in great scale in cloud computing and big data analytics. A critical issue concerns the throughput scalability: whether or not the throughput sustains as the systems scale in size. This issue is highly non-trivial as the systems can have complicated structures and advancing capabilities. We present necessary and sufficient conditions on throughput scalability of parallel and distributed processing systems with arbitrary structure and generally distributed service times. In particular, we present conditions under which scaling storage and scaling processing speed can recover throughput even when the system is not well-structured.

1 - Assortment Decisions with Substitutability and Complementarity
Xi Shan, University of Texas at Dallas, Richardson, TX, 75080, United States, xxs130630@utdallas.edu, Dorothee Honhon, Suresh P.Sethi

We consider the assortment plan of a retailer with complementary or substitutable goods/categories. We find that increasing the variety in one category can stimulate more variety in the other complementary category. For a single category retailer, increasing variety for that category will attract more customers but cost more on inventory. Now for a retailer with complementary categories, increasing variety for one category will not only bring more attraction and inventory cost, but also generate more customers having the willingness to visit the other category. And the other category can take this chance to earn more profit.

2 - Dynamic Optimization Models for Sourcing Problems
Nilofar Varzgani, PhD Candidate, Rutgers Business School, 113 Harrison Avenue, Apt 204, Harrison, NJ, 07029, United States, nilofarv@scarletmail.rutgers.edu, Michael N.Katehakis

When manufacturers are sourcing components there always comes the dilemma of deciding between having 1 supplier and using volume leverage to get the best possible cost advantage. On the other hand, this poses a supply disruption risk . Therefore, most manufacturers opt for the multi-supplier model where they have dual or more procurement requirements. The decision problem faced by the manufacturing company is twofold; election problem and volume allocation problem. We solve for this optimal selection and allocation problem as a one step process using a dynamic programming framework in a contract manufacturing framework.

3 - OEM Selling Channels and Supply Chain Performance
Chia-Wei Kuo, National Taiwan University, 85 Sec 4, Roosevelt Rd, Taipei, 106, Taiwan, cwkuo@ntu.edu.tw

This paper studies how an OEM's selling channel can serve as an instrument to enhance its product accessibility in the local market for developing countries. we find that authorizing the OEM selling channel can be a win-win strategy for both the brand (gaining more market share in the international market) and the OEM (earning more profits) because of economy of scales that lowers unit production costs.

4 - Renegotiation in Procurement Auctions with Endogenous Liability
Wei-Shiun Chang, National Cheng Kung University, No.1, University Road, Tainan City 701,, 701, Taiwan, wschang@mail.ncku.edu.tw, Rhea Salonga

The winners in the procurement auctions may find the auction prices unfavorable due to the Winner's Curse phenomenon. Practically buyers offer an opportunity to winning sellers to renegotiate the price in such a case in the hope of preventing sellers from bankrupt. We derive that sellers would be better off to delegate a subsidiary with less liability to bid on behalf of parent companies when renegotiation is allowed at the expense of procurers. We then test the theoretical predictions with experiments. The findings have important implications for procurement policy reform as well as to the procurers' selection of mechanisms (i.e. whether to use renegotiation) to resolve potential bankruptcy issues.

1 - A Social Network Perspective on user Adaptation Toward its System in Organizations

Yi Wu, Tianjin University, Tianjin, China, yiwu@tju.edu.cn

Social networks are vital mechanisms for users to adapt to changes induced by a new IT system in organizations. However, the effect of social networks on post-adoption IT use is not well understood. Drawing on coping theory and the social network literature, a cognitive-affective-behavioral classification of user adaptation is developed, and seeking-network closure and giving-network closure are identified as key network characteristics pertinent to post-adoption IT use. Thereafter, this paper establishes a theoretical link from network characteristics to post-adoption IT use through the underlying mechanisms of user adaptation.

2 - Doctor's Looking Glass Self: Empowerment and Satisfaction through Telemedicine

Sumate Permwonguswa, University of Colorado Denver, 3 30 E.10th Ave, Apt 506, Denver, CO, 80203, United States, sumate.permwonguswa@ucdenver.edu, Jiban Khuntia

Telemedicine provides higher accessibility for patients to healthcare. Yet, not many doctors adopt telemedicine in their practices. Analogous to patient empowerment, doctor empowerment may be a driver towards telemedicine adoption. We explore the role of empowerment on practice satisfaction of a doctor through the use of telemedicine. Relationships between the three types of empowerment on practice satisfaction have been studied empirically. We also argue that the relationships will be stronger when spatial and power distance orientations in the practice setting are less.

1 - Shipping Peak Demand for Online Sellers: Reserve and Surcharge

Ju Myung Song, Rutgers Business School, PhD Program, 1 Washington Park, Room 430C, Newark, NJ, 07102, United States, jumyungsong@gmail.com

Online retailing is changing the landscape of retail industry in countries as Amazon's market cap has recently doubled that of Wal-Mart in the US. Different from brick and mortar, online sellers rely on 3rd party logistics for the delivery of the goods but the hugely spiked demand during holiday seasons (Christmas in the US, Singles' day in China) poses a substantial challenge for the 3PLs to deliver on time. To better manage demand, 3PLs such as UPS, require the sellers to make reservation and to pay a surcharge for extra work. In this paper, we discuss how these shipping arrangements may affect the online sellers' inventory decisions, how to coordinate the channel for the sellers and shippers to win-win.

2 - The K-shortest Origins Problem

Stefan Poikonen, PhD Candidate, University of Maryland-College Park, 3406 Tulane Dr., Apt 22, Hyattsville, MD, 20783, United States, spoikone@math.umd.edu, Larry Levy, Bruce L. Golden

The k-shortest origins problem will be introduced. As brick-and-mortar retailers increase their online presence, a frequent option presented to online shoppers is to have their orders available for pick-up at a nearby store, because the "last mile" of delivery represents a large portion of the supply chain cost. A customer may be presented with a list of the k nearest pickup locations. Amazon has built over 1700 Amazon Locker locations expressly for this purpose. We present a method to compute the k nearest pickup locations for all customers rapidly. A single call of a modified version of Dijkstra's Algorithm and a phantom "supernode" are used.

3 - Heuristics for Chute and Dock Assignment Problem in a Shipping Area of Cross-docking Center

Takashi Irohara, Professor, Sophia University, 7-1 Kioi-cho, Chiyoda-ku, Tokyo, 102-8554, Japan, irohara@sophia.ac.jp

In this study, genetic algorithm based heuristic with local search is proposed to solve chute and dock assignment problem in a shipping are of cross-dock center. This problem is formulated as mixed integer programming problem to minimize material handling cost from chute to dock and the congestion of the dock in the shipping area. Numerical experiment was conducted to show the effectiveness of the proposed method.

4 - Optimal Middle Mile Transportation with Load Cancelation and Pick-up and Delivery Time Windows

Larissa P.G. Petroianu, PhD Student, University of Washington, University of Washington - 3900 E.Stevens Way NE, Mechanical Engineering Building, Room G6, Seattle, WA, 98195, United States, lpetroia@uw.edu, Mauricio G.C. Resende, Zelda B. Zabinsky

We develop a mixed-integer programming model of a planning and scheduling problem in middle mile transportation. Middle mile transportation consists of moving goods between facilities while satisfying several constraints, including time windows for pickup and delivery. One challenge is that the demand is stochastic, i.e., demand can be cancelled and ad-hoc demand created. We describe a heuristic for this problem and present computational results.

OM and Marketing Interface

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Xiajun Amy Pan, University of Florida, Gainesville, FL, 32611-7169, United States, amy.pan@warrington.ufl.edu

Co-Chair: Quan Ben Zheng, University of Florida, Gainesville, FL, United States, quan.zheng@warrington.ufl.edu

1 - Opaque Selling and Last-minute Selling: Revenue Management in Vertically Differentiated Markets

Hang Ren, University College London, Flat 28, Nansen Village, 21 Woodside Avenue, London, N12 8AQ, United Kingdom, hang.ren.13@ucl.ac.uk, Tingliang Huang

We analyze the performance of opaque selling as a clearance strategy in vertically differentiated markets. Compared to last-minute selling, opaque selling may increase revenue because consumers who wait for the sales cannot choose the preferred product type. Its disadvantage, however, lies in the inflexibility in segmenting different types of consumers. Both the advantage and the disadvantage are radically different from their counterparts in horizontally differentiated markets. This contrast generates opposite policy recommendations across the two settings.

2 - Add-on Pricing under Valuation Uncertainty

Quan Zheng, University of Florida, 302 Diamond Village, Apt 16, Gainesville, FL, 32603, United States, quan.zheng@warrington.ufl.edu, Xiajun Amy Pan

We incorporate a hitherto neglected feature in add-on pricing: the purchase time of base product (e.g., hotel room) is separated with the consumption time of add-on (e.g., Internet service). Consumers can either buy the add-on at a discount with valuation uncertainty or wait until the uncertainty is resolved but at a higher price. We first characterize the optimal selling strategies under various scenarios for a monopoly seller, and then consider duopoly competition with symmetric firms. Interestingly, the results show that there exist asymmetric equilibria in which symmetric firms employ different pricing schemes to alleviate price competition.

3 - Price Restraining Policies and Improving Profits by Increasing Search Frictions

Ozge Sahin, Johns Hopkins University, 524 Manhattan Avenue, Apt 6B, Brooklyn, NY, 11222, United States, ozge.sahin@jhu.edu, Liang Ding, Roman Kapuscinski

While online retail broadens manufacturer's access to consumers through an additional channel, prices are often lower in online stores than in physical stores. Customers experience products in physical store but purchase online for lower prices. As a result, physical store sales decrease and they stop promoting such products. However, for manufacturers, physical stores play a crucial role by showcasing products to customers. We find that deliberately adding search frictions, and using price restraining policies can improve manufacturer's, physical and online retailers' profits by allowing consumers to self-select into low price but high search cost or high price but low search cost retailers.

4 - Crowdfunding under Social Learning and Network Externalities

Fasheng Xu, Washington University in St. Louis, Saint Louis, MO, 63130, United States, fasheng.xu@wustl.edu, Fuqiang Zhang

This paper investigates how the presence of both social learning and network externalities affect the strategic interaction between a crowdfunding campaigner and a forward-looking consumer population. Our analysis yields three main insights. First, we find in the presence of social learning and strategic consumers with strong network externalities can lead to an upward-sloping demand curve. Second, we establish that the presence of network externalities has significant structural implications for optimal crowdfunding reward choice. Third, we characterize the optimal rewarding strategy when facing financial constraints and quantify the impact of the fundraising target.

Revenue Management, Pricing in Airline and Hotel Industry

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Ravi Kumar, rkumar04@pros.com

1 - Pricing Advance Purchase Products

Matthew Maxwell, SAS.Institute, Inc., 500 Sas Campus Drive, Cary, NC, 27513, United States, matt.maxwell@sas.com, Jennie Hu

Advance purchase products are characterized by non-refundable discounted products that are fully paid at the time of booking. Such products give providers increased revenue opportunities and protection against late cancellations; however, if priced incorrectly, these products may reduce overall revenue due to cannibalization of the full fare refundable product. We develop a closed-form model to predict the amount of purchases for each product given prices for both products. We verify that this model satisfies properties of rational behavior from customers and show how model parameters may be estimated and how to calculate optimal prices.

2 - Explicitly Incorporating Competition and Customer Choice in Dynamic Pricing

Siddharth Prakash Singh, Carnegie Mellon University, Tepper School of Business, 5000 Fobes Avenue, Pittsburgh, PA, 15213, United States, sps1@andrew.cmu.edu, Darius Walczak

We analyze a two-competitor dynamic pricing game introduced by Dudey (1992) and subsequently considered by Martinez-de-Albeniz and Talluri (2011). We allow more general distributions of customer valuation and expand the game to include customers who are loyal to each airline, in addition to customers who seek the lowest price in the market. This is particularly relevant in the airline industry where demand may be price-sensitive but dedicated to a particular carrier. We establish the non-existence of subgame-perfect pure strategy Nash equilibria in a market with loyal customers. However, when all customers are flexible, we are able to construct a subgame-perfect pure strategy Nash equilibrium.

3 - Travel Network Optimization Parallelization Techniques under Dependencies Between Daily Itineraries

Evan Davidson, PhD, PROS.Inc, 101 Montgomery St, Suite 400, San Francisco, CA, 94104, United States, edavidson@pros.com

Under many travel network optimization methodologies, often seen in the airline industry, pricing and revenue management problems are solved as separable by day, each day being treated independently. If this daily independence assumption is no longer applicable, here focusing on the passenger bus industry, other techniques must be used to make these large travel network problems tractable. Here we explore a heuristic to parallelize on overlapping sets of days and utilizing the results from only the middle days of each set. We explore the implications on feasibility, optimality, and performance under this parallelization heuristic.

4 - A Dynamic Pricing Model with Capacity Sharing for Airline Revenue Management

Ang Li, PROS, Inc., 3100 Main Street, Suite #900, Houston, TX, 77002, United States, ali@pros.com, Ravi Kumar, Darius Walczak

We consider a Revenue Management setting for airlines where limited capacity from a business compartment can be shared with an economy compartment on each flight. We develop several heuristic dynamic pricing policies for this problem based on a deterministic model and network decomposition related ideas and evaluate their performance via simulation.

Chair: Mingcheng Wei, University at Buffalo, Buffalo, NY, 14260, United States, mcwei@buffalo.edu

1 - Pricing and Design of Discretionary Service Lines

Laurens G.Debo, Dartmouth College, 100 Tuck Hall, Hanover, NH, 03755, United States, laurens.g.debo@tuck.dartmouth.edu, Cuihong Li

Discretionary services as services whose quality increases in the service duration such as e.g. personal care. In a congested environment, however, longer service time also increases the congestion. We discuss the optimal structure and pricing of a menu of services of different duration— a service line— when customers have heterogeneous quality sensitivity and are delay sensitive. We study both First In First Out (FIFO) and Shortest Processing Time disciplines (SPT). While prices under FIFO always increase, with SPT, they may be non-monotone, or, even decrease in quality (duration).

2 - Choosing to be Strategic: Implications of the Endogenous Adoption of Forward-looking Purchasing Behavior on Multiperiod Pricing

Arian Aflaki, Duke University, Durham, NC, 27708, United States, arian.aflaki@duke.edu, Pnina Feldman, Robert Swinney

We study whether consumers benefit from forward-looking behavior when they purchase from a firm that sets prices over multiple periods. We show that consumers do not necessarily benefit from strategic behavior, and therefore may choose to remain myopic if given the option. We then develop a model in which consumers choose to become strategic by exerting costly effort, and show that it is possible to increase firm profit, consumer, and social welfare simultaneously by increasing this cost. In contrast, strategies such as price commitment can reduce the cost of strategic behavior and harm all parties.

3 - Personalized Advertising and Learning Through High-dimensional Data with Limited Samples

Mingcheng Wei, University at Buffalo, 326C Jacobs Management Center, Buffalo, NY, 14260, United States, mcwei@buffalo.edu, Xue Wang, Tao Yao

In this paper, we propose a Minimax Concave Penalized Multi-Armed Bandit algorithm for a decision-maker facing high-dimensional data with latent sparse structure in an online learning and decision-making process. This algorithm performs favorably compared to other algorithms, especially when there is a high level of data sparsity or when the sample size is not too large.

1 - Entrepreneurial Positive Thinking About the Future Predicts Unethical Behaviors

Jacob Do-Hyung Cha, Seoul National University, Room 313, 58-dong, Seoul National University, Gwanak-gu, 150-742, Korea, Republic of, research.dohyung@gmail.com, Hye-Jin Cho

Psychologists argue that positive thinking about the future predict low performance due to (1) low efforts and (2) favor pro over con information. I propose that entrepreneurs' positive thinking about the future is positively related to his/her earnings manipulation behavior. Low effort may lead to low performance and this poor outcome may increase the pressures to compensate such low performance by manipulation of company earnings. Favoring positive information may lead to (morally) risky decisions, that is, manipulated earnings too. I use content analysis method to measure positive thinking about the future by utilizing corporate documents.

2 - The Strategic use of Opposition for European Patent

Xia Liu, Zhejiang University, Hangzhou, 310000, Hangzhou, 310000, China, liuxia0510@gmail.com

This paper analyses the relationship between technology ownership fragmentation and the opposition filing in the European Patent Office. I develop a two stages game for technology access bargaining. Opposition is more attractive under two conditions: when the ownership to external technologies is concentrated, and profit dissipation is over the licensing revenue for the potential licensee; when the ownership to external technologies is widely fragmented, yet the transaction cost is too high for the entrance. To empirically test this hypothesis, I use a data set that covers patent opposition cases during the period 1985-2005. Regression results confirma U-shape relationship.

3 - Why Innovating Firms Trademark (or Not): Identity Protection and the Maintenance of First Mover Advantage

Xiaoshu Bei, Duke University, 2514 Preston Ave, Durham, NC, 27705, United States, xiaoshu.bei@duke.edu

In this paper I study a special role of trademarks to sustain the innovator's first mover advantage. Even though both innovators and imitators file for trademarks, innovators who anticipate competition have significantly higher propensity to trademark. There is an inverted U relationship between the overall incentive to trademark and the level of competition. When competition is high, imitators decrease in their incentive to trademark, but innovators still have high incentive because trademarks help sustain the first mover advantage. Other factors that condition this role of trademarks include level of information asymmetry and size.

4 - Scope Advantage or Disadvantage? – Cost Spreading and Firm's Innovation Response to Demand Shock

Xiaoshu Bei, Duke University, 2514 Preston Ave, Durham, NC, 27705, United States, xiaoshu.bei@duke.edu

In this paper, I study firms' investment in innovation in response to exogenous shock in demand. I look at firms' patenting activity and how that is correlated with US exportation to China after China joined WTO. I use the cost spreading theory to explain the relationship between firms' structure/diversification strategy and their response to increase in demand. Consistent with early studies, both size and scope confer an advantage in innovation when facing demand pull. Vertically integrated firms have a much higher response in innovation, mostly due to their ability to scale up dynamically and capture the market opportunity. This enables them to attain a larger output to spread the cost of innovation.

5 - Dark Sides of Interpersonal Citizenship Behaviors for Innovation: A Social Network Approach

Hongzhi Chen, PhD Candidate, Purdue University, 146 Arnold Dr Apt 3, West Lafayette, IN, 47906, United States, hzchen@purdue.edu, Lusi Wu, Chunhua Chen

Assuming its desirable outcomes, researchers tend to focus on how to promote interpersonal citizenship behaviors (ICB), leaving its consequences untapped on. Using social network approach, this study examines dark sides of ICB in innovation process. Specifically, how performing and receiving ICB will affect an employee's structural positions within intra-organizational collaboration networks, which in turn unintentionally inhibit innovation through network closure and collaborative overload. Based on time-lagged data from 200 employees in a pharmaceutical R&D center, our findings will provide novel and practical insights on ICB and network dynamics, especially in innovation process.

1 - Winner Play Structures in Random Knockout Tournaments

Yang Cao, University of Southern California, 909 W. Temple St, Apt 354, Los Angeles, CA, 90012, United States, cao573@usc.edu

We consider a knockout tournament whose contestants are 1,2,...,n. Suppose that each player i has strength v_i, and a game between i and j is won by i with probability v_i/(v_i+v_j). The players are randomly assigned to positions 1,2,...,n. The players in the first two positions play a game in the first round, and then in round r, r = 2,3,...,n-1, the winner of the previous round plays with the player in position r+1. We call this tournament format the winner-play structure. We prove bounds on players' tournament win probabilities, provide efficient simulation algorithms, and propose conjectures with evidence. Moreover, we study a continue play model and give the stationary probabilities.

2 - Compactness Approaches for Importance Sampling

Alexander Shkolnik, Postdoctoral Scholar, University of California-Berkeley, Evans Hall 339, Berkeley, CA, 94720, United States, ads2@berkeley.edu

A standard approach for optimal importance sampling (IS) relies on large deviations (LD) theory. That is, LD techniques are employed to derive upper and lower bounds on the second and first moments of the IS estimator. This requires the development of a LD principle, a program that is frequently too difficult to implement for practical problems. We provide an analysis based on the LD counterpart of Prohorov's (relative compactness) theorem that circumvents many obstacles in this standard program. We demonstrate the effectiveness of the approach on several challenging problems involving Markov chains, affine processes and event timing models.

3 - Governance of Complex Transactions in Project Business Networks

Jaakko Kujala, Professor, University of Oulu, Oulu, Finland, jaakko.kujala@oulu.fi

The purpose of the study is to analyze the effectiveness of network form of governance to coordinate and safeguard complex transactions in inter-organizational project business network. The network form of governance is suggested to arise as a response for demand uncertainty, project uniqueness and project complexity. It is characterized by informal social systems rather than bureaucratic structures and formal contractual relationships. An agent-based simulation model is created to simulate the effectiveness of social mechanisms such as restricted access, macroculture, collective sanctions and reputation, and how structural embeddedness in a network facilitates use of these mechanisms.

4 - Characterization and Prediction of Hyper-jump Diffusion in Consensus Dynamics on Networks

Xin Su, PhD Student, Arizona State University, ASU - CIDSE, PO Box 878809, Room 553, Tempe, AZ, 85287-8809, United States, xinsu3@asu.edu, Theodore P. Pavlic

Network consensus dynamics have been studied for: modeling opinion diffusion, robotic formation-control policies, and development of particle swarm optimization (PSO) metaheuristics. A recent discovery is that stochastic link failures can lead to Levy-like hyper-jump diffusion, which might be used for new PSO strategies or to better understand sharp changes in public opinion. Here, we: (a) quantify the emergence of these jumps; (b) demonstrate the role of parameters in the control of this behavior; and (c) use information-theoretic insights to find real-time predictors for impending jumps.

5 - Multiply Reflected Variance Estimators for Simulation

Melike Meterelliyoz, Assistant Professor, TOBB University of Economics and Technology, Sogutozu Cad. No 43, Sogutozu, Ankara, 06560, Turkey, mkuyzu@etu.edu.tr, Kemal Dingeç, David Goldsman, Christos Alexopoulos

We consider new estimators for the variance parameter of a steady-state simulation output process that are based on the Reflection Principle of Brownian motion. These estimators are computed by invoking multiple reflections of the standardized time series of the underlying process, and thus generalize previous reflected estimators that are each based on only a single reflection point. Our current scheme can be exploited to produce low-bias, low-variance estimators that are superior to their single-reflection-point predecessors. We illustrate the enhanced performance of the multiply reflected estimators via exact calculations and Monte Carlo experiments.

1 - Sensing Specific Hazards from Online Reviews across Diverse Product Categories

Nohel Zaman, 258 Old Cedarfield Drive, Blacksburg, VA, 24060, United States, znohel@vt.edu, Alan Abrahams, Richard James Gruss

We focus on online reviews that report a physical health and safety concerns of consumers from product-usage in diverse product categories. We distinguish between events that are pathways to injury, and injury outcomes, and between actual injuries and potential injuries. We develop event-specific, injury-specific, and body-part specific "smoke" term lists. These terms can be used for detecting, categorizing, and prioritizing hazards across diverse consumer product categories. We determine which terms are generic and which are hazard-specific. This study facilitates rapid sensing of specific potential hazard events and outcomes, and maps online reviews to standard medical coding schemes.

2 - Aggregating Crowd Opinions using Statistical Learning

Qianzhou Du, Virginia Tech, Pamplin Business School, 100 Otey Street, Room 301, Blacksburg, VA, 24061, United States, qiand12@vt.edu

Recent studies have shown that aggregating crowd opinions has been an effective method to improve the performance of decision making. Most existing crowd opinion aggregation studies employ heuristics to determine a weighting scheme for individual judges based on their expertise or past prediction performance. However, those heuristics based methods often fail to determine the optimal weights and achieve the optimal prediction performance in the aggregated crowd opinion. We propose a new crowd opinion aggregation model, namely aggregating crowd opinions using statistical learning (ASL), which has a fitting procedure for the weighting scheme and a mechanism of estimating the probabilities of event outcomes based on statistical learning. Statistical learning is expected to capture hidden patterns in crowd opinions and assign better weights to individuals than heuristic based weighting methods. We empirically evaluate ASL in comparison to four baseline methods using real data collected from an online stock prediction community, StockTwits. The results show that ASL significantly outperforms all the baseline methods in terms of both a quadratic prediction score and prediction accuracy.

3 - Examining the Effect on Firm Value of Demand-side Supply Chain Disruptions in the Social Media Era

Christopher S. Kwaramba, Virginia Polytechnic Institute and State University, Blacksburg, VA, United States, shingik@vt.edu, Quinton J.Nottingham, Qianzhou Du, Alan Gang Wang

chis paper investigates the long-term stock price effects of social media content following supply chain disruptions based on a sample of 45 disruption announcements made during 2010-2016. We examine the stock price effect for a two-year event time frame beginning with one stock market year before a disruption announcement to one stock market year after. By the end of the year after the disruption announcement, the average return for a stock is about –28% but returns could be as low -47%.

Decision Analysis

Contributed Session

Chair: Xuan Wang, Louisiana State University, Baton Rouge, LA, United States, xwang35@lsu.edu

1 - Evaluating Classifiers Based on Cost Range to Minimize Decision Making Cost

Ramy Alsaffar, Graduate Student in LSU, LSU, Edward Gay Apartments, 275 W. Roosevelt Street, Baton Rouge, LA, 70802, United States, ramyalsaffar@yahoo.com

We believe using the hit rate is not enough to evaluate the performance of the classifier and it can be misleading due to overlooking an important element (decision cost). Furthermore, ROC is the most popular graph used to evaluate classifiers. However, one of the biggest ROC shortcomings is assuming equal FP and FN costs. Therefore, our goal is to reduce the total cost of decision making by selecting the classifier that has the least total misclassification cost. Nevertheless, the misclassification cost is unknown. To overcome such hurdle, we can test the data against a range of weight scale. Thus, we use the cost range and operating threshold range to show the performance differences among classifiers.

2 - Two-state Partially Observable Markov Decision Processes with Imperfect Information

Tal Ben-Zvi, Stevens Institute of Technology, 1 Castle Point on Hudson, Hoboken, NJ, 07030, United States, tbenzvi@stevens.edu, Tatyana Chernonog, Tal Avinadav

A process can be in either a stable or an unstable state interchangeably. The true state is unobservable and can only be inferred from observations. Several actions are available, including consulting with experts and obtaining (partial) information about the true state of the process for a fixed fee. The objective is to maximize the expected discounted value of the total future profits. We formulate the problem as a discrete-time Partially Observable Markov Decision Process (POMDP). We show that the expected profit function is convex and strictly increasing, and that the optimal policy has control limits. Also, we show that "dominance in expectation" suffices for a control limit structure.

3 - A Kalman Filtering Technique to Reduce Nonactionable Respiratory Rate and Endtidal CO2 Alarm Signals in a Continuously Monitored General Care Floor Patient

John Zaleski, Chief Analytics Officer, Bernoulli, 200 Cascade Blvd, Milford, CT, 06460, United States, jzaleski@bernoullihealth.com

False positive or non-actionable alarm signals along with true alarm signals are produced by Multi-parameter monitors and other bedside medical equipment within emergency departments, intensive care and general care floors. False alarm signals in these settings are a major source of distraction and a major patient safety risk. It is hypothesized that Kalman filtering is a viable means of mitigating these false alarms. An application of the Kalman filter to measured respiratory rate and end-tidal carbon dioxide illustrates its utility as an alarm signal mitigation method on data obtained from a general care floor patient undergoing continuous monitoring for a period of more than 28 hours.

4 - Perspectives on Entropy-based Weightings for Integrating Information

Huguette Tran, Professor, University of North Texas, 1307 West Highland St., Denton, TX, 76201, United States, Huguette.Tran@UNT.edu, Robert Pavur

In Data Fusion applications, data are often weighted according to their source reliability. A proposed weighting technique in the literature uses Shannon's entropy. This research provides a numerical illustration to use an alternative entropy-based method based on Pal and Pal (1991)'s formulation. The alternative formulation has a bounded entropy and may provide a weighting scheme more representative of the sources' reliability. The method is illustrated with an application of the newsvendor problem in which accurate parameter estimation is necessary for optimal profits.

5 - Comparison of Causal Inference Methods

Xuan Wang, PhD Student, Louisiana State University, 2200 Business Education Complex, Nicholson Extension, Baton Rouge, LA, 70803, United States, xwang35@lsu.edu, Helmut Schneider

As "Big Data" motivates an era of transformation, it not only offers many benefits, but also introduces challenges. Therefore, causal inference offers opportunities for maximizing the value of applying Big Data. This study focuses on evaluating various causal inference methods and provides recommendations. Propensity score matching, standardization, IP weighting, Bayesian network and orthogonal arrays will be discussed.

1 - Concurrent Fused Filament Fabrication with Multiple Extruders

Yu Jin, University of Arkansas, 4207 Bell Engineering Center, Fayetteville, AR, 72701, United States, yujin@uark.edu, Harry Pierson, Haitao Liao

Additive manufacturing (AM) is well-known for its capability in producing complex geometries. However, the fabrication speed of AM technology is considerably slower than traditional manufacturing processes A promising solution is the parallel processing of individual layers. In this research, a concurrent manufacturing strategy is proposed for improving the production speed of the Fused Filament Fabrication (FFF) process.

2 - Project Sustainability Strategies a Case of Textile Production

Rhythm Wadhwa, Prof, NTNU, Teknologiveien 22, Gjoevik, 2821, Norway, rhythmwadhwa@hotmail.com

A systematic literature review has been carried out focusing on cradle-to-grave textile production project sustainability. The literature review covers research published in leading journals in project management and textile production prior to 2017. Distinct perspectives have been proposed in sustianability research from the analysis.The findings of the review are complemented with an illustrative empirical case.

3 - Using Design of Experiments to Study the Significance of Different Control Parameters in Additive Manufacturing

Brett A.Shields, The University of Tennessee at Knoxville, 411 B.H. Goethert Parkway, Tullahoma, TN, United States, bshields@utsi.edu, Andrew Junfang Yu

In this research, the effects of control parameters on the resistivity and temperature gradient uniformity are studied for 3d printed graphene PLA. A thermal camera is used to observe the production process as the printer settings vary. Four factors (printer control parameters) are considered in the experimental design: build plate temperature, extruder temperature, print speed, and layer thickness.

Finance Theory and Empirics

Contributed Session

Chair: Hiroshi Ishijima, Chuo University, Tokyo, Japan, hiroshi.ishijima.jp@gmail.com

1 - Application of the Transmutation Operators to Parabolic Free Boundary Problems: A Numerical Method

Igor Kravchenko, ISCTE-IUL, Edifício II, Av. Prof. Aníbal Bettencourt, Lisbon, 1600-189, Portugal, ivkoh@iscte.pt

The numerical method for solving parabolic free boundary problems will be presented. The method is based on recent results from transmutation operators theory allowing one to construct efficiently a complete system of solutions for the parabolic equation, generalizing the system of heat polynomials. This techniques can be directly applied to path dependent options. The talk is based on the joint works with V. V. Kravchenko, S. Torba and J. C. Dias. "Pricing double barrier options on homogeneous diffusions: a Neumann series of Bessel functions representation" and "Solution of parabolic free boundary problems using transmuted heat polynomials"

2 - Stock Market Spoofing

Jussi Keppo, National University of Singapore, Mochtar Riady Building, BIZ 1 8-69, 15 Kent Ridge Drive, Singapore, 119245, Singapore, keppo@nus.edu.sg, Xianhua Peng

We use a unique trading dataset of one week to analyze the behavior of high-frequency traders. About 8% of institutional traders intentionally or unintentionally first enter and then quickly cancel a buy (or sell) limit order without actually buying (or selling) before the trader actually sells (or buys) a security. We show that the p-value for testing that all this behavior is a random event, and thus unintentional, is extremely small, equal to the probability of observing a 53-standard deviation event. Therefore, most likely at least part of the behavior is intentional and an indication of so-called "spoofing", an attempt to manipulate prices.

3 - Public Information, Investor Trading and Stock Bubble: Evidence from Chinese Stock Market

Kun Chen, Assistant Professor, Southern University of Science and Technology, China, 518055, China, chenk@sustc.edu.cn, Sisi Wu, Leon Zhao, Jian Yin

According to the resale option theory, asset bubble is caused by investor heterogeneous beliefs which are reflected in investor trading behaviors. In this study, we want to explain the formation of heterogeneous beliefs from the information processing perspective, and investigate the circular relations among public information, investor trading, and stock bubble. We focus on the 2015 Chinese stock bubble, and find that different sources of information, such as news, discussion boards, and analyst reports, and different measures of information, i.e. sentiment, coverage, and dispersion, have different impacts on trading behaviors of different investors.

4 - A Generalized Real Estate Pricing Model with Exogenous Affine-form Variables

Hiroshi Ishijima, Professor, Chuo University, 1-18 Ichigaya-tamachi Shinjuku, Tokyo, 1628478, Japan, hiroshi.ishijima.jp@gmail.com, Akira Maeda, Tomohiro Tsuruga

We develop a generalized real estate pricing model that incorporates hedonic attribute variables of real estate as well as exogenous variables in an affine form. We then conduct an empirical analysis to understand Japanese house prices by exogenous variables with hedonic variables controlled. Our analysis reveals that the financial asset prices and conventional hedonic variables serve as the major determinants of Japanese house prices. We also show evidence that low interest rates under the Abenomics monetary policy successfully stimulate Japanese house prices.

Supply Chain, Managing Disruptions

Contributed Session

Chair: Hoda Sabeti, West Virginia University, Morgantown, WV, United States, hoda.sabeti@gmail.com

1 - Flexible Supply Chain Network Design under Uncertainty through Capacity Planning

Nima Salehi Sadghiani, PhD Candidate, University of Michigan, 3735 GreenBrier Boulevard, Apt 223C, Ann Arbor, MI, 48105, United States, nsalehi@umich.edu, Mark Stephen Daskin

Managing uncertainty is one of the challenging issues in supply chains. Deviations from the expected values of key input parameters can make the deterministic formulations infeasible and/or inefficient much of the time. In this study, we address the need for an effective tool to incorporate potential uncertainties associated with the model parameters into sourcing decisions. In particular, we consider the effects of demand, exchange rate, and freight cost uncertainty into sourcing decisions of a manufacturing company. The solutions are compared to those of the current implementations in practice to show the inadequacy of the deterministic formulations in making real-world decisions.

2 - A Quantitative Foundation for Asset-based Design with Application to Supply Chains

RaSheka N. Robinson, Graduate Student, North Carolina A&T State University, 3217 Pleasant Garden Rd, Apt. 1G, Greensboro, NC, 27406, United States, rnrobins@aggies.ncat.edu

Traditionally system performance is measured by common metrics, such as cost, quality and delivery that measure the limitations of the system to 'fix' them. This paper will build upon these metrics by providing a quantitative basis for strength-based design of systems, using supply chains as a primary motivator. This asset-based approach will measure the assets in the system to determine their contributions. Asset-based views the participants in the supply chain as assets. These assets contribute to system function through various modes. The measures are aggregated according to mean and variance and analyzed to offer a greater understanding of supply chain formation and participant development.

3 - The Decision on Stimulating Shared Supplier Innovation under Market Competition

Cong Liu, Huazhong University of Science and Technology, Wuhan, China, cong_liu@hust.edu.cn

This paper construct a cost-sharing game model between the manufacturers and the shared-supplier, discussing the influence of competition degree and innovation cost on the equilibrium solution under different situation. The results show that when the competition degree of market is less, the cost-sharing ratio provided by the manufacturer is higher than that of non-cooperation, and the supplier's innovation level and the manufacturer's profit are higher than the non-cooperative situation. When the market competition degree is high, the cost-sharing ratio provided by the manufacturer is less than that of non-cooperation.

4 - Distributed Subset Reconfiguration Decisions for Fair Demand and Capacity Sharing in Collaborative Network

Ibrahim Yilmaz, State University of New York at Binghamton, Binghamton, NY, 13902, United States, iyilmaz1@binghamton.edu

This research aims a distributed subset reconfiguration decisions to enhance fairness and efficiency among a collaborative network of enterprises (CNEs) by Dynamic-distributed sharing protocol (D2-SP). D2-SP is inspired by the principles of Collaborative Control Theory and Contract Net Protocol. A novel protocol is investigated for control of CNEs. The performance of the proposed D2-SP is evaluated by comparing three sharing protocols (SPs): 1) Static-centralized, 2) Static-distributed, and 3) Dynamic-centralized SP. Experiments are conducted to analyze D2-SP in terms of efficiency, fairness, scalability, utilization of resources, and communication overhead.

5 - Flow Time Variability Estimation using Kriging-based Methods to Integrate Simulation and Real Data

Hoda Sabeti, West Virginia University, 390 Gilmore St., Morgantown, WV, 26505, United States, hoda.sabeti@gmail.com

Quoting a competitive and reliable lead time upon arrival a new order, is a key competitive advantage for manufacturers. Precise lead time quotation requires a good prediction for the mean and variability of the flow time. Due to the uncertainties in manufacturing processes, heteroscedasticity of the variance, and insufficient real time manufacturing data, it is challenging to provide high quality flow time estimation for a new order at its arrival time. This research focuses on predicting the flow time variability. To increase the accuracy, simulation data is integrated with the real data. A stochastic kriging based framework is adopted for infusing the data and predicting the flow time variance.

Operation Research Empowering Airline Crew Scheduling and Crew Planning

Sponsored: Aviation Applications

Sponsored Session

Chair: Abdelouahab Zaghrouti, GERAD Research Center, Université de Montréal Campus, 2920, Chemin de la Tour, Montreal, QC, H3T 1J4, Canada, abdelouahab.zaghrouti@gerad.ca

1 - Constraints Aggregation for Large-scale Airline Crew Pairing Problems

Francois Soumis, Professor, Polytechnique, Polytechnique, C.P. 6079, Montreal, QC, H3C 3A7, Canada, francois.soumis@gerad.ca, Mohammed Saddoune, François Lessard

The crew-pairing problem is modelled as a set-partitioning problem solved by columns generation. However solving a master problem of 50 000 constraints at each of the thousands iterations of the column generation in the branching tree request to much time. In some airlines the Rolling-Horizon heuristic (RH) divides the horizon into 2 days overlapping time slices. However solving 30 problems of 3000 flights requires many days and the quality of solutions in not so good. We introduce the Dynamic Constraints Aggregation to speed-up the master problem and permit to solve a weekly window of 14 000 flights in few hours. The rolling horizon with weekly windows produces solutions improved by up to 5% on salaries.

2 - Considering Crew Preferences in the Airline Crew Pairings to Improve the Crew Rostering

Frederic Quesnel, GERAD, 9382 Joseph-Melancon, Montreal, QC, H2M 2H8, Canada, frederic.quesnel@gerad.ca, Francois Soumis, Guy Desaulniers

The airline crew scheduling problem is usually divided in two steps : the crew pairing problem (CPP) and the crew rostering problems (CRP). While the goal of the CPP is to find feasible pairings at minimum cost, the CRP aims at finding a schedule that satisfy as many employee preferences as possible. The main challenge with this approach is that the pairings generated by the CPP may not be suitable for the objective of the CRP. In order to create pairings that are more compatible with the CRP, we propose a new mathematical formulation for the CPP that takes into account crew preferences. We show how such model can be solved with column generation and we present results showing the effectiveness of our method.

3 - Airline Reserve Planning

Mingzhou Jin, University of Tennessee-Knoxville, 525D John D. Tickle Engineering Building, Industrial and Systems Engineering, Knoxville, TN, 37996, United States, jin@utk.edu, Ying Zhang, Suresh Rangan

Reserve lines are planned in airlines for possible dropping of main crew lines. An approach integrating the demand forecasting, reserve pattern generation, reserve line optimization, and dynamic trip assignment is developed for improving the efficiency of reserve crew scheduling, measured by the utilization and coverage. A column generation algorithm is developed to generate patterns covering the forecasted reserve demands in a stochastic fashion. The approach can avoid the influence of forecasting errors caused by high uncertainty of reserve demands.

4 - An Improved Version of the Integral Simplex using Decomposition Algorithm

Abdelouahab Zaghrouti, Kronos Canadian Systems Inc, 3535 Queen Mary Rd, Montreal, QC, H3V. 1H8, Canada, abdelouahab.zaghrouti@gerad.ca, Issmail El Hallaoui, Francois Soumis

Integral Simplex Using Decomposition (ISUD) is an iterative method that efficiently solves set partitioning problems for the transportation industry. We introduce a new version of ISUD that improves both quality and performance. With its new approach, given a good initial solution, it presents high chances of reaching the best solution without branching. Optimality is reached for large instances five times faster than the previous version. In addition to its performance, an important advantage of the new version is that it opens the possibilities of its extension to arbitrary binary problems.

Supply Chain Optimization

Contributed Session

Chair: Weihang Zhu, Lamar University, Beaumont, TX, United States, weihang.zhu@lamar.edu

1 - The Impact of Adopting 3D Printing Technology on Inventory and Pricing Decisions in a Two-echelon Supply Chain

Sharareh Rajaei Dehkordi, PhD Student, New Jersey Institute of Technology, 10 Hill Street, Apt 2N, Newark, NJ, 07102, United States, sr552@njit.edu, Wenbo (Selina) Cai

As 3D printing technology becomes agiler and better able to react customer demands, one important question for the retailers is whether they should provide 3D printing services in their brick-and-mortar store in addition to the traditional off-the-shelf product? If so, what should be the retailers pricing scheme and optimal inventory level to achieve ahigher profit? In this study, the retailers' optimal joint decisions on inventory management policy and pricing scheme are developed while considering consumer preferences for self-designed, 3D printed products versus off-the-shelf products.

2 - A Supplier Selection and Supply Chain Coordination Model under Price Sensitive Demand and Profit Sharing

Barbara Venegas Quintrileo, Pennsylvania State University, University Park, PA, 16801, United States, bbv105@psu.edu, Jose Antonio Ventura

We study a supplier selection problem in a two stage centralized supply chain under price sensitive demand, formed by a buyer and a set of suppliers. Vendors have fixed production rates and produce a single item with no differences among them. A mixed integer nonlinear programming model under different lot sizing policies is presented, to determine the inventory policies and the final retail price for the customer, using a total supply chain optimization approach. Finally, a profit sharing method is proposed to allocate the benefits obtained through coordination. It restricts the model to pick solutions where each member's rate of return (ROI) is at least a fixed portion of the supply chain's ROI.

3 - Considering Production Planning and Scheduling Decisions in Supply Chain Network Design

Gokhan Memisoglu, Applied Research Scientist, LLamasoft, LLamasoft, Inc., 201 South Division St. Suite 200, Ann Arbor, MI, 48104, United States, gokhan.memisoglu@llamasoft.com, Ali Taghavi, Nejat Karabakal, Jason D. Judd

Production planning and scheduling decisions are important factors in supply chain design problems.. In this talk, we present how Supply Chain Guru (SCG), LLamasoft's network optimization tool, incorporates these decisions into its generic network design formulation.

4 - Buyer and Supplier Strategies for Hedging against Risk in the Ethanol Industry?

Iddrisu Awudu, Quinnipiac University, 12 Kaye Plaza, Apt E-22, Hamden, CT, 06514, United States, iddrisu.awudu@quinnipiac.edu, Anthony Afful-Dadzi e, Vinay Gonela

We model an ethanol supply chain with price uncertainties. We incorporate the concept of copula. We develop a stylized linear optimization problem and solve the resulting problem using Multi-cut decomposition algorithm. We provide insights using a case study in North Dakota.

5 - An Order Acceptance Model for Hybrid Production Strategy

Weihang Zhu, Associate Professor, Lamar University, PO Box 10032, Beaumont, TX, 77710, United States, weihang.zhu@lamar.edu, Arash Abedi

The hybrid production strategy (HPS), a combination of the make-to-order (MTO) and make-to-stock (MTS), has been employed for over a decade. In order for hybrid-production based manufacturing to fully utilize available resources, a compatible order acceptance method is vital. This talk first presents a framework to explain what process the orders undergo until they are satisfied. Within the framework, an order acceptance model (OAM) is proposed. It is able to simultaneously consider production strategy, production capacity, and customer priority, and thus lead to higher profits.

Facilities Planning and Design

Contributed Session

Chair: Li Wei, Huazhong University of Science and Technology, Wuhan, China, liweianthea@gmail.com

1 - Overlap Packing Problem for Layout Design of Task Volumes in Spacecraft

Churlzu Lim, Associate Professor, UNC-Charlotte, 9201 University City Boulevard, Charlotte, NC, 28223-0001, United States, clim2@uncc.edu, Simon M.Hsiang, Claudia Ramirez, Sherry S. Thaxton, Maijinn Chen, Jerry Myers

This study considers a packing problem that searches for a minimum-volume cube container to pack a given number of variously sized cuboids while allowing overlap between cuboids to certain extent. The problem was developed as part of designing arrangements of task volumes performed by astronauts in a spacecraft for a prolonged period of time. Mixed-integer linear programming model is proposed to minimize the volume of the cube container while enforcing additional constraints such as overlap limits, adjacency requirements, and orientation options. Numerical examples will be discussed.

2 - Techniques for Improving Safety on Medium Voltage Electrical Equipment

Raymundo Rivera, PhD Student, UT Health San Antonio, 1814 N Palmetto Ave., San Antonio, TX, 78208, United States, riverar5@uthscsa.edu
Raymundo Rivera, PhD Student, Mississippi State University, MS, United States, riverar5@uthscsa.edu, Linkan Bian

In the United States, the medium voltage electric grid and its complex electrical components which include customer-side automatic transfer switches, transformers, switchgear and breakers receive minimal inspections. When electrical failures develop the most critical issues are often the only ones addressed while the lesser problems are left untouched and fester until the next electrical failure occurs. This paper introduces the classification of datasets based on ultrasound waveforms, age, and type of equipment in order to minimize arc flash hazards to electrical personnel, minimize power outages, minimize lost revenue and reduce the risk of lost customer data.

3 - The Adoption Strategy of Electric Vehicle
Li Wei, Student, Huazhong University of Science and Technology, Wuhan, 430074, China, liweianthea@gmail.com

This paper applies game theory to study how EV manufacturer makes location and pricing decision when facing the competition of the gasoline car. We characterize a two-stage game model describing EV manufacturers' operation decisions and consumers' consumption decision, after solving the model we derive the optimal number of charging stations and the optimal charging price, and then analyze how city structure, customers' traveling demand and EV range affect the results.

Models of Co-production and Co-creation

Sponsored: Service Science

Sponsored Session

Chair: Paul R. Messinger, University of Alberta, Edmonton, AB, T6G 2R6, Canada, paul.messinger@ualberta.ca

1 - Competing with Co-created Products
Amit Pazgal, Rice University, Jones Graduate School of Management, 6100 Main Street (MS.- 531), Houston, TX, 77005, United States, pazgal@rice.edu, Dinah Vernik-Cohen, Niladri Syam

We analyze the strategic choices of two competing downstream firms who simultaneously decide whether or not to co-create with an upstream supplier. Within this framework we incorporate, endogenous pricing and effort choice by both the supplier and the competing firms. Firms contemplating co-creation with a supplier are faced with a trade-off. They can benefit from the supplier's innovation efforts and therefore obtain a better product than they themselves can produce. However, they may face the adverse effect of their own innovation efforts spilling over to their rivals via the supplier who would sell the co-created products to all firms. Our model captures this tension and offers several insights.

2 - Strategic Role of Self-service Co-production
Paul R.Messinger, University of Alberta, Faculty of Business, 3-20e Faculty Of Business Bldg, Edmonton, AB, T6G 2R6, Canada, paul.messinger@ualberta.ca, Kursad Asdemir, Bora Kolfal

This paper examines the strategic implications for duopoly firms offering a self-service option in a stylized game-theoretic model. Queuing behavior is modelled to equilibrate so that customers sort themselves into groups that choose the self-service or full service options according to what is best for them. The model also endogenously determines the boundary of the firm (which activities are conducted by the firm and which are done by customers outside the firm). By focusing on the offering of self-service as a strategic variable, this paper differs from much of past managerial research on self-service that focuses on the productivity gains to market participants.

3 - Co-creation: the Consumer Side with Bandwagon Effects
James D. Hess, Bauer Professor of Marketing Science, University of Houston, University of Houston, Houston, TX, 77204-6021, United States, jhess@uh.edu, Niladri Syam, Rambod Dargahi

We study the behavior of consumers who co-produce goods and services with a firm and ask how bandwagon effects (social preferences) on the consumers affect their co-production choices. Consumers have to make three related decisions: (1) buy the standard or customized product? (2) What is the optimal design of the customized product and how to split the design task between themselves and the firm ? (3) How should they take into account the preferences of other customers? Our main result finds that an increase in the bandwagon intensity can either increase or decrease the mass of co-producers. We have experimentally tested this main result.

Networks and Graphs

Contributed Session

Chair: Nima Safaei, Bank of Nova Scotia, North York, ON, Canada, nima.safaei@scotiabank.com

1 - Interactive Community in Temporal Networks
Jongeun Kim, University of Florida, 2901 SW. 13th St, Apt 212, Gainesville, FL, 32608, United States, kje0510@ufl.edu, Vladimir Boginski

One of the important research area in network analysis is detecting a significant cluster. Most proposed works have been done in static networks. However, many real-world networks including person-to-person communication networks, brain signal networks, dynamic sensor networks and infrastructural networks have a potential to gain better knowledge by applying temporal network frame which considers changing the connections through time. We will define the condition of an interactive community in a temporal network and design both exact approaches and rapid heuristics to find it.

2 - Derisking in Crossborder Payment Banking Networks
Nima Safaei, Associate Director, Network Analytics, Bank of Nova Scotia, Unit 1205, 72 Esther Shiner Blvd, North York, ON, M2K.0C4, Canada, nima.safaei@scotiabank.com, Ivan Sergienko

De-risking is defined as "the phenomenon of financial institutions terminating or restricting business relationships with clients to avoid, rather than manage, risk in line with the risk-based approach". This phenomenon raises profitability pressure due to increased competition and more regulations to mitigate the risk of money-laundry, terrorist financing, credit loss, etc. We propose a methodology to classify the banks in a cross-border network in terms of risks and benefits. Our analysis is supported by SWIFT customer payments data from an international bank.

Advances in Transportation Planning and Operations

Sponsored: TSL, Urban Transportation

Sponsored Session

Chair: Xia Yang, SUNY Polytechnic Institute, 100 Seymour Road, Troy, NY, 13502, United States, yangx2@sunyit.edu

1 - Bus Schedule Optimization for Multimodal Emergency Evacuation
Xia Yang, SUNY Polytechnic Institute, Utica, NY, 3502, United States, yangx2@sunyit.edu, Sean He

This study proposes a mixed integer linear programming model that optimizes the schedule of buses in a multimodal transportation system to minimize the total evacuation time for heavily populated urban areas. The proposed model factors evacuation traffic dynamics, evacuation priority, the cooperative behavior of evacuees, and the capacities of facilities in the multimodal transportation system. Numerical experiments are conducted to investigate the proposed model and its solution algorithm.

2 - Real-time Estimation of Value of Time Distribution using Measurements on Managed Lane Networks
Venktesh Pandey, University of Texas, Austin, TX, United States, venktesh@utexas.edu, Stephen Boyles

The value of time (VOT) distribution among drivers is critical for understanding the lane choice behavior of drivers and setting optimal tolls for travelers in a managed lane network. We propose a formulation for simultaneous estimation of traffic state and percentage of travelers in each VOT class in the population by measuring the flows before and after each diverge-point on managed lane networks. The performance of the estimation algorithm is tested on managed lane networks with multiple entrances and exits. The issues of non-observability of the states are also highlighted.

3 - Arterial Signal Coordination with Uneven Double Cycling and Secondary Bandwidth
Hongmin Tracy Zhou, Texas A&M Transportation Institute, 701 North Post Oak Rd, Suite 430, Houston, TX, 77024, United States, h-zhou@tti.tamu.edu, Gene Hawkins, Luca Quadrifoglio

Arterial signal coordination between large intersections often requires a long cycle length which may causes excessive delay at intersections of low volume cross streets. This paper describes two optimization models developed to enable uneven double cycling (UDC) at minor intersections where a background cycle has two sub-cycles of different lengths to address this issue. The first model maximizes variable bandwidths and minimizes through delay on cross streets at UDC intersections. The second model also maximizes secondary bandwidths for arterials with two or more consecutive UDC intersections. Simulation results show great potentials of the UDC control scheme.

4 - Credit Risk of Real Option in Private-Public-Partnership Based Road Infrastructure Project Evaluation under Market Realism
Choungryeol Lee, Purdue University, West Lafayette, IN, United States, lee1210@purdue.edu, Srinivas Peeta, Yong Hoon Kim

We propose an extended real option valuation (ROV) framework to price real options for PPP-based road projects subject to credit risk concerning the private firm's bankruptcy. This framework integrates the existing ROV frameworks and measurement of credit risk in terms of the expected loss from a public perspective. Results of numerical experiments show that impacts of credit risk on option value are significant and suggest that public access to proprietary information of the private firm is needed to accurately evaluate PPP-based road projects leveraged with real options.

Decision Analysis

Contributed Session

Chair: Seyede Yasaman Amirkiaee, University of North Texas, Denton, TX, United States, SeyedeYasaman.Amirkiaee@unt.edu

1 - Inferential Modelling and Decision Making under Uncertainty
Jian-Bo Yang, Professor, University of Manchester, F36 MBSE, Booth Street West, Manchester, United Kingdom, jian-bo.yang@manchester.ac.uk, Dong-Ling Xu, Chao Fu, Xiaobin Xu

This paper is aimed to investigate issues related to how to make the best use of imperfect data collected from different sources routinely for scientific inference & robust decision making. A data-driven method is introduced & numerical examples are examined to show how evidential reasoning (ER) can be conducted to implement and generalise Bayesian inference in situations where data can be incomplete, ambiguous or inaccurate with different degrees of reliability & weight. A real life case study on the diagnosis of irregularity faults of railway track is conducted to demonstrate a practical procedure for developing an ER-based diagnosis method.

2 - Utilization of Statistical Approaches for Comparing Association Rule Mining Algorithms
Sanam Azadiamin, Ohio University, 35 N Mckinley Ave. Apt 112, Athens, OH, 45701, United States, sa349416@ohio.edu, Gulser Koksal

Finding the most appropriate association rule mining algorithm according to its application area is studied using statistical approaches. For this purpose, test data is developed based on a statistical experimental design and logistic regression. Interesting rules are found considering pre-specified support level. Finally, the comparison is done compromising over several measures and using the interesting rules. Illustrative examples are provided.

3 - An Adaptive Heuristic for Feature Subset Selection Based on Feature Complementarity
Sumanta Singha, Doctoral Student, University of Kansas, 1654 Naismith Drive, Capitol Federal Hall, Lawrence, KS, 66045, United States, sumanta.singha@ku.edu, Prakash P. Shenoy

The paper presents a novel approach to feature subset selection, which optimizes relevance, redundancy, and complementarity using an adaptive framework, and determines the trade-off rule endogenously based on these factors. The heuristics explicitly characterizes complementarity, and allows the redundancy-complementarity ratio to guide the search process. Using benchmark datasets, the proposed heuristic outperforms many existing methods of feature subset selection.

4 - Networked Pattern Recognition Framework for Classification
Safak Yakti, Research Assistant, Binghamton University, Johnson City, NY, 13790, United States, syakti1@binghamton.edu, Salih Tutun, Mohammad Khasawneh

This research aims to propose a comprehensive new framework, namely Networked Pattern Recognition (NEPAR) Framework for different applications. The NEPAR and five different classification methods (SVM, NB, LR, DT, and kNN) are improved by adding information from the proposed network metrics. Information from observations is extracted by building the network, and feature properties for each observation are used to classify the output. Six different datasets (Australian credit approval, diabetes, breast cancer, abalone, SturPlus fMRI, German credit) are used to show the framework outperforms other traditional classification.

5 - Enhancing Lasso's Sparsity via Mixed Integer Quadratic Programming
Ahmed M. Marzouk, Southern Methodist University, Lyle School of Engineering, Dallas, TX, 75275-0123, United States, Marzouk Halit Uster

We present a Mixed Integer Quadratic program (MIQP) to find a sparse solution for linear regression (LR) models. We show that the proposed MIQP provides sparser solutions than that provided by LASSO without any degradation in the LR prediction power. Specifically, the average improvement in sparsity when using MIQP was 32.3% and the average computational time was less than one minute.

6 - Public Opinion on Self-driving Vehicles: A Comment Mining Approach
Seyede Yasaman Amirkiaee, PhD Student, University of North Texas, 1307 West Highland Street, BLB 375D, Denton, TX, 76201, United States, SeyedeYasaman.Amirkiaee@unt.edu, Nicholas Evangelopoulos

Automated driving vehicles are disrupting the transportation industry. As many top motor vehicle and high-tech companies are entering this market, it is important to look at public attitude towards this latest technology. While traditional research has relied on structured surveys, in this research, we are reviewing public opinion by mining posted comments on published news stories, promotional videos, and micro-blogging web sites (Twitter).

Chair: Anparasan Mahalingam, Purdue University, West Lafayette, IN, United States, anparasan@purdue.edu

1 - Silence in Identity Salience : the Perks and Downsides of Spanning Multiple Categories on Forming Collaboration Ties
Pyung Nahm, Seoul National University, 1 Gwanak-ro, Gwanak-gu, Seoul, 08826, Korea, Republic of, joeynahm@gmail.com

We explore the effects having an organizational identity that span multiple categories on the actor's formation of collaboration ties. We posit that actors without salient identities, spanning multiple categories, are likely to face 'multiple-category discount' when selecting potential partners. These actors are more likely to form ties with unexperienced alters because experienced alters question the competence of actors spanning diverse areas. Reputation, a stronger social judgment for competence, will eventually moderate the discounting effect. We utilized co-author network in the management field, analyzing all researches published in the top journals from 2000 to 2016.

2 - When Does Paying More Pay Off?
Hazhir Rahmandad, Associate Professor, MIT, 100 Main Steet, E62-442, Cambridge, MA, 02142, United States, hazhir@mit.edu, Zeynep Ton

Can well-paying and satisfying jobs accompany, or lead to, profitability in low-cost service sector? Building on qualitative data from a few case studies we map out the systemic feedback mechanisms that could enable good jobs in services. Using a simulation model we show that on a strategy space defined by two dimensions of task richness and compensation, two distinct local profitability peaks emerge: one with low compensation and task richness, representing employee cost minimization, and the good jobs peak with high compensation and task richness. Simulations establish the conditions under which each peak dominates, and the challenges of moving to the good jobs peak due to temporal tradeoffs.

3 - Untangle Interorganizational Collaboration from Value Cocreation Perspective
Marian Dan-Wei Wen, National Cheng Kung University, No. 1, University Rd., East Dist.,, Tainan, 70101, Taiwan, marian.wen@gmail.com, Shih-Chieh Fang, Ching-Ying Huang

Received literature on inter-organizational collaborations emphasizes value capture more than how value is jointly created. This research adopts value co-creation approach from service science to address (1) the variety of value that can be created, and (2) key factors making multiple organizations co-create value, then present a tentative research framework. Theoretically, this paper extends inter-organizational value creation by going into the multi-partner settings and promoting multiple organization collaborations. Practically, this paper reflects collaborations with other organizations can be viewed from a collaboration-oriented manner to make pies bigger.

4 - Forming Balance in Status Between Female Directors and Male CEOs: Through Adjusting Male CEO's Economic Status
Junghyun Mah, Seoul National University, KangnamGu, Irwonbondong Mokryun Town 107-601, Seoul, 06355, Korea, Republic of, junghyunmah@gmail.com

Little has been explored on how the subdivision of status for female directors and male CEOs invoke social comparison when determining male CEOs' compensation. Female directors enjoy the high economic status, whereas they occupy low social status compared to male CEOs. In contrast, male CEOs occupy high economic and social status. Status inconsistent female directors aim to balance their overall status with status consistent male CEOs through targeting male CEOs' economic status. It is observed by decreased growth rate of male CEOs' compensation, narrowed pay disparity, increased shareholder's wealth, and the number of board appointments by female directors moderates the influence.

5 - Information Systems Integration in Mergers and Acquisitions
Aditya N.Saharia, Associate Professor, Fordham University, Gabelli School of Business, 140 West 62nd Street, New York, NY, 10023, United States, saharia@fordham.edu

Often corporate mergers fail because (or create negative values) because of the difficulty in integrating IT systems and the operational and management processes they support. In this work we use a knowledge based view of the firm to identify critical success factors for post-merger IT integration.

6 - Evolution of Hierarchical and Modular Patterns in Strategic Networks

Anparasan Mahalingam, PhD Candidate, Purdue University, 403 W State Street, Krannert Building, West Lafayette, IN, 47906, United States, anparasan@purdue.edu, David Richard Johnson, Umit Ozmel

We have applied network analysis tools to a database of biopharmaceutical alliances, developing methods to identify emergent hierarchical and modular network structures, find sub-communities, and trace temporal dynamics. Findings suggest that smaller sub-communities organize hierarchically into larger networks with local clustering. Patterns and structures are consistent with features found in many other types of networks. These methods lead to greater understanding of the strategic implications of network structure and organization when fused with econometric analysis.

1 - Addressing Health Disparities at U.S. Community Health Centers: A Focus on Pregnancy-related Health Outcomes

Andreas Thorsen, Montana State University, Bozeman, MT, United States, andreas.thorsen@montana.edu, Maggie Thorsen, Rohith Mahdi Reddy, Ronald G.McGarvey

Federally qualified health centers (FQHCs) provide comprehensive health care services to under-served populations. We aim to identify whether there exist different typologies for FQHCs and to better understand the differences between and within these typologies in terms of efficiency, quality of care, and pregnancy-related health outcomes. We identify FQHC typologies by performing a latent class analysis incorporating information such as demographics and services provided. Then we apply data envelopment analysis to measure the efficiency of health centers within latent classes. The purpose of this analysis is to determine systematic issues that may hinder successful FQHC operations.

2 - A Demand Response Model for Biopower Generation to Identify Optimal Multi-state Collaborations

Ronald McGarvey, University of Missouri, IMSE and TSPA, E3437D Lafferre Hall, Columbia, MO, 65211, United States, mcgarveyr@missouri.edu, Bayram Dundar, Francisco X. Aguilar

In this study, we investigate the impact of energy policy-related regulations on biomass demand and procurement cost using econometric models. We develop a robust optimization model to identify min-cost approaches for reducing carbon emissions via biomass co-firing subject to spatially-explicit biomass availability constraints. We utilize a simulated annealing heuristic approach to solve the resultant robust mixed integer nonlinear programming model. We apply this model to a set of 18 states in the northern US to identify optimal sets of multi-state collaborations.

3 - Coupled Natural and Human System Model to Support Climate-adapted Water Management Policies in the Great Plains

Jessica Heier Stamm, Assistant Professor, Kansas State University, Manhattan, KS, United States, jlhs@k-state.edu, Gabriel Granco

Policy makers face challenges developing and enacting policies to help communities mitigate or adapt to climate change impacts. We study a coupled natural and human system in the U.S. Great Plains that is vulnerable to water supply challenges. In this talk, we describe a geographically explicit agent-based simulation model that integrates the decision making perspectives of community members, landowners, and policy makers with biophysical system models. We aim to identify water management policies that balance economic and environmental sustainability.

4 - Inventory Management of Blood Platelets at Hospitals

Suchithra Rajendran, The Pennsylvania State University, 265 Blue Course Drive, Apt 3E, State College, PA, 16803, United States, sur205@psu.edu, Arunachalam Ravindran

This research proposes stochastic mathematical models for blood platelet inventory management at the hospitals. On one side, there is a 20% wastage of platelets due to outdating and on the other side, there is severe blood shortage due to which surgeries are postponed by nearly 120 days. Therefore, it is necessary to minimize wastage and shortage of platelets. In this research, inventory models are developed to achieve this objective incorporating several real-life constraints. The result act as a decision support system to the hospital administrator.

1 - Cheating or Delighting Customers on Product Quality?

Fouad El Ouardighi, ESSEC Business School, Avenue B. Hirsch BP.105, Cergy Pontoise, 95021, France, elouardighi@essec.fr, Konstantin Kogan

In this paper, we claim that, though based on different tradeoffs, cheating and delighting policies are the two faces of the same coin. Cheating allows for inflated goodwill and provides a cheating rent as long as the cheating is not disclosed, while delighting allows for enhanced goodwill and yields a delighting rent as soon as the delighting is awarded. The conditions that allow for rent equalization between the two policy options are identified. We also characterize the conditions under which either cheating or delighting customers on quality is beneficial.

2 - Joint Optimization of Capacitated Assortment and Pricing Problem under the Tree Logit Model

Yanqiao Wang, UC Berkeley, 1945 Milvia St, Apt 101, Berkeley, CA, 94704, United States, yanqiao@berkeley.edu, Zuo-Jun Max Shen

Assortment and pricing decisions are of significant importance to firms and have huge influences on profit. How to jointly optimize over both assortment and prices draws increasing attention recently. In this paper, we study the joint capacitated assortment and price optimization problem where the consumer choosing behavior is governed under the multistage tree logit model. Under the cardinality constraints, we develop an efficient algorithm that runs in polynomial time to find the optimal assortment with optimal prices. Under the space constraints, we can obtain a 2-approximate solution within the same time scale compared to the cardinality constraints.

3 - Competition in Food Quality Standards when Consumer Confusion Exists

Yang Song, East China University of Science Technology, Meilong Road No.130, Shanghai, China, skye_y.song@qq.com

As food quality is a kind of credence attribute, Certification can reduce the problem of information asymmetry. This paper assumes that duopoly firms produce product with vertical differences and two different standards. We focus on the analysis on the equilibrium and our results show that the existence of two quality standards can increase the producer's benefits as well as social welfare. Especially, I takes into account the existence of consumer confusions. It shows that a second standard led to an increase in prices and a reduction in qualities. At last, comparison between the social effects of markets consisted of different consumers were made.

4 - Coordinating Customers' Choices for Cost-effective Healthcare Service Delivery

Harihara Natarajan, Associate Professor, University of Miami, Coral Gables, FL, United States, hari@miami.edu, Fang Fang

Service providers vary greatly in their costs to the insurance company, but may have little difference to the consumers in terms of coinsurance payment and other out-of-pocket expenses. As a result, without alignment, consumers may choose more expensive treatment that increases the cost to the insurance company. Facing this problems, we exam how an insurance company could provide incentives to consumers to gain alignment without compromising the quality of care or customer service.

5 - Profiting from Refund: the Value of No-shows

Yang Zhan, Shanghai Jiao Tong University, 1954 Huashan Road, Shanghai, 200030, China, zhanyangjy@sjtu.edu.cn

To migrate the negative effects of no-shows, a pre-charge strategy, which charges a deposit when a patient requests an appointment, is observed in an increasing number of clinics. We consider two policies including to refund or not to refund the deposit, respectively. Under the refund policy, the patient can get partial or full refunds, is assumed to report the cancellation for sure. While under the no-refund policy, the patient cannot get any refund, not reporting the cancellation, and no-shows may incur. We show that the refund policy can be more profitable (1) without charging a higher deposit compared to the no-refund policy (2) even when overbooking is allowed in the no-refund policy.

Retail Management

Contributed Session

Chair: Shin Woong Sung, KAIST, Daejeon, United States, sw.sung@kaist.ac.kr

1 - Sustainability Trends in Retail Sector : A Text Mining Approach
Youqin Pan, Salem State University, Bertolon School of Business, 352 Lafayette Street, Salem, MA, 01970, United States, ypan@salemstate.edu

This paper applies a text mining approach to discover sustainability trends in the retail sector. The findings demonstrate that green store operations, green transportation, consumer education, and employee engagement are considered as important sustainability issues or concerns in retail industry. Insights based on this study will help retail companies identify improvement opportunities by comparing its own sustainability efforts with the overall trends in the retail sector.

2 - Service Dependency and the Role of Labor in Retailing
Chien-Ming Chen, Associate Professor, Nanyang Technological University-Singapore, 50 Nanyang Avenue, Singapore, 639798, Singapore, cmchen@ntu.edu.sg, Howard Hao Chun Chuang

We empirically examine how service dependency of the shopper population may affect labor's effect on retail store performance. The results show that labor's marginal contribution to conversion and average sales are highly contingent on service dependency. Our study is based on multi-year panel data from a major retail chain in North America.

3 - Ship-from-store Operations in Omni-channel Retailing
Armagan Bayram, Assistant Professor, University of Michigan Dearborn, 31035 Morlock Street, Apt 716, Livonia, MI, 48152, United States, armagan@umich.edu, Bahriye Cesaret

We consider an omni-channel retailer having both online and store operations and implementing ship-from-store fulfillment model. In this model, store orders are fulfilled from store inventories, but for an online order the retailer can ship it either from the online distribution center or from any store location that maximizes its overall profit. We investigate dynamic fulfillment decisions: from which location to fulfill an online order when it arrives. We incorporate the uncertainty both in demand and in the cost of shipment to individual customers. We develop a stochastic dynamic framework and present some results on optimal fulfillment strategies.

4 - A Customer Choice Model for Estimating the Halo Effect
Reza Yousefi Maragheh, University of Illinois, Urbana-Champaign, Urbana, IL, United States, ysfmrgh2@illinois.edu, Alexandra Chronopoulou, James Mario Davis

According to Halo effect, customers value the same product differently if the offered assortment varies. A customer choice model is developed that captures the pairwise effect of products on each other's intrinsic values, i.e. the latter is a function of the offer set. This allows the model to violate the Independence of Irrelevant Alternatives property. A procedure is proposed for parameter estimation and sufficient identifiability conditions are derived. For special cases, closed form expressions are obtained. Simulation results confirm the theoretical findings. When testing the proposed model on synthetic data, it outperforms the MNL model in terms of AIC and in most cases in terms of BIC score.

5 - Environment Analysis for Global Operations Strategy in Retailing Industry
Yeming Gong, Em Lyon Business School, Building B, Office 1018, 23 Avenue Guy De Collongue, Ecully, 69134, France, gong@em-lyon.com, Jiawen Liu

Considering an operational decision in distribution centralization , we examine relationships between discretionary inputs of supply chain, non-discretionary inputs of environment, and organizational performance in retailing. We develop a non-discretionary DEA model to assess the corporate performance in retailing industry. Our main contribution is: (1) to provide a new method using non-discretionary DEA integrated with econometric analysis in environment analysis for GOS, and (2) to establish a new framework to understand the role of centralized distribution and its competitive environment in retailing supply chain strategy.

6 - Image-based Inventory Distribution System for Fashion Products using Convolutional Neural Network
Shin Woong Sung, KAIST, 291 Daehak-ro, Yuseong-gu, Daejeon, Korea, Republic of, sw.sung@kaist.ac.kr, Hyeonjun Sim, Hyunsuk Baek, Young Jae Jang

We present the image-based inventory distribution optimization method for fashion products. Due to the product variety and short product life cycles, the distribution of the fashion product to stores is challenging. Particularly for the product lines with limited quantity, the product mix is critical in the distribution decision. The proposed distribution method first identifies the visual similarity between products using convolutional neural network. Then mathematical optimization method determines the product mix and the distribution based on the visual similarity. This work is done with an academic-industry collaboration and the method has been tested and validated with actual data.

Project Management

Contributed Session

Chair: Sinan Obaidat, University of Arkansas, Fayetteville, AR, United States, sfobaida@uark.edu

1 - Efficient Reproduction Scheduling Against Defectives under Uncertainty
Atsushi Kurimoto, Osaka University, Osaka, Japan, atsushi.kurimoto@ist.osaka-u.ac.jp, Hiroshi Morita

There are many uncertain factors such as defectives and machine failure in production process. We have to deal with them by rescheduling or adaptive scheduling, which may cause the delivery delay and excess inventory. Robust schedule for uncertainty brings us the reduction of delivery delay and inventory. We consider to provide the appropriate production plan by taking into account of the uncertainty.

2 - Production Planning and Quality Testing under Random Yield
Candace Arai Yano, University of California-Berkeley, IEOR.Department, 4141 Etcheverry Hall, Berkeley, CA, 94720-1777, United States, yano@ieor.berkeley.edu, Sandra Transchel

We study a co-production system in which there is a two-stage testing process with limited capacity. Finished products are differentiated according to their quality levels in two dimensions, and the firm sells these products at different prices. Demand can be fulfilled using a substitute product of equal or higher quality but at the price of the requested quality. We develop a stochastic dynamic programming model with three types of decisions: (i) ordering decisions, (ii) testing policy, and (iii) allocation of the post-final-test inventory to the quality-differentiated demands.

3 - Performance Analysis of Multi-product Manufacturing Systems with Dedicated Finite Buffers
Kyungsu Park, University of Wisconsin-Madison, Madison, WI, United States, kyungsu@kaist.ac.kr, Jingshan Li

Many flexible manufacturing systems process multiple products with dedicated buffers. In such systems, scheduling and control polices play a critical role. Priority, cyclic, and WIP-based policies are among the most typical ones. In this talk, we study the performance of two-machine lines with multiple product types, unreliable Bernoulli machines, and finite dedicated buffers, under these three policies. Exact solutions for small scale systems are derived and iteration procedures are introduced for larger ones through decomposition. It is shown that the proposed method results in high accuracy in throughput estimation.

4 - A MILP Model for Job and Labor Scheduling to Minimize Weighted Tardiness and Labor Costs for Parallel Machines
Weihang Zhu, Associate Professor, Lamar University, PO Box 10032, Beaumont, TX, 77710, United States, weihang.zhu@lamar.edu, Sujay Mahale, Ezra Wari, Alberto Marquez

Scheduling problems often requires optimization of multiple resources. In this paper, a two stage mixed integer linear programming (MILP) model is formulated to optimize two resources sequentially based on their priorities: machines (first level resource) and labor (second level resource). Minimizing tardiness (continuous time model) for machines and the cost of temporary employees (discrete time model) for labor are set as objectives. With the resulting schedule for machine run and individual labor assignments, the proposed model enables organization to improve their production and labor planning and assist in efficient capacity utilization.

5 - Solution Approaches for an Integrated Process Configuration, Lot Sizing and Scheduling Problem in the Packaging Industry
Karim Perez Martinez, Federal University of São Carlos, Rua José Duarte de Souza, 36, São Carlos, 13564030, Brazil, karim@dep.ufscar.br, Yossiri Adulyasak, Raf Jans, Reinaldo Morabito, Eli Vitor Toso

We study an integrated process configuration, lot sizing and scheduling problem in a real environment of the packaging industry. Main decisions include determining which process configurations are used, how long they are used, and in what sequence. Non-linear mathematical models are presented and symmetry-breaking constraints are applied to the formulations. A Branch-and-cut algorithm and a MIP-based heuristic are proposed to solve the problem. Results show that the exact algorithm outperforms the linearized models solved by a commercial solver for all the instances tested and the heuristic finds good quality solutions for large instances in shorter computational times.

6 - Quality Control Sampling in Continuous Production
Sinan Obaidat, PhD Student, University of Arkansas, 1690 Live Oak Dr, Apt 12, Fayetteville, AR, 72704, United States, sfobaida@uark.edu, Haitao Liao

In this study, a quality control sampling for continuous production is proposed. Items are sampled during the production process at specified intervals such that one item is inspected at each interval. The production process is stopped for maintenance if the number of nonconforming items found in sampling exceeds a certain acceptance limit. The production time is divided into sampling cycles of fixed sizes, but it is not necessary to complete a sampling cycle if the number of nonconforming items exceeds the acceptance limit. The objective of this paper is to find the parameters of the sampling plan: sampling interval, sampling size, and the acceptance limit to minimize the total cost of quality.

Practice/Healthcare IV

Contributed Session

Chair: Leon Cui, Binghamton University, 62 Decatur St, Binghamton, NY, 13903, United States, cui@binghamton.edu

1 - Improving Inventory Management of Perishable Substitutable Goods
Gina Dumkrieger, ASU, Tempe, AZ, 85281, United States, gina.dumkrieger@asu.edu

For families of perishable good where substitution is possible (such as blood products or antibiotics) outdating can be reduced through proactive use of substitution in the inventory allocation process.

2 - Managing Access To Care At Primary Care Facilities
Sina Faridimehr, Wayne State University, 4815 Fourth Street, Manufacturing Engineering Building, Detroit, MI, 48202, United States, sina.faridimehr@wayne.edu, Saravanan Venkatachalam, Ratna Babu Chinnam

One of the most important challenges confronting healthcare facilities is the effective management of access for patients to primary care. In this study, we develop appointment scheduling models using two-stage stochastic programming to improve access to care while maintaining high levels of provider capacity utilization and improving patient flow in clinic.

3 - Effectiveness of a Rapid Response Team in a Large Hospital: An Empirical Study.
Valery Pavlov, Senior Lecturer, University of Auckland Business School, University of Auckland, Private Bag 92019, Auckland, 1142, New Zealand, v.pavlov@auckland.ac.nz, Ali Vahabzadeh

In order to identify critically ill patients in the wards and timely transfer them to an ICU, and to prevent unnecessary ICU admissions, hospitals around the world have implemented Rapid Response Teams (also known as CCOT, MET or PAR teams). To date, the evidence on their effectiveness, coming exclusively from the medical literatures, has been scarce and controversial. One possible explanation is that these studies did not fully account for operational factors. Using a 12-month data from an 800-bed hospital in New Zealand, we investigate the impact of the hospital's rapid response team on patient outcomes treating operational factors as instrumental variables.

4 - Systematic Layout Planning of A Radiology Reporting Area To Optimize Radiologists' Performance
Flavio S. Fogliatto, Associate Professor, Federal Univ of Rio Grande do Sul, Av. Osvaldo Aranha, 99/5o andar, Porto Alegre, RS, 90040020, Brazil, ffogliatto@producao.ufrgs.br, Carla Schwengber Ten Caten, Ricardo A. Cassel

Optimizing radiologists' performance is a major priority for managers of health services/systems, since the radiologists' reporting activity imposes a severe constraint on radiology productivity. Despite that, methods to optimize radiologists' reporting workplace layout are scarce in the literature. This study was performed in the Radiology Division (RD) of an 850-bed University-based general hospital. The analysis of the reporting workplace layout was carried out using the Systematic Layout Planning (SLP) method, in association with cluster analysis as a complementary tool in early stages of SLP.

5 - Improving Quality of Care At A Hypertension Clinic using A Mobile Health Application
Leon Cui, Assistant Professor, Binghamton University, 62 Decatur St, Binghamton, NY, 13903, United States, cui@binghamton.edu, Saligrama Agnihothri, Anu Banerjee, Ramanujapuram Ramanujan

Chronic conditions place a high cost burden on the healthcare system and deplete the quality of life for millions of Americans. To monitor their health, some hypertension patients now use mobile devices to measure blood pressure outside of the doctor's office. These mobile health apps benefit patients by (i) yielding more accurate readings compared to in-office measurements, and (ii) offering timely information to the physician. However, the magnitude of this benefit is unclear. We collect data from a local clinic that has adopted this technology, and use it to evaluate the impact of continuous monitoring of blood pressure via smartphone app on the quality of patient care.

Topics in Behavioral Operations Management

Sponsored: Behavioral Operations Management

Sponsored Session

Chair: Ruth Beer, Indiana University, Kelley School of Business, Bloomington, IN, 47404, United States, ruthbeer@indiana.edu

1 - Risk in Channels
Paola Mallucci, University of Wisconsin, 4261 Grainger Hall, 975 University Avenue, Madson, WI, 53706, United States, mallucci@wisc.edu

In a set of incentivized experiments we explore the role of risk in pricing decisions in a dyadic channel. We systematically vary who holds the risk while holding expected payoff constants across treatments. We find that subjects' behavior is inconsistent with classical economic theories, risk aversion as well as theories of fairness.

2 - Auctions, Efficient Coordination, and Strategic Complementarities
Anthony M. Kwasnica, Pennsylvania State University, 332 Business Bldg, University Park, PA, 16802, United States, kwasnica@psu.edu, James Fan

The likelihood of auctions to lead to efficient outcomes in order statistic coordination games as originally studied by Van Huyck et al. (1993) is re-examined under varying conditions. Specifically, we examine whether minimum order statistic games results in similarly positive results to those originally found in median order statistic games. We find that coordination on the efficient outcome as a result of a pre-play auction is sensitive to the degree of strategic complementarity. Our results are examined in relation to the behavioral learning model proposed by Crawford and Broseta (1998).

3 - Wage Transparency in Sales Agents Compensation Schemes
Javad Nasiry, Hong Kong University of Science and Technology-HKUST, Hong Kong, Hong Kong, nasiry@ust.hk, Xiaoyang Long

Sales agents with social preferences evaluate their pay in comparison with their peers and experience a positive or negative utility. We characterize the optimal salesforce compensation schemes in this context and characterize the conditions under which wage transparency benefits the firm.

4 - Monitoring or Disclosure? the Role of Observability in Buyer-supplier Collaborative Projects
Ruth Beer, Indiana University, Kelley School of Business, 314 W. 4th Street #404, Bloomington, IN, 47404, United States, ruthbeer@indiana.edu, Anyan Qi

Many manufacturers' projects (such as innovation and new product development) often involve tight collaboration with a key supplier. The success of such initiatives depends on both firms committing resources and generating high quality outputs. We study two ways in which a manufacturer can increase output observability (at a cost) in this setting: monitoring the supplier's progress and disclosing her own progress to the supplier.

361B

Behavioral Operations

Contributed Session

Chair: Sina Zare, University of Texas-Arlington, Arlington, TX, United States, sina.zare@uta.edu

1 - Suppliers Learning in Supply Chain Competition
Mohsen Ahmadian, University of Massachusetts-Boston, Boston, MA, United States, mohsen.ahmadian001@umb.edu, Ehsan Elahi, Roger H. Blake

Our research uses the results of laboratory experiments in which subjects playing the role of suppliers compete for the business of a buyer outsourcing the manufacture of a commodity product. These results show significant differences with predictions from theory, and our research uses the Quantal Response Equilibrium (QRE) to consider whether bounded rationality and learning effects can offer some explanation for these variances. By developing this model from the QRE framework, we will be able to evaluate learning effects and whether they vary under different scenarios of competition.

2 - CEO Scapegoating and Consumer Product Recalls
Kevin Mayo, Indiana University, 1309 E 10th Street, Bloomington, IN, 47405, United States, mayok@indiana.edu, George Ball, Alex Mills

Product recalls have significant impact to a firm's financial and legal standing as well as on consumer health and safety. In this study, we explore the relationship between CEO turnovers and product recalls. Do recalls lead to CEOs being fired or quitting? Do new CEOs scapegoat and blame problems on their predecessors by recalling soon after taking over? Using a recurrent hazard model with 40 years of consumer product recalls and CEO turnover data, we examine the hazard of a CEO turnover after a recall and a recall after a CEO turnover. Results support a recall scapegoating effect.

3 - Leadership, Social Preferences and Productivity: Evidence from Truck Drivers
Francisco Brahm, PhD Student, University of Cambridge, Trumpington 10, Cambridge, CB2 1AG, United Kingdom, fb435@cam.ac.uk

We explore how the traits of leaders affects team productivity in the context of 53 customer-delivery trucks where the driver leads a team of two/three helpers. We collect social preferences from lab-in-the-field behavioral games and personality traits from a big-five survey. We show that "generalized trust" and "altruism" improves daily performance across several measures of productivity and quality. In contrast, "trusting helpers" is detrimental, with Big five traits having negligible impact. We also show that going from employee-driver to owner-driver, and thus directly employing its helpers, increases performance, particularly if the driver is "altruistic" and "open to experience".

4 - Asymmetry and Sharing of Sales Information under Revenue Sharing Contract
Ummuhan Akbay, Visiting Instructor, Sabanci University, Istanbul, Turkey, ummuhana@sabanciuniv.edu

We study revenue sharing contract on a one manufacturer-one retailer supply chain under sales information asymmetry. The sales quantity to be disclosed to the manufacturer is determined by the retailer who has an opportunity to underreport. We investigate how the truth-telling behavior and ordering decisions of the retailer are affected by the contract parameters and the demand realization; how the manufacturer's contract parameters are affected by the possible distortion in the shared sales information; and how both firms' profits and the contract efficiency is affected in this scenario.

5 - Does Advance Warning Help Mitigate the Impact of Supply Chain Disruptions? An Experimental Investigation
Sourish Sarkar, Assistant Professor, Penn State-Erie, The Behrend College, 5500 Copper Dr, Apt 301, Erie, PA, 16509, United States, sourishs@gmail.com, Sanjay Kumar

We explored the impact of an advance warning of a disruption on supply chain performance. Using controlled laboratory settings, we considered disruptions at both upstream and downstream echelons. For each of these disruptions, scenarios with and without advance warning were compared. We also investigated the impact of communicating such warning to other echelons of the supply chain. We found a behavioral bias that results in worse performance in advance warning scenario for downstream disruptions.

6 - Gamified Newsvendor Experiment: the Impact of Leaderboards on Learning and Behavioral Biases
Sina Zare, University of Texas-Arlington, 1020 W. Abram, Apt 289, #103, Arlington, TX, 76013, United States, sina.zare@uta.edu

We present research examining how a gamified traditional Newsvendor experiment impacts individual's decision making performance. We hypothesized that a gamified Newsvendor experiment with leaderboards positively influence newsvendor's performance through improving learning process and mitigating the influence of behavioral biases.

Chair: Neda Masoud, University of Michigan, Ann, MI, 48109, United States, nmasoud@umich.edu

1 - Stochastic Control of Traffic Flow to Manage Ride-Sharing Platform
Qi Luo, University of Michigan, 2465 Lancashire Drive, Apt 2A, Ann Arbor, MI, 48109, United States, luoqi@umich.edu, Romesh Saigal

We investigate the Ride-Sharing Platform management using a continuous-time continuous-space approach. A monopolistic principal matches two sides of the market, i.e. supply (vacant vehicles) and demand (customers' trip requests) dynamically. The supply model prevents the exponential growth of state space by adopting multi-population traffic flow theory. The demand side employs a queuing model. We further formulate the platform's problem as an optimal stochastic control to maximize the revenue by redistributing initial conditions. This simple formulation enables to incorporate myopic agents' local optimum decisions without treating combinatorial explosion.

2 - Ride-Matching in Large-Scale Transportation Networks
Neda Masoud, University of Michigan, 2350 Hayward St., 2124 GG Brow, Ann Arbor, MI, 48109, United States, nmasoud@umich.edu, Yuexi Tu

This study presents a divide-and-conquer algorithm for solving the ride-matching problem in a large-scale peer-to-peer ridesharing system. The complexity of the ride-matching problem grows with the number of riders, drivers, and the rider-driver pairs that are eligible to be matched. The divide and conquer algorithm divides the ride-matching problem into multiple smaller sub-problems of the same structure, and combines the solutions to these sub-problems to propose an approximation for the original problem.

3 - A Hub and Shuttle Transit System for Ann Arbor
Pascal Van Hentenryck, University of Michigan, 1813 IOE Building, 1205 Beal Avenue, Ann Arbor, MI, 48108-2117, United States, pvanhent@umich.edu, Antoine Legrain, Connor Riley

This talk describes a novel Hub and Shuttle Transit System for the Ann Arbor Campus of the University of Michigan (about 7.5 million passengers a year). The system addresses both congestion and the infamous first/last mile problem. The talk describes the design and implementation of the new transit system, simulation results, and early feedback from deployment.

4 - Matching Assignment Game for Mobility as a Service Transportation Assignment
Saeid Rasulkhani, New York University, 328 91st Street, Apt 2R, Brooklyn, NY, 11209, United States, sr4262@nyu.edu, Joseph Y.J. Chow

The emergence of more transportation options in smart cities requires more generalized transportation assignment models. We develop a transportation assignment model based on a route-based bipartite matching assignment game. For any mobility as a service operating design, we can determine not just the flow of travelers, but also the route service provision decisions of the operator(s) and cost allocations for all parties. Stability conditions under congestion are explored.

5 - Semi-door-to-door On-demand Transit System: Analytics and Practice
Hao Zhou, Ford Motor Company, 2101 Village Road, Dearborn, MI, 48124, United States, hzhou35@ford.com

We will discuss Ford's various ongoing efforts in shared mobility, in particular, semi-door-to-door on demand ride sharing service. In contrast to traditional on-demand transit system that provides customers' door-to-door rides, semi-door-to-door ride-sharing service dynamically clusters customers and thus have higher ride-sharing potential.

We will discuss various analytics aspects of such ride-sharing system, efficiency evaluation, demand forecasting, dynamic pricing, etc.

Design and Planning of Ports

Sponsored: Transportation Science & Logistics

Sponsored Session

1 - A Framework for Building a Smart Port and Smart Port Index
Anahita Molavi, University of Houston, 4722 Calhoun Rd, E224, Engineering Bldg 2, Houston, TX, 77204-4007, United States, anahita.molavi@gmail.com, Gino J. Lim, Bruce Race

Globally, ports and harbors are facing stiffer competition for market share and delivering more effective and secure flow of goods. High performing ports are implementing smart technologies to better manage operations. We present a comprehensive literature review of the studies regarding Smart Port as a basis for a holistic definition for a Smart Port Index. The Smart Port Index in this paper is based on Key Performance Indicators and organized around four key elements: operations, environment, energy, and safety and security. Case studies and data analysis are used to test the KPIs to understand their characterization of the Smart Port performance of some busiest ports.

2 - Assessment of Container Port Efficiency using Data Envelopment Analysis

Sonal Jain, University of Houston, Houston, TX, 77204, United States, jsonal@gmail.com, Qianmei Feng

Maritime ports have become a major source of trade, with $900+ billion worth of goods moving in and out of United States by containers. Growing shipping capacity and severe congestion in American ports raises a concern on their state of efficiency. An assessment of relative efficiency of container ports can provide insight into a port's productivity and performance. This study applies the appropriate Data Envelopment Analysis (DEA) models to study changes in efficiency for 15 U.S. container ports. The relationships between inputs and outputs are examined using the available records since 2000.

3 - Modelling the Service Availability and Resource Allocation for Quay Crane Double Cycling via Closed Queuing Networks

Qingcheng Zeng, Dalian Maritime University, School of Transportation Management, Dalian, 116026, China, qzeng@dlmu.edu.cn, Xiaoju Zhang, Ping Wang

This paper addresses the resource allocation problem with quay crane double cycling in container terminals. The operation processes is formulated by closed queuing networks. A cost-minimizing optimization model is developed to obtain an optimal resource allocation schedule, and the objective function proves to have convex behaviour with one or two optimal solutions. The asymptotic results offer insight into the types of equipment that should be added to increase efficiency. The imbalances of service ability in each operation have a critical effect on equipment utilization and handling efficiency.

1 - Design of Flexibility Portfolio to Facilitate Integration of High Shares of Renewable Energy in Europe

Violette Berge, Energy Analyst and Optimization Consultant, Artelys, Montreal, QC, Canada, violette.berge@artelys.com

By 2030, the share of fluctuating renewable power generation could attain 30%, following EU targets. This raises the need for additional flexibility to balance demand and supply at all times. Although system flexibility can be provided by various technologies, there is no "one-size-fits-all" solution at a national level and the optimal flexibility portfolio depends on the peculiarities of each country. In this context and using its powerful tool Artelys Crystal Super Grid, Artelys carried out a study for the EC that aimed at evaluating the national flexibility needs and the optimal flexibility portfolio of flexibility solutions at the Member State level to ensure a cost-effective RES integration.

2 - Two Level Distribution Network Planning Problem with Distance Limited Intermediate Facilities

Ayse Selin Kocaman, Assistant Professor, Bilkent University, Endustri Muhendisligi, Ankara, 06800, Turkey, selin.kocaman@bilkent.edu.tr, Kagan Gokbayrak

We introduce a new two-level network planning problem which might have wide applications in the planning of centralized energy and water distribution networks for greenfield development. The network connects demand points to a source point via intermediate facilities in the continuous space. The intermediate facilities reside a primary network that has a tree topology rooted at the source. The demand points are connected to the intermediate facilities with a secondary network in star topology rooted at each intermediate facility. The coverage distance limit on the intermediate facilities can be associated with physical loss constraints in energy or water distribution networks.

3 - A New Approach to the Operation of Micro Grids in Rural Areas

Jose-Ignacio Munoz-Hernandez, University of Castilla-La Mancha, Edifico Politecnico - UCLM, Avda Camilo Jose Cela, S/N, Ciudad Real, 13071, Spain, joseignacio.munoz@uclm.es, Luis Serrano-Gomez

Distribution networks in rural areas are characterized by high seasonal consumption and alterations in the quality of the supply, which affect both the availability of the service and the electrical components connected to it. Moreover, extinction of the feed-in-tariff for renewable energy is generating uncertainty that is leading towards new solutions for maximizing the operating account. This work analyzes the possibility of establishing a new operating model for isolated micro grids, in rural areas, powered by renewable energy sources.

4 - Applying a Game Theory Approach for a Dynamic Energy Bilateral Contract Scheduling

Reinaldo Crispiniano Garcia, Associate Professor, University of Brasilia - UnB, SQS.403, BLOCO.R, APT. 106, Brasilia, 70237-180, Brazil, rcgar@yahoo.com, Javier Contreras, Janiele Custodio, Felipe Toledo, Paulo Vinicius Da Cunha, Matheus Barbosa

In deregulated electricity markets, contract parties (buyers and sellers) aim to deliver electricity in time intervals during the contract period to obtain the highest possible profits. The parties can operate in spot and retail energy markets. Since this problem includes different parties trying to maximize their own profit, a game theory approach is implemented for the contract settlement. A numerical example shows the properties of this optimization problem for contract scheduling. Moreover, the contract value and the contract volumes are determined to maximize the returns of the involved parties.

5 - Minimization of Investment Costs for Designing Electricity Distribution Networks

Stefan Feuerriegel, University of Freiburg, Platz der alten Synagoge, Freiburg, 79098, Germany, stefan.feuerriegel@is.uni-freiburg.de, Alexander Schlüter, Gunther Gust, Dirk G. Neumann

We minimize the investment costs for constructing or extending electricity distribution networks, that supply electricity to neighborhoods, while complying with physical constraints. This problem encompasses the optimization of both locations and capacities of conductor lines and is, thus, an extension of the NP-hard capacitated shortest spanning arborescence problem. For this reason, we propose a heuristic that decomposes the problem: it first identifies the network layout and then decides upon capacities, followed by a variable neighborhood search. Its performance is detailed in a real-world case study.

Dynamic and Stochastic Routing and Scheduling

Sponsored: Transportation Science & Logistics

Sponsored Session

Chair: Debdatta Sinha Roy, University of Maryland, 7699 Mowatt Lane, 3330 Van Munching Hall, College Park, MD, 20742, United States, debsroy@rhsmith.umd.edu

1 - An Exact Approach for the Vehicle Routing Problem with Time Windows and Flexible Delivery Locations

Alexander Döge, Technical University of Munich, Munich, Germany, alexander.doege@tum.de, Markus Frey, Rainer Kolisch, Guy Desaulniers

We present an extension of the vehicle routing problem (VRP): the VRP with time windows and flexible delivery locations (VRPTW-FL). In the VRPTW-FL, a customer is no longer automatically assigned to a service location. Instead, one of a set of potential service locations has to be chosen, each of which has a specific capacity. In order to solve the VRPTW-FL, we develop a branch-and-price-and-cut algorithm. In our economic analysis, we assess the benefit of location flexibility on a variety of performance metrics.

2 - Multiple Plan Approach for the Dynamic Team Orienteering Problem

Emre Kirac, Assistant Professor, University of Houston-Clear Lake, 2700 Bay Area Blvd., MC41, Houston, TX, 77058, United States, kirac@uhcl.edu, Ashlea Milburn

In this study, we introduce a new dynamic routing problem, namely the Dynamic Team Orienteering Problem (DTOP) in which some customers are known a priori while others are dynamic, each associated with a profit. The goal is to maximize the sum of collected profits by visiting a set of customer locations within a time limit. This problem arises in several practical applications such as disaster relief, technician, tourist and school bus routing problems. We adapt a Multiple Plan Approach (MPA) to solve the proposed problem. A total of 1161 new DTOP benchmark instances are introduced and solved.

3 - Simulation-based Learning for Dynamic Time Window Allocation in Attended Home Deliveries

Magdalena A.K. Lang, Research Assistant, RWTH Aachen University, Kackertstraße 7, Aachen, 52072, Germany, magdalena.lang@ada.rwth-aachen.de, Catherine Cleophas, Jan Fabian Ehmke

Allocating time slots to attended home delivery requests affects providers' delivery costs and future acceptable orders. As the travel time per order depends on the complete routing, revenue management controls face the challenge of undetermined capacity consumption on request arrival. Vehicle routing can approximate travel time but does not anticipate customer choice and future controls. Our simulation-based learning approach approximates the opportunity costs of delivery time slot allocation. It informs dynamic allocation decisions when requests arrive. We present results of a computational study.

4 - Models and Algorithms for the Traveling Salesman Problem with Time-dependent Service Times

Paolo Toth, Professor, University of Bologna, DEI, Viale Risorgimento 2, Bologna, I-40136, Italy, paolo.toth@unibo.it, Valentina Cacchiani, Carlos Contreras Bolton

We consider the "Traveling Salesman Problem with time-dependent Service Times" (TSPST), a variant of the classical Asymmetric TSP. In the TSPST, each customer requires a service time whose duration depends on the time at which the customer is visited. The TSPST calls for finding a Hamiltonian circuit minimizing the total duration of the circuit (i.e. the sum of the travel times and of the service times). A branch-and-cut algorithm and a metaheuristic are proposed. Computational experiments on benchmark TSPST instances are reported, showing the effectiveness of the proposed algorithms.

5 - Addressing Uncertainty in Meter Reading for Utility Companies using RFID Technology

Debdatta Sinha Roy, PhD Candidate, Robert H. Smith School of Business, University of Maryland, 7699 Mowatt Lane, 3330 Van Munching Hall, College Park, MD, 20742, United States, debsroy@rhsmith.umd.edu, Bruce L. Golden, Edward Andrew Wasil

Utility companies collect usage data from meters on a regular basis. It is done automatically using radio-frequency identification (RFID) technology. Each meter has a signal transmitter that is read by a receiver within a specified distance. It is a Close Enough Vehicle Routing Problem (CEVRP) on a street network. In practice, there is uncertainty while reading meters. The signal transmitted by an RFID tag is discontinuous and each meter differs with respect to the specified distance. These factors can lead to missed reads. We address this uncertainty using Bayesian statistics and data analytics and perform simulation experiments to show that we design improved routes for the vehicles.

1 - Models for Merging Fire and Emergency Medical Units

Cheng Hua, Yale School of Management, Yale School of Management, P.O. Box 208200, New Haven, CT, 06520-8200, United States, cheng.hua@yale.edu, Arthur J.Swersey, Fernando Y. Chiyoshi, Ana Paula Iannoni, Arthur J. Swersey

We consider an innovative emergency service spatial queuing system in which there are crossed trained personnel assigned to fire-medic units that respond to fire alarms or emergency medical calls. A fire-medic unit may be in one of three states: available, busy at a fire incident, or busy at an emergency medical call. To make the problem computationally tractable for typical real-world systems, we devise an approximation that solves two 2-states systems to determine steady state probabilities and performance measures and discuss its application in St. Paul, Minn. The model includes both fire-medic units and separate fire and emergency medical units.

2 - Antecedents of Service Provision by Manufacturing Firms

Sina Golara, Doctoral Candidate, Arizona State University, 1249 East Spence Avenue, Apt 336, Tempe, AZ, 85281, United States, sgolara@asu.edu, Nasim Mousavi, Kevin Dooley

This paper empirically investigates the drivers of servitization by manufacturing firms. We suggest that the extant diversification theory does not completely explain servitization. We study a sample of 2450 public manufacturing firms for the period of 1976 to 2006. We find that firms in industries characterized with high technology or firms in their earlier life cycle stage offer a higher level of service. We also demonstrate that a larger market share and larger stock of proprietary knowledge encourage manufacturers to introduce more services.

3 - Service Failure Recovery Strategies from the Consumer Perspective

Ahasan Harun, PhD Student, University of North Texas, 316 Fry Str,eet Apt 203, Denton, TX, 76201, United States, MdAhasanUddin.Harun@unt.edu, Md Rokonuzzaman, Victor R. Prybutok

This research develops and tests a model about consumer positive word of mouth intention after service failure. Antecedents such as service recovery strategies, recovery evaluation, and justice perception are evaluated in the context of the proposed theoretical framework. In addition to identifying the factors, we develop a survey to measure effective means to overcome service failure in a real situation. This approach overcomes the shortcomings of the currently predominant scenario-based survey research.

4 - Sharing Economy: A Literature Review and Directions for Future Research

Xianyong Wang, Student, Clemson University, 100 Sirrine Hall, Clemson, SC, 29634, United States, xianyon@clemson.edu

This paper aims to examine both empirical and theoretical studies published in leading business journals regarding sharing economy and hopes to provide a better understanding of its scope, business models, operations strategies, and its impacts on well-established industries. This paper also presents a theoretical framework to explore the potential directions for future research.

1 - Multidimensional Bayesian Persuasion

Youzong Xu, Xi'an Jiaotong-Liverpool University, 111 Ren'ai Road, Business Building 423B, Suzhou, 215123, China, xu.youzong@wustl.edu

This paper studies a Bayesian persuasion game on a multidimensional state and action space. We characterize Sender's optimal persuasion strategies and show that, when the conflict between Sender and Decision Maker is not very large, Sender benefits more from using a signaling system that provides correlated information for different dimensions of the state. When the conflict between Sender and Decision Maker is large, Sender benefits more from using a signaling system that provides independent information for different dimensions of the state. Regardless what signaling system that Sender uses, Decision Maker's welfare is not affected by Sender's persuasion.

2 - Dynamic Duopolistic Competition with Sticky Prices under Uncertainty

Luca Colombo, Deakin University, Melbourne Burwood Campus, 221 Burwood Hwy, Melbourne, VIC 3125, Australia, luca.colombo@deakin.edu.au, Paola Labrecciosa

We extend Fershtman and Kamien (Econometrica, 1987) to a stochastic environment. We study a differential game where two quantity-setting firms compete over an infinite time horizon under the assumption that the market price does not adjust instantaneously to the level specified by its demand function and is subject to stochastic fluctuations (governed by a Wiener process). We derive analytically the closed-loop (feedback) equilibrium strategies and the evolution path of the expected price. We show that demand uncertainty is pro (anti) competitive if market size is relatively small (large).

3 - Stackelberg Leadership in a Productive Asset Oligopoly

Paola Labrecciosa, Monash University, Department of Economics, Clayton Campus, Wellington Road, Melbourne, VIC 3800, Australia, paola.labrecciosa@monash.edu, Luca Colombo

We study a differential oligopoly game where m Stackelberg leaders and n-m Stackelberg followers are engaged in the exploitation of a common-pool renewable resource over an infinite time horizon. At each point in time, firms sell their harvest in the marketplace at a price that depends on total harvest. We derive a multiple-leader feedback Stackelberg equilibrium and proceed with a comparative dynamics analysis w.r.t. various parameters of interest. We also compare and contrast the multiple-leader feedback Stackelberg equilibrium with the Cournot equilibrium and obtain a number of novel results on the relative efficiency of the two equilibria.

4 - Network Externalities in a Buyer-seller Search Platform

Jing Xu, University of Pennsylvania, 209 S 33rd Street, Math Dept, Philadelphia, PA, 19104, United States, xjing@sas.upenn.edu

I model a setting where buyers search for sellers directly or through a platform with lower search costs, and the platform charges both sides for the transactions it facilitates. Equilibrium strategies are determined by two coexisting positive and negative cross-group externalities: (i) while buyers appreciate more choices of available sellers on the platform, (ii) increasing the number of available sellers makes the search for low-priced and high-value sellers harder due to an unfavorable price dispersion. A platform optimally adopts a threshold strategy of targeting sellers with lower prices to balance the competing externalities.

1 - Quintessence of Third Party (3PL) Logistics

Tuhin Sengupta, Indian Institute of Management-Indore, Rau-Pithampur Road, Indore, 453331, India, f13tuhins@iimidr.ac.in, Sudipendra Nath Roy

In this article, we provide a systematic literature review and contribute to academic understanding and practitioner needs of third party logistics (3PL) which had been developed over the last decade. Practical relevance of our study stems from mapping managerial perspectives to the academic body of knowledge. We made a sincere attempt to link our review with previous literature reviews for keeping the knowledge continuum intact from the genesis of 3PL. The paper also identifies different research gaps; conceptual, contextual and methodological, which will facilitate understanding and aid to identify opportunities for future research in 3PL context.

2 - Studying the Tradeoff Between Police Presence and Response Time

Fatemeh Mousapour, University at Buffalo, 338 Bell Hall, Buffalo, NY, 14260, United States, fmousapo@buffalo.edu, Jose Luis Walteros, Rajan Batta

Rapid response time and adequate coverage are two key factors in police patrol problems respectively to stop, deter and prevent a crime. Our approach is to integrate the hypercube queueing model with a coverage objective to examine the tradeoff between police presence and response time in the context of server cooperation. Computational results are presented based on case study used by other researchers from Northern Israel.

3 - Optimization of NGL Rail Car Distribution

Robert A.Russell, Professor of Operations Management, University of Tulsa, Finance & Operations Mgmt Dept, 800 South Tucker Drive, Tulsa, OK, 74104, United States, rrussell@utulsa.edu

A goal programming network model is developed to optimize the allocation and distribution of NGL rail cars from production plants to supply terminals over a one year planning horizon. Key factors include contracted purchase amounts, distributions costs, tiered terminal storage capacities, and NGL future prices.

4 - A Two-stage Close-loop Queueing Network with Different Sizes of Workload and Service Rates

Yujiao Sun, Dalian University of Technology, Ganjingzi District, 2 Linggong Road, Dalian, China, sunyujiao@126.com, Ping Wang, Qingcheng Zeng, Xiangpei Hu

We model an intermodal logistics hub as a two-stage close-loop network with one server at one stage, and two servers at the other with different sizes of workload and service rates. We argue the existence of an optimal number of customers regarding the system utilization rate. Case-based numerical results justify the relationships between the number of customers and utilization rate.

Scheduling

Contributed Session

Chair: Yuping Lin, Tsinghua-Berkeley Shenzhen Institute, Tsinghua University, Shenzhen, China, linyuping@berkeley.edu

1 - A Branch-and-price Algorithm for Solving Bi-criteria Batch Scheduling Problems in Hybrid Flow Shops

Rasaratnam Logendran, Professor, Oregon State University, School of Mech Industrial & Mfgr. Engr., Rogers Hall Rm 204, Corvallis, OR, 97331-6001, United States, logen.logendran@oregonstate.edu, Omid Shahvari

We address a batching and scheduling problem consisting of several jobs belonging to pre-determined groups as inconsistent batches with respect to desired lower bounds on batch sizes in hybrid flow shops. The objective is to simultaneously minimize the total weighted completion time and total weighted tardiness of jobs. By implementing an efficient MILP model, the optimal solution or good quality lower bound of medium- and large-size problems is established with a Branch-and-Price algorithm based on Dantzig-Wolfe-Decomposition.

2 - Research on New Techniques for Multi-project Scheduling

David Poza, INSISOC - University of Valladolid, Paseo del Cauce, 59, Valladolid, 47011, Spain, poza@insisoc.org, Felix Villafañez, Javier Pajares, Adolfo López-Paredes

Very few software tools for project scheduling support multi-project resource leveling, which is an essential feature in order to obtain a feasible schedule when resources are shared between several projects. We compare the results yielded by well-known commercial scheduling software with those of the newest algorithms proposed by the latest research on this topic. We claim that these achievements in the field of Operations Research should be incorporated in commercial software in the interest of small and medium enterprises.

3 - Integrated Staff Scheduling at a Medical Emergency Service: An Optimization Approach

Hendrik Vermuyten, PhD Student, KU. Leuven, Warmoesberg 26, Brussel, 2800, Belgium, hendrik.vermuyten@kuleuven.be Hendrik Vermuyten, PhD Student, Universidade de Lisboa, Av. Rovisco Pais 1, Lisbon, 1049-001, Portugal, hendrik.vermuyten@kuleuven.be, Joana Namorado Rosa, Ines Marques, Ana Barbosa-Póvoa

In this article, we study a real-life personnel scheduling problem at the Portuguese National Institute for Medical Emergencies (INEM). We develop a column generation-based diving heuristic to solve our problem. Two column generation schemes and two branching methods are compared. While a commercial IP solver does not succeed in finding a reasonably good solution within an acceptable time, our method succeeds in finding a much better solution in a relatively short amount of time.

4 - Dynamic Airline Scheduling with Multiple Runways while Considering Separation Time Between Sequential Actions

Sheida Gohari, Research Graduate Assistant, SUNY at Binghampton, 4400 Vestal Parkway East,, Binghamton, NY, 13902, United States, gohari.sheyda@gmail.com, Sarah S. Lam

Increasing demand of aircraft travels has encouraged the airline industries to focus more on the optimization of airline scheduling. This research addresses airline scheduling while avoiding aircraft collusions and considering the separation time between two sequential actions. The objective is to minimize the earliness and tardiness costs dynamically in a multiple-runways system. Mathematical programming and agent-based models are developed for this research problem. The results will be compared with existing approaches in the literature.

5 - Comparison of Various Workforce Policies for Retail Store Workforce Scheduling Problem

Peeyush Pandey, Assitant Professor, Indian Institute of Management-Rohtak, Rohtak, 124001, India, f12peeyushp@iimidr.ac.in, Hasmukh Gajjar, Bhavin J. Shah

We generate different workforce demand patterns for a retail store traffic to compare various workforce policies. In particular, we analyse full time workforce, working time account, overtime, and hybrid (mix of full time and part time workers) workforce policies from retailer's perspective.

6 - Electric Bus Scheduling Problem with the Sizing of Bus Charging Station

Yuping Lin, Tsinghua-Berkeley Shenzhen Institute, Tsinghua University, Shenzhen, China, linyuping@berkeley.edu Yuping Lin, Industrial Engineering and Operations Research Department, UC Berkeley, Berkeley, CA, United States, linyuping@berkeley.edu, Max Shen, Max Shen, Max Shen, Kai Zhang, Lixin Miao

Besides operation timetable, electric bus scheduling problem needs to take charging time and limited driving range into consideration to schedule operation trips and charging for each bus. On the other hand, supporting charging infrastructure is required in the electric bus system. The original bus scheduling optimization without considering charging facility utilization will result in high charging facility cost. Combining bus scheduling problem with the sizing of charging station, the objective is to balance the number of electric buses and charging piles needed to minimize their total cost and a mixed integer programming is formulated.

Sponsored Session

Chair: Trevor S Hale, University of Houston-Downtown, One Main Street, Houston, TX, 77002, United States, halet@uhd.edu

1 - Dynamic Ambulance Location with Time-dependent Parameters: A Two-stage Stochastic Programming

Chun Peng, PhD Candidate, Beijing Institute of Technology, Haidian District, 5 South Street, Beijing, 100081, China, pengchun12.18@163.com
Chun Peng, PhD Candidate, HEC Montreal, Montreal, QC, H3T.2A7, Canada, pengchun12.18@163.com

In this paper, we highlight a novel two-stage stochastic programming framework that accounts for stochastic nature of emergency demand and time-dependent parameters for multi-period ambulance location. Besides minimizing total cost, we embed chance constraint in the recourse to guarantee a reliable coverage level. Furthermore, we present another stochastic model with generalized chance constraint that forcing violated probability over all possible level, to make a trade-off between coverage and cost management. An enhanced decomposition scheme is developed for the large-scale MIPs. Finally, a real-life case study is conducted and some managerial insights are drawn for EMS managers.

2 - Mathematical Programming Approaches for Facility Location Problems with Neighborhoods

Victor Blanco, University of Granada, Dpt. Quant. Meth. Economics & Business, Fac. Ciencias Economicas y Empresariales, Granada, 18011, Spain, vblanco@ugr.es

We introduce a new version of the classical p-median facility location problem in which it is assumed that the exact position of the potential facilities is unknown. Instead, assuming that the facilities are embedded in $\mathbb{R}^d$, the open facilities are required to belong to a region around their initial estimated positions: the neighborhoods. Two decisions have to be made: (1) determinate the open facilities; and (2) compute of the positions of them into their neighborhoods, at global minimum cost. We present several MINLP formulations for ordered median location problems and describe two math-heuristic approaches that allow us to solve larger instances at smaller CPU times.

3 - Population-based Metaheuristics for Fairer Facility Location

Christopher M. Rump, Applied Statistics and Operations Research, Bowling Green State University, 344 Business Administration Building, Bowling Green, OH, 43403-0267, United States, cmrump@bgsu.edu, Cameron R.King, Robert Green

We study complements to classic facility location problems on a discrete network. These complementary problems provide fairer solutions for decision makers seeking to consider the impact beyond extremal focus on either one (center) or all (median) customers. However, solving these problems is more computationally demanding than their well-known counterparts as they lose the incentive that customers should travel to the closest open facility. We employ two meta-heuristics, particle swarm optimization and adaptive large neighborhood search, to find good solutions to these intractable problems.

4 - A Graph Theoretic Approach to the Location Allocation Problem on a Network

Trevor S.Hale, Professor, University of Houston - Downtown, One Main Street, Houston, TX, 77002, United States, halet@uhd.edu, Ryan Pepper, Michelle Hutnik, Faizul Huq

Building upon previous research that developed graph-theoretic solutions for the location-allocation problem on a path, this research constructs graph-theoretic solutions for the location-allocation problem on cycles, stars, and complete graphs. This knowledge is then leveraged to help predict solutions for more general graphs. Some avenues of future research are also delineated.

1 - Airline Cargo Business Efficiency Measurement using DEA_PCA

Hossein Najmi, University of North Texas, Denton, TX, 76203-5017, United States, hossein.najmi@unt.edu, Seock-Jin Hong

In this study, we show that air cargo growth rate is declining. In addition, a negative relationship exists between the cargo business ratio and airline's efficiency in airlines, which serve passengers and cargo (combination carriers) using exclusive freighter from 2008 to 2015. The authors suggest that combination carriers should assist their customers in positioning air cargo capability as part of their integrated supply chain strategies. Such effort will help air cargo avoid commoditization.

2 - An Airport Task Assignment Problem with Travel Time and Purity Consideration

Fan Xiao, Ms, Tongji University, Zhangwu Rd 1, Tongji Building A, 1913, Shanghai, 200092, China, 892225786@qq.com, Zhe Liang

We study an airport task assignment problem with travel time and purity consideration, which is to assign a list of airport tasks to a set of shifts designed for airport personnel, so that the total operation cost is minimized. There are two major differences between the problem studied in this paper and the traditional assignment problem. First, we consider the travel time between different tasks, so it is not only to determine the assignment of the tasks, but also the routing between different tasks. The second is to consider shift purity in this problem, i.e., to limit the number of task types/qualifications in each shift. We propose a column generation algorithm to solve the problem efficiently.

3 - Flight Outsourcing to Regional Airlines

Soheil Sibdari, Associate Professor, University of Massachusetts Dartmouth, 1933 Commonwealth Avenue, Unit 408, Boston, MA, 02135, United States, ssibdari@umassd.edu, Farbod Farhadi

In this paper we address the reasons behind outsourcing flights to regional airlines. We show how outsourcing improves airline operations by adjusting their capacity. We also study the competitive effects of flight outsourcing on the U.S. domestic airline market.

4 - Sustainable Hub Location Model under Uncertainty in Aviation Industry

Suresh Kumar Jakhar, Assistant Professor, Indian Institute of Management Lucknow, Lucknow, 226013, India, skj@iiml.ac.in, Himanshu Rathore, Devendra Singh

Literature on Sustainable Hub Location models (SHLP) is limited because of their computational complexity and multidimensional nature (Mohammadi et al. 2014). We propose a realistic SHLP model in aviation industry by using chance constraint programming nested in queuing theory (M/D/s) to incorporate noise pollution and GHG emissions during the entire landing and take-off cycle of the aircraft. It determines a sustainable network strategy. To solve the NP hard formulation, we propose a methodology based on Fireworks metaheuristic algorithm embedded in Benders decomposition approach.

5 - A Stochastic Optimization Model for Fleet Assignment under Uncertainty Conditions

Daniel Felipe Otero, Instructor, Universidad de los Andes, Cr 1 este #19 A.40, Bogotá, Cundinamarca, Colombia, otero.df@uniandes.edu.co, Edwin Camilo Quiroga Gomez, Andres Medaglia

The variability in operational times has a great impact on aircraft scheduling. This work analyzes fleet assignment, considering the stochastic behavior of operational times. To solve the Fleet Assignment Problem (FAP), we propose a stabilized column generation problem, applying a set of specialized auxiliary shortest path models, based on lineal and dynamic programming (k-Shortest Path Problem with Resource Constraint - SPPRC). Finally, employing a Monte Carlo simulation, the On - Time Performance (OTP) of the fleet assignment is evaluated in specific scenarios.

Approaches to Teaching Operations Management

Sponsored: INFORMEd

Sponsored Session

Chair: Dorothy Klotz, Fordham Univeristy, 140 West 62nd Street, New York City, NY, 10023, United States, klotz@fordham.edu

1 - Building the Complete Operations Management Course Around a Web-based Simulation Game

Ardavan Asef-Vaziri, Professor, College of Business and Economics, Dept of Systems and Operations MGMT, 18111 Nordhoff Street, Northridge, CA, 91330-8378, United States, aa2035@csun.edu

We describe how a simulation game can be implemented as a bridge interfacing the concepts, techniques, and procedures thought in an OM course and real-world applications. Students examine their theoretical take-away in a pseudo-real-life environment. Our experience shows that after playing these games, the students realize that understanding the course material plays a significant role in their performance in real-life applications.

2 - Case Study: Challenges in Assembly Line Design
Balaraman Rajan, Assistant Professor, California State University East Bay, 25800 Carlos Bee Blvd, Hayward, CA, 94542, United States, balaraman.rajan@csueastbay.edu, Ravichandran Narasimhan

In this case study we discuss the production plan of two different assembly lines and how the activities can be reorganized to meet an increase in demand. The case can be used for teaching topics in operations and supply chain management at both undergraduate and graduate level. The first part of the case focuses on topics including capacity and bottleneck analysis, line balancing, and capacity requirement analysis. The second part of the case involves Just In Time manufacturing and developing a production plan. The case also demonstrates the usefulness of process flow and precedence diagrams.

3 - A Simulation Companion for 'the Goal" Match/Dice Game
Tom Brady, Purdue University, 1401 S US.Hwy 421, Westville, IN, 46391, United States, tbradyjr@pnw.edu

Since its release in 1986, The GOAL has become the seminal book in Operations Management. One of the most oft-cited passages of the book is the Boy Scout camping trip where the main concept of the book, statistical fluctuations and dependent events are introduced through a simple match/dice game. While simple in concept, most people who read the book do not get the full understanding of the concepts. I have used a physical and computer-based simulation of this game at the undergraduate, graduate, and executive levels and have seen the level of understanding greatly improved. The simulation has allowed many embellishments to be added to the simple game that extend the learning concepts in many directions.

4 - A Best Practice Approach for a Hybrid Delivery of an Undergraduate Operations Management Course
Dorothy Klotz, Professor of Management Systems, Fordham Univeristy, 140 West 62nd Street, New York City, NY, 10023, United States, klotz@fordham.edu

The modular design of both the course and the learning materials facilitated the successful transition of quantitative content online while reserving classroom time for active learning exercises. Online technologies were used to pace student learning and maintain student accountability. This approach not only resulted in a dramatic reduction in student seat time, but also resulted in improved learning outcomes.

1 - Bayesian Dynamic Linear Models for Strategic Asset Allocation
Jared D.Fisher, University of Texas, 2110 Speedway Stop B6500, Austin, TX, 78712, United States, jared.fisher@phd.mccombs.utexas.edu, Carlos Carvalho, Davide Pettenuzzo

We find statistical and economic evidence of the predictability of risk premia for multiple risky assets. We present a unifying model that accounts for parameter uncertainty, stochastic volatility, and time-varying parameters through a Bayesian dynamic linear model framework with variance discounting. To account for model uncertainty, we average over many potential models of different combinations of predictors and discount factors. For an investor allocating his wealth between a risk-free asset, stocks, and bonds with maturities from 2 to 10 years, we demonstrate an ensemble of features that is preferable to others, including the models assumed by the efficient markets hypothesis.

2 - The Curious Case of Negative Volatility
Christoph Merkle, Associate Professor, Kuehne Logistics University, Grosser Grasbrook 17, Hamburg, 20457, Germany, christoph.merkle@the-klu.org

Investors mostly perceive their own portfolio as no more volatile than the market portfolio. Taking into account observed portfolio betas, this implies a belief in very low idiosyncratic portfolio volatility, which is even negative for a considerable fraction of the population. Possible explanations are extreme overconfidence in combination with a misunderstanding how market and portfolio volatility are related. The identified bias strongly contributes to underdiversification, as a belief in negative idiosyncratic volatility conceals the benefit of diversification.

3 - Optimal Pairs Trading with Dynamic Mean-variance
Dongmei Zhu, Southeast University, Nanjing, China, dongmeizhu2013@126.com

Pairs trading strategy has been popularly adopted by hedge funds.In this paper, we investigate optimal pairs trading strategies for dynamic trading problems.The price difference of a pair of securities is modeled by an Ornstein-Uhlenbeck (OU) process.We study and formulate the mean-variance (MV) portfolio problem and the optimization problem is solved dynamically by utilizing the purely-buy-and-sell-securities strategy.We extend the results to optimally allocate money in pairs of securities and riskless asset and transform the primal optimization problem into a quadratic optimization problem with a closed-form solution.

4 - Using Social Media Sentiment in Automatic Portfolio Rebalancing
Jing-Rung Yu, National Chi-Nan University, Nantou, Taiwan, jingrungyu@gmail.com, Wan-Jiun Paul Chiou, Cing-Hung Hung, Wen-Kuei Dong, Yi-Hsuan Chang

Studies have documented the impact of the social media on stock pricing. We analyze sentiments by applying the Stock Market Lexicon to quantify the posted opinions in the Twitter combining with various portfolio models to construct optimal asset allocation. Using the daily returns and the tweets of the component stocks in S&P 500 Index during July 1, 2016 to January 31, 2017, we rebalance portfolio by identifying the 10 most tweeted stocks in previous three days. The empirical results show the dynamic rebalancing portfolios incorporating social media opinions outperform the fixed rebalancing portfolios in various measures.

1 - Performance Analysis of Finite Production Run-based Manufacturing
Liang Zhang, University of Connecticut, 371 Fairfield Way, Unit 4157, Storrs, CT, 06269, United States, liang@engr.uconn.edu, Zhiyang Jia

Many manufacturing systems operate under finite production runs. In such systems, a certain number of products (e.g., a customer order) are entered into the system. The in-process buffers are typically empty when a production run starts. This leads to transient period to build up the throughput and inventory during the process. One of the key problems for such systems is to calculate the performance of the system while completing such a production run. In this abstract, we discuss analytical and approximate methods to accomplish this.

2 - Management of a Shared Spectrum Network in Wireless Communications – A Queueing Approach
Shining Wu, Assistant Professor, The Hong Kong Polytechnic University, LMS.Dept, Hong Kong, 999077, Hong Kong, sn.wu@polyu.edu.hk, Jiheng Zhang, Rachel Q. Zhang

We consider a band of the electromagnetic spectrum with a finite number of identical channels shared by both licensed and unlicensed users. Such a network differs from most many-server, two-class queues in service systems including call centers due to the restrictions imposed on the unlicensed users in order to limit interference to the licensed users. We first approximate the key performance indicators under the asymptotic regime and then study the optimal sharing decisions of the system to maximize the system throughput rate while maintaining the delay probability of the licensed users below a certain level. Our analysis reveals a number of distinctive properties of the system.

3 - Online Priority Service Pricing with Heterogeneous Customers
Ping Cao, University of Science and Technology of China, University of Science and Technology of China, Hefei, 230026, China, pcao@ustc.edu.cn, Jingui Xie, Yaolei Wang

Consider a service system with a single server and two queues (i.e., the VIP queue and the ordinary queue), in which the server gives priority to the VIP queue. Customers are heterogeneous in their waiting cost rate, the distribution of which is unknown. If the arriving customer joins the VIP queue, he will be charged a fee K. The service system's objective is to maximize his long-run average profit by setting the additional fee. We find that there might be multiple equilibria of customers' chosen behavior under a fixed fee and the system can always reach the largest equilibrium by setting a proper initial delay announcement. Later, we use an online optimization method to find the optimal charged fee.

4 - New Perspective on Performance Measurement in Multi-server Queuing Systems
Hung Tuan Do, University of Vermont, 55 Colchester Avenue, 207 Kalkin Hall, Burlington, VT, 05405, United States, hdo@uvm.edu, Masha Shunko, Alan Scheller-Wolf

In some service systems, performance in the right tail of the queue size and/or waiting time distribution is the main source of managerial concern. We propose a new perspective on analyzing performance of such systems by defining new stochastic orders to compare the tail of distributions and performance measures based on these orders. We also propose a class of control policies that guarantee Pareto improvement based on the newly dened measures.

Inventory Management in Vehicle Routing

Sponsored: Transportation Science & Logistics

Sponsored Session

Chair: Ingrid Marcela Monroy Licht, McMaster University, 2685 Kent Avenue, Apt 201, Montreal, QC, H3S 1M8, Canada, marcela.monroy@polymtl.ca

1 - Predictive Analytics and Routing Optimization for an Urban Food Delivery Service

Alexander Hess, Research Assistant, WHU. - Otto Beisheim School of Management, Burgplatz 2, Vallendar, 56179, Germany, alexander.hess@whu.edu

This talk illustrates the application of predictive analytics in conjunction with vehicle routing for an urban food delivery service. In particular, we show how an improved routing decreases the waiting time for the customers. Further, the ETAs for each delivery can be given with greater accuracy.

2 - Dynamic Inventory Routing Problem with Traffic Congestions

Gitae Kim, Hanbat National University, Dept. of Industrial Management Engineering, School of Engineering, Daejeon, 34158, Korea, Republic of, gitaekimemail@gmail.com

Vehicle routing problem (VRP) is a complex problem in operations research. When VRP combines with inventory problem, the complexity increases. The combined problem, so called inventory routing problem (IRP), has been studied in recent decades. Like other problems, there are uncertainties in IRP. To cope with uncertain or dynamic situations, dynamic or stochastic IRP has to be considered. However, most studies for stochastic IRP assume that the demand is stochastic. In dynamic VRP, traffic congestion plays an important role for dynamic conditions. Thus, we suggest a stochastic and dynamic IRP model with traffic congestions. We also provide a solution method and numerical results for the problem.

3 - Inventory Routing Problem with Returnable Containers

Ingrid Marcela Monroy Licht, Postdoctoral Fellow, McMaster University, Michael G. DeGroote School of Business, Hamilton, ON, ONL8S, Canada, lichti@mcmaster.ca, Kai Huang

We present a problem inspired by the gas supply industry where a company provides customers with filled containers in a finite period. Over the days, the customers release the containers; therefore empty containers are accumulated on customer sites depending on the rate consumption. The containers belong to the company; consequently the empty containers should be collected at customers to re-use. This case is modeled as an inventory routing problem with additional considerations. The supplier carries routing and inventory cost, while satisfies the periodic demands of his customers. A branch and price algorithm is proposed to solve the problem. Some computational experiments are analyzed.

Sponsored Session

Chair: Ali Ekici, Ozyegin University, Endustri Muhendisligi Bolumu, Nisantepe Mahallesi Ormak Sokak No:13, Istanbul, na, Turkey, aliekici@gmail.com

1 - Dynamic Vehicle Routing Problem with Roaming Delivery Locations

Gizem Ozbaygin, PhD Candidate, Bilkent University, Dept. of Industrial Engineering, Ankara, Turkey, ozbaygin@bilkent.edu.tr, Martin W. P.Savelsbergh

Motivated by the increasing interest in trunk delivery applications, we study the vehicle routing problem with roaming delivery locations (VRPRDL) in a dynamic setting where there may be deviations from original customer itineraries. We propose a rolling-horizon based solution framework that uses the branch-and-price algorithm developed for the VRPRDL to re-optimize the vehicle routes every time an itinerary update is realized and test its efficiency.

2 - Arc Tour Problems with Complex Objectives

Mehmet Basdere, Northwestern University, Technological Institute, 2145 Sheridan Road, Evanston, IL, 60208, United States, MehmetBasdere2016@u.northwestern.edu, Karen Smilowitz, Sanjay Mehrotra

In this talk, we present a visit order-based approach and corresponding reformulations for time- and sequence-dependent arc tour problems. Our application comes from marathon course design where the aim is to find a valid simple cycle which visits a predetermined subset of landmark streets without preventing the public access to critical facilities in the network. Time-dependent objective functions are used to measure metrics that change over different stages of the race while sequence-dependent ones are used to measure total turn angle and incline change throughout the course.

3 - Comparison of Several Clustering Algorithms for an Inventory Routing Problem

Okan Orsan Ozener, Ozyegin University, Nisantepe Mh. Orman Sk. No 13 Cekmekoy, Istanbul, 34794, Turkey, orsan.ozener@ozyegin.edu.tr, Ali Ekici

We propose several clustering algorithms as a subroutine of an integrated solution approach for a variant of inventory routing problem. In the clustering phase, we generate several (possibly overlapping) clusters and choose a subset of these generated clusters by solving a set partitioning problem. We determine the cost of serving each cluster by a new tour generation-based algorithm. We compare both the clustering algorithms against each other and the new tour generation-based algorithm against a benchmark algorithm in the literature. The proposed algorithm not only finds results with lower optimality gaps but also finds feasible solutions for difficult instances.

4 - An Application of Inventory Routing Problem in Humanitarian Relief Supplies Distribution

Ali Ekici, Ozyegin University, Endustri Muhendisligi Bolumu, Nisantepe Mahallesi Ormak Sokak No:13, Istanbul, Turkey, aliekici@gmail.com, Okan Orsan Ozener, Emre Cankaya

Motivated by the practices in humanitarian relief chain, we study an application of inventory routing problem in distribution of humanitarian relief supplies. Different from the classical route cost/length minimization objective in routing problems, our objective is to make a fair distribution to the affected areas. In order to address this distribution problem, we propose a three-phase (clustering, routing and improvement) solution approach. In the proposed solution approach, we take the interaction between routing and allocation decisions into account by first solving the routing problem based on an approximate allocation and then improving the allocation based on the routing decision.

1 - Robust Optimal Management of Highway Pavement a Utilitarian Approach to User vs. Agency Costs

Umit Deniz Tursun, University of Illinois, 205 N Mathews Ave., Urbana, IL, 61801, United States, umitdeniz.tursun@gmail.com

Management of highway pavement requires considering a very extensive set of structural performance and environmental impacts simultaneously from both agency and user perspectives. Framework for employing mathematical decision modelling to address analytic approach need for addressing life cycle impacts. A constrained optimization formulation with multi-attribute utility function that reflects the users' and agencys' incentives serving as the objective function under feasibility constraints is presented. A case study on Illinois Tollway authority network is presented.

2 - Demand Monotonicity of a Pavement Cost Function Used to Determine Aumann-shapley Values in Highway Cost Allocation

Saurav Kumar Dubey, PhD Student, University of Tennessee at Knoxville, 1615 Laurel Avenue, Box 203, Knoxville, TN, 37916, United States, skumardu@utk.edu, Alberto Garcia-Diaz

Pavement Thickness and Traffic Lanes are two fundamental requirements of a highway design project. Viewing lanes and 18-kip Equivalent Single-Axle Load (ESAL) as two types of players, a pavement cost function is used to determine the average marginal cost for players also known as the Aumann-Shapley values to allocate cost among vehicle classes. This approach results in large number of players for which an efficient form of computing A-S value is needed. This article will derive a compact form for discrete A-S value whose pavement cost function will be proven to have monotonically increasing cost when demand (ESALs) is increased.

3 - Multiple Change-point Modeling and Exact Bayesian Inference of Degradation Signal for Prognostics Improvement

Yuxin Wen, PhD Student, University of Texas-El Paso, El Paso, TX, 79968, United States, ywen@miners.utep.edu

We propose a Bayesian multiple change-point modeling framework to better capture the degradation path for prognostics improvement. At the offline modeling stage, a novel stochastic process is proposed to model the joint prior of change-points and positions. At the online monitoring and RUL prediction stage, a recursive updating algorithm is developed to exactly calculate the posterior distribution and RUL prediction sequentially. To control the computational cost, a fixed-support-size strategy at the online stage and a partial Monte Carlo strategy in the RUL prediction are proposed. The effectiveness and advantages of the proposed method are demonstrated simulation and real case studies.

4 - Economic Impact of Raised Medians on Businesses in South Carolina

Samaneh Shiri, University of South Carolina, 1076 Pavilion Tower Circle, Columbia, SC, 29201-2361, United States, shiri@email.sc.edu, Mohammad Torkjazi, Nathan Huynh

Access management techniques affect economic activities along highway corridors. Raised medians that restrict left turns at mid-block are often considered as an effective access management technique which has been shown to improve traffic operations and safety. However, such restrictions also limit access to driveways. In this study, the economic impact of raised medians on businesses in South Carolina is examined using two methods: (1) surveys to study the perception of businesses and customers about raised medians, and (2) an assessment of the actual impact of a raised median on sales volume of adjacent businesses.

1 - Stochastic Modeling and Diagnosis of Leak Areas for Surface Assembly

Jie Ren, Graduate Research Assistant, Florida State Unigersity, Tallahassee, FL, 32310, United States, jr14r@my.fsu.edu, Hui Wang, Chiwoo Park

Assembly through mating a pair of machined surfaces plays a crucial role in automotive powertrain production, and the mating errors during the assembly can cause internal leakage and functional problems. The surface mating errors are difficult to diagnose because they are not measurable. To address these limitations, this talk presents a novel diagnostic method to predict potential leak areas given the measurements on the profiles of mating surfaces. The effectiveness of the proposed method is verified by case studies. The approach provides practical guidance for the subsequent assembly process as well as troubleshooting in surface machining processes.

2 - Causation-based Monitoring and Diagnosis for Multivariate Categorical Processes with Ordinal Information

Xiaochen Xian, UW-Madison, Madison, WI, United States, xxian@wisc.edu, Jian Li, Kaibo Liu

The monitoring and diagnosis of multivariate categorical processes (MCPs) have drawn increasing attention lately. In these applications, there usually exists natural order among the attribute levels of some categorical variables, such as good, neutral, and bad for measuring the product quality. In this paper, we leverage Bayesian networks to characterize MCPs with a causal structure, where the categorical variables can be either nominal, ordinal, or a combination of both. We develop one general control chart and one directional control chart, both of which fully exploit the causal relationships and the ordinal information for better process monitoring and diagnosis.

3 - System Redesign under Unknown Demand Rates

Qianru Ge, TU/e, Paviljoen N.5, IE&IS, Den Dolech 2, Postbus 5, Eindhoven, 5612 AZ, Netherlands, q.ge@tue.nl, Willem van Jaarsveld, Zumbul Atan

We consider a newly developed system sold under a PBC. The system is subject to failures with a random failure rate. The OEM is responsible for the availability of the system and makes a redesign decision at each decision period. The trade-off is that low failure rates require high redesign costs while high failure rates result in high repair and penalty costs. We use a MDP model to support the decision. As more information become available over time, we use Bayesian model to update the failure rate distribution. We show that the optimal redesign policy has a nondecreasing control limit structure. We benchmark the optimal policy against the policy only optimizing the initial design but with no redesigns.

4 - Estimation of Spatiotemporally-varying Parameters in Partial Differential Equation Models

Xi Zhang, Peking University, 298 Chengfu Road, Founder Building 512, Beijing, China, xi.zhang@pku.edu.cn, Di Wang

Estimation of temperature field provides a prerequisite opportunity to understand the dynamics of complex systems in many areas. By combining the data collected from sensor networks, the accuracy of the estimation could be greatly improved. This article presents an estimation method to model the spatiotemporal dynamics of a temperature field by integrating a physical dynamics model and a spatiotemporal Gaussian process. Results of the studies give some insight into the spatiotemporal dynamics of a temperature field and provide guidance to the optimum design of engineering structures to conserve energy and reduce production cost.

1 - Optimizing Condition based Maintenance for Systems with Degrading Sensors

Anahita Khojandi, University of Tennessee, 521 Tickle Building, Knoxville, TN, 37996, United States, khojandi@utk.edu, Mahboubeh Madadi

We consider a degrading system with non-silent failures. System failure is costly and it requires an immediate system replacement. The system status may be partially observed using a set of heterogeneous sensors at a given cost. The sensors are noisy and their noise level is a function of the sensor status. Our goal is to develop a POMDP model to determine the optimal condition based maintenance scheme to minimize the total expected discounted cost.

2 - A Decomposition Algorithm to Measure Redundancy in Structured Linear Systems

Vishnu Vijayaraghavan, Texas A&M.University, 400 Nagle Street, College Station, TX, 77840, United States, vishnunitr@tamu.edu, Kiavash Kianfar, Yu Ding, Hamid R. Parsaei

The degree of redundancy of linear sensor systems is a measure of robustness of the system against sensor failures. Finding the degree of redundancy for structured linear systems is proven to be NP-hard. Bound and decompose, mixed integer programming, l1-minimization methods have all been studied and compared in the literature. We propose a mixed integer programming based decomposition technique that utilizes the bordered block diagonal structure inherent in most practical linear sensor systems to decompose the problem into much smaller sub-problems on which the computations are performed, thereby leading to significant reductions in run time.

3 - Hierarchical Spatially Varying Coefficient Process Model

Heeyoung Kim, Assistant Professor, Industrial and Systems Engineering, Daejon, Korea, Republic of, heeyoungkim@kaist.ac.kr

The spatially varying coefficient process model is a non-stationary approach to explaining spatial heterogeneity by allowing coefficients to vary across space. In this study, we develop a methodology for generalizing this model to accommodate geographically hierarchical data. We consider two-level hierarchical structures and allow for the coefficients of both low-level and high-level units to vary over space.

4 - Optimizing Periodic Inspection Frequencies for a Class of Stochastically Degrading Systems

Mahboubeh Madadi, Louisiana Tech University, College of Engineering and Science, P.O. Box 10348, Ruston, LA, 71272, United States, madadi@latech.edu, David Kaufman, Murat Kurt

We consider existing models that optimize repair-replacement decisions for systems the degradation status of which follow a discrete time Markov chain over a set of finite states and can be revealed only by costly inspections. Given worse conditions imply higher operation costs, we utilize first-order stochastic dominance relationship among the powers of IFR-structured degradation matrices to propose approximately-optimal periodic inspection decisions that minimize the total expected discounted cost due to the operation, repair, and inspection. We illustrate our approach through numerical examples.

1 - A Novel MILP Based Approach to Multi-class Data Classification Problem

Fatih Rahim, Koç University, Koç Üniversitesi, Rumelifeneri Yolu, Sariyer, Istanbul, 34450, Turkey, frahim@ku.edu.tr, Metin Turkay

Multi-class data classification is a supervised machine learning problem that involves assigning data to multiple groups. We present a novel MILP-based approach that splits each class's data set into subsets such that the subsets of different classes are separable by a hyperplane. The hyperplanes form a polyhedral region for each subset and the regions of different classes are disjoint. A MILP model is used to find the optimal separation by minimizing the total number of regions and misclassified samples. A preprocessing step is proposed to simplify the problem considering pairwise separation of classes. We evaluated the convex hulls of subsets and the polyhedral regions for the testing phase.

2 - What Factors Influence Consumer's Online Purchase Decision? the Driving Effect of Customer Perceived Value

Peng Zhu, Nanjing University of Science and Technology, 200 Xiaolingwei Street, Nanjing, 210094, China, p.zhu@outlook.com, Yuefen Wang, Mingsheng Zhao

What factors influence consumers' online purchase decisions? This paper points out that in the online shopping mode, customer perceived value includes three dimensions: Product perceived value, Service perceived value and Social perceived value. Based on this three dimensions, the paper constructs online purchase decision impact model and collects Taobao's massive consumer purchase behavior data. Through large sample analysis, the research found that the length of online reviews, the volume of goods sold, the sellers' credit rating, the sellers' DSR service score and the time length of the online shop have positive impact on the consumer's online purchase decision.

3 - Decision Making Process for Selecting Efficient and Cost Effective Motors for Humanoid Robot Arm

Tejas Huddar, Mechanical Engineer, Texas A&M.University-Kingsville, 4510 Eisenhauer Rd, San Antonio, TX, 78218, United States, tejashuddar@gmail.com, Joon-Yeoul Oh

Selecting an option from numerous available choices in market has always been a vague task, especially, in a component selection of robot systems. The objective of this research is to develop a decision-making process for the best set selection of motors from various options considering three criteria: weight, cost and lifting capacity. The suggested decision-making process uses profile model, checklist model, AHP and lastly presents LP and NLP models using the correlations of the criteria. The results show that the suggested method is effective yet efficient not only in this problem but also in cases that need to select the best candidate from large available options.

1 - Team Formation in Social Networks

Nihal Berktas, Bilkent University, Ankara, Turkey, nihal.berktas@bilkent.edu.tr, Hande Yaman

People work in teams to complete a job or project that requires a number of skills and that needs to be finished by a deadline that cannot be met by one individual. The success of a team depends on the technical capabilities of people as well as the quality of the communication among them. We study the team formation problem in which communication is taken into consideration by assuming the potential members constitute a social network. We develop integer programs for different versions of the problem and present computational results using different data sets.

2 - An Overview of Recent Advances in Pyomo

William E. Hart, Sandia National Laboratories, 8625 Napa Valley Road NE, Albuquerque, NM, 87122, United States, wehart@sandia.gov, John Siirola

Pyomo is a Python-based, open-source optimization modeling language with a diverse set of optimization capabilities. This presentation will review significant advances in recent Pyomo releases, including advanced modeling of subproblems with blocks, automatic differentiation, modeling with units, and a new kernel software layer for advanced scripting applications.

3 - Cyclic Best First Search: using Contours to Guide Branch-and-bound Algorithms

Wenda Zhang, University of Illinois at Urbana-Champaign, 1618 Melrose Park Court, Apt 1722, Urbana, IL, 61801, United States, wzhang95@illinois.edu, David R.Morrison, Jason Sauppe, Sheldon H. Jacobson, Edward C. Sewell

The cyclic best-first search (CBFS) strategy is a modification of BFS that groups search tree subproblems into contours, and repeatedly cycles through all non-empty contours to select subproblems to explore. In this paper, the theoretical properties of CBFS are analyzed. CBFS is proved to be a generalization of all other search strategies. Further, a bound is proved between the number of subproblems explored by BFS and the number of children generated by CBFS, given a fixed branching strategy and set of pruning rules. Finally, a discussion of heuristic contour-labeling functions is provided, and proof-of-concept computational results for mixed-integer programming problems are shown.

4 - Decentralized Online Integer Programming

Ezgi Karabulut, Georgia Institute of Technology, Atlanta, GA, United States, ezgi.karabulut@gatech.edu, Shabbir Ahmed, George L. Nemhauser

We consider a set of agents that need to coordinate their actions to optimize the sum of their objectives while satisfying a common resource constraint. The objective functions of the players are unknown to them a priori and are revealed in an online manner. The resulting problem is an online optimization problem to optimally allocate the resource among the players prior to observing the item values. We show that for any deterministic online algorithm for this problem, there exists a lower bound of $\Omega(T)$ on regret. Furthermore, when the players' integer programs satisfy a special concavity condition, we propose a randomized online algorithm that guarantees an upper bound of $O(\sqrt{T})$ on the expected regret.

1 - Advancements of the Double Pivot Simplex Method

Fabio T.Vitor, Kansas State University, 2061 Rathbone Hall, 1701B Platt St., Manhattan, KS, 66506, United States, fabioftv@k-state.edu, Todd W. Easton

Recently, Vitor and Easton introduced the Double Pivot Simplex Method (DPSM). Each iteration of the Simplex Method (SM) pivots on exactly one variable. In contrast, DPSM can pivot on two variables at a time. The talk will briefly present DPSM and focus on the computational comparison of DPSM and SM. Both methods are implemented using several CPLEX routines. Computational experiments demonstrate that DPSM requires approximately 40% fewer pivots than SM when tested on some benchmark instances. Additional comments will be provided on DPSM's impact to degenerate linear programs.

2 - Diet Problem with Ingredient Preferences

Fariborz Y. Partovi, Professor, Drexel University, 3141 Chestnut St, Philadelphia, PA, 19104, United States, partovi@drexel.edu

It has been close to seventy years since the Diet problem was introduced by Stigler (Stigler 1945). However the problem with the classical Diet models is based on lack of proper presentation of food preferences. For many people, especially when they are eating outside their home, the content of the food as far as nutrition is concern, maybe not, as important as the taste of the food or other consumptions. In this article we modify Diet problem using extensions of Data Envelopment analysis to satisfy customer's preferences.

3 - Finding Enclosures of the Optimal Set of Interval Linear Programming Problems: An Empirical Analysis

Mohsen Mohammadi Dehcheshmeh, University of Louisville, Louisville, KY, United States, m0moha15@louisville.edu, Monica Gentili

Determining the set of optimal solutions for an interval linear programming problem is challenging due to the possibility of non-convex and/or disconnected optimal sets. Several approximation methods have been developed to compute enclosures of the optimal set, that is a super set that includes it. In this study, we present an experimental analysis to compare the quality of the enclosures obtained by different existing methods in the literature.

4 - On the Structure of the Inverse-feasible Region of a Linear Program

Onur Tavaslioglu, University of Pittsburgh, 7171 Buffalo Speedway, Apt 1934, Houston, TX, 77025, United States, ont1@pitt.edu, Taewoo Lee, Andrew J.Schaefer

Given a feasible solution, inverse linear programming considers perturbing the objective vector of a linear program such that the solution is optimal and the perturbation is minimum under an Lp norm. We study the polyhedral characterization of the feasible region of an inverse linear programming problem. We characterize the inverse-feasible region to show the relationship between the dimensions of the minimum faces and inverse-feasible regions, which gives necessary and sufficient conditions of the extreme, boundary, and inner points of a linear program. We characterize the set of objective vectors that generate a selected unique optimal solution for a considered linear program.

1 - Designing Resilient Electric Networks under Natural Hazards

Tomas Ignacio Lagos, University of Chile, Beauchef 851, Santiago, 7640031, Chile, tomas.lagos.gonzalez@gmail.com

We propose an optimization framework for designing a resilient electric power grid under high impact low probability events such as earthquakes. An Optimization via Simulation approach is used to solve this discrete decision problem, where the measure of resilience is the expected energy not supplied, assessed through an existing simulator that contains historical earthquake data, fragility curves of the network components, and a unit commitment model. We use this framework to discuss various approximation methods applied to select subsets of scenarios and take optimal decisions on network investment.

2 - Modeling Dependent Outages of Electricity Power Plants

Vishwakant Malladi, University of Texas-Austin, McCombs School of Business, CBA 5.202, IROM, Austin, TX, 78712, United States, vishwakant@gmail.com, Stathis Tompaidis, Rafael Mendoza

We propose a new framework to model dependence of outages of electricity power plants. Our framework accounts for commonality in outages, such as weather events and fuel shortages using a unique data set of actual outages. We calibrate our model for the Electricity Reliability Council of Texas (ERCOT) and the Western Electricity Coordinating Council (WECC) regions. We find strong evidence of dependence in outages both in the input fuel and the geographic location of the power plants and discuss the consequences of this dependence on the reliability of electricity supply.

3 - Resilience Assessment of Interdependent Gas Network and Electrical Power System Infrastructures: A Quantitative Approach

Mohammad Najarian, PhD Student, University of Houston, E206, Engineering Bldg 2, 4722 Calhoun Rd, Houston, TX, 77204-4008, United States, mohammad.najarian@gmail.com, Masoud Barati, Gino J. Lim

To reduce the consequences of hazards resilience must be incorporated into the design of the electrical power systems(EPS) and it must be quantified.The interdependence between EPS and other critical infrastructures, such as natural gas systems (NGS), compounds the complexity of resilience measurement. In this paper, we provide a method to measure and analyze the impact of NGS resilience on the EPS resilience. This method is also used to assign limited resources to both EPS and NGS aiming at increasing the resilience of the EPS. For this, a combination of security-constrained unit commitment with gas dependency constraint and Monte Carlo simulation is used.

1 - Real-time Data-driven Detection of Low-quality Synchrophasor Measurements

Meng Wu, PhD Student, Texas A&M.University, College Station, TX, 77840, United States, mariewumeng@gmail.com, Le Xie

An online data-driven approach is proposed for the detection of low-quality synchrophasor measurements. The proposed method leverages the spatio-temporal similarities among multiple-time-instant synchrophasor data, and formulates the low-quality synchrophasor data as spatio-temporal outliers. A density-based local outlier detection technique is proposed to detect the spatio-temporal outliers. This data-driven approach involves no system modeling information. The algorithm can operate under both normal and fault-on system conditions, with fast computation speed suitable for online applications. The effectiveness of the proposed approach is verified via case studies.

2 - Smart Grid Security through Synchrophasor Data: Real-time Detection of Attacks on AC State Estimation

Biplab Sikdar, PhD, National University of Singapore, bsikdar@nus.edu.sg

One of the most important functions in the control and monitoring of a power grid is AC state estimation whose output is used by Energy Management System (EMS) applications such as economic dispatch, contingency analysis, and optimal power flow. Protecting the state estimator against cyber-attacks that bias its outputs is thus of critical importance. This paper proposes a simple non-iterative technique for detecting false data injection attacks on AC state estimators, by using synchrophasor data. As the proposed method is independent of the state estimator outputs and does not depend on any EMS functionality, it can be used to test the data even before the execution of the state estimation algorithm.

3 - Reconstructing the Power Grid Dynamic Model from Sparse Measurements

Andrey Y. Lokhov, Los Alamos National Laboratory, CNLS, MS.B258, Los Alamos, NM, 87545, United States, lokhov@lanl.gov, Deepjyoti Deka, Marc Vuffray, Michael Chertkov

We describe the problem of parameter reconstruction in the power grid dynamics from sparsely located phasor measurement units (PMUs) observations. We assume that the dynamics is described by a system of coupled linearized second-order differential swing equations. In the ambient regime, fluctuations on individual nodes are assumed to be independent and Gaussian distributed. The goal is to reconstruct the inertia and damping coefficients of generators, as well as line susceptances. We discuss how this learning task can be efficiently combined with the problem of state estimation of consumption in the grid, and solved using regularized maximum likelihood and least-squares estimators.

4 - High-dimensional Data Analytics of PMU Measurements by Exploiting Low-dimensional Models

Meng Wang, Rensselaer Polytechnic Institute, Troy, NY, United States, wangm7@rpi.edu

The increasingly denser coverage of phasor measurement units (PMUs) enables dynamic visibility into power systems. The large amounts of data obtained by PMUs impose significant challenges to data management and information extraction. Interestingly, the spatial-temporal blocks of PMU data exhibit low-dimensional structures despite the high ambient dimensions. Such low-dimensionality can be exploited to enable and simplify multiple PMU data analysis tasks under the same framework.

Rounding: Methods and Applications

Sponsored: Optimization, Integer and Discrete Optimization

Sponsored Session

Chair: Arash Asadpour, New York University, New York University, New York, NY, 10012, United States, aasadpou@stern.nyu.edu

1 - Assignment Mechanismsunder Distributional Constraints

Shameli Ali, Stanford University, Stanford, CA, 94305, United States, shameli@stanford.edu, Itai Ashlagi, Amin Saberi

We study the allocation of heterogeneous positions to agents under distributional constraints. Each agent has a public type, and a private ranking over positions. The goal is to find a Pareto efficient assignment that maximizes the number of assigned agents. A natural benchmark is the solution of a linear programming relaxation that allows agents to be assigned to positions fractionally. We introduce a mechanism that achieves this goal while violating each constraint by a small number. This mechanism is strategyproof if agents' acceptable positions are public. We also propose a weakly strategyproof mechanism that improves upon the first mechanism by finding an ordinally efficient assignment.

2 - Stable Matching with Proportionality Constraints

Rakesh Vinay Vohra, University of Pennsylvania, Economics Department, 3718 Locust Walk, Philadelphia, PA, 19104, United States, rvohra@sas.upenn.edu, Nguyen Thanh

The problem of finding stable matches that meet distributional concerns is usually formulated by imposing various side constraints. Prior work has focused on constraints whose "right hand sides" are absolute numbers specified before the preferences or number of agents on the "proposing" side are known. In many cases it is more natural to express the relevant constraints as proportions. We treat such constraints as soft, but provide ex-post guarantees on how well the constraints are satisfied while preserving stability. Our technique requires an extension of Scarf's lemma, which is of independent interest.

3 - Approximate Random Allocation Mechanisms

Akbarpour Mohammad, Stanford University, Stanford, CA, United States, mohamwad@stanford.edu

We extend the scope of random allocation mechanisms, in which the mechanism first identifies a feasible "expected allocation" and then implements it by randomizing over nearby feasible integer allocations. Previous literature had shown that the cases in which this is possible are sharply limited. By constructing a new rounding algorithm, we show that if some of the feasibility constraints can be treated as "goals" rather than hard constraints then, subject to weak conditions that we identify, any expected allocation that satisfies all the constraints and goals can be implemented by randomizing among nearby integer allocations that satisfy all the hard constraints exactly and the goals approximately. By defining ex post utilities as goals, we are able to improve the ex post properties of several classic assignment mechanisms, such as the random serial dictatorship.

4 - A Primal-dual Framework for Decomposition and Rounding Methods in Assemble-to-order Systems

Levi DeValve, Duke University, 716 Turmeric Lane, Durham, NC, 27713, United States, levi.devalve@duke.edu, Sasa Pekec, Yehua Wei

We develop a primal-dual framework that allows a systematic approach to assessing heuristic performance in hard integer programs, and apply it to the assemble to order (ATO) problem. Our high level approach is to: (i) solve a relaxation to obtain a dual solution, (ii) construct a primal solution from the relaxation, and (iii) use our primal-dual framework to provide approximation guarantees. We demonstrate the versatility of our approach by analyzing various ATO heuristics within a unified primal-dual framework. In particular, for ATO, we provide performance bounds for LP rounding schemes and newsvendor decompositions, as well as insights into issues driving performance.

Chair: Marco Luebbecke, RWTH Aachen University, Aachen, Germany, marco.luebbecke@rwth-aachen.de

1 - Mixed-integer Quadratic Optimization Formulations for Eliminating Multicollinearity based on Variance Inflation Factor

Yuichi Takano, Senshu University, Kawasaki, Japan, ytakano@isc.senshu-u.ac.jp, Ryuta Tamura, Ken Kobayashi, Ryuhei Miyashiro, Kazuhide Nakata, Tomomi Matsui

The variance inflation factor, VIF, is the most frequently used indicator for detecting multicollinearity in multiple linear regression models. This talk presents mixed-integer quadratic optimization formulations for selecting the best subset of explanatory variables under upper-bound constraints on VIF of selected variables. Computational results illustrate the effectiveness of our optimization formulations based on comparisons with conventional local search algorithms.

2 - Modeling Road Vulnerability to Snow using Mixed Integer Optimization

Tony Rodriguez, University of Tennessee, Knoxville, TN, 37996, United States, trodrig5@vols.utk.edu, Olufemi Omitaomu, Jim Ostrowski

As the number and severity of snowfall events continue to grow, the need to intelligently direct road maintenance during these snowfall events will also grow. In several locations, local governments lack the resources to completely treat all roadways during snow events. As a result, many schools, businesses, and government offices must be unnecessarily closed, which directly impacts the social, educational, and economic well-being of citizens and institutions. In this work, we propose a mixed integer programming formulation to optimally allocate resources to manage snowfall on roads using meteorological, geographical, and environmental parameters.

3 - Mathematical Programming for Regression Subset Selection with Diagnostic Constraints

Seokhyun Chung, Korea University, Korea Univ. New Engineering Building, 214, Seongbuk-gu, Seoul, Korea, Republic of, csh98016@gmail.com, Young Woong Park, Taesu Cheong

Many existing algorithms for regression subset selection focus on minimizing objective function such as sum of squared errors (SSE). However, it is also important to satisfy all underlying assumptions and diagnostics of linear regression. In this paper, we propose a mixed integer quadratic programming model to minimize SSE and satisfy regression assumptions and diagnostics. A procedure is also proposed to obtain near-feasible solutions when a solution satisfying all constraints cannot be easily found. A computational study is provided with real-world data.

4 - Sparse Classication: A Discrete Optimization Perspective

Jean Pauphilet, PhD Candidate, Massachusetts Institute of Technology, 77 Massachusetts Avenue, Building E40-103, Cambridge, MA, 02139, United States, jpauph@mit.edu, Dimitris Bertsimas, Bart Paul Gerard Van Parys

In this paper, we formulate the sparse classification problem as a mixed-integer convex optimization problem and propose a cutting-plane algorithm to solve it exactly. For sparse logistic regression and sparse SVM our algorithm finds optimal solutions for n and p in the 10,000s within minutes. If there is enough data, the algorithm is fast, accurately detects all the true features and returns no false features. In contrast, Lasso persistently returns incorrect ones, even as the number of observations increases. Finally, we apply our method in genomics. Sparse classification returns a classifier based on 32 genes only, while Lasso selects 172 with a similar predictive accuracy.

5 - Learning When to Use a Decomposition

Marco Luebbecke, Professor, RWTH Aachen University, Operations Research, Kackertstr. 7, Aachen, D-52072, Germany, marco.luebbecke@rwth-aachen.de, Markus Kruber, Axel Parmentier

Applying a Dantzig-Wolfe decomposition to a mixed-integer program (MIP) aims at exploiting an embedded model structure. Recently, automating the process and embedding it in standard MIP solvers have been proposed, with the detection of a decomposable model structure as key element. If the detected structure reflects the (usually unknown) actual structure of the MIP well, the solver may be much faster on the reformulated model than on the original. We propose a supervised learning approach to decide whether or not a reformulation should be applied. First numerical experiments show a significant performance improvement on structured instances, with little deterioration on others.

1 - Potential for Widespread Electrification of Vehicle Travel

Jessika Trancik, Massachusetts Institute of Technology, 77 Massachusetts Avenue, E40-241, Cambridge, MA, 02139, United States, trancik@mit.edu

Electric vehicles can contribute to climate change mitigation but only if vehicle range matches travelers' needs. Evaluating electric vehicle range against a population's needs is challenging because detailed driving behavior must be accounted for. Here we develop a model to combine information from expansive travel surveys with high-resolution GPS data to estimate the energy requirements of personal vehicle trips across the U.S. We find that the energy requirements of most driving days could be met by today's affordable electric vehicles. For the highest-energy days, other vehicle technologies are likely needed, and predictive models combined with car sharing could play an important role.

2 - Identifying Portfolios of Energy Technologies that are Robust to Multiple Models

Franklyn Kanyako, Research Assistant, University of Massachusetts, Amherst, Amherst, MA, 01003, United States, fkanyako@umass.edu, Erin Baker

This project investigates the problem of allocating R&D funds across low-carbon energy technologies in the context of climate change. Multiple expert elicitation on the future cost of low energy technologies are used as input into three Integrated Assessment Models(IAMs), GCAM, WITCH, and MESSAGE. IAMs are designed with a different representation of processes and assumptions about the economy, energy, and policy, which create an uncertainty known as model uncertainty. Outputs from these models are used to conduct robust portfolio decision analysis to identify the non-dominated portfolio of alternatives that are robust to all models.

3 - Improving Land Use Efficiency of Utility-scale Solar Photovoltaics

Jeremiah Johnson, University of Michigan, 440 Church Street, Dana Building, Ann Arbor, MI, 48109, United States, jxjohns@umich.edu, Noah Mitchell-Ward

This study explores the ability and limitations to increase the land use efficiency of solar photovoltaic generation through decisions available to solar project developers. To achieve this, we developed a physics-based model to determine solar angles and shading impacts as a function of time, location, collector orientation, and collector tilt. Using Typical Meteorological Year data, we determine the maximum solar generation per unit of land area for various locations and module efficiencies. These findings show the potential reductions in land use for utility-scale solar, as well as the tradeoff between generation per module and generation per land area, as driven by shading losses.

4 - Valuing Offshore Wind Energy

Zana Cranmer, Bentley University, Waltham, MA, United States, zanacranmer@gmail.com, Erin Baker

Much attention has been paid to the environmental costs of offshore wind energy in terms of the impacts on ecosystems and species such as birds, bats, and marine wildlife. For comparison, we need to understand the value of permitting offshore wind farms in terms of mitigating global climate change. We develop a model for estimating the value of permitting offshore wind projects globally over the rest of the century and estimate that the value ranges between $25 billion to $48.8 trillion dollars in a business as usual case. The corresponding value of technological change ranges from about $474 billion to $45.2 trillion dollars in this case.

Enhancements of Stochastic Approximation

Sponsored: Optimization, Optimization Under Uncertainty

Sponsored Session

Chair: Uday Shanbhag, Pennsylvania State University, University Park, 310 Leonhard Bldg, University Park, PA, 16802, United States, udaybag@psu.edu

1 - On the Analysis of Accelerated Variable Sample-size Stochastic Approximation (VSSA)

Uday Shanbhag, Pennsylvania State University, University Park, 310 Leonhard Bldg, University Park, PA, 16802, United States, udaybag@psu.edu

Traditional stochastic approximation (SA) schemes employ a single gradient or a fixed batch of noisy gradients in computing a new iterate. To mitigate computational complexity, we consider increasing sample size when the total simulation budget is finite. We present amongst the first stochastic generalizations of Nesterov's accelerated gradient scheme where we first show that when the objective is strongly convex, the expected sub-optimality error diminishes at a geometric rate while upon termination. Also, for convex case we can recover optimal convergence rate as well.

2 - A Unifying Selftuned Stepsize Rule for Stochastic Mirror Descent Methods

Nahidsadat Majlesinasab, Oklahoma state university, nahid.majlesinasab@okstate.edu, Farzad Yousefian, Arash Pourhabib

Motivated by big data applications, we consider stochastic mirror descent methods for solving stochastic convex optimization problems. The performance of this class of methods is very sensitive to the choice of the stepsize sequence. We present a unifying self-tuned stepsize for smooth and nonsmooth problems such that: (i) it is characterized in terms of problem parameters and algorithm's settings; and (ii) under this update rule, a suitably defined error metric is minimized. We present the performance of this update rule for the soft margin linear SVM problem over different large datasets.

3 - On Variable Sample-size Stochastic Mirror-descent and Fista-like Schemes for Nonsmooth Stochastic Optimization

Afrooz Jalilzadeh, 424 Waupelani Drive, Apt Q34, State College, PA, 16801, United States, Azj5286@psu.edu, Uday Shanbhag

Traditional stochastic approximation (SA) schemes with convex constraints employ a single gradient and a projection on a convex set in computing an update. To reduce computational complexity, we consider two schemes; nonsmooth Variable Sample-Size Stochastic Mirror-Descent (VS-SSMD) and Variable sample-size FISTA (VS-FISTA), in which N_k samples are utilized at step k and the total simulation budget is M. Under a strong convexity assumption, we prove linear convergence of iterates. Additionally, we show that the proposed VS-FISTA scheme for merely convex case displays the deterministic O(1/k^2) convergence rate.

4 - Sampling-based Schemes for the Solution for Two-stage Risk-limiting Economic Dispatch Problems

Wendian Wan, Pennsylvania State University, University Park, PA, United States, wzw121@psu.edu

Risk Limiting Dispatch (RLD) is a new operating paradigm that uses real-time information about supply and demand, integrating complex stochastic nature of power system. Tradeoff between computational complexity and accuracy need to be considered by system operator. In this talk, two-stage risk-limiting economic dispatch problem is formulated and a sampling-based schemes has been utilized in order to meet the scalability requirement of power system.

Sponsored Session

Chair: Alexander Vinel, Auburn University, Auburn University, Auburn, AL, 36832, United States, alexander.vinel@auburn.edu

1 - Risk-averse Stochastic Optimization Model for Hazardous Material Transportation using Risk Parity and Modern Risk Measures

Nasrin Mohabbati Kalejahi, PhD Candidate, Auburn University, Auburn, AL, United States, nasrin@auburn.edu, Alexander Vinel

Hazardous material (hazmat) transportation problem aims to ship hazmats from an origin to one or several destinations through a road network. Using a single optimal path repeatedly over time increases the risk of accidents for the population in surrounding area. One of the biggest challenges in hazmat transportation is to reach risk equity over the network. In this research, risk parity concept is combined with modern risk measures and a risk-reward-diversification framework is developed. The objective of the optimization model is to find multiple routes and fairly distribute the exposure to risk in the transportation network to guarantee the equal risk contribution of each route to the total risk.

2 - An Alternate Way of Real Options Valuation with Loss Function
Kyongsun Kim, Auburn University, Auburn, AL, United States, kimkyon@auburn.edu, Chan Park

Adopting the financial option pricing method for real options implicitly assumes the project value follows a geometric Brownian motion. Because of many practical difficulties of formulating real option strategies based on financial option framework, we propose an alternative method for valuing non-financial assets with the standardized loss function that provides practically identical results with the well-known Black-Scholes formula.

3 - Obtaining Lower Bounds for Multi-stage Risk-averse Stochastic Mixed-integer Programs
Ge Guo, Iowa State University, 3004 Black Engineering Building, Iowa State University, Ames, IA, 50011-2164, United States, geguo@iastate.edu, Sarah M.Ryan

Traditional stochastic programming is risk-neutral in the sense that it is concerned with the optimization of an expectation criterion. In many applications, however, the decision makers are more concerned about large losses. Thus, risk-averse optimization has attracted attention in stochastic programming. We present a method to obtain convergent and tight lower bounds from the Progressive Hedging algorithm (PHA) for multi-stage risk-averse stochastic mixed-integer programs focusing on time-consistent risk measures. This method can assess solution quality for PHA and also integrate with exact algorithms that rely on lower bounds. We report computational results on lot sizing instances.

4 - Identifying Error- and Attack-resilient Clusters in Networks under Decision-dependent Uncertainties
Hossein Dashti, hdashti@email.arizona.edu, Pavlo A. Krokhmal

Network robustness is crucial in many areas such as energy and defense. Possible disruptions may affect network's functionality. One of the key robustness requirements is every pair of nodes are connected through number of short intermediate links. Moreover, having multiple paths makes such a cluster more robust. The cluster represents a R-robust 2-club, which is a subgraph with at least R disjoint paths of length at most 2 connecting each pair of nodes. Uncertainty manifested as stochastic errors/attacks in different nodes. If one can reinforce the network components against future threats, the goal is to determine optimal reinforcements that would yield a cluster with minimum risk of disruptions.

1 - Applications of Wasserstein Distance in Distributionally Robust Optimization
Ye Wang, University of Southern California, 3767 Clarington Avenue, Apt 206, Los Angeles, CA, 90034, United States, wang141@usc.edu

Wasserstein distance is a statistical metric that describes a distance function between two probability distributions. In our research, we consider the entropy maximization problem and the highest density region optimization problem in which we will search through all distributions whose Wasserstein distance to the empirical distribution of a given set of data points is sufficiently small.

2 - Robust Binary Linear Programming under Implementation Uncertainty
Jose E. Ramirez, PhD Student, Texas A&M.University, 3131 TAMU, College Station, TX, 77843, United States, ramirez.jose@tamu.edu, Victor J. Leon

This paper studies robust binary linear programming in the presence of uncertainties that may prevent the implementation of solutions exactly as prescribed. A formal model of this type of uncertainty, termed implementation uncertainty, is presented and used to develop a robust binary linear programming formulation under implementation uncertainty. The solution approach involves a mixed-binary linear program reformulation used in conjunction with identified structural properties, allowing the generation of a set of optimal solutions. Three methods to control the level of conservatism are developed including a cardinality-constrained reformulation of the original problem.

3 - A Robust Optimisation Approach to the Manpower Planning Problem
Gar Goei Loke, Public Service Division, 9 Jalan Grisek, Singapore, 419440, Singapore, e0012863@u.nus.edu, Melvyn Sim

A Robust Optimisation approach is applied to the manpower planning problem of optimal recruitment and progression through a hierarchy, under constraints of budget, productivity, headcount and managerial span of control. The model also incorporates employees' time-in-grade as a determinant, and is endogenic in this sense. A Satisficing approach was adopted, which guarantees that the probability of violation of constraints is controlled up to T time periods. The effectiveness and robustness of the model is tested against existing methods in the literature and compared.

4 - A Robust Optimization Approach to Transshipment Problem under Demand Uncertainty
Nafiseh Ghorbani Renani, Graduate Research Assistant, The University of Oklahoma, 519 South University Blvd, Apt 21, Norman, OK, 73069, United States, Nafiseh.ghorbani.renani-1@ou.edu

In each country, there are a number of food supply companies which are in charge of distributing food properly throughout cities. In fact, the main duty of these organizations is preventing of the food shortage. In such a company, the role of network flow management has become bold. Since demand is uncertain in this situation, two different probabilistic linear programming models have been suggested by using stochastic method and robust optimization method to find the optimum solution. This study is mainly focusing on a multi-period robust optimization model for transshipment of N products among N cities for a food supply company.

5 - Data Driven Robust Optimization for Logistics and Transportation Problems
Mehdi Behroozi, Assistant Professor, Northeastern University, Boston, MA, 02115, United States, m.behroozi@neu.edu, John Gunnar Carlsson

Using Wasserstein metric in defining the ambiguity set in robust optimization allows us to circumvent common overestimation that arises when other procedures are used. In this paper, we consider a distributionally robust version of the Euclidean travelling salesman problem in which we compute the worst-case spatial distribution of demand against all distributions whose Wasserstein distance to an observed demand distribution is bounded from above. We compare the advantages of this method with other approaches for describing the region of uncertainty, such as taking convex combinations of observed demand vectors or imposing constraints on the moments of the spatial demand distribution.

Keynote: A Probabilistic Theory of Deep Learning

Invited Session

1 - A Probabilistic Theory of Deep Learning
Rich Baraniuk, Rice University

A grand challenge in machine learning is the development of computational algorithms that match or outperform humans in perceptual inference tasks that are complicated by nuisance variation. For instance, visual object recognition involves the unknown object position, orientation, and scale in object recognition while speech recognition involves the unknown voice pronunciation, pitch, and speed. Recently, a new breed of deep learning algorithms have emerged for high-nuisance inference tasks that routinely yield pattern recognition systems with near- or super-human capabilities. But a fundamental question remains: Why do they work? Intuitions abound, but a coherent framework for understanding, analyzing, and synthesizing deep learning architectures has remained elusive. We answer this question by developing a new probabilistic framework for deep learning based on the Deep Rendering Model: a generative probabilistic model that explicitly captures latent nuisance variation. By relaxing the generative model to a discriminative one, we can recover two of the current leading deep learning systems, deep convolutional neural networks and random decision forests, providing insights into their successes and shortcomings, a principled route to their improvement, and new avenues for exploration.

1 - Forecast Combining for Multivariate Probability Distributions

Xiaochun Meng, PhD Student, Saïd Business School, University of Oxford, Park End St, Oxford, OX1 1HP, United Kingdom, xiaochun.meng@sbs.ox.ac.uk, James W. Taylor

When faced with several competing forecasts, accuracy is very often improved by forming a combination of the individual forecasts. In addition to theoretical and empirical results regarding the combination of point forecasts, recent research supports the use of combining for probabilistic forecasting. For marginal distributions, it has been shown that combining quantiles is preferable to combining probabilities. We investigate whether this is also the case for joint distributions. Our empirical results concern forecasts of the joint distribution of the daily maximum and minimum temperature, which relates to the probabilistic forecasting of extreme weather events, such as heat waves.

2 - Sample Size Determination for Split Testing Based on Expected Cumulative Regret

Daniel Frey, Professor, Massachusetts Institute of Technology, 77 Massachusettes Avenue, Room 3-449D, Cambridge, MA, 02139, United States, danfrey@mit.edu, Nandan Sudarsanam, Balaji Pitchai Kannu, Ravindran Balaraman

Our work presents theoretical results for determining optimal sample size for A/B tests in the online setting. Unlike traditional criteria of Type 1 and 2 errors used in sample size determination, the online setting imposes the additional cost of poor performance incurred during the testing phase. We model the theoretical means of the tested alternatives, as well as the noise in the system across a range of probability distributions. In the case which explores Gaussian distributions (for both the means as well as noise), our solution for the sample size simplifies to a function of the trial horizon and a ratio of the standard deviations of the distributions.

3 - Quantile Markov Decision Processes

Huaiyang Zhong, Stanford University, 119 Quillen Ct, Apt 217A, Stanford, CA, 94305, United States, hzhong34@stanford.edu, Xiaocheng Li, Margaret L. Brandeau

Sequential decision making is an important task widely appeared in the fields of operations research, management science, artificial intelligence and stochastic control. In this work, we novelly introduce the framework of Quantile Markov Decision Process (QMDP) which enables us to maximize quantiles of the cumulative reward in the Markov decision process. We provide an efficient dynamic programming algorithm to solve QMDP with analysis from both theoretical and algorithmic perspectives.

1 - Downside Risk Aversion and Cumulative Prospect Theory

Qiulin Yang, Lancaster University, Lancaster, United Kingdom, q.yang5@lancaster.ac.uk, Zhan Pang, James Huang

The increasingly popular Cumulative Prospect Theory (CPT) has challenged the Expected Utility Theory (EUT) in describing individuals' choices of risky prospects. Our paper attempts to bridge CPT and EUT by providing a choice-theoretic characterization of the tradeoff between overall risk (variance) and downside risk for downside risk averse decision makers in the CPT paradigm. We also discuss the intrinsic relationships between the defined downside risk change and the familiar skewness measures. Moreover, we show that our analysis for S-shaped value functions can be readily extended to reverse S-shaped value functions.

2 - Stochastic Dominance and Value of Information

N. Onur Bakir, Associate Professor, Istanbul Kemerburgaz University, Istanbul Kemerburgaz Üniversitesi, Mahmutbey Dilmenler Caddesi, No:26,, Istanbul, 34217, Turkey, onur.bakir@kemerburgaz.edu.tr

In this study we analyze the information acquisition problem in a multi-action setting where a decision maker chooses among multiple lotteries. In particular, we comparatively evaluate information on two lotteries that are related to each other in the sense of restricted stochastic dominance. We show in general that drawing conclusions on ranking of information for a risk averse decision maker is possible for specifically structured information alternatives.

3 - A Framework for Dealing with Baseline Uncertainty: An Analysis of China's Carbon Intensity Target

Anastasis Giannousakis, Potsdam Institute for Climate Impact Research, Telegraphenberg A.31, Potsdam, 14473, Germany, giannou@pik-potsdam.de, Elmar Kriegler, Lavinia Baumstark

Intensity targets are being used as alternatives to quantity targets in the presence of baseline uncertainty. Currently, nearly one third of global emissions are under indexed control. We propose a framework to assess to what extent this is a meaningful alternative. Analyzing the Chinese intensity target with respect to situations were in multi-stage policy design either choice of target can be implemented we highlight the importance of explicitly accounting for uncertainty in economic growth, as it can lead to substantial amounts of hot-air or unexpected costs. We also identify what type of structural transformations could be more economic and how target updating creates risk of stranded assets.

4 - A New Correlation Coefficient for Aggregating Incomplete Rankings Equitably

Adolfo R. Escobedo, Arizono State University, Tempe, AZ, 77802, United States, adres@asu.edu

The consensus ranking problem is central to group decision-making. It involves finding an ordinal evaluation which minimizes the collective disagreement relative to a set of individual preferences over a set of competing objects; two common examples are corporate project selection and academic paper competitions. Although different measures for quantifying agreement between rankings can be employed, those founded on axiomatic distances are regarded as the most suitable due to their intuitive appeal and social choice-related axiomatic properties. This work introduces a ranking correlation coefficient founded on the Kendall tau distance metric, and it establishes its equivalence to an axiomatic ranking distance designed to handle a realistic variety of ranking formats including those containing non-strict (i.e., with-ties) and incomplete (i.e., null) preferences. Moreover, it demonstrates that alternative ranking correlation coefficients inadvertently introduce systemic biases when considering the same variety of preferences, thus rendering them inadequate for aggregating rankings in the general case. The efficacy of the presented ranking correlation coefficient to solve the consensus ranking problem and to provide alternative optimal solutions is illustrated via computational results of a new combinatorial branch-and-bound algorithm.

Machine Learning & Causality

Sponsored: Applied Probability

Sponsored Session

Chair: Nathan Kallus,Massachusetts Institute of Technology, Cambridge, MA, 02139, United States, kallus@mit.edu

1 - Balanced Policy Evaluation and Learning

Nathan Kallus, Cornell University, New York, NY, 02139, United States, kallus@cornell.edu

Policy learning from observational data aims to transform electronic health records to personalized treatment regimes, transactional records to personalized pricing strategies, and click-streams to personalized advertising campaigns. However, existing inverse propensity weighting and doubly robust methods rely on a problematic plug-in approaches that leads to dealing with division by near zeros, data waste, and awkward two-stage procedures. I present a new approach based on optimal balance and demonstrate how it outperforms existing approaches and explain why, as supported by theory characterizing the method and regret bounds.

2 - Off-policy Evaluation and Optimization with Continuous Treatments

Angela Zhou, Cornell University, Ithaca, NY, United States, az434@cornell.edu, Nathan Kallus

We develop new methods for off-policy evaluation and learning with continuous treatments, going beyond previous work on discrete treatments. Using observational data such as electronic health and transactional records, our method is able to learn effective policies in such contexts as medical dosing and personalized discounts. Our estimator uses a kernel to smoothly reweight data by the proximity of proposed treatments and performs well in a case study on personalized warfarin dosing. We analyze the bias and error of our method and prove favorable regret bounds that support this empirical success.

3 - Efficient Policy Learning

Stefan Wager, Stanford GSB, Stanford, CA, 94305, United States, swager@stanford.edu

There is considerable interest in methods that reduce the problem of learning good treatment assignment policies to the problem of accurate policy evaluation. Given a class of candidate policies, these methods first effectively evaluate each policy individually, and then learn a policy by optimizing the estimated value function. Despite the wealth of proposed methods, the literature remains largely silent on questions of statistical optimality, and there are only limited results characterizing which policy evaluation strategies lead to better learned policies than others. Here, we consider efficiency bounds for policy learning, and propose new methods motivated by this optimality theory.

4 - Sensitivity Analysis for the Sample Average Treatment Effect under Effect Heterogeneity

Colin Fogarty, Massachusetts Institute of Technology, Cambridge, MA, 02114, United States, cfogarty@mit.edu

In observational studies, a sensitivity analysis assesses how strong unmeasured confounding needs to be to alter the study's findings. Methods for sensitivity analysis have been established under the assumption that the treatment effect is constant for all individuals. While innocuous for the analysis of randomized experiments, it has been argued in observational studies that certain patterns of unobserved effect heterogeneity may render the performed sensitivity analysis inadequate. We present a method for conducting a sensitivity analysis in the presence of effect heterogeneity. In so doing, we illustrate that concerns about the constant treatment effect model are largely unwarranted.

1 - How to Operationalize Modern Personalization Algorithms

Vivek Farias, MIT, 100 Main Street, Cambridge, MA, 02142, United States, vivekf@mit.edu, Andrew A.Li, Deeksha Sinha

Modern recommender systems rely on encoding preferences via a mapping of users and items to a latent space, and while there exist sophisticated methods to estimate such mappings, the problem of efficiently operationalizing these embeddings is not well-understood. Thus motivated, we propose a sublinear time algorithm for this problem, and show that it achieves a constant-factor approximation under general random utility choice models. Our algorithm relies on a new sublinear time sampling scheme, which we develop to solve a class of problems that subsumes the classic nearest neighbor problem. We demonstrate the efficacy of our approach on a massive content discovery dataset from Outbrain.

2 - A Conditional Gradient Approach for Nonparametric Estimation of Mixtures of Choice Models

Ashwin Venkataraman, New York University, 719 Broadway, 7th Floor, New York, NY, 10003, United States, ashwin@cs.nyu.edu, Srikanth Jagabathula, Lakshminarayanan Subramanian

We propose a new method to nonparametrically estimate the mixture of logit models from aggregated sales transactions and product availability data. We formulate the estimation problem as an infinite-dimensional constrained convex program and use the conditional gradient (aka Frank-Wolfe) algorithm to solve it. We characterize the structure of the estimated mixing distribution. In two real-world case studies, we outperform the EM benchmark on speed (16x faster), in-sample fit (up to 24% gains in the log-likelihood loss), and predictive (28% gains on the RMSE metric in predicting market shares) and decision accuracies (extracts 1.4x more revenue).

3 - Discrimination with Incomplete Information in the Sharing Economy: Field Evidence from Airbnb

Dennis Zhang, 8342 Delcrest Drive, Apt 328, University City, MO, 63124, United States, denniszhang@wustl.edu, Ruomeng Cui, Jun Li

Recent research has found widespread discrimination by hosts against guests of certain races in online marketplaces, which endangers the very basis of a sharing economy — building trust in the communities. In this paper, we explore the root cause of discrimination and how to eliminate discrimination by conducting two randomized field experiments among 1,256 hosts on Airbnb.

4 - Multi-dimensional Decision Making in Operations: An Experimental Investigation of Joint Pricing and Quantity Decisions

Necati Tereyagoglu, Assistant Professor, Georgia Institute of Technology, 800 W Peachtree St NW, Atlanta, GA, 30308, United States, necati.tereyagoglu@scheller.gatech.edu, Karthik Ramachandran, Yusen Xia

Firms in several industries like medicine, retail and publishing must jointly determine the price and production quantity of their products well in advance of the selling season. In this study, we experimentally examine subjects' performance when they jointly determine price and quantities. We find that subjects systematically deviate from the theoretically optimal price and quantity levels. In a series of follow-up experiments, we isolate several factors that influence decision-making in this context. We show that decisions improve by making subjects more aware of interdependence and by reducing the uncertainty.

Customer Choice in Retail Operations

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Adam J. Mersereau, University of North Carolina, Chapel Hill, NC, 27599-3490, United States, ajm@unc.edu

1 - Online Assortment Optimization when Customers Refine Their Search

Zhichao Feng, University of Texas at Dallas, 2200 Waterview Pkwy, Apt 1828, Richardson, TX, 75080, United States, zxf140830@utdallas.edu, Shengqi Ye, Dorothee Honhon

When shopping online, a consumer often searches a keyword and checks the products displayed by the retailer. In many cases, the retailer has numerous products matching the keyword, with different features and functionalities, but is only able to show a subset of them due to limited displaying space. The assortment shown by the retailer influences the consumer's decision to buy or not. In addition, when the consumer is not familiar with the product category, the assortment may trigger interest in a specific product feature, leading the consumer to refine her search, and focus only on products with this feature. Taking this into consideration, we study the online retailer's optimal assortment decision.

2 - On Consumption and Composition of N-packs

John H. Semple, SMU, 6212 Bishop Blvd, Dallas, TX, 75205, United States, jsemple@mail.cox.smu.edu, Aydin Alptekinoglu

We consider the optimal consumption of a pack of n substitutable products within a general random utility framework. Using dynamic programming, we demonstrate that many basic properties of this problem are independent of the error distribution.

3 - Learning Choice Model Trees: Recursively Segmenting Individuals to Better Understand Their Choices

Michael Young, Doctoral Candidate, Harvard Business School, Boston, MA, United States, miyoung@hbs.edu, Kris Johnson Ferreira, Mohammed Ali Aouad

Choice modeling is a technique used by many retailers to better understand the impact of operational levers, e.g. price, on the customer's product choice. Similarly, customer segmentation is a common practice used to personalize the customer's shopping experience, e.g. targeted ads/offers. In this work, we combine a popular machine learning technique with a choice model in order to jointly achieve both choice modeling and customer segmentation objectives.

4 - Management and Effects of In-Store Promotional Displays
Oguz Cetin, Kenan Flagler Business School, 213 Ivy Meadow Lane, Durham, NC, 27707, United States, oguz_cetin@kenan-flagler.unc.edu, Adam J.Mersereau, Ali Kemal Parlakturk

We examine a brick-and-mortar retailer's choice of product to include in a promotional display. The display provides a visibility advantage to both the featured product and its category, but it also has consequences on customer traffic and substitution. Retailers need to understand the promotional display problem because it is a powerful demand-shaping lever and as an input to its negotiations with manufacturers. We develop analytical insights using a problem formulation based on a nested multinomial logit model of customer choice. Our work provides guidance for how retailers can use and value promotional displays effectively.

Models in Sustainable Operations Management

Sponsored: Manufacturing & Service Oper Mgmt, Sustainable Operations

Sponsored Session

Chair: Foad Iravani, University of Washington, Seattle, WA, 98195-3226, United States, firavani@uw.edu

1 - Peak Load Energy Management by Direct Load Control Contracts
Ali Fattahi, ali.fattahi.1@anderson.ucla.edu, Sriram Dasu, Reza Ahmadi

Energy firms use direct load control contracts (DLCCs) to curtail customers' electricity consumption during peak load periods via remote control devices. The question is: when and which groups of customers should reduce their energy consumption, and for how long? Implementing DLCCs require solving a stochastic dynamic optimization problem each day. We develop a near-optimum heuristic procedure with two simplifications in our approximation scheme: aggregating the customer groups into a single group, and ignoring the detailed structure of the uncertainty. We show that the asymptotic relative error of our heuristic approach is zero.

2 - Optimal Allocation Rules with Waste Considerations
Sara Rezaee Vessal, HEC Paris, Paris, France, sara.rezaee-vessal@hec.edu, Sam Aflaki

We study capacity allocation of a scarce and perishable product among stockout-averse retailers that face stochastic demand. We focus on two commonly practiced allocation mechanisms and using a dynamic model characterize the conditions under which each allocation mechanism performs superior from a waste and profit point of view.

3 - Wind Generation Strategic Bidding in a Competitive Electricity Market
Ali Shantia, HEC, Paris, France, ali.shantia@hec.edu, Owen Wu, Roman Kapuscinski

We empirically study how strategic behaviour of renewable generators translates to their higher profitability. Using the day-ahead and real-time market data, provided by Midcontinent Independent System Operator (MISO), we study what differentiates the bidding behaviour of wind generators. We also analyze whether such strategic behaviours practically increase wind generation profitability.

4 - That's Not Fair: Tariff Structures for Electricity Markets with Rooftop Solar
Siddharth Prakash Singh, Carnegie Mellon University, Pittsburgh, PA, United States, sps1@andrew.cmu.edu, Alan Scheller-Wolf

Increased penetration of rooftop solar has led to decreased utility company profitability and undesirable cross-subsidization among customers. Regulatory responses have been controversial: changes in Nevada induced SolarCity, the market leader in solar systems, to suspend local operations. We demonstrate that choosing the right tariff structure is crucial to fair regulation: the sort proposed in Nevada have limited ability to allocate the financial losses (or gains) from solar adoption among different parties. We then present a contract, featuring full retail price repurchasing solar customers that does offers full flexibility. We illustrate our findings numerically.

Decision Making for Hospitals and Health Systems

Sponsored: Health Applications

Sponsored Session

Chair: Jens Brunner, University of Augsburg, Universitÿtsstraße 16, Faculty Business Administration/Economics, Augsburg, 86159, Germany, jens.brunner@unikat.uni-augsburg.de

1 - Dynamic Capacity Allocation for Elective Surgeries
Steven Shechter, University of British Columbia, Vancouver, BC, V6T.1Z2, Canada, steven.shechter@sauder.ubc.ca

We model a longer-term, dynamic capacity planning problem, in which a children's hospital semiannually apportions available operating room time to di erent surgical specialties. We consider an objective of minimizing urgency-weighted wait time, and use approximation methods to identify good solutions. We also discuss the use a probabilistic model of the queueing discipline to represent noisy patient selection patterns observed in practice.

2 - Market-Based Risk Adjustment in Capitated Healthcare Systems
Zhaowei She, Georgia Institute of Technology, Atlanta, GA, United States, zshe3@gatech.edu, Turgay Ayer

Risk adjustment is essential component of all capitated healthcare systems, such as Medicare Advantage and Medicaid Managed Care. However, it is hard for payers to perfectly predict their customers' cost patterns based on pure statistical methods. To complement the existing statistical risk adjustment models, this study presents a market based risk adjustment model where perfect risk adjustment can be endogenously generated by proper market segmentation. Specifically, we explicitly characterize the competitive bidding outcomes in Medicare Advantage in a queueing framework, and show that the proposed mechanism can help CMS to achieve the targeted service levels more cost efficiently.

3 - Task-related Resident Scheduling under Uncertainty using Column Generation
Jens Brunner, University of Augsburg, Universitÿtsstraße 16, Faculty Business Administration/Economics, Augsburg, 86159, Germany, jens.brunner@unikat.uni-augsburg.de, Sebastian Kraul

Residents have to perform different tasks while passing several departments in a specific time period. Hospitals have to make efforts to get the best candidates for their programs but need to stay cost-efficient. We present a cyclic optimization model to generate robust training schedules determining the optimal number of residents. The model allows hospital management to derive employment policies. Solving the problem efficiently, we present a new pattern generation approach for the Dantzig-Wolfe decomposition. We present preliminary results using real-world data.

Machine Learning in Medicine

Sponsored: Health Applications

Sponsored Session

Chair: Dimitris Bertsimas, Massachusetts Institute of Technology, Cambridge, MA, 02139, United States, dbertsim@mit.edu

Co-Chair: Ying Zhuo, Massachusetts Institute of Technology, 70 Lincoln Street, Unit L612, Boston, MA, 02111-2670, United States, zhuo@mit.edu

1 - Predicting Response and Adverse Events in Immunotherapy-treated Patients
Ying Zhuo, Massachusetts Institute of Technology, 70 Lincoln Street, Unit L612, Boston, MA, 02111-2670, United States, zhuo@mit.edu, Dimitris Bertsimas

Recent development in immunotherapies has shown remarkable efficacy in treating melanoma and lung cancer patients, yet the response and adverse events associated with use of immunotherapy are highly variable across patients. We aim to build highly individualized predictive models. We obtained 11 years of electronic health records (EHR) from a large cancer center with hundreds of features: demographics, genomics, vitals, lab tests, etc. We fitted state-of-the-art machine learning models to predict 60-, 90- and 180-day mortality and adverse events such as rash, colitis, and hepatitis.

2 - Estimating Risk of Morbity and Mortality After Emergency Surgery with Machine Learning

Jack W. Dunn, Massachusetts Institute of Technology, 24 Hardwick St, Unit 1, Cambridge, MA, 02141, United States, jackdunn@mit.edu, Lauren E.Berk, Dimitris Bertsimas, Haytham Kaafarani, Thomas Peponis, George Velmahos

Emergency surgery comprises an ever-increasing proportion of hospitalizations, and carries a higher risk of morbidity and mortality compared to non-emergent or elective procedures. We apply novel machine learning methods to develop models that predict the risk of mortality and associated co-morbidities following emergency surgery. Our approach delivers best-in-class accuracy whilst remaining intuitive and interpretable. We demonstrate the power of these models for patient counselling prior to surgery, as well as for benchmarking and improving the quality of emergency surgery care.

3 - Predicting Mortality to Prevent Deaths on the Liver Transplant Waitlist

Yuchen Wang, Massachusetts Institute of Technology, Cambridge, MA, United States, yuchenw@mit.edu, Dimitris Bertsimas, Jerry L. Kung, Nikolaos Trichakis, Parsia Vagefi

Current organ allocation process uses the Model for End-Stage Liver Disease (MELD) score to rank disease severity. We propose a new data-driven analytics-based method to predict the mortality rate within three months for patients on the liver transplantation waitlist. Our model not only outperforms the MELD score in accurately predicting mortality, but also addresses several of its shortcomings with respect to its inability to generalize to cancer patients.

4 - Identifying Exceptional Responders in Randomized Trials via Mixed-integer Optimization

Alexander Weinstein, Massachusetts Institute of Technology, Cambridge, MA, United States, amw22@mit.edu, Dimitris Bertsimas, Nikita Korolko

In randomized clinical trials, there may be a benefit to identifying subgroups of the study population for which a treatment was exceptionally effective or ineffective. In this chapter, we present an efficient mixed-integer optimization formulation that can directly find an interpretable subset with maximum (or minimum) average treatment effect. Using both simulated and real data from randomized trials, we demonstrate the effectiveness and stability of the optimization approach in identifying subsets with exceptional response and verifying their statistical significance.

Remote Patient Monitoring and mHealth Applications

Sponsored: Health Applications

Sponsored Session

Chair: Julie Lynn Hammett, Texas A&M University, College Station, TX, 77840, United States, jhammett@tamu.edu

1 - Quantifiable Fatigue Risk Assessment through Activity Recognition

Karla Ivette Gonzalez Coronado, Texas A&M.University, 23908 Killerbee Lane, New Caney, TX, 77357, United States, kalleyranch08@tamu.edu

The development of a modern fatigue risk assessment is necessary. An algorithm to classify activities and a person's heart rate variability through the day to track fatigue throughout the day is a solution for this. To develop this, 30 participants took part in a 90-minute study to identify and objectively define attributes of accelerometer readings, heart rate, breathing rate, and skin temperature and their role in understanding common daily activities. The activities included sitting, walking, picking up boxes, going up/down stairs, pulling ropes, and working on a computer. An application in mHealth is possible through the integration of this algorithm into smartwatches and smartphones.

2 - Remote Patient Monitoring System Model

Julie Lynn Hammett, Texas A&M.University, 301 Holleman Dr E, Apt 728, College Station, TX, 77840, United States, jhammett@tamu.edu

Healthcare providers are facing an increasing number of patients requiring long-term care, introducing new challenges to providing fast and affordable care. We present ongoing research to create a framework for the design, development, and implementation of remote patient monitoring (RPM) for chronic care. Using System Dynamics modeling, we demonstrate the potential impact of a remote health system on resource utilization in the healthcare continuum. The model shows the change in burden on existing resources when the flow of patients through a primary care facility changes.

3 - Activity Estimation using Ambient Sensor Network Data

Yan Wang, University of South Florida, 4202 E Fowler Ave, ENB118, Tampa, FL, 33620, United States, yanwang2@mail.usf.edu

Data from ambient sensor networks deployed in residential environments is used in daily activity recognition, behavior pattern discovery, abnormal behavior detection and physical and mental health assessment. In this work, we describe a spatio-temporal status tracking algorithm based Pyroelectric Infrared (PIR) motion sensor data to estimate resident's location, time outside of home and sleep behaviors. The significance of this information is discussed as it relates to monitoring chronic health conditions and enabling older adults to age-in-place safely and independently.

4 - Occupant Activity Profiles from Smart Home Sensor Event Streams

Garrick Aden-Buie, University of South Florida, 4202 E Fowler Ave, ENB118, Tamp, FL, 33620, United States, gadenbuie@mail.usf.edu

Faced with a growing elderly population, learning and characterizing activity profiles of smart home occupants will support senior health care management for older adults living in homes augmented by ambient intelligence solutions that combine ubiquitous computing and artificial intelligence. In this work, we explore a bag of n-grams approach for creating occupant-specific activity profiles from event streams collected from passive, embedded sensors in real-world sensor networks in the homes of several older adults.

1 - Learning from Operational Experience and Benchmark Failure Experience in Telecom Sector in India

Shaili Singh, Research Scholar, Indian Institute of Management, IIM Rohtak, Rohtak, 124001, India, singhshaili631@gmail.com, Mahua Guha

Organizations learn from their own experiences and from experiences of peer organizations. Focus of this study is on learning from success and failure experiences. We identify success as enhanced operating experience and failure as benchmark failure experience which is measured based on the key performance indices set by Telecom Regulatory Authority of India and analyse the influence of aspiration performance discrepancy on organizational learning. Our findings suggest that in case of operating experience for performance above aspiration, firms fail to learn but for benchmark failure experience, firms learn from themselves. For performance below aspiration, we found no significant results.

2 - Learning Manufacturing Networks

Dimitrios Katselis, University of Illinois at Urbana-Champaign, Urbana, IL, 61801, United States, katselis@illinois.edu, Seo Taek Kong, Carolyn Beck, R. Srikant

Manufacturing networks are described by task precedence relationships, which indicate the flow of work in the network. The precedence relationships are designed by systems engineers, but they are often implemented quite differently than the intended design. The goal is to infer the precedence relationships in the implemented network using data about the observed start and end times of various tasks in the network. We will present an algorithm for performing the network inference and obtain bounds on the sample complexity by exploiting a relationship with the coupon collector problem.

3 - Arterial Probabilistic Traffic Modeling with Vehicle Probe Data using Machine Learning

Bahar Zarin, PhD Candidate, University of Maryland, College Park, College Park, MD, 20742, United States, bzarin@umd.edu, Ali Haghani

This study proposes a probabilistic modeling framework for the prediction of arterial travel time distribution using Probe Data. We modeled spatiotemporal correlations of the network, including the intersections, using machine learning. We also investigated the effects of other factors such as driver behavior on the travel time. The data used in this study are INRIX vehicle trajectory and Open Street Map.

4 - Predicting Stock Market Short-term Price Based on Machine Learning

Xing Wang, Auburn Univeristy, 371 W Glenn Avenue, Apt 14, Auburn, AL, 36830, United States, xzw0005@auburn.edu, Bin Weng, Lin Lu, Fadel Mounir Megahed, Alexander Vinel

New forms of collective intelligent have emerged with the rise of the Internet. The changes on these platforms will significantly affect the stock market. In this study, we combined disparate online data sources with the traditional time series signal. Several machine learning techniques are applied to train a short-term price prediction model, including decision tree, support vector machine, boosting, as well as different neural network architectures in deep learning. The internal nature and applicability of these models would be analyzed, and their performances would be compared.

5 - Conducting Confirmatory Factory Analysis on an Instrument to Measure Systems Thinking Capacity

Morteza Nagahi, PhD Student, Graduate Research Assistant, Mississippi State University, 450 Campus Trails, Apt 229B, Starkville, MS, 39759, United States, mn852@msstate.edu

The Instrument to Assess Capacity for Systems Thinking was developed to measure individual systems thinking capacity, providing a useful baseline to facilitate agent-assignments, training, and education for effective complex systems problems. The research-based instrument generates systems thinking profiles by capturing the state of individual inclination toward systemic thinking as well as a preference for engaging and solving complex system problems. Researchers perform confirmatory factor analysis (CFA)to verify the factor structure of the construct and evaluate construct validity.

6 - Bilevel Programs for Cross Validation in Classification Models

Joseph Kapena Agor, PhD Student, North Carolina State University, 2500 Stinson Drive, Apt C, Raleigh, NC, 27695, United States, jkagor@ncsu.edu

Statistical methods that utilize cross validation for model selection are shown to be effective in the classification process while identifying the most important features that influence the classification. In this work, we propose a bilevel framework to be used in the cross validation procedure and develop a novel genetic algorithm as a solution approach. We implement the proposed framework and solution procedure in an influenza classification case study where we classify the antigenic variation between influenza virus strains. Our results demonstrate that bilevel programming can improve the strength of classification models when implemented in the cross validation process.

Supply Chain Economics

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: C Gizem Korpeoglu, University College London, London, WC1E 6BT, United Kingdom, c.korpeoglu@ucl.ac.uk

1 - Supplier Diversification under Random Yield: the Impact of Price Postponement

Nan Yang, University of Miami, Coral Gables, FL, United States, nyang@bus.miami.edu, Lingxiu Dong, Guang Xiao

We characterize a firm's pricing and sourcing decisions under supply yield uncertainty, and study the interplay between supply diversification and pricing. We compare the optimal sourcing decisions under two pricing schemes: ex ante pricing and responsive pricing. Although the firm is better off with responsive pricing, the effect of price postponement on the optimal sourcing decision and the firm's need for supply diversification varies and is influenced by factors such as unit procurement cost, supply portfolio, and supply reliability.

2 - Inventory Strategy of Omni-channel

Xiaolin Xu, Nanjing University, School of Business, 23 Hankou Road, Nanjing, 210093, China, xuxl@nju.edu.cn, Ming Hu, Weili Xue, Yi Yang

The future of retailing seems to be omnichannel as the mix of online vs. offline selling. Online retailers such as Amazon move offline by setting up local stores, whereas brick-and-mortar retailers such as Walmart and Target have long set up online stores. We show that buy-online, pick-up-in-store strategy has a drastically different impact on retailers of different natures.

3 - Consumer Taste Uncertainty in the Context of Store Brand and National Brand Competition

Arcan Nalca, Smith School of Business, Queen's University, Goodes Hall Queen's University, Kingston, ON, K7L.3N6, Canada, arcan.nalca@queensu.ca, Tamer Boyaci, Saibal Ray

We study how a retailer can benefit from acquiring information about uncertain consumer tastes in the presence of competition between the retailer's store brand and a manufacturer's national brand. We identify retailer's optimal information sharing strategy with the manufacturer as well as the equilibrium product positioning and pricing of the brands. We find that, when the store brand introduction is not very costly, the retailer voluntarily shares information with the manufacturer so that the both product are better positioned even though this increases the competition between the brands.

4 - Supply Chain Expansion and Integration

C. Gizem Korpeoglu, University College London, Gower Street, London, WC1E 6BT, United Kingdom, c.korpeoglu@ucl.ac.uk, Ersin Korpeoglu, Soo-Haeng Cho

We study expansion and integration of supply chains where multiple suppliers sell to multiple retailers. Though retailers influence wholesale price in practice, prior literature fails to capture this influence. To overcome this limitation, we develop a novel model that considers retailers' buyer power. We show that more retailers raise wholesale price and can improve retailer profits, and that supply chain expansion is more beneficial than prior literature finds. We then show that integration of two supply chains may reduce total profits in a retailer-oriented supply chain. This result suggests that as UK disintegrates from EU via Brexit, supply chain profits may increase in UK and decrease in EU.

Auctions/Mechanism Design

Contributed Session

Chair: Wenwei Wang, Hong Kong University of Science & Technology, Kowloon, Hong Kong, wwangaw@connect.ust.hk

1 - Creating a Transition Schedule for Broadcast Television

Karla L.Hoffman, George Mason University, System Eng. and Operations Research Dept, 4400 University Drive Mailstop 4a6, Fairfax, VA, 22030, United States, khoffman@gmu.edu

Due to the successful Broadcast Incentive Auction, many television stations in the United States and Canada will be required to move to new channels. In many cases, one station will not be able to move to its new channel until another station vacates its old channel. This difficulty led the FCC to create a phased transition plan to ensure that television stations maintain coverage during the transition while completing the entire transition in 39 months. In this talk, we will present the problems presented by the transition and the methodology that the FCC used to resolve these issues.

2 - Sequential Effects and Bidder Heterogeneity in B2B Auctions

Alex Scott, Assistant Professor, Northeastern University, 216 Hayden Hall, Boston, MA, 02038, United States, f.scott@northeastern.edu

We study a longitudinal dataset of truckload spot auctions in which we observe exogenously-imposed business constraints on the bidding firms - some firms can perform work only using assets that they own and operate, while others must outsource work - i.e., brokers. These business constraints manifest themselves in strikingly different behavior by the bidding firms in single and sequential auctions. Brokers adjust their prices in subsequent auctions based on whether they won or lost the previous auction, while firms who operate assets decide whether or not to place a bid. We examine other sources of heterogeneity and discuss implications for our focal industry.

3 - Deterministic Truthful Mechanisms for Interval Scheduling with Applications to Cloud Computing

Peter McGlaughlin, Graduate Student, University of Illinois at Urbana-Champaign, 117 Transportation Building, 104 S. Mathews Ave, Urbana, IL, 61801, United States, mcglghl2@illinois.edu, Jugal Garg

Motivated by cloud computing, we study a market-based approach for scheduling where jobs have hard deadlines and prefer earlier completion times. In our model, completing a job earns its present value. Users submit job requirements to the cloud provider who non-preemptively schedules jobs to maximize social welfare, i.e. the present value of completed jobs. Using a greedy algorithm, we obtain a $1/(1-b)$ approximation to the optimal schedule, where $b < 1$ is the discount factor shared by all jobs. For sufficiently small b, this beats the best known approximation algorithms applicable to the problem. Finally, we construct a pricing rule to incentivize users to truthfully report all job requirements.

4 - Mechanism Design with Efficiency and Equality

Wenwei Wang, Hong Kong University of Science & Technology, Room 5569, Academic Building, HKUST, Kowloon, Hong Kong, wwangaw@connect.ust.hk, Zhou Chen, Qi Qi, Changjun Wang

In this work, we consider the problem of allocating a set of homogeneous goods among multiple strategic players to balance the efficiency and equality from a game-theoretic perspective. We develop a general truthful mechanism framework which optimally maximizes the resource holder's efficiency while guaranteeing some equality constraints. We use the Generalized Gini index as the equality measure, and fully characterize the optimal allocations. Based on the characteristics, we propose a polynomial-time algorithm that computes the optimal allocation and corresponding truthful payments for any bids profile. We also show how the optimal efficiency varies under varying equality constraints.

Information and On-Demand Services

Sponsored: Manufacturing & Service Oper Mgmt, Service Operations

Sponsored Session

Chair: Luyi Yang, University of Chicago, Chicago, IL, 60615, United States, lyang6@chicagobooth.edu

1 - The Impact of Bilateral Rating System on Online to Offline Platforms

Chen Jin, University of Pennsylvania, 3730 Walnut Street, 500 Jon M. Huntsman Hall, Philadelphia, PA, 19104, United States, jinchen1@wharton.upenn.edu, Kartik Hosanagar, Senthil Veeraraghavan

Platforms like Uber and Lyft adopt a bilateral rating system (BRS) that allows service providers to rate customers and to make accepting/rejecting decisions based on the customers' rating much the same way as the privilege enjoyed by customers exclusively in the traditional on-line platforms, e.g., eBay and Amazon that implement a unilateral rating system (URS). This novel feature of the rating system changes fundamentally the service providers' effort structure and also affects the pricing strategy of the platform. With a stylized model, we compare URS and BRS in the context of ride-sharing service to study their impact on the decisions as well as revenue/welfare of all stakeholders.

2 - Efficient Inaccuracy: Information Sharing in a Queue

Jianfu Wang, Nanyang Business School, Nanyang Technological University, Block S3-B2C-85, 50 Nanyang Avenue, Singapore, 639798, Singapore, wangjf@ntu.edu.sg, Ming Hu

Shared congestion information takes the form of a snapshot of the service system with a time stamp. Future customers can access the information shared by previous customers. We focus on the equilibrium behavior of customers with shared, lagged queue length information to address the following research question: How does this shared information structure affect the throughput and social welfare compared with the full and no information structures?

3 - Queues with Redundancy: Is Waiting in Multiple Lines Fair?

Leela Aarthy Nageswaran, Tepper School of Business, 5000 Forbes Avenue, Pittsburgh, PA, 15213, United States, lnageswa@andrew.cmu.edu, Alan Scheller-Wolf

In a service system, a redundant customer is one who may join multiple queues simultaneously and is "served" when any one of her copies completes service; systems with redundant customers range from supermarkets with multiple checkout lines to multiple listing for organ transplants. We study the performance of two queues serving two classes of customers, one of which is redundant. We show that non-redundant customers forming independent Poisson streams to each queue prefer that the other class be redundant as opposed to non-redundantly joining the shortest queue if the queues are symmetric (i.e., in this case redundancy is fair); however, this may not hold if the queues have different loads.

4 - "Your Order has Been Picked Up and Will Arrive Shortly": Innovation in Service Delivery

Andrew E. Frazelle, Duke University-Fuqua School of Business, 540 South LaSalle Street, #4340, Durham, NC, 27705, United States, andrew.frazelle@duke.edu, Pnina Feldman, Robert Swinney

On demand delivery has been one of the hottest VC sectors in recent years. However, while service providers benefit from gaining access to uncharted demand for delivery, without the ability to increase capacity, their revenue from walk-in customers may be harmed. We examine conditions under which on demand delivery platforms benefits consumers and the firm.

1 - Human Machine Interface using Axiomatic Design Industrial Case of Drone Tracker

Rhythm Wadhwa, NTNU, Teknologiveien 22, Gjoevik, 2821, Norway, rhythmwadhwa@hotmail.com

The paper presents a novel application of axiomatic design in combination with AHP process used in early product development of a drone human machine interface for sports applications. The product is intended and was field tested for professional downhill skiiers and skateboarders. Axiomatic design was used for decoupling the design parameters associated with the functional requirements.

2 - Resilience Assessment in Sports

Marcela Gomez, USF, Tampa, FL, United States, marcelag1@mail.usf.edu, Daniel Hernando Romero

In sports, operational resilience is defined as the ability of a team or player to overcome difficulties and comeback from a adverse result to be able to draw or win a game. Resilience metrics are proposed and evaluated in soccer and other sports. Our model will enable to decision makers to make online decisions while the team or player is in disadvantage.

3 - Analysis of College Football Wins and Their Effect on School Athletics Revenue

Mikhail Gordon, University of Pittsburgh, 241 Mervis Hall, Pittsburgh, PA, 15260, United States, m.gordon@pitt.edu

The use of hierarchical linear regression leads to information linking the revenue of an NCAA school to the number of wins of that school's football team. This analysis includes differences between divisions and conferences in which the schools lie.

Decision Support Systems

Contributed Session

Chair: Lin Guo, University of Oklahoma, Norman, OK, United States, lin.guo@ou.edu

1 - Developing Robust Strategic Partnership Portfolios in the Retail Industry using a Multi-stage Knapsack Model

Stanislaus Solomon, Assistant Professor of Supply Chain Management, Sam Houston State University, 1821 Avenue I, 236S.Smith Hutson Building, Huntsville, TX, 77341, United States, solomon@shsu.edu, Esha Christie, Jason Riley

The selection and development of suppliers in the retail industry is critical to supply chain robustness and profitability. This research focuses on the implementation of a multi-stage knapsack model that considers conflicting objectives and provides decision support on the appropriate strategic partnership portfolios to develop, based on the decision maker's criteria. Experimental results from a case study will be presented.

2 - Stochastic Modeling for Biofuel Supply Chains

Edgar Gutierrez-Franco, University of Central Florida, 12104 Napiers Circle, Orlando, FL, 32826, United States, edgargutierrezfranco@gmail.com, Qipeng Phil Zheng, Alfonso Sarmiento, Luis Rabelo

This research is proposing a formal methodology for decision-making for a renewable supply chain, based on deterministic and stochastic optimization models. This methodology takes into account the forecast of available technology for vehicles using probabilistic scenarios to represent the biofuel regulations. The decision support system allows the planner to determine which and where the bio-refineries have to be opened, the amount and period of time of raw material to be sown depending on their life cycle, production plans, optimal flows of products and inventory. The methodology became a decision tool for strategic and tactical levels in a supply chain.

3 - A Systems Thinking Approach for Waste Management in University Campuses

Misagh Faezipour, Assistant Professor, Middle Tennessee State University, 1500 Greenland Drive, Engineering Technology, Box 19, Murfreesboro, TN, 37132, United States, Misagh.Faezipour@mtsu.edu

United States is among the top leading trash generators in the world and accounts for more than 30% of the waste worldwide. The threat of waste will cause enormous social, economic, environmental, health, and safety consequences. Universities produce large amounts of trash each year. This paper explores the application of system dynamics modeling in universities to better manage waste.

4 - Exploration of the Solution Space of Compromise Decision Support Problems with a Large Number of Goals

Lin Guo, University of Oklahoma, Norman, OK, United States, lin.guo@ou.edu, Warren Smith, Janet Katherine Allen, Farrokh Mistree

In this paper, we propose an approach for exploration of the solution space of a compromise Decision Support Problems model with ten goals. Since the complexity of exploration of the solution space grows steadily with the increasing of the number of goals, we approximate the problem by using Principal Components Analysis to identify the main goals that represent more than eighty percent of the design preferences; and then we convert the other goals into constraints. In this way, we can reduce the dimension of the problem and save the exploration time while maintain our design space in a satisficing level. An example of supply chain design is used to show the advantage of this approach.

1 - IMPT Treatment Planning Optimization Considering RBE and LET

Gino J.Lim, University of Houston, Houston, TX, United States, ginolim@uh.edu, Guven Kaya, Jiming Peng

We present optimization models and algorithms to obtain optimal beamlet intensities considering relative biological effectiveness (RBE) in intensity modulated radiation therapy. Based on three RBE biophysical models, quadratic programming optimization models (RBEMs) are developed with the use of linear energy transfer (LET) values. We implement a functional parallelism approach to achieve substantial speed gains. We also compare results of RBEMs with the traditional dose-based fluence map optimization model. Two cancer cases; prostate and head-and-neck (including LET data) are tested.

2 - Learning from Many: Partner Exposure and Team Familiarity in Fluid Teams

Jonas Oddur Jonasson, MIT.Sloan School of Management, 30 Memorial Drive, E62-588, Cambridge, MA, 02142, United States, joj@mit.edu, Zeynep O.Aksin Karaesmen, Sarang Deo, Kamalini Ramdas

We use data from London Ambulance Service to study the impact of partner exposure of new paramedics on their operational performance. We find that the greater diversity in prior partners directly improves performance for an unstandardized process. For a more standardized process, this effect is moderated by a new recruit's total experience. We explore the implications of our results for team formation strategies by balancing the benefits of partner diversity with those of team familiarity.

3 - Modeling Emotional Health and Quality of Therapeutic Alliance using Data from Chat Conversations

Shishir Dash, Ginger.io, SanFrancisco, CA, United States, shishir.dash@gmail.com, Sai Moturu

Each year, one in five people suffer from stress, anxiety or depression. Apps providing chat-based talk therapy, video sessions with professionals and self-care tools are crucial to addressing the huge access and cost hurdles in this space. They also enable the continuous modeling of the therapeutic alliance and patient progress. We present initial analysis of a large trove of anonymized conversation data collected via the Ginger.io app to (a) identify indicators of depression and anxiety, (b) triage users to the right level of care, and (c) identify successful talk-therapeutic strategies. We aim to show how these technologies can help build a more scalable and efficient mental health care system.

4 - Kidney Transplant Wait List Management: Patient Assessment and Prioritization

Joseph Milner, University of Toronto, Toronto, ON, Canada, milner@rotman.utoronto.ca, Adam Diamant

We consider the admission control problem for the kidney transplant wait list for a major research and teaching hospital located in Toronto, Ont. With increasing demand and limited diagnostic capacity, the transplant program seeks to ensure sufficient patients of each type are maintained on the list. Uncertain supply leads to significant delays in obtaining an organ. Because patient states are dynamic, there are significant costs to being maintained on the list. We develop an evidence-based policy to lower patient costs while maintaining hospital service levels.

1 - Tactical Demand Forecasting from an Industry Perspective – Opportunities and Challenges

Divya Prakash, Intel, 5000 W. Chandler Blvd, Chandler, AZ, 85226, United States, divya.prakash@intel.com, Nital S. Patel

Changing business landscape is driving changes in supply chain design resulting in the need to be more responsive to market needs. Given the manufacturing lead times along with the changing demand landscape it is crucial to closely examine the horizon and fidelity of tactical forecasting for purposes of optimizing supply chain efficiency. The presentation will focus on technologies to help manage forecasting inaccuracies, to improve responsiveness, and also find opportunities to improve the forecast itself. The presentation will also cover some of the opportunities and challenges for further improvements and hopefully encourage a dialog on research directions.

2 - Automation of Strategy with Respect to Supply Chain using Neural Networks

Kumail Selani, Arizona State University, Mesa, AZ, United States, kselani@asu.edu

We will discuss and demonstrate a working model that exemplifies how automation of strategy with respect to supply chain can capitalize on the available data. The proposed technique makes use of neural networks embedded in an IDEF0 environment. It is founded on the IDEF0 strategy model as presented in the paper "Automation of strategy using IDEF0 — A proof of concept" (Operations Research Perspectives (ORP) Dec. 2015 by Waissi et.al.). We will look at the unique advantage of neural networks in their ability to map variable data points to show trends and relationships, their high flexibility, adaptability and explore how supply chain strategy can be automated using this novel machine learning approach.

3 - A Three-dimensional Modelling Approach for Short-term Demand Forecasting

Jay Patel, Arizona State University, Tempe, AZ, United States, jdpatel2@asu.edu

Forecasting methods are either quantitative or qualitative, or combination of both. Any practical forecasting model is a combination of both. A novel approach is being introduced in this paper. We will construct a three-dimensional model for short-term demand forecasting by treating the supply chain as a "hybrid three-dimensional ecosystem". The first two dimension include quantitative and qualitative techniques, and the third dimension is a weighting matrix to combine the two dimensions into one model. We will first analyze supply chain forecasting models using the first two dimensions, and then develop the weighting matrix. We will then combine the dimensions into an integrated model.

4 - Facility Location Problem with Joint Disruptions using Subordinated Markov Chains

Vishwakant Malladi, Doctoral Student, University of Texas-Austin, McCombs School of Business, CBA 5.202, IROM, Austin, TX, 78712, United States, vishwakant@gmail.com

Classical facility location problems do not incorporate the possibility of correlated disruptions amongst facilities and often result in optimal solutions that are too conservative. We propose using subordinated Markov chains to model the probability of the correlated risk of disruptions which offers a more realistic disruptions scenarios. We also present a new methodology to solve the facility location problem with correlated disruptions. Optimal solutions considering correlated disruptions show improved performance over traditional disruption models

1 - New Experience Good Introduction Decisions

Eylem Koca, Assistant Professor, Ozyegin University, Nisantasi Mah. Orman Sk. 34-36, Cekmekoy Campus, Istanbul, 34794, Turkey, eylem.koca@ozyegin.edu.tr

We investigate the two crucial decisions when introducing new experience goods: 1) preannouncements, and 2) availability of return policies. In our model, the main role of preannouncements is that of making product information available in order to reduce the product fit uncertainty for the consumers; the preannouncement timing decides on the available information. Coupled with this, we study the possibility of the firm selling the products in two forms simultaneously - with and without a return policy - and we characterize the conditions for which doing so is optimal.

2 - When to Offer Free Extended Warranty? Customer Segmentation, Repairing Cost, and Product Reliability

Wen-Hsing Ting, National Taiwan University, Taipei, Taiwan, d04724017@ntu.edu.tw, Ling-Chieh Kung

We study a firm's optimal design of base and extended warranty plans when product reliability is exogenous or endogenous. We consider customers with different needs of repairing a damaged product and find that the firm's decision depends two critical factors, the number of frequent users and customers' repairing cost without warranty production. When the reliability is exogenous and the number of frequent users is large, the firm should sell extended warranty when customer's repairing cost is either high or low but should not if moderate. With endogenous reliability, free extended warranty should be offered if customers' repairing cost is low. The warranty should be life-long under some conditions.

3 - Pricing and Availability Strategies with Strategic Customer Behavior and Scarcity Effects

Hanqing Liu, City University of Hong Kong, Hong Kong, work.lhq@gmail.com, Peng Hu, Stephen Shum

We study the dynamic pricing and availability decisions of a firm that repeatedly introduces new generations of a product over time. Customers are strategic and are affected by two types of scarcity effects: direct scarcity effect and relative scarcity effect. Firm-induced scarcity is never optimal in the absence of scarcity effects but it can be optimal when customers are affected by scarcity effects. We study the long-run optimal policy of the firm and characterize when firm-induced scarcity is optimal. Our results show that the firm's long-run optimal policy may be a constant availability policy or a varying availability policy, depending on certain parameters.

4 - To Buy or Not to Buy? Purchasing Decision and Spillover Effect of the Sharing Economy for the Manufacturing Industry

Jie Yang, Phd Candidate, Tianjin University, Nankai District, 92 Weijin Road, Tianjin, 300072, China, nemoyj1989@126.com, Daozhi Zhao

We first study how the presence of sharing economy affects the consumer's purchasing decision. We focus on this question, and identify the conditions for consumers to purchase products. In the presence of the conspicuous consumption, we develop a model in which consumers make purchase decisions and then have the option to participate in a sharing economy contingent on a realized usage level. We compare the consumers' purchase decisions to a situation where ex-post sharing is impossible. Second, we investigate the spillover effect of the sharing economy on the manufacturing industry.

Stochastic Models for Shared Transportation

Sponsored: Applied Probability

Sponsored Session

Chair: Siddhartha Banerjee, Cornell University, Ithaca, NY, 14853, United States, sbanerjee@cornell.edu

1 - The Value of State Dependent Control in Ride-sharing Systems

Pengyu Qian, Columbia Business School, Columbia Business School, c/o PhD Office, New York, NY, 10027, United States, PQian20@gsb.columbia.edu, Yash Kanoria, Siddhartha Banerjee

We consider the design of state-dependent control policies for a closed queueing network model of ride-sharing systems, where the platform can choose which car to match to any incoming passenger. We propose a gradient-based control policy associated with a novel Lyapunov function, and show that this is rate-function optimal, i.e., under mild conditions, it minimizes the asymptotic rate of demand-dropping as the number of vehicles scales to infinity. We further show how this large-deviations approach can be used to study the trade-off between estimation, computation and performance.

2 - Minimizing Multimodular Functions and Allocating Capacity in Bike-sharing Systems

Daniel Freund, 1, 109 Lake St, Ithaca, NY, 14850, United States, danielrfreund1990@gmail.com, Shane Henderson, David B. Shmoys

Bike-share systems (BSS) allow users to rent and return a bike at any station within the system. Whereas the question of how to mitigate the effects of resulting imbalances using rebalancing has received much attention, our work considers the more strategic question of how to allocate dock capacity within such systems. Extending known models from the rebalancing literature and connecting it to the literature on discrete convexity, we present a provably polynomial algorithm that finds the optimal allocation of docks within such systems. Our work has yielded improvements for the BSS in major American cities like Boston, Chicago, and NYC, where strategically reallocating docks has improved service.

3 - Online Matching in a Ride Sharing Platform

Chinmoy Dutta, Lyft, San Francisco, CA, United States, cdutta@lyft.com, Adam Greenhall, Keshav Puranmalka, Chris Sholley

We study the online problem of matching passengers with each other for sharing rides. Our setting is motivated by real-world ride-sharing platforms like Lyft. In this setting, a passenger can request a ride at any time, and the task of the matching algorithm is to find another ride to match with it. A ride can get matched only to another ride that arrived close in time, and there is a bounded time interval to match a ride since its arrival. The efficiency of a match between two given rides defines the weight of the match. The goal of the matching algorithm is to maximize the total weight of the matching constructed over a given time interval. We present algorithms and bounds for this problem.

1 - Revisiting the Two-sample Z-test from the Perspective of Almost Stochastic Dominance

Chin Hon Tan, National University of Singapore, 1 Engineering Drive 2, Department of Industrial and Systems Engineer, Singapore, 117576, Singapore, isetch@nus.edu.sg

The two-sample z-test is often used to compare the mean of two populations. However, such tests are not sufficient for studying preferences between two uncertain prospects. In particular, the z-test only accounts for sampling errors and neglects the risk preferences of the decision maker. In practice, the preferences of the decision maker is unclear. Here, we revisit the two-sample z-test in light of recent advances in the almost stochastic dominance literature which expound on the relationship between preferences and distribution moments.

2 - Video Streaming in Distributed Erasure-coded Storage Systems

Vaneet Aggarwal, Purdue University, 315 N. Grant St., West Lafayette, IN, 47906, United States, vaneet@purdue.edu, Abubakr Al-Abassi

This work considers video streaming over distributed systems where the video segments are encoded using an erasure code for better reliability thus being the first work to our best knowledge that considers video streaming over erasure-coded distributed cloud systems. The download time of each coded chunk of each video segment is characterized and ordered statistics over the choice of the erasure-coded chunks is used to obtain the playback time of different video segments. Using the playback times, bounds on the moment generating function of the stall duration is used to bound the mean stall duration. This metric represents an important quality of experience (QoE) measure for the end users.

3 - Additive Model for Unbalanced Longitudinal Data via Smooth Backfitting

Suneel Babu Chatla, PhD Candidate, National Tsing Hua University, Hsinchu, 30013, Taiwan, suneel.chatla@iss.nthu.edu.tw, Li-Shan Huang

We propose a new method for estimating an additive model for the unbalanced longitudinal data using smooth backfitting. Our method uses the concept of global smoothing matrix and it enables estimating the regression function at the data points in addition to the grid points. We use profile least square technique to estimate the correlation structure over repeated measurements. We prove that the proposed estimator is asymptotically efficient compared to the estimator obtained using working independence assumption. A Monte Carlo simulation study was conducted in order to evaluate the finite sample performance of the estimators. A real data application is also provided.

4 - Predictive Control and Fault Detection of Natural Gas Networks

Kevin Melendez, PhD Student, University of South Florida, 4411 Shady Terrace Lane, Apt 303, Tampa, FL, 33613, United States, kmelendez7@mail.usf.edu, Tapas K. Das, Changhyun Kwon

The objective of this study is to generate a comprehensive methodology to optimally design and operate a natural gas network. A Mixed Integer Nonlinear Programming model is proposed to locate the pipelines and compression stations while minimizing the total cost over a planning horizon. A Bayesian approach is used for demand forecasting and a model predictive control strategy is introduced for maintaining the network on the optimal operation point. Finally, multivariate statistics methods are used for early fault detection. The proposed methodology aims to help the engineers of a natural gas company with the decision-making and the online control and atypical operating condition identification.

5 - Confidence Sets for Split Points in Model Based Regression Trees

Suneel Babu Chatla, National Tsing Hua University, Hsinchu, 30013, Taiwan, suneel.chatla@iss.nthu.edu.tw, Galit Shmueli

Model-based (MOB) trees are popular for their ability to incorporate parametric models into classification and regression trees. The existing MOB uses an exhaustive search to identify the split points and it is computationally very intensive. In addition, there is no way to assess the variability of the identified split points, which is crucial for the statistical generalizability of the results. To solve this problem, we propose a new split point estimation method which uses the change point framework. We consider two popular bootstrap methods to estimate the confidence sets: conditional and smooth. From a simulation study, we find that the smooth bootstrap provides much narrower confidence sets.

Production and Scheduling

Contributed Session

Chair: Zhengyang Hu, Iowa State University, Ames, IA, United States, zhengya@iastate.edu

1 - Optimal Integration of Solar Power to Minimize Operational Costs and Carbon Dioxide Footprint in a Production System

Samuel Trevino, PhD Graduate Research Assistant, University of Tennessee, 525 John D. Tickle Engineering Building, 851 Neyland Dr., Knoxville, TN, 37996, United States, strevin1@vols.utk.edu

Production scheduling problems have generally been studied from a lean manufacturing perspective, however, energy consumption and environmental footprint have not been completely considered. To fill this gap, an optimal production planning framework for a production system is presented utilizing on-site solar power generation to minimize its energy consumption costs and CO2 footprint. Integrating uncertainty in both equipment reliability and customer demand, the multi-objective optimization model presents insights into the economically feasible solar power capacity to be installed and how production inventory planning can offset solar source uncertainty.

2 - A Client Server Framework for a Job Shop Scheduling System to Minimize Tardiness and Labor Overtime Costs under Labor and Machine Constraints

Weihang Zhu, Associate Professor, Lamar University, PO Box 10032, Beaumont, TX, 77710, United States, weihang.zhu@lamar.edu, Sujay Mahale, Alberto Marquez

Simultaneous scheduling of machine and labor in a job shop is a NP hard problem. In this study, we developed a system for minimizing tardiness and overtime labor costs in a job shop style service manufacturing facility, while incorporating client server framework for schedule visibility. The core of the optimization engine is a double sequenced simulated annealing algorithm. The model includes various machine and labor constraints including sequence dependent setups, labor availability and overtime regulations, and dispatching rules for the different parallel machine centers.

3 - Integrated Ordering and Scheduling Optimization for Make-to-order Supply Chains under Uncertainty: A Stochastic Programming Approach

Yue Sha, Tsinghua University, Tsinghua University, Beijing, Beijing, 10084, China, shay15@mails.tsinghua.edu.cn, Hui Cao

Customer driven supply chain management is recognized as a viable approach to the rapid changing market demand. Yet the coordination strategies have been little studied to align supply chain operations on a make-to-order basis. This work tries to integrate the material ordering and job scheduling decisions considering uncertain processing times and resource consumptions. The problem is formulated as a stochastic integer program incorporating decision dependent uncertainties. With the proposed approximation algorithm, numerical experiments show that the integrated policy significantly reduces the total cost.

4 - Robust Project Scheduling Integrated with Materials Ordering under Uncertain Environment

Yan Zhang, Doctoral Candidate, Huazhong University of Science and Technology, Hongshan District, 1037 Luoyu Road, Wuhan, China, zhangyan0621@hust.edu.cn, Nanfang Cui

Project Scheduling and Materials Ordering Problem (PSMOP) generates not only the project schedule but also the corresponding martials ordering plan. In our study, we consider the uncertainty of activity durations and propose a robust project schedule. We first get a baseline schedule with deterministic activity durations via genetic algorithm, basing on which a creative robust schedule is obtained by an iteration algorithm under uncertain circumstances. Finally, under different project uncertainties, computational experiments are conducted to compare the two schedules and we show that the robust schedule performs better.

5 - Hybrid Lot-sizing and Scheduling Production under Uncertainties

Zhengyang Hu, Iowa State University, 3020 Regency Ct, Unit 68, Ames, IA, 50010-2701, United States, zhengya@iastate.edu, Guiping Hu

Lot-sizing and scheduling, one of the medium-term production problems in assembly manufactories, is universally challenged with the need to reduce cost and improve customer satisfaction. A hybrid decision making model is proposed to address the combination of uncertainties on the shop floor considering real time information. Stochastic programming is adopted for random machine failure time and robust optimization is utilized to address the uncertain demand. Sample average approximation is introduced to generate discrete scenarios. The model is able to minimize the overall production cost as well as adjust satisfaction of customers based on the market environment.

Chair: Lifei Sheng, University of British Columbia, Vancouver, BC, Canada, fay.sheng@sauder.ubc.ca

1 - Cloud Deployment Model and Impact on Provider's and Users' Incentives to Invest in Security

Mingwen Yang, University of Texas-Dallas, Richardson, TX, United States, mxy131030@utdallas.edu, Varghese S. Jacob, Srinivasan Raghunathan

Cloud computing has emerged as a key strategy to meet the IT needs of firms. Despite its benefits, cloud computing's adoption and growth is hindered by information security concerns. The security of a cloud is the joint responsibility of the cloud provider and cloud users, but the extent to which the provider and users can affect the cloud security through their efforts depends on the cloud deployment model. In this study, we focus on how the cloud deployment model affects the incentives of the cloud provider and users to invest in security, which, in turn, affects the price charged by the cloud provider, the demand, and the provider's profit.

2 - Understanding Determinants of Idea Quality in On-line Communities

Orcun Temizkan, Assistant Proffesor, Ozyegin University, Cekmekoy Campus, Nisantepe Mah. Orman Sok., Istanbul, 34794, Turkey, orcun.temizkan@ozyegin.edu.tr, Ram Kumar

This research proposes a model to understand determinants of Idea Quality in on-line communities. The proposed model integrates multiple types of variables including creator (idea generator) characteristics, contributor (idea developer) characteristics and idea characteristics. Theories from the organization and innovation literature are used to develop the model. Empirical results using data from Stack Overflow will be presented.

3 - Once Bitten, Twice Shy? Examining Customer Responses to Stolen Customer Data

John N. Angelis, Assistant Professor, Elizabethtown College, 1 Alpha Drive, Elizabethtown, PA, United States, angelisj@etown.edu, Joseph C.Miller

Data breaches represent an increasing nuisance for companies. Nonetheless, the impact on future business remains underinvestigated. We surveyed 400 individuals with four unique real-world data breaches. The nuances of each case differed in two dimensions: 1) localization of the breach and 2) individualization of affected customers. We use critical components of both the Theory of Reasoned Action (TRA) and Technology Acceptance Model (TAM) in our model of business revisits. Localization has a significant effect on company opinions, while individualization has a significant effect on attitudes about the crime. We find that mainly opinions about the company have a significant effect on revisits.

4 - Innovation vs. Security: Customer Demand Reaction to Adverse Events and Industry Innovation

Melanie Lisa Yeo, Assistant Professor, University of California-Merced, Merced, CA, 95340, United States, melanie.yeo@gmail.com, Raymond Patterson, Jacquelyn Rees Ulmer, Erik Rolland

We examine the tradeoff between product innovation and the risk of security breaches in digitally-enabled products. The demand for a product, such as a mobile phone, is often influenced by innovations in features. We explore the trade-off between investing in product features and security. Using a continuous-time markov chain model, we explore the impact of differing customer demand reactions to security breaches on feature investment.

5 - Designing Services in the Presence of Customer Churn

Lifei Sheng, University of British Columbia, Sauder School of Business, 2053 Main Mall, Vancouver, BC, V6T.1Z2, Canada, fay.sheng@sauder.ubc.ca, Christopher Ryan

We explore how to design experiential services, in particular determine the quality and sequence of activities, to maximize customer satisfaction. We assume that customers are subject to memory decay and are free to quit the service at any time. This model fits experiential goods that must first be experienced by users before their value is understood. Examples include freemium software where the goal is maximize customer utility by the end of some initial phase subject to the possibility of early quitting. We show that the quality of the experience should be scheduled in a U-shape. The quitting option and memory decay lead to high service quality at the beginning and at the end of the trial period.

1 - Impact of Free-flow Operation on Drayage Productivity

Samaneh Shiri, University of South Carolina, 1076 Pavilion Tower Circle, Columbia, SC, 29201-2361, United States, shiri@email.sc.edu, Nathan Huynh

In the last decades, due to increase in international trade volume, the world container terminal throughput has increased enormously. As a result, terminals are under pressure to develop strategies to accommodate demands and increase the efficiency of their operation. The Port of Los Angeles has launched a container free-flow operation to reduce truck turn time, free up terminal space and optimize container moves. This study assesses the impact of free-flow operation on drayage productivity using the previously developed drayage scheduling model by the authors. To efficiently solve the model a reactive tabu search algorithm combined with an insertion heuristic is used.

2 - Improving Supply Chain Production Reliability through Risk-averse Interdiction

Mehdi Zolghadrasli, Stevens Institute of Technology, Hoboken, NJ, United States, mzolghad@stevens.edu, Ricardo A.Collado

We consider the problem of quality assurance on industrial assembly lines where checking all productions is impossible due to sampling cost and physical limitations. Given the total sampling budget, we determine the optimum sampling rate on each production line by solving a risk-averse multi-stage stochastic optimization problem on the production network. By leveraging the theory of dynamic coherent risk measures, we obtain a method that minimizes the probability of defective items reaching the consumers. We show that our method performs well even under erroneous beliefs/data about the reliability of each machine and process.

3 - A Multi-product Production/distribution System Design Problem with Direct Shipments and Lateral Transshipments

Jianing Zhi, Penn State-Erie, The Behrend College, Black School of Business, Burke Center 228, 5101 Jordan Road, Erie, PA, 16563, United States, jzz5296@psu.edu, Burcu B.Keskin

We investigate a multi-product, three-stage production/distribution system design problem with the direct shipment and lateral transshipment capabilities. Our goal is to find the most efficient network design to minimize the total fixed facility and transportation costs. Specifically, we locate p capacitated distribution centers in the second stage from a set of candidate locations. We propose two solution algorithms based on simulated annealing and GRASP heuristics. Both long-term and short-term memory lists are applied to maintain an efficient local search, combined with a custom greedy solver that can effectively evaluate the quality of a solution candidate.

4 - Optimal Supply Network for Biomass Co-firing Power Plant Considering Advanced Woody Biomass Feedstock Logistics

Sangpil Ko, Michigan Technological University, 1400 Townsend Dr., Houghton, MI, 49931, United States, sangpilk@mtu.edu, Pasi T. Lautala

One of the most implementable technologies to generate electricity with less environmental emissions is co-firing biomass in existing coal-fired power plant. One of the challenges for co-firing is procurement cost for biomass feedstock and as part of it, the cost of biomass transportation. Our study considers the advanced woody biomass feedstock logistics that allows for a local biomass processing depot where the biomass is torrefied and densified prior to transport to the plant. One research finding revealed large capacity power plants with a small inventory of forest residue nearby gain more benefits from such arrangements under the advanced biomass feedstock logistics scenario.

Online Business Models

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Simone Marinesi, Wharton, Philadelphia, PA, 75003, United States, marinesi@wharton.upenn.edu

1 - Social Pricing in Sharing Economy: Theory and Empirical Evidence from Airbnb

Yao Cui, Cornell University, Ithaca, NY, United States, yao.cui@cornell.edu, Ming Hu

An important difference between the lodging sharing economy platforms (e.g., Airbnb) and the traditional hotels is that in sharing economy, the guest may have social interactions with the host. In this paper, we study the effects of social interactions on rental pricing in sharing economy. To investigate the effects, we analyze a theory model and also test our theory with an empirical study using a dataset of Airbnb transactions and listing attributes.

2 - Designing Rewards-based Crowdfunding Campaigns for Strategic Contributors

Soudipta Chakraborty, Duke University, 100 Fuqua Drive, Durham, NC, 27708, United States, sc390@duke.edu, Robert Swinney

We study a model of rewards crowdfunding with the all or nothing funding mechanism. The creator of a crowdfunding campaign sets a target funding level and the campaign is successful only if the funding it receives meets this target. The contributors incur a transaction cost while pledging to a campaign. As a result, they behave strategically and decide whether to pledge before the target is met or to incur a waiting cost and delay their pledge until the campaign succeeds. We study how a creator who encounters such strategic behavior should design her crowdfunding campaign.

3 - Reward-based Crowdfunding Campaigns: Informational Value and Access to Venture Capital

Rachel Rong Chen, University of California-Davis, 3208 Gallagher Hall, One Shields Avenue, Davis, CA, 95616, United States, rachen@ucdavis.edu, Esther Gal-Or, Paolo Roma

Consider an entrepreneur who designs a reward-based crowdfunding campaign when the campaign provides a demand signal for the product and subsequent Venture Capital (VC) is needed. Her design entails choosing both the campaign goal, and the pledge level that entitles backers to the product if it becomes available. While failure to reach the goal sends a negative signal likely to eliminate the entrepreneur's access to VC funding, succeeding does not guarantee subsequent VC funding either. We examine how the informativeness of the campaign and considerations related to gaining access to VC funding affect the choice of campaign instruments, as well as the decision of whether to run a campaign.

4 - The Dark Side of Crowdfunding

Simone Marinesi, Wharton, 201 S.25th Street, Apt 621, Philadelphia, PA, 75003, United States, marinesi@wharton.upenn.edu, Elena Belavina, Gerry Tsoukalas

We explore the pros and cons of reward-based crowdfunding by comparing it with traditional bank funding, accounting for two characteristics of crowdfunding: the unobservability of products' true performance (performance opacity) and risk of entrepreneurs' misbehavior (moral hazard). We find that both features hampers crowdfunding profits, and characterize how their interaction and its implications for profit and welfare. We then propose an improved crowdfunding design that remedies the negative consequences of such features.

Revenue Optimization in Online Markets

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Vahideh Manshadi, Yale University, New Haven, CT, 06511, United States, vahideh.manshadi@yale.edu

1 - Promotion Planning of Network Goods

Saed Alizamir, Yale University, 339 Willow St., New Haven, CT, 06511, United States, saed.alizamir@yale.edu, Ningyuan Chen, Sang Kim, Vahideh Manshadi

Many products/services exhibit network externality: a customer who consumes the good increases the utility of consumption for her neighbors. To promote diffusion of the good in the network, the firm can initially charge a lower price. The price is raised to a higher level when enough consumers join the pool of adopters. We find that it is optimal for the firm to stop the promotion when the total externality of the existing users reaches a threshold, which depends on the adjacency matrix. We investigate how the structure of the network affects the firm's optimal strategy and profit, and show that more heterogeneity among customers increases the firm's revenue; a balanced network yields the lowest revenue.

2 - Online Bipartite Matching in Two-sided Markets

Van-Anh Truong, Columbia University, 500 West 120th Street, 338 Mudd Hall, New York, NY, 10027, United States, vt2196@columbia.edu, Xinshang Wang

We study a class of bipartite matching problems in which demand and supply units of various types arrive randomly and sequentially over time. Supply units can wait for a fixed amount of time, but demand units must be matched irrevocably upon arrival to existing supply units if any, or rejected. The above problem is motivated by two-sided crowdsourcing markets in which demand and supply are matched by an intermediary firm, which earns a revenue on each transaction. We provide the first efficient algorithms with worst-case performance guarantees for this class of problems.

3 - Online Resource Allocation under Partially Learnable Demand
Vahideh Manshadi, Yale University, 165 Whitney Ave, Rm 3473, New Haven, CT, 06511, United States, vahideh.manshadi@yale.edu

We study a basic online resource allocation problem where stochastic information about demand is unknown a priori, and it can only be partially learned. We design online algorithms that significantly outperform those that do not utilize the partial information, highlighting the value of (even partial) learning in online resource allocation.

4 - Dynamic Recommendation at Checkout under Inventory Constraintconstraint
Xi Chen, New York University, 44 W. 4th St, NYU. KMC Room 8-50, New York, NY, 10012, United States, xchen3@stern.nyu.edu, Will Ma, David Simchi-Levi, Linwei Xin

This talk is motivated by a new checkout recommendation system at Walmart's online grocery, which offers a customer an assortment of up to 8 items that can be added to an existing order, at potentially discounted prices. We formalize this as an online assortment planning problem under limited inventory. Multiple item prices, combined with customer withdrawal when their initially selected items stock out, pose additional challenges for the development of an effective online policy. We overcome these challenges by introducing the notion of an inventory protection level in expectation, and present an online algorithm with bounded competitive ratio for arbitrary arrival sequences.

Innovative Practices in Hotel and Sports Revenue Management

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Pelin Pekgun, University of South Carolina, Columbia, SC, 29205, United States, Pelin.Pekgun@moore.sc.edu

Co-Chair: Ovunc Yilmaz, University of Notre Dame, Mendoza College of Business, Columbia, SC, 29201, United States, oyilmaz@email.sc.edu

1 - Dynamic Availability and Pricing of Time-limited Upgrade Offers
Xiao Zhang, The University of Texas at Dallas, 800 West Campbell Rd, Richardson, TX, 75080, United States, xiao.zhang@utdallas.edu, Metin Cakanyildirim, Ozalp Ozer

Upgrade, a strategy used in the travel industry to balance supply-demand mismatches among products of different quality levels, is usually implemented either at the booking time or at the check-in time. We study a revenue management problem of a firm that sells two products at fixed prices and offers upgrades dynamically. The optimal policy specifies the timing, the pricing, and the quantity of the dynamic upgrades.

2 - The Effects of Peer Reviews and Manager Responses on the Hotel Ratings
Saram Han, 110 Joanne Dr., Ithaca, NY, 14850, United States, sh2322@cornell.edu

This study examines how the interaction between the members of the TripAdvisor community affects the ratings of future review writers. Specifically, using the peer-effect model, we aim to examine both peer reviews and manager responses' influence on a future reviewer's rating. The effect of the reviews are captured at two different points: 1) before booking the hotel, and 2) during the review-writing process. We examine how the information received at the expectation stage affects the evaluation about the hotel. The effect of the peer reviews is also analyzed by different contributor levels. Lastly, we discuss the effect of manager responses regarding their response style.

3 - An Empirical Look at the Team-specific Ticket Options Market?
Guangzhi Shang, Florida State University, Department of Marketing, College of Business, Tallahassee, FL, 32306, United States, gshang@fsu.edu, Ovunc Yilmaz, Mark Ferguson, Pelin Pekgun

Team-specific ticket options, where fans can make a team-specific reservation for the right and obligation to purchase a face value ticket if their team qualifies for the final game, has recently gained popularity in the sports industry. Over the past two years, a significant portion of the College Football National Championship game tickets was allocated to Teamtix, a company offering these options. In this study, we investigate the drivers of prices and transaction volumes in Teamtix's marketplace using their Twitter feed and detailed game/ranking information.

Innovation/Entrepreneurship

Contributed Session

Chair: Xiaojin Liu, University of Virginia, Charlottesville, VA, United States, liux@darden.virginia.edu

1 - How Does the Entrepreneur with Shortages Evaluate the Hidden Market?
Sinan Erzurumlu, Associate Professor, Babson College, 231 Forest St, Babson Park, MA, 02457, United States, serzurumlu@babson.edu, Ethem Canakoglu, Yaman Erzurumlu

When entrepreneurs evaluate a business opportunity, they assess its value, and the value of the business based on internal factors, including their risk preference and shortages of resources, routines, reputation and regulations along with external factors including market-related uncertainties. These internal and external factors may impede the entrepreneur's ability to directly evaluate the true state of the market for a business opportunity; hence the market is considered 'hidden'. We present a Markov decision process model to evaluate the hidden market for the business opportunity. We provide an algorithm that explains how entrepreneurs can implement a market-evaluation procedure.

2 - CEO Duality Leadership, Security Analysts Feedback and Corporate Research and Development Investments
Jacob Do-Hyung Cha, Seoul National University, Room 313, 58-dong, Seoul National University, Gwanak-gu, 150-742, Korea, Republic of, research.dohyung@gmail.com, Hye-Jin Cho

A commonly held view is that a hazardous short-termism has taken hold across the publicly held firms. Critics say that top managers have become myopic due to capital market pressures. This study examines whether CEO duality leadership can mitigate this myopic behavior in the context of corporate R&D investments under the pressures from the capital market intermediaries - securities analysts. I propose that CEO duality tend to cut R&D investments when the CEO faces the pressures from the capital market which is consistent with the agency theorists. I test this hypothesis by a large-scale, cross-industry data from a sample of U.S. manufacturing firms during the period of 1992 to 2014.

3 - Innovation in a Dynamic Technology Landscape
Kibae Kim, Research Assistant Professor, KAIST, Daehakro 291, Yuseong, Daejeon, 34191, Korea, Republic of, kibaejjang@kaist.ac.kr, Jorn Altmann

Although previous studies suggest innovation strategies on the ground of technology recombination in a technology landscape, they do not discuss two restricting assumptions that exist in their analysis: the technology space is (1) compact and (2) invariant. In this research we replace these assumptions with realistic ones by redefining the technology space at a meta level and admitting the evolution of technology landscape. Based on these assumptions we analyze innovation strategies using patent data, and show the effect of innovation strategies varies according to how the technology landscape evolves.

4 - Technology Convergence and its Market Performance
Kibae Kim, Research Assistant Professor, KAIST, Daehakro 291, Yuseong, Daejeon, 34191, Korea, Republic of, kibaejjang@kaist.ac.kr, Wonjoon Kim

Although technological convergence is a paradigm of innovation dominating technology advances across a variety of industry sectors, innovation studies have not yet explored the economic impact of convergence patterns. In this research, we examine whether the market performance causes from the combination of pre-existing technologies or the re-use of converged technologies. To do so, we design a knowledge flow network, which consists of technologies and citation relations, to analyze the combination in backward flowings and the reuse in forward ones. Our findings emphasizes both reuse and combination of technologies and the impact of industry sectors.

5 - How does Social Orientation Influence Firm Innovation
Xiaojin Liu, University of Virginia, Charlottesville, VA, 22903, United States, liux@darden.virginia.edu, Raul Chao, Jared D. Harris

Corporate social responsibility (CSR) has gained momentum as a driver of long term competitiveness. Appling portfolio and resource allocation theory to understand how firms manage funding for CSR projects, this research addresses the questions of whether and how firm social orientation relates to firm innovation. We empirically find that in the long term, both proactive and reactive social orientation can strengthen firm innovation. However, such benefits are moderated by the firm's technological and business contexts.

Simulation and Optimization

Contributed Session

Chair: Si Zhang, Shanghai University, Shanghai, China, zhangsi817@sina.com

1 - Resilience Based Network Design under Uncertainty

Xiaoge Zhang, Vanderbilt University, 6501 Harding Pike, Apt. P-25, Nashville, TN, 37205, United States, zxgcqupt@gmail.com, Sankaran Mahadevan, Shankar Sankararaman, Kai Goebel

A nonlinear function is introduced to characterize the component restoration behavior in the presence of a disruptive event. The introduction of such a function facilitates the modeling of absorptive ability, restoration capability and recovery speed related with each system component. A system resilience constraint is formulated to impose that the system resilience at a given time meet a desired target. We use the maximum flow through the network as an indicator of system performance. Our objective is to design an optimal network that incurs the least cost, but meets a system resilience constraint. Two numerical examples are used to illustrate the effectiveness of the proposed method.

2 - A New Reinforcement Learning Algorithm for Average Reward with Numerical Results on Total Productive Maintenance

Angelo Encapera, Missouir University of Science and Technology, 15512 Tamarac Ct, Wichita, KS, 67230, United States, amet3b@mst.edu, Abhijit Gosavi

We present a new Reinforcement Learning (RL) algorithm for average reward Markov decision processes (MDPs) and semi-Markov decision processes (SMDPs). The existing RL algorithm for SMDPs, namely R-SMART, requires exploration decay. Our new algorithm, named iSMART, is fully exploratory and hence eliminates the need for turning the exploration decay. iSMART is designed using principles of deep learning for RL. We present numerical results on small cases, as well as with a larger case study on Total Preventive Maintenance. The new algorithm is more robust than its precursor R-SMART and generates near-optimal solutions on all test cases studied.

3 - Actor-critics Revisited: A New Bounded Algorithm and Numerical Results with Revenue Management

Ryan J. Lawhead, Missouri University of Science and Technology, 113 West 16th St, Rolla, MO, 65401, United States, rjlm97@mst.edu, Abhijit Gosavi

Actor-Critics are Reinforcement Learning algorithms that can solve large-scale Markov Decision Processes (MDPs) and semi-MDPs. The classical actor-critic has a critical drawback in that the actor's values get unbounded. The artificial bounding required as a result limits the exploration of the state-action space, which can cause sub-optimal behavior even on small-scale problems. We propose a new version that keeps the actor's values bounded, allowing the algorithm to search the state-action space more thoroughly and generate optimal solutions. We also present results on a large-scale problems from airline revenue management where our algorithm outperforms a standard industrial heuristic.

4 - Heuristic Algorithm for Initial Sample Size in Ranking and Selection Problem

Ruijing Wu, Phd Student, Shanghai Jiao Tong University, 2334 Willowbrook Drive, Apt 258, Shanghai, 200030, China, wu_ruijing@yeah.net

Ranking and selection problem is to choose the best system from a set of systems. When variance are unknown, it is necessary to take some initial samples to estimate it. In most procedures, initial sample size (ISS) is predetermined and fixed. In this paper, we present a heuristic algorithm to calculate ISS, which is a generalization of the idea in Hartmann (1991). To check the validity and effectiveness of our algorithm, we implement it on KN procedure and compare it with KN procedure and Hartmann's method. The numerical experiments show that our procedure can (1) guarantee the probability of correct selection; (2) reduce the total sample size by 20%-80%.

5 - Path Planning of Multiple Unmanned Surface Vehicle under Communication Constraint

Md Saiful Islam, Texas Tech University, 2500 Broadway, Lubbock, TX, 79409, United States, md-saiful.islam@ttu.edu, Timothy I. Matis

Unmanned Surface Vehicles (USV) in current application has limited payload and endurance. Multiple USV's are often used to overcome these limitations but, path planning of multiple USV's mostly uses either leader - follower approach or formation fleet which leads to a myopic optimization problem. Only the leader vehicle have the ability to make an independent decision. To avoid this problem, USV's in this study will be considered as mobile agents where each USV can make a decision independently and will maintain communication with other members of the team.

6 - Efficient Computing Budget Allocation for Optimal Subset Selection with Correlated Sampling

Si Zhang, Shanghai University, Shang-Da Road No. 599, Shanghai, China, zhangsi817@sina.com, Loo Hay Lee, Ek Peng Chew, Chun-Hung Chen

This study mainly considers the problem selecting the top-m alternatives under the environment with correlation. Correlation demonstrates the relationship between alternatives and can provide more information when comparing two alternatives. Hence, it is sometimes intentionally introduced into simulation to reduce the variance of the difference between two alternatives. We model the optimal subset selection problem with correlated sampling based on the optimal computing budget allocation framework and derive the respective optimal allocation rules.

Supply Chain, Decision Analysis

Contributed Session

Chair: Shuxiao Sun, Peking University, Beijing, China, sunshuxiao@pku.edu.cn

1 - Game Theoretic Modeling of a Biofuel Supply Chain with Existence of Incentives to Promote Cellulosic Based Biofuel Production

Amirsaman Hamzeh Bajgiran, PhD Candidate, University of Wisconsin-Milwaukee, 1320 E Capitol Drive, Apt 205, Milwaukee, WI, 53211, United States, hamzehb2@uwm.edu, Jaejin Jang, Xiang Fang

We consider a biofuel supply chain (BSC) problem in which a farmer supplies two downstream refineries with non-identical crops (corn and energy crop) to study the feasibility of reaching the goal of RFS. The problem has been modeled as a multi-leaders one follower game to capture the farmer's decisions on land use as well as refineries' proposed prices to the farmer. We have considered subsidizing the farmer and the refinery which uses energy crop to study whether it is capable of enhancing advanced biofuel production. This work can provide insights for governments and help them to make effective policy-making decisions to achieve their goals.

2 - Optimal Advertising and Pricing in a Dynamic Omnichannel Supply Chain

Yang Bai, Ajou University, Suwon, Korea, Republic of, b198716y@hotmail.com, Byeong-Yun Chang

Channel coordination and advertising promotion strategy play an important role in modern lives. In this research, we examine an effective and efficient coo-petition model and consider advertising decisions for a retailer directing omni-channel. We derived the N-A model in dynamic analysis of coo-petition in an omni-channel. Using the optimal omni-channel model, we obtain the optimal dynamic pricing and advertising decisions.

3 - Leadership and Information Flow in a Supply Chain with Coopetition

Maosen Zhou, Shenzhen University, No.3688, Nanhai Road, Shenzhen, China, moussin@gmail.com, Qingyu Zhang

We study the issue of coopetition in a two-echelon supply chain where competing manufacturers purchase through a common GPO to achieve economies of scale. Our game-theoretical modeling generalizes information structures about uncertain demand with horizontal and vertical information flows, and quantifies horizontal coopetition under different vertical leadership. By analyzing the effects of coopetition, leadership, information flow, and their interplay, managerial insights into exploiting the relationship and information structures for coopetitive supply chains will be provided.

4 - Entry Deterrence and Price Competition under Asymmetric Information

Jooyol Maeng, Assistant Professor, Pacific Lutheran University, School of Business, 12180 Park Avenue S, Tacoma, WA, 98447-0003, United States, maengjy@plu.edu, Sungyong Choi

An incumbent has an incentive to deter entry of a potential entrant by lowering pre-entry price. We study limit pricing in a price-based duopoly market under asymmetric demand information. We present a separating perfect Bayesian equilibrium, which indicates the incumbent with private information can successfully deter entry.

5 - Horizontal vs. Vertical Cooperation in Supply Chains under Competition

Shuxiao Sun, Doctoral Candidate, Peking University, No.5 Yiheyuan Road Haidian District, Beijing, Beijing, 100871, China, sunshuxiao@pku.edu.cn, Xiaona Zheng

We study the impact of horizontal and vertical cooperation with different degree on firms' profits in two-tier supply chains. The cooperating firm maximizes its own profit and a proportion of its partner's. We find that, when retailers are asymmetric in variable cost or market base, under horizontal cooperation, the "strong" retailer is always better off while the "weak" one is likely to get worse; under vertical cooperation, the manufacturer prefers cooperation with the "weak" player whereas the supply chain favors "an alliance between giants." Finally, we extent our model to one manufacturer and multiple retailers.

Manufacturing

Contributed Session

Chair: Sanam Azadiamin, Ohio University, Athens, OH, United States, sa349416@ohio.edu

1 - A MILP Formulation for Combined Planning and Scheduling of Multistage Multipurpose Batch Plants

Zhaohui Li, Shanghai Jiao Tong University, 1954 Huashan Road, Shanghai, 20030, China, lzh_cathy@sjtu.edu.cn, Yongpei Guan, Guohua Wan

A mixed formulation is presented for a real world planning and scheduling instance with multistage, multipurpose batch plants in rolling horizon. Besides, the input of storage between mixing and filling is discrete while the output is continuous. Sequence dependent setup and storage expiration are also taken into consideration. Lot sizing is achieved from an aggregation planning model for management's sake, based on which a schedule model is formulated to get the optimal scheduling. Simulation is conducted to find the bottleneck of this procedure.

2 - Optimization of Automated Guided Vehicle Dispatching in Shop Floors

Shiyang Huang, Iowa State University, 0076 Black Engineering, Ames, IA, 50011, United States, shuang@iastate.edu, Guiping Hu

Automated guided vehicle (AGV) have been widely adopted for material handling on shop floors. We proposed a series of strategies to guide the dispatching of AGV based on heuristic rules and optimization models of material handling on shop floors. The optimization models were formulated and specially solved with designed algorithms that were proved to be more efficient than common solution techniques. The strategies were demonstrated in a case study based on a shop floor in literature, and the simulation results showed that the proposed methods outperformed classic strategy in optimizing different criteria on the shop floor.

3 - A New Hybrid Supply Chain Strategy with Expected Demand in Regional Facilities and a Common Service Plant

Sanam Azadiamin, Ohio University, 35 N. Mckinley Ave. Apt 112, Athens, OH, 45701, United States, sa349416@ohio.edu, Gursel Suer

A hybrid global supply chain strategy is proposed where regional plants are designed to meet expected demand whereas one service plant covers the remaining demand in all regions. This strategy requires transportation lead times and safety stocks to be considered to achieve a certain service level at a minimum cost. The relation between service levels and safety stocks is explored.

Production and Scheduling

Contributed Session

Chair: Feifan Wang, Arizona State University, Tempe, AZ, United States, feifan.wang@asu.edu

1 - Assembly Line Balancing: the Difficulty of Solving Certain Instances

Jorge Pereira Gude, Universidad Adolfo Ibanez, 750 Avda Padre Hurtado, Office 216-C, Vina del Mar, 2530852, Chile, jorge.pereira@uai.cl

The simple assembly line balancing problem is a classical optimization problem, which has been widely studied in the literature. While recent effort has been geared towards the identification of difficult instances, the question of what makes them difficult is still open. In this work, several new exact solutions procedures are put forward and their behavior under different instance characteristics is considered. An extensive computational experiment with these methods allows us to close several open instances and to give some insight into the difficulty of solving certain instances.

2 - Multi-job Production Systems: Theory and Application

Pooya Alavian, PhD Candidate, University of michigan, Ann Arbor, MI, 48109, United States, alavian@umich.edu, Semyon M. Meerkov

Multi-job production (MJP) is a class of flexible manufacturing systems intended to produce different job types based on a product-mix or build-schedule.In MJP, jobs are processed by the same sequence of operations, but with different processing times for each job type.We introduce the Work-based model, use it to characterize MJP systems, analyze the performance of MJP systems as functions of the product-mix, and report an application in automotive industry.

3 - Flexible Maintenance Schedules for Multistage Degradation Systems

Yunyi Kang, Arizona State University, 1850 E Hayden Lane, Apt 207, Tempe, AZ, 85281, United States, ykang37@asu.edu, Feng Ju

We present a flexible preventative maintenance problem on two-machine-and-one-buffer manufacturing systems, in which machines are subject to multi-stage degradation. Condition-based maintenance decisions are made on both machines, considering machine degradation stages and the buffer level. Moreover, flexible policies are included such that a machine can be recovered to any better operating state, comparing to which to only the best operating state is possible in many previous work. A Markov decision model is formulated to find the optimal maintenance policy in finite production runs and computational experiments are designed to show the improvements comparing to other policies.

4 - Hierarchy Machine Setup for Lot Scheduling at Assembly and Test Facilities

Youngbum Hur, PhD Candidate, University of Texas at Austin, 11500 Jollyville Road, #1917, Austin, TX, 78759, United States, Youngbum.hur@utexas.edu, Jonathan F.Bard

The importance of machine setups has been neglected in scheduling assembly and test (AT) operations in semiconductor back-end facilities. We examine the full dimensions of the problem in a multi-machine, multi-tooling environment with minimize the number of demand shortages and maximize weighted throughput. Our model determines machine setups, lot assignments and lot sequences using a greedy randomized adaptive search procedure (GRASP). In this paper, we consider a hierarchical approach to scheduling lots and to investigate the impact of different setup times and hierarchy rule. The performance of methodology is evaluated using data provided by a semiconductor company.

5 - An Integrated Approach to Production Planning and Scheduling for Automotive Wiring Harness Cut and Crimping Lines

Jeongin Koo, Korea Institute of Industrial Technology, 89, Yangdaegiro-gil, Ipjang-myeon, Seobuk-gu, Researcher Bldg, Cheonan, 31056, Korea, Republic of, jikoo@kitech.re.kr, Minjae Ko, Hwanju Ryu, Sangsik Ha, Hyunchul Tae

This study considers a production scheduling problem of automotive wiring harness cut and crimping lines where all the harnesses should be processed manually or automatically by different types of machines. To produce wiring harnesses, every order of wiring harness production should be handled by the process allocation processes, the equipment allocation processes, and equipment scheduling in the cut and crimping lines. Given allocated processes for each wire to produce, we formulate an mixed integer linear programming model of the equipment allocation and scheduling to solve the case study of the wiring harness production line.

6 - Real Time Control of Geometric Serial Lines with Residence Time Constraints

Feifan Wang, Arizona State University, 669 S.Mill Ave, Tempe, AZ, 85281, United States, feifan.wang@asu.edu, Feng Ju

Scrap due to residence time constraints are commonly seen in manufacturing systems. In such systems, minimum and maximum waiting times for each part are enforced in the buffer. To optimize the trade-off between production rate and scrap rate, an on-off control policy for a two-machine geometric production system is derived using Markov decision processes with state approximation. An iteration method is further provided to improve the control policy.

Supply Chain, Risk Management

Contributed Session

Chair: John Kros, East Carolina University, Greenville, NC, United States, krosj@ecu.edu

1 - Mitigating Supply Chain Risk through Supply Chain Responsiveness a Prioritization Approach

Seyed Vahid Reza Nooraie, NC A&T.State University, 2205 Newgarden Road, Greensboro, NC, 27410-1718, United States, snooraie@aggies.ncat.edu, Paul M.Stanfield, Mahour Parast, Masoud Narenji, Saeed Zamiri Marvizadeh

The global market is characterized by decreasing product life cycles, rapid change in customer demands, and shortened lead time to respond to environmental uncertainty. In such situations, the capability of a firm to quickly respond to changes in its external environment is an initial determinant of the firm's performance. This can only be possible when the supply chain is responsive. The purpose of this paper is to identify different factors for responsive supply chains. Based on a review of the literature, we propose a conceptual model for supply chain responsiveness that encompasses practices such as flexibility, agility, internal integration, and visibility.

2 - Optimization-based High Performance Packaging for Moldable Items

Roshanak Akram, Graduate Research Assistant, University of Tennessee, Knoxville, 851 Neyland Drive, 525 John D. Tickle Building, Knoxville, TN, 37996, United States, roshanak@utk.edu, Rupy Sawhney

A food supplying company, constantly strives to improve the delivery of items, which reach their intended recipient in form of meal bags. Defects in packaging the meal bags into the boxes or transporting them improperly along the supply chain cause quality defects. These defects are not acceptable within company's high quality standards. A three-pronged approach is proposed:Improve packaging by developing a high-performance optimization algorithm for moldable food bagsImprove inspection by developing an automated machine-learning based inspection system, andImprove accountability and identify training opportunities in the supply chain by connecting an observed defect to its root cause.

3 - Does Traceability Help Product Quality?

Chao Liang, Cheung Kong Graduate School of Business, Main Campus, Oriental Plaza 2/F,, Tower E2, 1 East Chang An Ave.,, Beijing, 100738, China, cliang@ckgsb.edu.cn, Xianjun Geng

In a supply chain with one manufacturer and one supplier, we study how traceability impacts the manufacturer and the supplier's incentive to improve product quality. Interestingly, we find that traceability may reduce the final product's quality.

4 - The Impact of Counterfeiting on Cost and Service Delivery in the Supply Chain

John F. Kros, Vincent K. McMahon Distinguished Professor, East Carolina University, College of Business Dept of M&SCM, 3205 Harold Bate Building, Greenville, NC, 27858-4353, United States, krosj@ecu.edu, Scott Dellana, W. Jason Rowe

Counterfeiting of goods is an emerging stream of research. Firms are increasingly facing a multitude of challenges in preventing inferior products from reaching end-users. The emphasis has largely focused on counterfeiting risks in relation to the deleterious effects on brand image and customer perceptions of unethical behavior by final-tier channel members. Research is lacking which considers the implications of counterfeiting as a disruptive force in the supply chain. Our study aims to research the extent to which firms seek to detect the presence of counterfeiting and the subsequent effects the detection and occurrence of counterfeiting has on costs and service delivery in the supply chain.

1 - An Integrated Airline Recovery Approach Capturing Passenger Compensation Impacts

Luis Cadarso, Rey Juan Carlos University, Camino del Molino s/n, Fuenlabrada, 28943, Spain, luis.cadarso@urjc.es, Vikrant Vaze

The European flight delay compensation regulation (EC) No 261/2004 establishes common rules on compensation to passengers in the event of disruptions. We develop an integrated approach that recovers airline timetable, fleet assignment, aircraft routings, and passenger itineraries capturing the impacts of airlines' decisions on passenger compensation. We evaluate scenarios involving disruptions, and optimize recovery decisions to maximize profits by modeling passenger no-shows after disruptions.

2 - Optimal Control of Flight Parameters for Re-scheduling Airline Operations

Ángel Marín, Technical University of Madrid, Madrid, Spain, angel.marin@upm.es, Jesús Gabriel Galindo, Luis Cadarso

Flight planning determines the route, speed, and fuel burn of a flight. In case of disruptions, it has been usually either poorly addressed or obviated. We present a novel approach addressing airline recovery, which integrates flight planning and passenger re-scheduling and develop an integrated non-linear model that recovers airline timetable and passenger itineraries capturing the impacts of airlines' decisions on passenger compensation and loss of goodwill. We evaluate scenarios involving disruptions, and optimize recovery decisions to maximize profits.

3 - Sequential Approach for Solving the Dynamic Aircraft Recovery Problem

Bruno F. Santos, Assistant Professor, Delft University of Technology, Delft, Netherlands, b.f.santos@tudelft.nl, Jeroen Vink, Wim J.C. Verhagen, Ivo Medeiros, Ricardo Filho

This paper presents a new approach for solving the recovery of aircraft routing, using a heuristic that iteratively solves selections of the airline's fleet. An initial solution is always presented in seconds, after which potential reductions of disruption cost are investigated. The model is solved dynamically, re-solving the airline's schedule based on new disruption information starting from the last found solution. Aircraft specific requirements such as maintenance schedules are taken into consideration. The selection heuristic can find an optimal solution in 90% of the disruption instances tested, while on average only requiring 4% of the time needed to find the global optimum.

4 - Stochastic Dynamic Airline Disruption Management using Airport Stochastic Delay Data

Lavanya Marla, University of Illinois at Urbana-Champaign, Urbana, IL, United States, lavanyam@illinois.edu, Jane Lee, Alexandre Jacquillat

We present and evaluate an approach which integrates advanced disruption management (incorporating flight planning) with a stochastic and dynamic decision framework, to create a more robust handling of the disruptions caused by congestion at the airport. We develop an online algorithm that utilizes a rolling horizon approach for solving the recovery model with flight planning, where the future expected cost of stochastic disruptions are used as input for look-ahead period. We show empirically that having a look-ahead period with stochastic airport information reduces recovery costs compared to a naïve model.

Supply Chain, Competition

Contributed Session

Chair: Lisha Duan, The Pennsylvania State University, University Park, PA, United States, lud149@psu.edu

1 - Supply Chain Network Equilibrium Model under Carbon Cap and Trade

Yiping Jiang, Associate Professor, Nanjing Agricultural University, 40 Dian Jiang Tai Road, Pukou, Nanjing, 210031, China, ypjiang@njau.edu.cn, Xiaoling FU

This paper investigates the network equilibrium problem in a supply chain network considering carbon allowance trading and demand uncertainty. We first link carbon cap-and-trade with transaction decisions in a supply chain network, and identify its unique characteristics. Then we formulate this problem as a network equilibrium optimization model, and further convert it into a monotone variational inequality. Next, we propose a projection-based prediction correction algorithm to solve the developed model. Finally, we report the numerical results and give some management insights.

2 - An Integrated Model for a Two-attribute Warranty Policy Involving the Manufacturer, Suppliers, and Distributors

Amitava Mitra, Professor, Auburn University, College of Business, Lowder Building Suite 419, Auburn, AL, 36849-5266, United States, mitraam@auburn.edu

A two-attribute warranty policy, consisting of warranty period and usage limit, is considered. A portion of the warranty costs, incurred by a manufacturer, is usually assigned to the suppliers associated with the particular part/component failure through a "burden ratio". Additionally, the manufacturer may pay a commission to the distributor/retailer of products based on the achieved market share. An integrated model is developed from the manufacturer's perspective involving the decision variables of unit product price, warranty period, usage limit, commission paid, and burden ratio.

3 - Effectiveness of Coordination Mechanisms Based on the Exchange Prices

Ali Hassanzadeh Kalshani, Graduate Student, University of California-Irvine, 1723 Verona Place, Irvine, CA, 92617, United States, ahassan2@uci.edu, John G.Turner, Luyi Gui

In many real-world settings where resources are shared, decentralized agents (e.g., individual competing firms) maximize their profits, and in so doing, choose to use an amount of resources. Motivated by a desire to understand the theoretical and structural underpinnings of what makes coordinating decentralized agents hard or easy, we study what is known as the Price of Anarchy, defined as the ratio of the combined profit achieved by all decentralized agents to the profit achievable by a monopolist which owns all of the resources herself.

4 - System of Systems Approach to Develop an Energy Water Nexus Model under Uncertainty

Afshin Ghassemi, University of Illinois at Chicago, 1200 W. Harrison St, Chicago, IL, 60607, United States, Aghass2@uic.edu, Michael J. Scott

A water-energy nexus model is an interdependent systems approach to study two infrastructure subsystems, energy and water, simultaneously. A robust, linear, mixed-integer, multi-period model is proposed to study the water-energy nexus as an integrated system. The proposed model leads to decreased total system cost and limits total system pollution (e.g., waste water pollution). Moreover, the robust model is immune to a reasonable amount of uncertainty (e.g., water demand uncertainty). The model solutions include detailed decisions for all existing sub-systems in the water-energy nexus.

5 - A Mixed- Integer Quadratic Consolidation Model for a Two-echelon Supply Chain

Sepideh Alavi, PhD Candidate, University of Wisconsin Milwaukee, 3202 N Maryland Ave, Milwaukee, WI, 53202, United States, alavi@uwm.edu, Matthew Petering, Anthony Ross

This paper proposes a shipment consolidation model addressing production and consolidation decisions by a manufacturer which provides inventory replenishments to multiple distribution centers (DCs). The model is not restricted to specific rules such as aggregation of shipments at regular times or consolidating when a predetermined quantity is accumulated. We develop a mixed-integer quadratic optimization model to simultaneously determine the optimal inventory replenishment and consolidation times. Numerical results, obtained via MIQP and a genetic algorithm are discussed.

6 - A Dynamic Supplier Selection and Inventory Management Model in a Serial Supply Chain with a Novel Price Break Scheme and Flexible Time Periods

Lisha Duan, PhD Student, The Pennsylvania State University, University Park, PA, United States, lud149@psu.edu, José Ventura

A new supplier price break scheme is introduced and incorporated into an integrated inventory planning model for a serial supply chain that minimizes the overall incurred cost including procurement, inventory holding, production, and transportation. A mixed-integer linear programming(MILP)formulation is presented addressing this multi-period, multi-supplier, and multi-stage problem with time-varying demand. Then, the length of the time period is considered as a variable. A new MILP formulation is derived. Sufficient evidence demonstrates that the length of the time period has a significant influence on supplier selection, lot sizing allocation, and inventory planning decisions.

1 - Single-machine Common Due Date Earliness/tardiness Scheduling with Machine Unavailability

Kerem Bulbul, Associate Professor, Sabanci University, Faculty of Engineering & Natural Sciences, Orhanli, Tuzla, Istanbul, 34956, Turkey, bulbul@sabanciuniv.edu, Safia Kedad-Sidhoum, Halil Sen

We study the problem of scheduling a single machine as to minimize the total deviation of the job completion times from an unrestrictive common due date when one or several fixed intervals of unavailability are present in the planning horizon. Several interesting cases are identified and explored, depending on the resumability scheme (resumable, non-resumable, semi-resumable) and the location of the interval of machine unavailability with respect to the common due date. The focus of analysis is on structural properties and drawing the boundary between polynomially solvable and NP-complete cases. Pseudo-polynomial DP algorithms are devised for NP-complete variants in the ordinary sense.

2 - No Wait Open Shop Scheduling Problem with Sequence Dependent Setups and Release Dates

Rahman Khorramfar, PhD Student at North Carolina State University, North Carolina State University, Raleigh, NC, United States, rahman.khorramfar@gmail.com

This paper deals with no-wait open shop scheduling with sequence dependent setup times and release dates, minimizing total completion times. We present three formulation of the problem based on different decision variable paradigms and investigate some computational aspects of the models. For large size problems, we first propose a novel encoding and decoding scheme, and present four particle Swarm Optimization (PSO)-based algorithms and four Tabu Search (TS)-base algorithms. To evaluate the performance of the algorithms we carry out two cpmputational experiments.The evaluation of algorithms indicate that one of the TS-based algorithms slightly outperforms the others.

3 - Performance of Various Formulations for Machine Scheduling Problems with and with out Setups

Ekin Koker, University of Massachusetts, Mechanical and Industrial Engineering, 160 Governors Drive, Amherst, MA, 01003, United States, ekoker@umass.edu, Ana Muriel

Machine scheduling problems are one of the most widely studied problem families in operations research. Yet, due to their challenging nature, most of the literature has focused on developing heuristics, testing meta-heuristics or exploring the effectiveness of dispatching rules. Comparison of different modeling techniques in exact approaches such as mixed integer programming has received surprisingly little attention. In this paper, we computationally compare the effectiveness of formulations based on direct positional variables against relative positional variables in a variety of machine scheduling problems, including parallel machine and flow shop settings with and without setups.

4 - Minimizing Labor Costs in Picker-to-parts Warehouses with Delivery Due Time Windows

Arpan Rijal, PhD Candidate, Erasmus University, Postbus 1738, Rotterdam, 3000 DR, Netherlands, rijal@rsm.nl

Many picker-to-parts face temporal and spatial limitations in the staging process. To address these limitations, orders have to be brought to staging lanes within a predefined due time window before they are loaded onto trucks and shipped. We study the scheduling of order-pickers in picker-to-parts warehouses with hard pick delivery due time windows. We formulate the problem and evaluate its complexity. Additionally, we present an efficient heuristics to tackle real-sized instances.

1 - Managing Service Design in Decentralized Supply Chains

Huaqing Wang, Emporia State University, 1 Kellogg Circle, Cremer Hall, Emporia, KS, 66801, United States, hwang4@emporia.edu, Haresh B. Gurnani, Yu Tang

Customers buying certain products may lack functional knowledge and need help after purchase. The retailer (or manufacturer) can invest in pre-sales effort to educate customers; We study the service channel design problem with different structures and show that the retailer would even be worse off in a cost-sharing contract.

2 - Optimal Practice of Bundling in a Duopoly

Araz Khodabakhshian, UCLA, 501 Gayley Avenue, Apt 11, Los Angeles, CA, 90024, United States, arazkhodabakhshian@gmail.com, Uday S.Karmarkar, Guillaume Roels

Service bundles are common in many industries, but there are also several examples of firms that choose not to bundle. We study bundling in the presence of competition to examine its implications for bundling strategy. We model the bundling strategy of two firms offering two products to heterogeneous customer populations as a two-stage non-cooperative game. Firms can practice mixed bundling. In the first stage, firms choose their product offering combinations. In the second, they simultaneously choose prices for their offerings. We modeled this game as a price competition and show that in equilibrium, at most one firm bundles. We also study the quantity competition dual of this game.

3 - Surge Capacity: From Individual Hospitals to Communities
Yu Wang, Indiana University Bloomington, 1309 E Tenth Street, Bloomington, IN, 47405, United States, yw39@indiana.edu, Kurt M.Bretthauer, Alex Mills

We study how hospitals and communities create surge capacity to respond to sudden increases in demand, such as mass-casualty incidents. We discuss our earlier work, where we modeled the effectiveness of response and mitigation strategies for individual hospitals. Now, we consider how decisions of individual hospitals contribute to community capacity when their joint effort is required to address an incident.

4 - Routing Heterogeneous Jobs to Heterogeneous Servers: A Global Optimization-based Approach
Vahid Nourbakhsh, University of California-Irvine, The Paul Merage School of Business, Irvine, CA, 92617, United States, vahidn@uci.edu, John G.Turner

We study the problem of routing heterogeneous jobs to heterogeneous servers, where the service rate is job-server dependent. We employ a math programming approach which is desirable since it can easily be embedded within larger planning problems. For nonconcave objective function of maximizing the service level, i.e., the probability that a job is served within an acceptable waiting time, we develop an optimization algorithm called fixed-ratio shifting envelopes to find near-optimal solutions to our math program, and design online routing policies, which make use of these solutions. To showcase our model, we apply our model and method to the problem of assigning Irvine districts to fire stations.

1 - Metrics to Characterize Temporal Patterns in Lifespans of Artifacts
Soumyo D. Moitra, Senior Member of Technical Staff, Software Engineering Institute, 5000 Forbes Avenue, Pittsburgh, PA, 15213, United States, smoitra@sei.cmu.edu

This paper discusses some metrics that are useful to model the lifespans of artifacts observed over time that do not follow a traditional lifecycle. Some examples these stochastic point processes are presented and some metrics are developed that help to characterize their patterns and allow the lifespans to be clustered. Results from simulated data are presented and the paper discusses how the metrics can be applied and interpreted.

2 - The Application of Machine Learning in Management Science – Compared with China and the International
Xuan Wei, PHD Student, Harbin Engineering University, Harbin, 150001, China, weixuangood@qq.com, Wei Chen

Based on bibliometrics theory and the data from the database of Web of Science, the Chinese Social Sciences Citation Index and the Chinese Science Citation Database, this paper draws maps include the map of co-occurring keywords, co-cited authors and co-cited references from 1998 to 2015 by the use of a visual analysis tool——Cite Space. From this, research hot points, knowledge foundation and evolution of the theory of machine learning in management science in both China and other countries or areas are analyzed and contrasted.Acknowledgment: This paper is funded by the International Exchange Program of Harbin Engineering University for Innovation-oriented Talents Cultivation.

3 - Relatedness in Diversification and Performance of Public Firms
Muhammad Zubair, Beaconhouse National University, Lahore, Pakistan, zubair.m@outlook.com

This study empirically examines the link between relatedness in the diversification of a firm and its inventory performance. The study is based on firms' annual financial and segment sales data in addition to US industry input-output data.

4 - Multiple Methods Analyses of the Relationship Between the Quality Management Practices and Operation Performance
Heng Xie, University of North Texas, 1307 West Highland Street, Denton, TX, 76201, United States, Heng.Xie@unt.edu, Xianghui (Richard) Peng, Victor R. Prybutok

This study employs latent semantic analysis and meta-analysis to investigate the impact of the quality management (QM) on an organization's operation performance. The correlation and gaps between QM practices and industry performance are examined. Multiple methods of data analyses are used to analyzed the results from empirical based Baldridge Award studies.

5 - Super Size Me? the Effect of Franchise Size and Geographic Location on Compliance with Corporate Brand-building Initiatives
Benjamin Lawrence, Cornell University, 565B Statler Hall, Ithaca, NY, 14853, United States, benlawrence@cornell.edu, Brett Massimino

We examine the effects of a retail outlet's governance structure and distance from headquarters on compliance with corporate-driven initiatives. We obtain proprietary data from a large, national restaurant chain - capturing performance for ~1,000 outlets over a 3-year period - and supplement these with data with several other secondary sources. We address potential endogeneity by incorporating several instrumental variables into our analyses. Surprisingly, we find compliance tends to increase with an outlet's distance from headquarters. We further find an interaction with franchise size, indicating contextual dependencies novel to extant literature on distributed operations.

Electric Vehicle Charging Problems and Freight Transportation

Sponsored: TSL, Urban Transportation

Sponsored Session

Chair: Trilce Encarnacion, Rensselaer Polytechnic Institute, 110 8th Street, Jonsson Engineering Center # 4049, Troy, NY, 12180, United States, encart@rpi.edu

1 - Integrated Modelling of Dynamic and Static Charging Facilities for Electric Vehicles
Xiaotong Sun, University of Michigan, Ann Arbor, MI, 48109, United States, xtsun@umich.edu

This paper investigates the optimal deployment of both charging stations and charging lanes considering the interaction between transportation and power networks. A network equilibrium model is firstly developed to capture the interdependency among route choice, recharging plan of electric vehicles and price of electricity. A mixed-integer bi-level program is then formulated to deploy charging facilities to minimize the social cost in the coupled networks. Several state-of-art solution algorithms are applied to solve this model, and their performances are compared in different numerical experiments.

2 - Robust Planning of Dynamic Wireless Charging Infrastructure for Battery Electric Buses
Ziqi Song, Utah State University, 4110 Old Main Hill, Logan, UT, 84322-4110, United States, ziqi.song@usu.edu, Zhaocai Liu, Ye Song

Battery electric buses with zero tailpipe emissions have great potential in improving environmental sustainability and livability of urban areas. However, the problems of high cost and limited range associated with on-board batteries have substantially limited the popularity of battery electric buses. The technology of dynamic wireless power transfer (DWPT), which provides bus operators with the ability to charge buses while in motion, can effectively alleviate the drawbacks of electric buses. In this paper, we address the problem of simultaneously selecting the optimal location of the DWPT facilities and designing the optimal battery sizes of electric buses for a DWPT electric bus system.

3 - Impact of Congestion Pricing Schemes on Routing Costs and Emissions
Shu Zhang, Chongqing University, Chongqing, China, zhangshu@cqu.edu.cn, Ann Melissa Campbell, Jan Fabian Ehmke

Many city governments have introduced toll charges to discourage vehicles from entering the inner city to reduce congestion. However, little research has been done to examine the impact of congestion charges on commercial fleets, especially on resulting costs and emissions. In this study, we consider a vehicle routing problem considering different pricing schemes for several city types. We find that higher congestion charges may not necessarily lead to less emissions, and some congestion pricing schemes may even increase the emissions in the city center.

4 - Impacts of Congestion on Supply Chains
Trilce Encarnacion, Rensselaer Polytechnic Institute, 110 8th Street, Jonsson Engineering Center # 4049, Troy, NY, 12180, United States, encart@rpi.edu, Jose Holguin-Veras,

Congestion in urban areas heavily impact supply chains, we present a methodology to assess the economic impacts of congestion on logistic costs and estimate the direct environmental impacts of urban freight activity. In designing the methodology, the following objectives guided the process: (1) Applicability; (2) Comparability; (3) Practicality; and (4) Robustness. In order to test the principles developed, pre-pilot studies were conducted in three Latin American Cities: Barranquilla, Colombia; Santiago, Chile and Sao Paulo, Brazil. Results from these pilot tests will also be discussed

5 - Last-Mile Distribution and Horizontal Cooperation in Urban Logistics

Javier Faulin, Public University of Navarre, Pamplona, Spain, javier.faulin@unavarra.es, Adrian Serrano-Hernandez, Christian Fikar, Patrick Hirsch, Alejandro Garcia del Valle

This talk introduces the topics of Last-Mile Distribution and Horizontal Cooperation in an integrated way showing the key role of Horizontal Cooperation as a new strategy for goods distribution optimization in urban logistics. This approximation is particularly interesting knowing the importance of smart distribution as a new paradigm of e-commerce. We have used an agent-based simulation to measure savings in lead times in an assorted group of Horizontal Cooperation agreements among some distribution companies. Moreover, the impact of store-wholesaler structure is investigated to improve the final urban delivery. Finally, we have provided some computational results to enhance the role of Horizontal Cooperation in urban distribution

1 - Coalition with out Trust: the Intra-brain Connectivity and Inter-brain Synchronization of Herd Behaviors in an Economic Bubble Game

Jonathan Tong, Phd. program Student, National Taiwan University, 7F., No. 28, Ln. 325, Zhungjing Rd.,, Taipei, 110, Taiwan, d03323003@ntu.edu.tw

Economic bubbles form and burst because of human beings' higher-order reasoning, believing in earning pure capital gains due to other people's similar beliefs. We design a two-person investment game that simulates the natural situation of the form and the burst of economic bubbles. Using hyper-scanning fMRI to look into the correlation and the interaction of subjects' brain activities, we are able to gain insights about the coupling phenomenon of the two minds in the context of strategic interaction.

2 - Phases of Physical 3D Networks

Soodabeh Milanlouei, Northeastern University, Boston, MA, 02130, United States, milanlouei.s@husky.neu.edu, Nima Dehmamy, Albert-Laszlo Barabasi

In many real networks, from neural cells forming a brain to bundles of cables, the nodes and links have physical reality, unable to cross each other. Therefore, their physical layouts are jointly determined by these non-crossing conditions and their tight-packed nature, limiting how they can evolve. By ignoring the physical reality and dimensions of the links and nodes, current network layout algorithms are inherently unable to capture the properties of such real networks. Hence, we develop and study a series of 3D layout models that observe the physical constraints we encounter, allowing us to systematically explore how these limitations affect the network layout.

3 - From Mind Reading to Mind Sharing: A Study on Neural Correlates of Cognitive and Affective Tom and their Applications to Salesforce Enhancement

Jonathan Tong, PhD Program Student, National Taiwan University, 7F., No. 28, Ln.325, Zhungjing Rd.,, Taipei, 110, Taiwan, d03323003@ntu.edu.tw

Adopting the approaches of neuromarketing and social cognitive neuroscience, our purpose is to study the neural dynamics of sales' mind reading capabilities via a Chinese Drinking Game experiment with hyper-scanning of fMRI and how mind reading predicts their real performance.

4- Determinants of Alcohol Consumption Among College Students

Lu Xu, Ph.D candidate, University of North Texas, 1155 Union Circle #305249, Denton, TX, 76203-5017, United States, lu.xu@unt.edu, Gayle Prybutok, Victor R.Prybutok, Alexandra Ruuska

This research examines factors influencing the amount of alcohol consumed by college students. Predictor variables include demographics, academic factors, social factors, and alcohol-related factors. Data from 431 college students was collected using a Qualtrics survey that incorporates the Student Alcohol questionnaire. Linear regression was employed to analyze the data. The findings emphasize when effective intervention is needed.

5 - Budget Constraint Newsvendor Model in Reverse Supply Chain with Customer Driven Substitution

Jie Zhang, Virginia Institute of Technology, 820 Newport Terrace, Blacksburg, VA, 24060, United States, jiezhang@vt.edu, Subhash C.Sarin

In our model, there exist uncertain demand of new product and remanufactured product. Customers can choose the other product if their first choice product is out of stock. The quantity of remanufactured products is limited by the quantity of the collected cores. The budget consists of collection cost, and production cost for each products. We determine the optimal quantity of each products and analyze the effect of the substitution rate.

1 - Evaluating System Quality in Healthcare Industry by using Hybrid MCDM Methods

Maryam Soltanpour Gharibdosuti, Binghamton University, 62 Floral Ave, Apt 8, Binghamton, NY, 13905, United States, msoltan1@binghamton.edu

With the birth of electronic commerce, monitoring and enhancing the electronic service quality (e-sq.), hospitals use it as an appropriate media to facilitate information exchange between patients and providers, to improve their offered services This paper presents a quality evaluation model for measuring the performance of hospitals' web sites. The model is developed on the basis of a conceptual framework, which consists of three major e-service quality dimensions, including reliability, responsiveness and quality of information, which are main issues of Web sites. A hybrid multi criteria decision-making methods are used in the evaluation procedure.

2 - Cultivation of Soft Skills in the Construction Industry

Mahdi Safa, Assistant Professor, Lamar University, 5350 Old Dowlen Rd, Apt. 127, Beaumont, TX, 77706, United States, msmahdisafa@gmail.com, Kelly Weeks, Jeff Dyson, Shiblee Shakik Ahmed

Success in the construction industry largely depends on an amalgamation of technical skills and soft skills. Construction companies striving to survive on limited budgets and tight profit margins are looking for ways to improve workforce productivity. A key consideration for the workforce productivity improvement is to identify key soft skill gaps that need to be prioritized for training and development of professionals. Hence, a questionnaire based survey has been conducted with 250 professionals from Texas. The results show that among various soft skills, communication, time management, and work ethics have been identified as the most fundamental and relevant skills required to excel.

3 - A Parametric Activity Based Cost Estimation Framework Utilizing Conceptual Process Modeling

Zahra Banakar, P.h.D Candidate, University of Texas at Arlington, 2211 Twin Elms Dr, Arlington, TX, 76012, United States, zahra.banakar@mavs.uta.edu, Brian L.Huff

In order to have the most accurate production costs estimation, accurate cost information in a useful form is needed. This paper presents a cost estimation framework that integrates both activity and parametric cost estimation methods to increase the ease, accuracy, and speed of producing cost estimates for a family of products or services. The paper will discuss how process description capture methods can be used to identify the activities that drive cost. Also, a costing model based on the conceptual system description method will provide a more generic costing tool.

1 - A Multi-attribute Simulator for Policy Evaluation in Humanitarian Fleet Management

Liyi Gu, University of Maryland, 7621 Mowatt Ln, College Park, MD, 20742, United States, lgu@rhsmith.umd.edu, Ilya O. Ryzhov, Mahyar Eftekhar

We develop a stochastic, dynamic multi-attribute simulation framework for fleet management in humanitarian development programs, which encompasses purchase, sale and vehicle assignment decisions. We empirically estimate demand (mission distances) and vehicle operational costs, and build a simulator to compare different policies. Preliminary results are discussed.

2 - Antecedents of Financial Recovery Effectiveness from Floods: A Structural Econometric Analysis of Flooding in Thailand

Niratcha Tungtisanont, Clemson University, 100 Sirrine Hall, Management Dept, Clemson, SC, 29634, United States, ntungti@g.clemson.edu, Aleda Roth, Bernardo F. Quiroga

Using a sample survey of approximately 34,000 households in Thailand with data pre-, during- and post-flood disaster in 2011. Taking a service operations lens, our study aims to identify where and how in the flood cycle can various stakeholders—individuals, communities and governments act to increase the likelihood of a successful service recovery. More specifically, this research asks the question of what type of strategic actions can policy makers take in order to better allocate precious resources in pre-, during-, and post-flood phases to improve the overall effectiveness of the recovery process?

3 - Volunteer Management in Charity Storehouses

Gloria Urrea, Universita della Svizzera Italiana, Lugano, Switzerland, gloria.urrea@usi.ch, Alfonso J. Pedraza-Martinez, Maria Besiou

We study volunteer management at a large faith-based organization that operates a steady aid delivery system. The whole supply chain operates exclusively with volunteers (from supply to delivery). We study the preparation of beneficiaries' orders by volunteers in the storehouse as a function of volunteer experience and warehouse congestion. Using empirical data, we build a simulation model to explore the drivers of on-time order fulfillment at the storehouse level.

4 - Proactive and Reactive Supply Management for Emergency Relief Period: Effects of Demand and Supply Uncertainties and Budget Limit

Mahyar Eftekhar, Arizona State University, BA 433, Main Campus, P.O. Box 874706, Tempe, AZ, 85287, United States, eftekhar@asu.edu, Jeannette Song, Scott Webster

To fulfill beneficiaries' demands, humanitarian organizations should design a cost-efficient and time-effective procurement policy. We consider and analyze two common supply management policies: pre-positioning and local-purchasing. Our analysis takes demand, supply, and budget uncertainties into account.

Chair: Tuhin Sengupta, Indian Institute of Management-Indore, Indore, India, f13tuhins@iimidr.ac.in

1 - Aligning Price Adjustment Protection with Return Policy

Moutaz J.Khouja, University of North Carolina-Charlotte, BISOM.Department, College of Business, Charlotte, NC, 28223, United States, mjkhouja@uncc.edu, Haya Ajjan, Xin Liu

Retailers provide a return policy because it reduces the risk customers might perceive in purchasing. Retailers also provide price adjustment protection policy under which the retailer promises to refund consumers the difference between the full price and the discount price, should the product's price drop within a specified duration of time after purchase. We identify the optimal duration of the two policies. We also examine their effect on optimal inventory and pricing decisions.

2 - Self Price Beating in a Market with Preference Interdependence and Uncertainty

Ting Luo, California State University Fullerton, 800 N State College Blvd, Fullerton, CA, 92831, United States, ting.luo@fullerton.edu, Lijia Shi, Upender Subramanian

Self price beating pricing strategy promises the early buyers that if the seller lowers the price in the later period, an ex post price refund that is more than the price difference will be refunded to them. We study self price beating as a pricing policy when there is market externality and uncertainty. We find this strategy blends advantages of both price commitment and no price commitment, and it produces the highest total profit as well.

3 - Designing Product Rollovers and Managing Style Obsolescence

Esma Koca, PhD Candidate, Imperial College Business School, PhD Students Postbox, Tanaka Building, Level 2, Imperial College Business School, London, SW2 7AZ, United Kingdom, e.koca13@imperial.ac.uk, Tommaso Valletti, Wolfram Wiesemann

When releasing a new version of a durable product, a firm should consider whether to convince its consumer base to upgrade while attracting new consumers. To this end, the firm designs a rollover strategy, which selects the price of the new product, as well as whether to continue the sales of the old product at a discount (dual rollover) or not (solo rollover). We argue that the effectiveness of a rollover crucially depends on the consumers' perception of the obsolescence of the old version, and that the firm can influence obsolescence by a prudent timing of the new product launch. We explore the impact of the timing decision in solo and dual rollovers in markets consisting of myopic and strategic consumers.

4 - Product Quality and Incentives in Handicraft Supply Chain

Tuhin Sengupta, Indian Institute of Management-Indore, Rau-Pithampur Road, Indore, 453331, India, f13tuhins@iimidr.ac.in

In this article, we study how retailers, taking into account customer preferences, design its product to meet its objectives. We study how preferences of different customer segments and the degree of customer knowledge about the handicraft products drive the quality and pricing decisions of a retailer. Furthermore, we examine the implications for a manufacturer in the cooperative setting against the profit maximizing private setting.

Chair: Ameera Ibrahim, Saint Mary's College of California, Moraga, CA, United States, ai7@stmarys-ca.edu

1 - Markdown Optimization using Randomized Decomposition Approach

Andrew Vakhutinsky, Consulting Member of Technical Staff, Oracle, 35 Network Dr., Burlington, MA, 01803, United States, andrew.vakhutinsky@oracle.com, Kresimir Mihic, Su-Ming Wu

Despite the fact that markdown optimization problem has been known for more than twenty years, it still presents certain challenges for the real-life instances due to non-linearity of the demand function and complex side constraints. We present a new approach to solving MDO called randomized decomposition (RD). RD solver randomly selects subsets of the decision variables and finds an optimal solution for the variables in each subset, keeping all other variables fixed. We describe the results of our computational experiments comparing different solution approaches including MILP-based formulations based on the linearization of the demand function.

2 - Multi-location Multi-product Substitution with Strategic Consumers

Chengfan Hou, Tsinghua University, Beijing, 100084, China, houcf16@mails.tsinghua.edu.cn, Tianhu Deng, Qiankai Qing, Jianghua Zhang, Simin Huang

In this paper, we explicitly model when does a customer prefer to purchase at another store an item that is out of stock at a given store, rather than substituting it with a different item at the same store. From the perspective of a retail chain owner, we found the following: First, under a constant service level, the effective demand rate is higher when a product's inventory is spread over more stores. Second, this relative increment increases with increase in cost of visiting a store and consumer valuation of the substitute product, but decreases with service level and consumer valuation of the primary product. Third, the results still hold when extended to an exogenous model.

3 - A Randomized Pricing Strategy with Price Guarantee

Jianghua Wu, Professor, Renmin University of China, 59 Zhongguancun Street, Beijing, 100872, China, jwu@ruc.edu.cn, Xian Wu, Yunjie Wang

This study proposes a randomized pricing strategy with posterior price guarantee for online retailers. We assume there are two segments of consumers with different valuations to the product. The price variation is set as a Markov process in which theprice randomly switches between high level and low level. Given the price guarantee, once the retailer offers promotion within the guarantee period, the retailer has to pay the price difference back to those who buy at regular price and claim the guarantee. This price strategy encourages consumers to buy instantly at the high price instead of waiting for the low price. we derive the optimal prices promotion probability, and length of guarantee period.

4 - Optimal Bundle-size Pricing

Ameera Ibrahim, Assistant Professor, Saint Mary's College of California, 1928 Saint Mary's Road, Moraga, CA, 94575, United States, ai7@stmarys-ca.edu

We analyze the bundle-size pricing problem in retail. Consumers can choose N goods, from a larger pool of J goods, for a fixed price that depends on the number of goods in the bundle. With the objective of maximizing the total profit, the retailer decides on the optimal assortment of bundles and their prices. We propose a mixed-integer nonlinear model that is then reformulated into a mixed-integer linear model and its computational tractability is demonstrated. Managerial insights are derived based on the computational results.

Project Management

Contributed Session

Chair: Yigal Gerchak, Tel Aviv University, Tel-Aviv, Israel, yigal@post.tau.ac.il

1 - Moral Hazard Problem and Incentive Contract in Engineering Procurement and Construction Project

Wanshan Zhu, Tsinghua University, Dept of Industrial Engineering, Shunde Building #613, Beijing, 100084, China, zhuws@tsinghua.edu.cn, Zhenzhen Chen, Pascale Crama, Xiaobo Zhao

In Engineering Procurement Construction (EPC) projects, the End User contracts with the main contractor on the overall quality of the project, while the main contractor subcontracts the project to several subcontractors. The subcontracting stage may incur moral hazard problem due to the unobservable efforts of the subcontractors. We study the optimal incentive contracts between the main contractor and several sub-contractors from the main contractor's perspective, aiming to motivate the sub-contractors to exert high efforts. As a result, the project can obtain a high overall quality, and the main contractor gains high profit.

2 - Research on Government Guarantees of Highway Public-private Partnerships Projects

Zhenyao Wu, Southwest Jiaotong University, China, NO.111 North of 2nd Ring Road, Chengdu, 610031, China, zhenyao2512@163.com, Bin Shuai, Peng Hu

In Public-private Partnerships (PPP) projects, government usually provides government guarantees to attract private sectors. This paper established model to value the government guarantees. The Monte Carlo simulation was adopted to simulate operating parameters in the model. Finally, the model was applied to a highway PPP project. The authors find that the impact of tariff on the net present value is greater than that of minimum traffic guarantee (MTG) in the project. In addition, the optimal option is a compound option of MTG and traffic cap. The research not only can help government develop reasonable guarantee policies but also can help private sectors to make better investment decisions.

3 - Moments and Distribution of the NPV of a Project

Stefan Creemers, IESEG School of Management, Rue de la Digue 3, Lille, 59000, France, sc@cromso.com Stefan Creemers, KU. Leuven, Naamsestraat 69, Leuven, 3000, Belgium, sc@cromso.com

We study the NPV of a project with multiple stages that are executed in sequence. A cash flow may be incurred at the start of each stage, and a payoff is obtained at the end of the project. The duration of a stage is a random variable with a general distribution function. For such projects, we obtain exact, closed-form expressions for the moments of the NPV, and develop a highly accurate closed-form approximation of the NPV distribution itself. Our work has direct applications in the fields of project selection, project portfolio management, and project valuation. In addition, our work is closely related to the work of CPM/PERT, however, whereas CPM/PERT deals with project completion time, we focus on NPV.

4 - A Multi-skill Approach to Property Maintenance Considering Spatial, Temporal and Resource Constraints

Anthony Vatterott, University of Missouri-Saint Louis, 6254 Walsh, Saint Louis, MO, 63109, United States, anthonygvatterott@gmail.com, Norman Womer, Haitao Li

This paper proposes the application of a novel mathematical model to aid in the scheduling and assignment of construction and maintenance tasks, considering the multi-skilled workforce. Data from a case firm was analyzed so that operational insights into the necessity of such a model could be considered. The optimization approach to multi-skilled resource allocation considers the temporal and spatial demands of a geographically dispersed property management portfolio. Generalization of this data allows a hierarchical framework of skill and task development that can be used to assign the best-capable worker to the most cost-efficient task, considering deadlines, priorities and availability.

5 - Comparison of Strategies of Assigning a Project to Agents where Activities Can Succeed or Fail

Yigal Gerchak, Professor, Tel Aviv University, Department of Industrial Engineering, Ramat-Aviv, Tel-Aviv, 69978, Israel, yigal@post.tau.ac.il, Christian Schmid

R&D projects consist of multiple activities which can fail, but all need to succeed for the project to succeed. Should each activity be assigned to a different agent, or all activities to one agent, where in the latter case several agents are working on the entire project in parallel, and it is sufficient if one of them succeeds? We consider the effect of advantageous specialization, of a deadline, and of heterogeneous activities.

Business Applications

Contributed Session

Chair: Dongdong Ge, Shanghai University of Finance and Economics, Shanghai, China, dongdong@gmail.com

1 - Fraud Detection in Sports Based on Quantitative Compliance

Leif Meier, Professor, HS.Bremerhaven, An der Karlstadt 8, Bremerhaven, 27568, Germany, lmeier@hs-bremerhaven.de

Compliance Management describes the management of regulations in business operations, driven by qualitative analysis in the past. A quantitative Compliance view is highly required to manage restrictions and obligations from regulations and to identify outliers in a massive number of transactions from automated and global business operations. Latest national and international business scandals and corruption in sports have led to a significant reputational and also financial damage, which could destroy industries. This work presents an OR approach for Fraud Detection in Sports from Quantitative Compliance with similar models used in Finance for Anti-Money-Laundering identification.

2 - Inventory Decision Support for a Glass Fabricator

Matthew D. Dean, Associate Professor of Business Administration, University of Southern Maine, School of Business, 113 Luther Bonney Hall, Portland, ME, 04104, United States, matthew.d.dean@gmail.com

We describe a project that is helping a local glass and metal fabricator improve its inventory replenishment system. Historically, it relied on a manual inventory system controlled by a single person with many years of experience. We developed a user-friendly web-based application with an embedded linear programming model that recommends purchasing decisions to the buyer.

3 - Key Performance Metrics for Successful Business Initiatives

Suchitra Veera, Strategy and Analytics Consultant, Snayu Inc, 4512 Dartmoore Lane, Colleyville, TX, 76034, United States, suchitra.veera@gmail.com

The objective of this session is to present the topic of the use of performance measurement and tracking metrics for successful business initiatives delivery. Various types of metrics used in measurement of project/program and initiative delivery success will be discussed including cost, schedule and scope related metrics such as earned value, CPI, SPI along with those that are used in agile and lean projects.

4 - Extending the Role of Information Technology Capability and Impact on Firm Performance using New Metrics and Industry Sector Analysis

Chuan Tian, University of Oklahoma, Norman, OK, United States, chuan.tian-1@ou.edu, Radhika Santhanam, Pascal Nitiema

The linkage between IT (Information Technology) capability and the firm performances remains to be an academic focus. Earlier studies revealed conflicting results. Drawing on Resource Based View (RBV) and incorporating the new features of IT application, this paper empirically investigates the impact of IT capability on firms' performances based on data from 2008 to 2012. Further, the study finds that firms with advanced IT capability are less volatile compared with companies without. Last, the study validates the positive moderating effect of ICT intensity on the pair of relationship. The result of this study is an important enrichment and extension of the original theoretical framework.

5 - Regularized Estimation for High-dimensional Multi-block Vector Autoregressive Models and its Applications

George Michailidis, University of Florida, UF Informatics Institute, 432 Newell Drive, Gainesville, FL, 32611-8545, United States, gmichail@ufl.edu

Dynamical systems comprising of multiple components originate in many scientific areas. A pertinent example examines interactions between equity markets and the potential for contagion during crisis periods. We consider a multi-block system with Granger-causal ordering between blocks, wherein the blocks temporal dynamics are described by vector autoregressive processes and are influenced by blocks higher in the system hierarchy. We briefly discuss estimation and inference issues in a high-dimensional setting. We illustrate the model by examining log-returns of the S&P 100 and the Euro Stoxx 50 components stocks for the 2002-2016, to understand linkages between the two equity markets.

6 - Challenges and Opportunities for Operations Research in China in the A.I. Era

Dongdong Ge, Professor, Shanghai University of Finance and Economics, School of Information management and eng, 777 Guoding Road, Shanghai, 200433, China, dongdong@gmail.com

This talk shares the speaker's experience, confusion and efforts to answer the recent challenges in teaching and research arising from OR/OM fields due to the coming A.I. era. We try to explain from our observation what happened and what is happening in real industry in China, what are business trends and research opportunities we shall pay attention to, how we shall position OR/OM in a competition with CS, Statistics and other subjects.

Psychology of Queueing G++—^{a}—-+ and Hand Hygiene

Sponsored: Behavioral Operations Management

Sponsored Session

Chair: Kenneth Schultz, Air Force Institute of Technology, Air Force Institute of Technology, WPAFB, OH, 45433, United States, kschultz@afit.edu

1 - Beyond Fixed Effects: A Psychological Perspective on Servers' Operational Performance in Service Queuing Systems

Ahmad M. Ashkanani, Kuwait University, Shuwaikh, Kuwait, aashk965@gmail.com, Benjamin B.Dunford

Previous research in service queuing literature has treated servers' psychological factors as fixed effects, which limits our understanding of the behavioral drivers of servers' operational performance. Using longitudinal data from servers in a call center with pooled queuing system and limited financial incentives, we find that these factors are more important than currently understood. We find servers reduce their service rate as workload increases, suggesting a social-loafing behavior. However, intrinsically motivated servers were more resilient to workload effects. Finally, we find no evidence for a relationship between extrinsic motivation and servers' productivity in our setting.

2 - Managing Hand-hygiene as a Prospective Memory Task

Reidar Hagtvedt, PhD, University of Alberta School of Busines, 3-23 Business Building, Edmonton, AB, AB T6G 2R6, Canada, hagtvedt@ualberta.ca, Kenneth Schultz, Trish Reay, Sarah Forgie

Hand-hygiene is governed by Standard Operating Procedures in health-care settings, but is notable for low adherence. We use prospective memory to provide a theoretical framework for the use of cues, time, and disruptions to prompt hand-hygiene. Using data from a hospital, we use survival analysis to test our hypotheses, and find e.g. that accumulated cues impact adherence.

3 - An Empirical Study of Customer Patience and Abandonment in Online Wait for Customer Service: the Role of Delay Announcements and Customer Meandering

Galit Yom-Tov, Technion - Israel Inst of Technology, Haifa, Israel, gality@technion.ac.il, Anat Rafaeli, Monika Westphal

We study the impact of delay announcements, and shifting focus to another web location (meandering) on customer patience and abandonment during online wait. 3 experimental studies (n=3329) show that announcing a delay decreases the likelihood to abandon, and that 20% of the customers balk regardless of the delay announced. Also, customers anchor on the delay content, and this affects their likelihood to abandon. Lastly, customer meandering decreases the likelihood to abandon. Our findings carry important implications for the study of queue wait and the management of service operations.

4 - Load Effects on Service Times

Kenneth Schultz, Air Force Institute of Technology, Department of Operational Sciences, 2950 Hobson Way, WPAFB, OH, 45433, United States, kschultz@afit.edu, Mohammad Delasay, Armann Ingolfsson, Bora Kolfal

We develop a general framework to analyze the influence of system load on service times in queueing systems. Our framework unifies previous results and ties them to possible future studies to help empirical and analytical researchers to investigate and model the ways in which load impacts service times.

Behavioral Operations

Contributed Session

Chair: Mohammad S. Jalali, Massachusetts Institute of Technology, Cambridge, MA, United States, jalali@mit.edu

1 - The Price of Privacy: Experimental Evidence for the Value of Privacy

Rachel Cummings, California Institute of Technology, 1200 E California Boulevard, MC 305-16, Pasadena, CA, 91125, United States, racheladcummings@gmail.com
Rachel Cummings, Georgia Institute of Technology, Atlanta, GA, United States, racheladcummings@gmail.com, Katrina A. Ligett, Ori Heffetz

We measure people's willingness to pay for privacy, through a series of multi-player behavioral experiments where we vary the information that players see about the actions of others. In each session, many pairs of participants play a Dictator Game in the same room. After all decisions are made, we reveal a noisy signal about the Dictator's contribution to their partner that is correct with some (pre-determined) probability, and a random contribution otherwise. By varying the information sharing policy, we can measure how people trade off money for privacy. We show that people's value for privacy does not match the monotone, linear model that is typically assumed in theory.

2 - Considering Human Decision Making in Revenue Management Given Diverse Decision Tasks

Claudia Schuetze, RWTH Aachen University, Kackertstrasse 7, Aachen, 52072, Germany, claudia.schuetze@rwth-aachen.de, Catherine Cleophas

Revenue management is a crucial success factor for many service industries. To complement automated revenue management systems, firms employ revenue analysts. Therefore, we investigate human decision making to draw conclusions for the design of decision support systems. Analysts are tasked to balance multiple objectives. As automated revenue management systems rarely consider multiple criterias, we analyse how well analysts are able to do this. Furthermore, analysts influence system parameters rather than accepting individual customer requests. We test this type of analysts' task, given aspects of anchoring and algorithm trust.

3 - The Combination and Estimation Uncertainty in the Determination of Airlines Personalizing Recommendations

Mengxi Chen, Shanghai Jiao Tong University, Huashan Road No.1954, Shanghai, 200030, China, mengxi1002@126.com

Strategy of consumer choice are now of increasing significance in both academia and practice for the aviation market. We hope to find out some kind of relationship between variables to gain insight about passengers' choices in situations where data are sufficiently available in order to fix best personalized contents to each individual passenger. We use data mining for predicting air passengers' choice, than, an application to the real case of China Airline. We conclude passengers' dynamic decision making processes provide aviation industry better understanding of the passengers' choices and develop effective strategies to maintain customer relationship.

4 - A Dynamic Simulation Game for Cybersecurity Capability Development

Mohammad S. Jalali, Research Faculty, Massachusetts Institute of Technology, 77 Massachusetts Avenue, Cambridge, MA, 02139, United States, jalali@mit.edu, Zhen Fang

Despite the rise of frequency and intensity of cyber attacks, many organizations are still negligent in the management of their cybersecurity practices. As a response to this failing, we developed a simulation game intended to help managers make investment decisions for building cybersecurity capabilities. Experienced professionals in cybersecurity from different industries and non-experienced students participated in the simulation game. We compared their performances and observed several types of behaviors in the results of the simulation runs.

Autonomous Systems Optimization I

Invited: TSL, Urban Transportation

Invited Session

Chair: Alireza Talebpour, Northwestern University, 600 Foster Street, Transportation Center 3rd Floor, Evanston, IL, 60208, United States, atalebpour@civil.tamu.edu

1 - Platooning in the Presence of a Speed Drop: A Generalized Control Model

Sina Arefizadeh, Graduate Student, Texas A&M.University, College Station, TX, 77843, United States, sinaarefizadeh@tamu.edu, Alireza Talebpour, Igor Zelenko

Designing an autonomous vehicle platooning strategy for tracking a reference velocity profile can improve travel time reliability. Accordingly, this study introduces a generalized control model to track a desired velocity profile, while ensuring safety in the platoons of autonomous vehicles. Defining appropriate error terms, we changed the tracking velocity profile problem into a stability problem. Considering the error term in tracking the velocity profile coupled with error term associated with keeping safe distance from the leader, the proposed method controls the maximum of the two error terms for each vehicle. We showed that the error terms remain bounded throughout the time and space. Two scenarios were simulated, with and without initial perturbations, and results confirmed the effectiveness of the proposed control model in tracking the speed drop, while ensuring safety and string stability.

2 - Design and Operations of Autonomous Vehicle Car-Sharing Systems (AVCS)

Zhiheng Xu, Ph.D, University at Buffalo, Buffalo, NY, 14228, United States, zhihengx@buffalo.edu

We present a time-space optimization model for design and operations of future Autonomous Vehicle Car-Sharing Systems (AVCS). In addition to design and operations decisions, the proposed model explicitly considers empty vehicle relocation and demand shift between AVCS and privately owned autonomous vehicles.

3 - Microscopic Traffic Modeling of Collisions with the Incorporation of Connected and Autonomous Vehicles

Claire E. Silverstein, George Washington University, Washington, DC, United States, csilvs@email.gwu.edu, Samer H.Hamdar

Interactions between individual drivers and error in the decision-making process have been recognized as major sources of unsafe and unstable traffic conditions. Two main avenues that reduce/remove human error from the driving experience are being pursued. Autonomous vehicles utilize sensing technology to take over the driving task, while connected vehicles incorporate vehicle-to-vehicle and vehicle-to-infrastructure communication to obtain and share information, allowing the driver/vehicle to make improved driving choices. This research tests the traffic safety of different market penetration rates (MPRs) of connected and autonomous vehicles on the microscopic level with collision formation. This leads to the optimization of MPRs of the various vehicle types based on safety. The inclusion of lateral trajectory during the lane-changing process allows for more robustness when analyzing vehicular movements and angled collisions.

4 - Collaborative Platooning of Automated Vehicles using Variable Time-Gaps

Aria HasanzadeZonuzy, Texas A&M.University, College Station, TX, United States, azonuzy@tamu.edu, Srinivas Shakkottai, Alireza Talebpour, Sina Arefizadeh, Swaroop Darbha

Connected automated vehicles could be coordinated to safely attain the maximum traffic flow, such as those engendered by the merger of two strings of vehicles. Strings of vehicles have to be shaped correctly in terms of the inter-vehicular time-gap and velocity to ensure that such operation is feasible. However, controllers that can achieve such traffic shaping over the multiple dimensions of target time-gap and velocity over a region of space are unknown. The objective of this work is to design such a controller, and to show that we can design candidate time-gap and velocity profiles such that it can stabilize the string of vehicles in attaining the target profiles. Our analysis is based on studying the system in the spatial rather than the time domain, which enables us to study stability as in terms of minimizing errors from the target profile and across vehicles as a function of location.

Disruption Management

Contributed Session

Chair: Churlzu Lim, UNC-Charlotte, Charlotte, NC, United States, clim2@uncc.edu

1 - A Bi-objective Optimization Model for System Resilience

Daniel Hernando Romero, University of South Florida, Tampa, FL, 33613, United States, danielromero@mail.usf.edu, Aritra Pal, Alex Savachkin

Most system resilience optimization models have a single objective based on a specific resilience metric. There is a need to expand such approaches to offer solutions based on different metrics or dimensions of resilience. We offer a bi-objective model to analyze two main dimensions of system resilience, the absorptive and restorative capacities. The model provides a Pareto front of non-dominated solutions enabling a decision maker to select suitable hardening and recovery strategies.

2 - Vulnerability Analysis of Critical Infrastructures under Disruptions using Monte Carlo Method

Chao Fang, Associate Professor, Wuhan University, Economics and Management School, Wuhan, 430072, China, chao.fang@whu.edu.cn

Reliable and safe critical infrastructures are essential for the sustainable development of modern societies. Considerable attention has been paid to analyzing and mitigating the vulnerability of critical infrastructures, especially against the increasing occurrence of disruptive events such as man-made or natural disasters. In this paper, we use Monte Carlo method to simulate the disruptions attacking the modelled infrastructure network. The innovation is that new metrics based on flow information are proposed in order to predict the propagation of consequences. The application to China High-Speed Rail illustrate the approach with respect to enhancing the system's reliability.

3 - Facility Protection Model for the Supply of Emergency and Perishable Products

Girish Chandra Dey, IIT.Kharagpur, Qtr No. EM/G-18, IIT.Khargpur Campus, IIT.Khargpur Campus, Kharagpur, 721302, India, deygirish@gmail.com, Mamata Jenamani

We present facility protection model considering the importance of maximum distance limits for the supply of emergency products like medical supplies or perishable products during the disruptions. We formulate it as a tri-level mixed integer problem, which considers capacitated facilities, interdiction, and fortification budget limits simultaneously. Then we reformulate it to a bi-level problem and solve it by implicit enumeration (IE) algorithm performed on a binary tree. We report computational results obtained from 64 randomly generated test instances.

4 - Applying Stackelberg-game Model under Credit Guarantee Mechanism with Information Asymmetry

Cheng-Feng Wu, Hubei University of Economics, No.8 Yang Qiaohu Road, Jiangxia, Wuhan, 430205, China, wuchengfeng@hbue.edu.cn

The strait of capital shortage in small and medium enterprises(SMEs) causes them difficult to fulfill orders. Furthermore, a buyer is concerned about supplier disruption when placing an order with his SME supplier. Therefore, obtaining and operating financial support for SMEs is a significant issue. The supplier thoughtfully allocates its borrowed money to production and technology after buyer promises the financial institution a commitment in credit guarantee. This study tries to develop the model to examine the issue of sourcing model under Stackelberg-game with credit guarantee scheme.

5 - Minimization of Restoration Time for Disrupted Power Distribution Network

Churlzu Lim, Associate Professor, UNC-Charlotte, 9201 University City Boulevard, Charlotte, NC, 28223-0001, United States, clim2@uncc.edu, Bhavish G. Golla, Badrul Chowdhury, Andrew N.Kling

This study considers scheduling repair crews to restore power distribution systems that are affected by a high impact low frequency event. Given a set of information pieces including locations of faults, estimated repair times for faults, available resources, and estimated travel times between fault locations, the goal is to assign repair jobs to each repair crew team in a specific sequence that minimizes the system restoration time. Two alternative mixed integer programming formulations as well as a heuristic method are presented and numerically compared in solution qualities and efforts.

1 - Firm's Multi Periodic Decision Making about Carbon Emission Reduction under Cap & Trade

Yuan Baiyun, Henan Polytechnic University, 2001 Century Avenue, jiaozuo, China, yuanbaiyun@hpu.edu.cn

Under the government's Cap and Trade pilot policy, multi-period dynamic optimization about carbon emissions reduction of enterprises is discussed. Considering the policy that government limits the total amount of enterprise's carbon emissions and allows that the carbon emissions quota can be traded among enterprises in multi-period, we study enterprise's optimal carbon emission reduction strategy to maximize the sum of discounting profit per year by optimal control theory, and analyze how some parameters affect enterprise's optimal carbon emission reduction strategy of each period, such as the trading prices of carbon emissions quota and initial carbon emission quotas.

2 - Automation's Effect on Green Production: Does it Translate to Improved Competitiveness?

Kelly Weeks, Assistant Professor, Lamar University, 4400 MLK Blvd., Beaumont, TX, 77110, United States, kweeks1@lamar.edu, Mahdi Safa

This research builds upon and, as recommended, expands the work of Rao and Holt (2005). This paper will provide a longitudinal study of the impact of automation in a manufacturing setting. We will then try to determine automations impact, perhaps even inadvertently, on green production, the overall supply chain and ultimately upon competitiveness. This study provides multiple international samples, which few predecessors, if any, have done.

3 - Parallel Surrogate Multi Objective Optimization of Computationally Expensive Problems with Environmental Applications

Christine A. Shoemaker, Distinguished Professor, National University of Singapore, office E1A 06-12, Singapore, 14853, Singapore, ceesca@nus.edu.sg, Taimoor Akhtar

A "Multi-Objective Population-based Parallel Local Surrogate-Assisted" candidate search algorithm (MOPLS) is proposed for efficient and parallel multi-objective optimization of computationally expensive simulation optimization problems. Application to test problems and a 15-dimensional watershed model, and comparison against GOMORS, ParEGO and AMALGAM, shows that MOPLS is more efficient within a limited evaluation budget, especially when parallel speed-up is considered.

Simulation

Contributed Session

Chair: Di Wu, Georgia Institute of Technology, Atlanta, GA, United States, dwu80@gatech.edu

1 - Computation Methods for Simulation Optimization using Gaussian Markov Random Fields

Eunhye Song, The Pennsylvania State University, 310 Leonhard Building, The Pennsylvania State University, Room C210, University Park, PA, 16802-4400, United States, eunhyesong2016@u.northwestern.edu, Mark Semelhago, Barry L. Nelson, Andreas Waechter

At the core of Gaussian Process (GP) regression-based simulation optimization algorithms is a GP representing knowledge about the objective function whose conditional distribution is updated as more of the feasible region is explored. Computing the conditional distribution requires inverting a large, dense covariance matrix whose size grows as more solutions are sampled. When a GP is a Gaussian Markov Random Field, then it is particularly suited for a problem with discrete solutions since updating its conditional distribution involves a very sparse precision matrix. In this talk, we discuss how to exploit this sparse-matrix structure to reduce the computation overhead even further.

2 - A Simulation Optimization for Two Stage Decision Making

Wei Xie, Assistant Professor, Rensselaer Polytechnic Institute, 110 8th Street, CII, Room 5207, Troy, NY, 12180, United States, xiew3@rpi.edu, Yuan Yi

To support the dynamic decision making, we study discrete two-stage optimization with the unknown objective estimated by simulation. We introduce a global-local metamodel-assisted approach that can efficiently use the simulation resource to solve for the first- and second-stage decisions. The local metamodel allows us to solve a set of deterministic recourse problems sharing the same first stage action. Then, the global metamodel accounting for the errors introduced in the second-stage optimization can efficiently search for the optimal first-stage decision. Our algorithm is global convergent, and numerical study indicates it achieves substantial efficiency and accuracy.

3 - A Simulation Calibration Framework for the Production Control

Wei Xie, Assistant Professor, Rensselaer Polytechnic Institute, 110 8th Street, CII, Room 5207, Troy, NY, 12180, United States, xiew3@rpi.edu

A simplified stochastic simulation model can be used to guide real-time decision making for a complex real system. To support a reliable guidance, we propose a simulation calibration framework for the production control. The calibrated simulation system is able to capture the dynamic behaviors in the historical output data and predict the future outputs for the real system. The proposed framework delivers credible intervals for calibration parameters and also a prediction interval for the future output. Empirical studies demonstrate efficacy of our approach.

4 - Optimal Robust and Tolerance Design for Computer Experiments with Mixture Proportion Inputs

Mei Han, City Unversity of Hong Kong, Hong Kong, meihan2-c@my.cityu.edu.hk, Matthias Hwai Yong Tan

Computer experiments often have inputs that are proportions of components in a mixture. In these mixture computer experiments, it can be of interest to perform robust and tolerance design on the mixture proportions. Traditionally, manufacturing of mixture products is controlled via interval tolerances for mixture amounts. In this paper, an optimal tolerance region for proportions, which gives optimal quality cost among all possible tolerance regions for mixture proportions with the same acceptance probability, is proposed for integrated parameter and tolerance design in mixture computer experiments. Real examples are given to demonstrate the advantages of the optimal tolerance region.

5 - An Efficient Power Network Damage Assessment via UAVs under Uncertain Environments

Hoyoung Na, PhD Candidate, University of Arizona, Tucson, AZ, 85721, United States, nhy4201@email.arizona.edu, Jaeyoung Cho, Young-Jun Son

This study proposes a novel meta-algorithm for efficient power network damage assessment using unmanned aerial vehicles (UAVs) in the events of power failures. A genetic programming-based hyper-heuristic (GPHH) as an offline path planner is developed to generate the paths of UAVs, which are expected to minimize the total operating cost and the damage assessment completion time under uncertain environments (e.g., wind speed and direction, remaining battery times). The effectiveness of the proposed algorithm is demonstrated for a power network system in Roanoke, VA, USA which is represented by physics-based real time simulation model in Unity3D.

6 - Fixed Budget Ranking and Selection under Input Uncertainty

Di Wu, Georgia Institute of Technology, 755 Ferst Drive, NW, Atlanta, GA, 30318, United States, dwu80@gatech.edu, Enlu Zhou

Ranking and selection has been studied mostly under the assumption of accurate input model. When there is input uncertainty, a direct application of traditional algorithms may result in poor probability of correct selection. We consider a new problem where a finite budget is available for collecting input data as well as running simulation. Four algorithms are developed to select the best system for single-stage and multistage scenarios. We also investigate the large deviations property in a fixed allocation asymptotic regime, and reveal that the probability of false selection still enjoys exponential decay even in the presence of input uncertainty.

1 - Approximate Random Allocation Mechanisms

Mohammad Akbarpour, Assistant Professor, Stanford University, Stanford, CA, United States, mohamwad@stanford.edu, Afshin Nikzad

We extend the scope of random allocation mechanisms, where the mechanism first identifies a feasible "expected allocation" and then implements it by randomizing over nearby feasible integer allocations. Previous literature had shown that the cases in which this is possible are sharply limited. By introducing a new rounding algorithm, we show that if some of the feasibility constraints can be treated as goals rather than hard constraints then, subject to weak conditions that we identify, any expected allocation that satisfies all the constraints and goals can be implemented by randomizing among nearby integer allocations that satisfy all the hard constraints exactly and the goals approximately.

2 - A Complete Asset Market Approach to the Determination of Equilibria for Incomplete Asset Markets

Chuangyin Dang, City University of Hong Kong, Dept of Systems Eng & Eng Mgmt, 83 Tat Chee Avenue, Kowloon, Hong Kong, mecdang@cityu.edu.hk

In incomplete asset markets, there are an insufficient number of contingent claims instruments to provide households with all potentially desirable credit arrangements. This insufficiency can cause discontinuity of the excess demand function at prices for which the asset return matrix loses its full rank. To overcome this discontinuity, we make use of the product of the asset return matrix and its transpose as a new asset return matrix. With the introduction of an extra variable and a convex combination of the new asset return matrix and an identity matrix, we establish an artificial complete asset market, which assures the existence of a smooth path to an economic equilibrium.

3 - E-commerce Platforms and International Trade: A Large-scale Field Experiment

Xiang Hui, MIT, Cambridge, MA, 02139, United States, xianghui@mit.edu

Information technology has enabled businesses of all sizes to sell globally. Exploiting a site-wide randomized experiment on eBay, I show that an e-commerce platform could further increase on-site international trade by 2.9% in the short run and 12.3% in the long run through integrating an existing service of handling customs clearance and international shipping. The increase comes from "disadvantaged" groups (small and medium sellers, distant countries, and less profitable products). Foreign consumers benefit from an 8.3% larger product variety. I discuss the role of "nudging" and reducing export entry costs for facilitating exports from small firms.

4 - Generalized Additive Model with Embedded Variable Selection for Bankruptcy Prediction

Laura María García, University De Los Andes, Bogota, Colombia, garcia.lm@uniandes.edu.co, Carlos Felipe Valencia Arboleda, Sergio Andrés Cabrales

In this study, we explore the trade-off between interpretability and predictive performance in the problem of bankruptcy prediction using finantial ratios. We propose a generalized additive model with an innovative embedded variable selection methodology that selects zero, linear or non-linear effects through penalization. Our experimental results demonstrate that the proposed model performs well in terms of predictive power and generalization, providing a good balance between flexibility and interpretability. The findings of this research show that non-linear methods are necessary to understand the behavior of the retail industry in Colombia.

5 - Cost-efficiency of Brazilian Water Distribution and Sewage Collection Services: Some Recent Evidence

Fernando Garcia Freitas, Advisor, National Confederation of Services, Saint Hilaire, 118 - 22, Sao Paulo, 01423040, Brazil, fernando.garcia.freitas@gmail.com

This paper discusses the determinants of production costs in residential water distribution and sewage collection in Brazil. We estimate two distinct stochastic cost frontier models Aigner, Lovell and Schmidt (1977) and Battese and Coelli (1995) for a sample of 23,329 observations from 2009 to 2014. A translog specification is adopted for both models. Cost depends on the relative price of inputs and the level of services provided. Estimations reveal statistically significant parameters for most of variables in the two distinct models and that inefficiency is heterogeneous among groups of firms. The main result obtained is that open capital firms are more efficient than closed capital ones.

Scheduling

Contributed Session

Chair: ZhenTao Hu, HUST, Wuhan, China, gentlehzt@163.com

1 - Multiple Objective Optimization for Bus Scheduling Problem in Vietnam

Ho Thanh Phong, International University, Ho Chi Minh City, Vietnam, KP6, Linh Trung, Thu Duc Dist., Ho Chi Minh City, Viet Nam, htphong@hcmiu.edu.vn, Nguyen Thanh Phong

The multi-objective transit network design and frequency setting problem (TNDFSP) involves finding a set of routes constituting a public transit network with three objectives, namely, minimizing user cost, minimizing operator cost and minimizing the congestion score. A Genetic Algorithm (GA) was applied to solve that multi-objective problem, resulting the selection of the "best compromise" solution among the non-dominated transit network solutions. The research was applied and expected to improve the bus service in Ho Chi Minh city, Vietnam.

2 - Scheduling Software Updates for Connected Cars with Limited Availability

Carlos E.De Andrade, AT&T Labs Research, 200 Laurel Avenue South, A5-1E33, Middletwon, NJ, 07748, United States, cea@research.att.com, Simon D.Byers, Vijay Gopalakrishnan, Emir Halepovic, David J. Poole, Lien Tran, Chris Volinsky

The number of connected cars has increased over the past years, and they became an important component of Internet-of-Things. Such vehicles use the cellular networks for several activities, and among them, the Firmware Over-The-Air updates could be potentially challenging to the network. With millions of connected cars expected to be deployed over the next years, it is important to understand their impact on cellular networks, as much as create schedules for such downloads. We present a new scheduling model that accommodates the constraints for such scenario, which usually does not appear in other scheduling problems in the literature, and comment the peculiarities of such solution.

3 - Reallocatable Multi-skilled Resource Constrained Project Scheduling Problem: Mathematical Modeling and Solution Approaches

ZhenTao Hu, HUST, Wuhan, China, gentlehzt@163.com

In this paper we propose an extension of the multi-skilled resource constrained project scheduling problem(MSRCPSP): the Reallocatable multi-skilled resource constrained project scheduling problem(RMSRCPSP). In the RMSRCPSP the resources in use are allowed to be replaced by other resources that master skills the processing activities need. To solve this problem, we apply a priority-based heuristic algorithm, which makes use of resource weight and extend the parallel scheme by introducing a resource shifting procedure. A series of computational tests including small scale and large scale instances shows that the heuristics algorithm is very effective.

Facility Location II

Sponsored: TSL, Facility Logistics

Sponsored Session

Chair: Tan C Miller, Rider University, 12 Winding Way, Morris Plains, NJ, 07950, United States, tanjean@verizon.net

1 - The Mean-var Median Problem on a Network with Probabilistic Demand Weights

Jiamin Wang, Professor, Long Island University, Post Campus, Roth Hall 202, 720 Northern Boulevard, Brookville, NY, 11548-1300, United States, jiamin.wang@liu.edu, Chunlin Xin

We consider a network facility location problem where the number of potential customers at each node is a random variable. The classical median problem is extended to minimize the expected network length subject to a value-at-risk constraint. Different risk measures are compared to motivate the study. We analyze the property of the optimal solution and identify a finite set of dominant points. Efficient solution procedures are then developed to solve the model. The solutions to the problem are also examined to get managerial insights.

2 - A Cutting Plane Method for Competitive Facility Location under Random Utility Maximization Models

Tien Anh Mai, Postdoctoral researcher, CP 6128 Succursale Centre-Ville, Apt 8, Montreal, QC, H3W1C5, Canada, maitien86@gmail.com

This work concerns the facility location problem in competitive market, where the demand of users is captured by a random utility maximization model. Existing approaches often use the logit model, and formulate the problem in a mixed-integer linear programming model. In this paper, we formulate the problem under the mixed logit model, which is more general and fully flexible. We propose a new approach based on a cutting plane method to exactly and quickly solve the nonlinear problem. We test our algorithm and show that our algorithm is much faster, compared to existing approaches.

3 - Optimizing Product Allocation in a Milkrun Picking System

Jelmer Pier van der Gaast, Postdoctoral Researcher, Rijksuniversiteit Groningen, Nettelbosje 2, Groningen, 9747 AE, Netherlands, j.p.van.der.gaast@rug.nl

In a milkrun order picking system, an order picker picks orders that arrive in real time during the picking process; by dynamically changing the stops on the picker's current picking route. The advantage of milkrun picking is that it reduces order picking set-up time and worker travel time compared to conventional systems. We study order throughput times of multi-line orders and model the system as a cyclic polling system with simultaneous batch arrivals. This allows us to study the effect of different product allocations in an optimization framework for a real-world application.

4 - Effective Methods for Solving the Bicriteria Pcenter Pdispersion Problem

Golbarg Kazemi Tutunchi, Senior Operations Research Specialist, SAS.institute Inc., 100 SAS.campus Dr., Cary, NC, 27513, United States, golbarg.tutunchi@sas.com, Yahya Fathi

We propose an IP model for the bi-criteria p-center and p-dispersion problems via the set covering and the node packing problems. We further study the structure of the proposed model, and we introduce a new family of valid inequalities to solve this IP model more effectively. Through a limited computational experiment we demonstrate the effectiveness of the proposed valid inequalities.

5 - A Manufacturing Network Design and Contingency Planning Model

Tan C. Miller, Director of Global Supply Chain Management Program, Rider University, 12 Winding Way, Morris Plains, NJ, 07950, United States, tanjean@verizon.net, Renato De Matta

We enhance a traditional network facility location manufacturing and distribution model to provide extensive contingency and scenario planning capabilities. Specifically, we develop and test a combination strategic network design model that in addition to solving for the optimal profit maximizing locations, also facilitates trade-off analyses between different levels and costs of manufacturing capacity investments and inventory investments.

Aviation Applications

Contributed Session

Chair: Dan Larsen, University of Cincinnati, 1807 Sycamore Valley Drive, Apartment T2, Reston, VA, 20190-4561, United States, asel.dan@msn.com

1 - A Novel Approach to Model and Solve Discrete Truss Sizing Problems

Mohammad Shahabsafa, Lehigh University, 200 West Packer Ave,, Bethlehem, PA, 18015, United States, mos313@lehigh.edu, Tamas Terlaky, Ali Mohammad-Nezhad, Luis F.Zuluaga, Sicheng He, Joaquim Martins

We consider various mathematical optimization models for the truss topology design problem with the objective to minimize the weight of the structure. The non-convex Euler bucking constraints and Hooks law are also considered. We are interested in truss design problems when the cross sectional areas of the bars take only discrete values. We propose Mixed Integer Linear Optimization Model (MILO) reformulation of the non-convex models. The resulting MILO models are not solvable with existing MILO softwares. We propose a solution methodology to solve the MILO models, and present numerical experiments to demonstrate the performance of the methodology.

2 - Capacity Modeling of Mixed-mode Runway Operations

Rajesh Piplani, Associate Professor, Nanyang Technological University, School of MAE, 50 Nanyang Avenue N3-2C-84, Singapore, 639798, Singapore, mrpiplani@ntu.edu.sg, Wai Lun Cheung

Capacity estimation of airports (defined by runway capacity) is important in planning to meet the long-term growth of air traffic as seen by most regions around the world. In this research, we develop analytical models for capacity estimation (maximum throughput) of a runway operating in mixed-mode. Existing models only consider certain arrival-departure sequences whereas our models take into account optimized arrival departure sequences developed as part of a sister project. We plan to extend the models to two or more runways arranged in different configurations, and also plan to study the relationship between delay and realized throughput, which in turn is affected by traffic mix.

3 - Deliver or Not?: Revenue Management for Future Drone-based Delivery Services

Heng Chen, University of Nebraska-Lincoln, CBA 250, 1240 R.Street, Lincoln, NE, 68588, United States, heng@unl.edu, Senay Solak

Drones are expected to fulfill future commercial delivery services for retailers and courier companies. We study some revenue management problems for these companies to determine when the drone-based delivery options should be enabled under stochastic demand. A dynamic programming model is developed. Both analytical and numerical analyses are provided.

4 - Natural Language Processing

Dan Larsen, The MITRE Corpororation, 7525 Colshire Dr, MS.N329, McLean, VA, 22102, United States, dalarsen@mitre.org

Free-form, natural language aviation safety reporting narratives are an integral part of aviation safety analysis. However, it is difficult to apply machine learning algorithms to domain-specific natural language data using libraries trained on edited English-language sources, such as news wire articles. We demonstrate the application of rule-based processes and open-source Natural Language Processing libraries on a domain-specific corpus in a closed-loop system. This process standardizes references to common aviation terms such as SIDs and STARs, abbreviations, misspellings, and key phrase identification.

Forecasting

Contributed Session

Chair: Fabian Taigel, University of Wuerzburg, Wuerzburg, Germany, fabian.taigel@uni-wuerzburg.de

1 - Spare Parts Planning under Uncertain Demand Rates

Erwin van Wingerden, PhD Student, Eindhoven University of Technology, Eindhoven, Netherlands, e.v.wingerden@tue.nl, Tarkan Tan, Geert-Jan Van Houtum

In this paper we consider a multi-item inventory problem with a backorder constraint. Demand follows a Poisson distribution but instead of assuming the demand rate is given, as is commonly done, we allow for uncertainty in the demand rate. When dealing with new products and a lack of data, the demand rate commonly based on estimates and uncertain. First we show that uncertainty of the demand rate is similar to an uncertain lead time. Next, we show that base stock levels and costs are always higher in the case when there is more uncertainty regarding the demand. Finally, we present numerical results where we consider different distributions for the demand rate among which uniformly distributed demand rates.

2 - Event Forecasting in Call Centers

Ger M. Koole, Vrije Universiteit Amsterdam, Department of Mathematics, De Boelelaan 1081A, Amsterdam, 1081 HV, Netherlands, ger.koole@vu.nl

In this talk we will present recent advances in call center forecasting, especially those related to the forecasting of events such as holidays, billions, and marketing actions. We show how this leads to highly accurate and accountable forecasts.

3 - On Estimation of Cross Elasticity of Demand to Forecast Sparse Time-series Data for E-commerce Applications

Arash Pourhabib, Walmart Labs, 10 Pacific Bay Cir, Apt 204, San Bruno, CA, 94066, United States, apourhabib@walmartlabs.com, Antony Joseph, John Bowman, Jagtej S. Bewli

Cross elasticity characterizes the change in demand for an item as a result of a change in price, or any other features, for another item. Accurate demand forecast hinges upon accurate estimation of cross elasticity, which is a challenging task in eCommerce operations, mainly due to the existence of a large number of low-selling items.

We propose a data-driven method to estimate cross elasticity by taking into account the sparse structure of the eCommerce data. We use an error correcting model approximation to a system of differential equations. We demonstrate that such an approach improves the accuracy of demand forecast.

4 - Hierarchical Forecasting and Multiple Aggregation Prediction Algorithm Combined Intermittent Demand Forecasting and Inventory Control

Li Shalang, Peking University, Beijing, 100078, China, 1301110862@pku.edu.cn, Lei Ming, G.Keong Leong, Honghui Deng

This paper reviews the intermittent demand forecasting methods and compares hierarchical forecasting methods and multiple aggregation prediction algorithm forecasting methods and then proposes a new forecasting method by combining these two methods. We use the procurement data of the State Grid Corporation of China to study these demand forecasting methods. In terms of forecasting performance, we use two forecasting error measurements as well as a real data based inventory simulation experiment. The results of the case study indicate that forecasting methods will generate smaller forecasting error and are better than the previous forecasting methods in terms of inventory performance.

5 - Prescriptive Analytics in Practice - Integrating Machine Learning with Inventory Management for a Fast-casual Restaurant

Fabian Taigel, University of Wuerzburg, Wuerzburg, Germany, fabian.taigel@uni-wuerzburg.de, Jan Meller

We propose a new, integrated approach for data-driven inventory management by combining tree-based machine learning techniques with the well-known newsvendor logic. We compare our model with various competing methods from the literature and benchmark it in a real -world application for a restaurant chain. We obtain very promising first results and provide relevant insights both for practice and theory, as we are able to identify fundamental drivers of the model's performance and apply our approach to a real world data set.

Finance, Banking and Insurance

Contributed Session

Chair: Markku Kallio, Aalto University School of Business, Helsinki, Finland, markku.kallio@aalto.fi

1 - Evaluating Size Effect on Cost Inefficiency of Commercial Banks with DEA

Jean-Raymond Fontin, Student, National Taiwan University of Science and Technology, No.43, Sec. 4, Keelung Rd., Da'an Dist.,, Taipei City, 10607, Taiwan, d10501812@mail.ntust.edu.tw

This study evaluates the determinants of size effect on cost inefficiency of commercial banks in low income countries using undesirable outputs DEA models. It covers a total of 9 countries and 108 banks over the period of 2013-2015. The results have shown that small banks are more efficient, and also support the "skimping" hypothesis; contrary to what most researchers have found. Small inefficient banks suffer from bad management problem that leads to cost inefficiency. Aggressive and well-capitalized small inefficient banks devote excessive resources to optimize their asset quality management and increase their investment portfolio to compensate for their costs.

2 - Financing Multiple Suppliers in Assembly Systems Buyer vs. Bank Financing

Shiming Deng, Professor, Huazhong University of Science and Technology, 4318 Collins Court, Apt 5, Mountain View, CA, 94040, United States, dengsm@gmail.com, Chaocheng Gu, Gangshu Cai, Li Yanhai

This paper compares buyer finance with bank finance in a supply chain with one assembler and multiple heterogeneous capital-constrained component suppliers. We characterize the equilibrium solutions for different financing schemes. We show that in buyer finance the assembler should charge the suppliers the lowest possible interest rate, which may be even below its own unit capital cost. The assembler may offer buyer finance even if its own unit capital cost is higher than banks' risk-free interest rate. We also identify the conditions under which buyer finance is better than bank finance, and demonstrate how initial capitals, costs, and heterogeneity affect the selection of financing scheme.

3 - Cooperative Mitigation of Contagion in Financial Networks

Markku Kallio, Professor (emeritus), Aalto University School of Business, Pohjoiskaari 17 D.17, Helsinki, FIN-00200, Finland, markku.kallio@aalto.fi, Aein Khabazian

We examine the financial network as a cooperative game. Governments can act as facilitators enforcing incentives for banks to cooperate and prevent the escalation of a financial crisis. To determine the characteristic function of the cooperative game, we develop clearing payment models for alternative coalitions competing in the market and show that the proposed models have unique equilibrium solutions satisfying the clearing conditions. As a solution concept, we use nucleolus which implies a possible subsidizing pattern among the banks. For a demonstration we use major European banks and a scenario which is linked to the adverse economic scenario used in 2016 EU-wide stress testing.

Reliability

Contributed Session

Chair: Rachel Ravid, ORT Braude College, Kamon, Israel, ravidmichael@gmail.com

1 - Bandwidth Sharing with Phase-type File Size Distributions

Weina Wang, Postdoc, University of Illinois at Urbana-Champaign, Urbana, IL, United States, weinaw@illinois.edu, Siva Theja Maguluri, R. Srikant, Lei Ying

We study a connection-level model for bandwidth sharing among data transfer flows due to Massoulié and Roberts, where file sizes have phase-type distributions and proportionally fair bandwidth allocation is used. We analyze the expected number of files in steady-state by setting the steady-state drift of an appropriately chosen Lyapunov function equal to zero. We obtain asymptotically tight bounds on the expected number of files in the system in the heavy-traffic regime. Our results show that the expected number of files under proportionally fair bandwidth allocation is insensitive to file size distributions, thus complementing the diffusion approximation result of Vlasiou, Zhang, and Zwart.

2 - Approximation Methods to Analyze Merge Configurations of Open Queueing Networks with Multiple Servers and Blocking

Guy L.Curry, Senior Professor, Texas A&M.University, MS-3131, College Station, TX, 77843, United States, g-curry@tamu.edu

Open queueing networks that contain merge configurations with blocking result in combinatorial sequencing for waiting jobs to enter the merge queue. Lee and Pollock developed a methodology for decomposing the system and analyzing individual queues. The merge queue with after-service blocking of the predecessor machines can be aggregated and the probabilities easily calculated. The Lee and Pollock approach is extended in this paper to multiple machines with non-identical servers.

3 - Queueing System with Feedback Vacations and Disasters

George Mytalas, CUNY, New York, NY, United States, george.mytalas@brooklyn.cuny.edu, Michael A. Zazanis

A queueing system with batch Poisson arrivals and Bernoulli feedback which is subject to disasters and repairs is analyzed. Further, the server, when idle, takes repeated vacations of random length. We analyze this system using the supplementary variables technique and we obtain the probability generating function of the stationary queue length distribution, the Laplace transform of the busy period distribution. We also provide expressions for performance measures and we present a delicate method to derive waiting times.

4 - Waiting Time Analysis in Network of Polling Queues

Ravi Suman, University of Wisconsin-Madison, 2302 University Avenue, Apartment #207, Apartment #207, Madison, WI, 53726, United States, rsuman@wisc.edu, Ananth Krishnamurthy

We analyze a network of polling queues with multiple products and multiple stations. We assume that external arrivals to the network follow a Poisson process, and that each station can be modelled as single server queue with exponentially distributed service times for each product. We establish a stochastic model to analyze this system and develop a procedure to estimate mean waiting times at each station under different service disciplines.

5 - A New Look on the Shortest Queue System with Jockeying

Rachel Ravid, Dr, ORT Braude College, Doar Na Bikat Beit Hakerem, Kamon, 20112, Israel, ravidmichael@gmail.com

We introduce a Markov queueing system with Poisson arrivals, exponential services and jockeying between two parallel and equivalent servers. An arriving customer admits to the shortest line, (when the lines are equal the customer admits to any line with probability 1/2). Every transition, of only the last customer in line, from the longer line to the shorter line is accompanied by a certain fixed cost. Thus, a transition from the longer queue to the shorter queue occurs whenever the difference between the lines reaches a certain discrete threshold (T =2,3, ...). In this study we focus on the stochastic analysis of the number of transitions of an arbitrary customer.

Repair Planning and Disruption Management

Sponsored: Transportation Science & Logistics

Sponsored Session

Chair: Kazuaki Okubo, Ehime University, Matsuyama, 0, Japan, okubo@cee.ehime-u.ac.jp

1 - An MIP Approach for Planning Pothole Repairs

Fatemeh Aarabi, University at Buffalo, 4280 Chestnut Ridge Road, Apt F3, Amherst, NY, 14228, United States, faarabi@buffalo.edu, Jee Eun Kang, Rajan Batta

Potholes degrade the functionality of roadway networks (throughput of traffic flow) in addition to concerns of safety and vehicle damages. A suitable repair planning strategy is developed to minimize total traffic flow throughput degraded over time. The proposed MIP model determines the optimal decisions of repair segment, type, and timing given limited resources. We apply the proposed model to a New York City case study.

2 - A Reliability based Planning Model for Bridge Maintenance under Different Management Agencies

Kazuaki Okubo, Associate Professor, Ehime University, 3 Bunkyo Machi, Matsuyama City, Matsuyama, 790-8577, Japan, okubo@cee.ehime-u.ac.jp, Pang-jo Chun, Haruna Suzuki

We develop a bridge maintenance and repair planning model based on the traffic assignment model with variable demand. The objective is minimizing social cost, the sum of road network user cost, maintenance and repair cost , with considering potential bridge failures and the differences in management agencies of each bridge. We show the numerical results by using the bridge inspection data in Shikoku region, Japan.

Machine Learning Algorithms and Applications in Dynamic Environments

Sponsored: Data Mining

Sponsored Session

Chair: Seoung Bum Kim, sbkim1@korea.ac.kr

1 - Dynamic Adjustment of Dispatching Rule Selection
Sangmin Lee, Korea University, Seoul, Korea, Republic of, smlee5679@gmail.com, Seoung Bum Kim

In the semiconductor industry, dispatching rule selection is a challenging task because of high uncertainty caused by a gap between planned capacity and actual capability. This study presents a dynamic dispatching rule selection method with multivariate multiple regression. To demonstrate the effectiveness and applicability of the proposed method, we conduct simulation study using real data from semiconductor fabrication plant in one of the leading semiconductor companies in South Korea.

2 - Label Propagation Algorithm with Consensus Matrix
Jaehong Yu, Korea University, Seoul, Korea, Republic of, dreamer77445@gmail.com, Seoung Bum Kim

This paper proposes a consensus matrix-based label propagation algorithm for semisupervised classification. The proposed algorithm constructs a consensus matrix to accommodate various characteristics of data and propagates label information using the iterative label fitting algorithm. The experimental results confirm that the proposed algorithm demonstrated superior performance compared to the competitors.

3 - Multi-co-training for Document Classification using Multi-views
Donghwa Kim, Korea University, 145 Anam Roo, Seoul, 02841, Korea, Republic of, donghwa89@korea.ac.kr, Deokseong Seo, Suhyoun Cho, Pilsung Kang

The purpose of document classification is to assign the most appropriate label to given documents. The main difficulties of document classification are insufficient label information and irreversible document representation. In this paper, we propose a multi-co-training based of different representations to improve the performance of document classification. In order to increase the difference of feature sets, we transform a document based on three different representation methods: term frequency-document frequency (TF-IDF) based on bag-of-words scheme, topic distribution based on latent Dirichlet allocation (LDA), and neural network-based document embedding known as Doc2Vec.

4 - Autoregressive Forests for Multivariate Time-series Modeling
Kerem Tuncel, Boaziçi University, Istanbul, Turkey, keremsinantuncel@gmail.com, Mustafa Gokce Baydogan

Multivariate Time Series (MTS) modeling has received significant attention in the last decade. E cient representations are required to deal with the high dimensionality of MTS. However, most of the traditional approaches assume independence or linear dependence between the variables of MTS which is unrealistic. To handle these problems, we propose an autoregressive tree based ensemble approach that can model the nonlinear behavior embedded in the time-series. An error-based representation based on the learned models is the basis of the proposed nonparametric vector autoregression approach. This is very similar to time series kernels used for multivariate time series classification problems.

Chair: Monica Gentili, IPAT, Georgia Institute of Technology, 75 5th Street NW, Suite 600, Atlanta, GA, 30308, United States, mgentili@unisa.it

1 - An Online Cost-sharing Mechanism for Horizontal Supply Chains
Maged M. Dessouky, University of Southern California, 3715 McClintock Avenue, GER.240, Los Angeles, CA, 90089-0193, United States, maged@usc.edu, Han Zou, John Gunnar Carlsson

This research addresses the cost allocation problem in a real-time cost sharing transportation system, which results from horizontal cooperation among multiple suppliers. We formulate the cost allocation problem for the dynamic vehicle routing environment, where only part of the customers are known in advance, and the rest become known in real time. We propose an online cost-sharing mechanism coupled with specially designed cost functions. The mechanism can be incorporated with a look-ahead dynamic vehicle routing framework that explicitly forecasts future customer requests.

2 - Investigating the Impacts of Information Sharing on Intermodal Infrastructure Investment Decision-making Process under Demand Uncertainty
Irina Benedyk, Purdue, 2411 Neil Armstrong Drrive, # 2A, West Lafayette, IN, 47906, United States, birina@purdue.edu, Srinivas Peeta

We investigate the impacts of investment-related information shared between private sector (that is, timing, expansion and operational strategies) on intermodal infrastructure investment decision-making process under demand uncertainty. In addition, we study the impacts of public-private partnership arrangements (which include risk allocation, financial burden and asset ownership) on intermodal infrastructure investment behavior of private sector under market competition. The study findings will help to understand the value of information in intermodal infrastructure investment decision and its impact on investment related uncertainties that affect the return of the investment.

3 - Reliable Facility Location Design under Disruption Risks and Congestion in Continuous Spaces
Zhaodong Wang, University of Illinois, 502 E Michigan Ave, Apt 21, Urbana, IL, 61801, United States, zwang137@illinois.edu, Siyang Xie, Yanfeng Ouyang

This paper develops analytical methods to evaluate the expected system performance with considerations of facility disruptions under a class of continuous traffic equilibrium. Closed-form solution can be evaluated in polynomial time for heterogeneous independent disruptions. A Lagrangian-relaxation-based optimization framework is proposed based on the analytical results to optimize the facility location design.

4 - Best and Worst Values of the Optimal Cost of the Interval Transportation Problem
Monica Gentili, University of Louisville, JB Speed Building, Room 304, Louisville, KY, 40292, United States, monica.gentili@louisville.edu, Raffaele Cerulli, Ciriaco D'Ambrosio

We study the transportation problem with interval supply and demand parameters (ITP), that is, the transportation problem where supply and demand are uncertain and vary in given ranges. We are interested in determining the best and the worst values of the optimal cost of ITP among all the realizations of the uncertain parameters within the intervals. We prove some general properties of the best and the worst optimum values and propose efficient algorithms to determine them.

Traffic and Pedestrian Modeling

Sponsored: Transportation Science & Logistics

Sponsored Session

Chair: Rui Ma, University of California, Davis, 1930 Sycamore Ln, #10, Davis, CA, 95616, United States, drma@ucdavis.edu

1 - A Comprehensive Assessment of Various Factors on Driving Ability of Individuals
Maxim A. Dulebenets, Florida A&M.University-Florida State University, 2300 Bluff Oak Way, Apt. 8408, Tallahassee, FL, 32311, United States, mdlbnets@gmail.com, Olumide Abioye, Eren Erman Ozguven, Ren Moses, Walter Boot, Thobias Sando

The majority of models used in transportation planning for estimating travel time and other performance indicators are primarily based on the traffic flow and roadway geometric characteristics. However, in reality there is a variety of other factors that have to be considered (e.g., driver characteristics, weather conditions, temporary attributes, etc.). This study performs a state-of-the-art review of the academic literature to identify a wide spectrum of different factors that may affect the driving ability of individuals.

2 - Investigating Drivers' Perception of Travel Time Reliability using a Full-scale Driving Simulator
Zohreh Rashidi Moghaddam, Morgan State University, 1700 E Cold Spring Ln, Baltimore, MD, 21251, United States, zoras1@morgan.edu, Mansoureh Jeihani

This study investigates travelers' perception of travel time reliability using a full-scale high-fidelity driving simulator. Participants in this study experienced driving in a realistic network in Maryland to make a route choice decision in different scenarios based on the travel time information shown on a Variable Message Sign. Driving experience was also accompanied by a stated preference (SP) survey with similar scenarios to determine their willingness to detour on a Likert scale. Multinomial Probit Model and Ordinal regression has been applied to model travelers route choice behavior and their willingness to detour respectively.

3 - A Stochastic Program Approach for Path Reconstruction Oriented Sensor Location Model

Ning Zhu, Tianjin University, Tianjin, Weijin Road no. 92, China, Tianjin, China, zhuning@tju.edu.cn, Fu Chenyi, Ma Shoufeng

Path flow identification is of particular interest for a number of traffic applications. We propose a scenario based two stage stochastic programming framework which considers the uncertainty of the link-path matrix. The first stage model aims to minimize the total traffic sensor installation cost and the expected penalty for uncovered and undifferentiated paths. The second stage model attempts to minimize uncovered and undifferentiated paths for a given sensor location pattern and a specific scenario. A branch and bound based integer L-shaped algorithm is presented. Extensive numerical experiments are conducted to verify the effectiveness of the proposed models and algorithm.

4 - Investigating Significant Features Contributing on Safety of Pedestrians at Intersections Over the Years

Hamidreza Ahady Dolatsara, Auburn University, 311 West Glenn Ave., Apt. 28, Auburn, AL, 36830, United States, hamid@auburn.edu

The objective of this study is investigating factors affect safety of pedestrians over the years. For this purpose Machine learning algorithms will utilize to extract the important features and predicting crash frequencies at intersections.

5 - The Morning Commute Problem with Ridesharing and Dynamic Parking Charges

Rui Ma, University of California, Davis, 2041 Academic Surge, University of California, One Shields Avenue, Davis, CA, 95616, United States, drma@ucdavis.edu, Michael Zhang

We study the traffic flow patterns in a single bottleneck corridor with a dynamic ridesharing mode and dynamic parking charges. Besides the scheme with constant parking charges and ridesharing payments, dynamic parking charges and ridesharing payments are derived to achieve congestion-free traffic in the corridor. With the dynamic ridesharing ratios, it is found that genuinely nonlinear departure rates and travel time functions can be generated in certain ridesharing cases, which was not observed in the traditional ADL model (Arnott et al., 1990) for the morning commute problems without ridesharing or with constant ridesharing ratios.

Data Analytics to Advance the Science of Health Care Delivery

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Devashish Das, Mayo Clinic, Rochester, MN, 55901, United States, das.devashish@mayo.edu

1 - Data Analytics Framework for Online Chronic Disease Management Based on Remote Health Information Systems with a Case Study in Smart Asthma Management

Junbo Son, University of Delaware, 303 Alfred Lerner Hall, Newark, DE, 19716, United States, junboson@udel.edu, Shiyu Zhou, Patricia Brennan

An array of advancements in information technology has resulted in a next-generation health information system based on remote patient monitoring technology and such system is especially emphasized in chronic disease management because of the system's consistent monitoring capability. In this paper, we first discuss some pitfalls of analyzing data from the remote health systems that may mislead patients and their care providers. Then, we introduce a set of principles that enables more effective data analytics based on remotely acquired patient data. We believe the discussion in this paper is crucial for unleashing a new era of technology-enabled and data-driven chronic disease management.

2 - Impact of Resuscitation Activations on Patients Left Behind in an Emergency Department

Xiaochen Xian, 936 Eagle Heights Apt C, Madison, WI, 53705, United States, xxian@wisc.edu, Mustafa Y Sir, Devashish Das, Kalyan Pasupathy

In the Mayo Clinic Emergency Department, a level one trauma center, a resuscitation team is formed by pulling resources from different treatment areas on a rotational basis to respond to incoming trauma patients. This impacts the care delivery process of patients that are left behind by the staff members responding to the resuscitation activation. We use a functional regression model to study the impact of these activations and system recovery time. This model can help design a workload-based resuscitation model instead of a rotation-based model.

3 - Personalizing Depression Treatment Follow-up via Rule-based Method

Ying Lin, University of Houston, Houston, TX, United States, ylin58@uh.edu, Shuai Huang, Shan Liu

Depression is a common mental illness with complex and heterogeneous progression dynamics. Risk grouping of depression treatment population based on their longitudinal patterns has the potential to enable cost-effective monitoring policy design. This study aimed at identifying a set of risk-predictive longitudinal patterns that predict depression progression and segment population into subgroups with different risk implications using rule-based method. We applied the rule-based method on an electronic health record dataset of depression treatment population and identified 12 rules that provide better individual prognostics and enable cost-effective monitoring policy design.

4 - Improving Accuracy of Non-invasive Hemoglobin Monitors: A Functional Regression Model for Streaming SPHB Data

Devashish Das, Mayo Clinic, 2015, 41st Street NW, F47, Rochester, MN, 55901, United States, das.devashish@mayo.edu, Kalyan Pasupathy, Nadeem N. Haddad, Susan Hallbeck, Martin Zielinski, Mustafa Y. Sir

In this article, we propose a method of improving accuracy of SpHb monitors, which are non-invasive hemoglobin monitoring tools with potential to improve critical care protocols in trauma care. The proposed method is based on fitting smooth spline functions to SpHb measurements collected over a time window and then use a functional regression model fit to predict the adjusted SpHb measurement for the end of the time window. The accuracy of the proposed method is compared to traditional methods.

Uncertainty Analysis in Modeling, Control, and Optimization

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Du Dongping, Texas Tech University, Lubbock, TX, 79409, United States, dongping.du@ttu.edu

1 - Generalized Polynomial Chaos-based Uncertainty Propagation in Multi-scale Modeling of Cardiac Electrophysiology

Zhiyong Hu, Texas Tech University, Lubbock, TX, United States, zhiyong.hu@ttu.edu, Dongping Du

Cardiac modeling has been widely used in physical experiments and clinical studies to uncover disease mechanism and investigate treatment strategies. Cardiac functions involve many uncertainties resulting from intrinsic variability. However, most of the existing cardiac models cannot efficiently quantify the effect of uncertainty on model prediction. This study develops a Generalized Polynomial Chaos based uncertainty propagation technique to propagate parametric uncertainties across multi-scale organizational level of cardiac ion channel, cell, and tissue. The method shows superior performance, compared with the Monte Carlo method, in computational efficiency and accuracy.

2 - Porosity Analysis for Additive Manufacturing by Augmented Spatiotemporal Point Process

Chenang Liu, Virginia Tech, 837 Claytor Square, Blacksburg, VA, 24060, United States, lchenang@vt.edu, Jia Liu, Zhenyu Kong, Prahalad Rao

Porosity is one major defect in additive manufacturing (AM) process. The research on modeling, forecasting, and control of porosity is critical to improve AM part quality. Using spatial and temporal correlations of pores due to layer-wise building, an augmented spatiotemporal point process is proposed to identify and forecast areas prone to pores on next layers. By this method, the distribution of pores captured from CT scan images is effectively represented by the proposed augmented point patterns incorporating morphological features of pores. This method is demonstrated by a real AM part with CT scan images.

3 - Physics-driven Spatiotemporal Regularization for High-dimensional Predictive Modeling

Bing Yao, Pennsylvania State University, 801 B6 Southgate Dr, University Park, PA, 16802, United States, bzy111@psu.edu, Hui Yang

Rapid advancement of distributed sensing and imaging bring a lot of high-dimensional spatiotemporal data in complex systems. Traditional regression fails to describe the spatial and temporal correlation of these data, and is not generally applicable for predictive modeling in these systems. This talk presents a physics-driven spatiotemporal regularization (STRE) method for high-dimensional predictive modeling in complex dynamic systems. This model is implemented to predict the electric potentials on the heart surface from the ECG data on the body surface. The model performance is evaluated and validated in both a simulated two-sphere geometry and a realistic torso-heart geometry.

4 - Blending of Computer Experiment Models with and with out Tuning Parameters

Patxi Fernandez-Zelaia, Georgia Institute of Technology, Atlanta, GA, United States, pfz3@gatech.edu, Rui Tuo, V. Roshan Joseph

This work focuses on the building of efficient statistical models from different classes of complex computer simulations and cheap analytical solutions. The computer experiments considered are deterministic yet contain numerical errors associated with real-valued tuning parameters. Additional errors corresponding to different computer code classes may be associated with the physical granularity or solution algorithm found in each code. Following recent work nonstationary Gaussian Process models are employed to blend predictions across tuning parameters. Blending of cross-class computer codes and analytical solutions is achieved utilizing unknown latent tuning parameters.

1 - Robust Optimization: Sensitivity to Uncertainty in Scalar and Vector Case

Giovanni Paolo Crespi, Associate Professor, Universita' degli studi dell'Insubria, Via Monte Generoso, 71, Varese, 21100, Italy, giovanni.crespi@uninsubria.it, Matteo Rocca, Daishi Kuroiwa

How robust solutions react to changes in the uncertainty set? We prove their location w.r.t. the magnitude of a possible decrease in uncertainty, i.e. when the uncertainty set shrinks. Uncertainty may arise from incomplete information about people's (stakeholders, voters, etc.) perception about a specific issue. When the decision maker (DM) has to look for approval, they might need to define the strategy that displeases the minority. Robust optimization allows such a solution. Nevertheless, such a solution might be far from the strategy that the DM wishes to uphold betraying the DM's goals. Our results allow such a distance to be measured and to steer the robust solution closer to the desirable one.

2 - Advances in Pseudo-cut Strategies for Global Optimization

Christopher Riley, Assistant Professor of Management, Delta State University, Cleveland, MS, United States, criley@deltastate.edu, Leon S.Lasdon, Fred W. Glover, Cesar Rego

Pseudo-cuts are linear cutting planes that provide temporary, but possibly invalid, restrictions on the solution space of complex optimization problems, to guide a solution process toward a global optimum. We provide new pseudo-cuts for nonlinear optimization using scatter search and tabu tunneling mechanisms, and present computational results showing the merit of our approach.

3 - An Approach for Robust Multiobjective Optimization Through a Superiority and Robustness Tradeoff Framework

Adham Mohammed, Research and Teaching Assistant, Cairo University, Faculty of Engineering at Cairo University, Cairo University Avenue, Giza, 12613, Egypt, adham@cu.edu.eg, Mohamed Gadallah, Sayed Metwalli

This paper introduces an approach for Robust Multi-Objective Optimization that considers the two aspects of solution merit: performance superiority and robustness. A multi-objective formulation is proposed, combining the Performance Superiority Objectives with derived Performance Robustness Objectives. The multi-objective analysis is carried out and the Pareto frontier is obtained. This Pareto is then perturbed via Monte Carlo simulation and Feasibility Robustness is used for selecting a reduced Pareto. An Absolute Minimization Index is finally used to select the best single solution from this reduced Pareto. A results comparison with Goal Programming is provided through test problems.

4 - Surrogation Based Tight Bounds for Indefinite Separable Multiconstrained Quadratic Programs

Jaehwan Jeong, Assistant Professor, Radford University, Department of Management, P.O. Box 6954, Radford, VA, 24142, United States, jjeong5@radford.edu, Chanaka Edirisinghe

A linear-time bounding algorithm is developed for indefinite separable quadratic programs. It surrogates multiple constraints to form a single constraint within an iterative scheme to generate a sequence of indefinite knapsack sub-problems that are solvable based on our previous research. The computational analysis with two-constraint case shows the superiority of our method relative to CPLEX.

5 - Analytics Optimization for Lot Sizing

Tao Wu, Data Scientist, Dow Chemical, 7109 Arrowhead Circle, Midland, MI, 48642-8110, United States, danielwu9999@gmail.com

We develop an analytics optimization method for lot sizing where the information is utilized for an analytics-based branching and selection procedure to fix setup variables. Comparisons with other methods indicate that the optimization method is computationally tractable and can obtain better results.

1 - Sentiment Analysis of Blog Text Based on CNN and OCC Model

Peng Wu, Professor, Nanjing University of Science &Technology, No.200, Xiaolingwei Road, Nanjing, Jiangsu, 210094, China, wupeng@njust.edu.cn, Heng wang Liu, Si Shen

This paper proposed a Sentiment Analysis model based on OCC (Ortony, Clore, and Collins) model and Convolution Neural Network(CNN)model from the perspective of cognition. A system of fuzzy inferential rules of blog users' emotion is formulated based on OCC model. The blog texts are represented by vectors and are used for training a polarity classification model based on CNN model. The competence of the proposed model is assessed through experiments on both Chinese and English online user' blog texts. The results shows the OCC model can improve the accuracy of the annotation the emotion tendency, and the analyzing results of CNN is significantly higher than the method of SVM(Support Vector Machine).

2 - A Doubly Adaptive Inferential Method for Monotone Graph Invariants

Junwei Lu, Princeton University, Princeton, NJ, United States, junweil@princeton.edu, Matey Neykov, Han Liu

We aim to infer some graph invariants in graphical models (e.g., the maximum degree, the number of connected subgraphs, the number of singletons). We propose a new inferential framework called skip-down for testing nested multiple hypotheses and constructing confidence intervals of the unknown graph invariants under undirected graphical models. Compared to perfect graph recovery, our methods require significantly weaker conditions. Theoretically, we prove that the length of the obtained confidence intervals are optimal and doubly adaptive.

3 - Flipping Out: Exploring Motion Classification Methodologies

Destie Provenzano, Deloitte, Arlington, VA, 22209, United States, destie@destie.com, Joel Bock

The classification of real-time movement from video data using empirically-based learning algorithms is difficult. This study explored methods to simplify the feature construction process, and accelerate learning to predict physical maneuvers from a database of gymnastics videos. Beyond classifying movements, assessment of how well a maneuver has been executed is enabled by this novel approach. Salient results from these numerical experiments will be presented, including increased precision and sensitivity as compared to previous methods.

4 - A New Rational Classification Approach by using the Novel Mixed Data Binarization Method

Muhammed Sutcu, Abdullah Gul University, Endustri Muhendisligi Bolumu, Kayseri, 38060, Turkey, muhammed.sutcu@agu.edu.tr, Omer Batuhan Kizilisik

In this study, we propose a new methodology for classifying the similar customers in same classes and then find the most suitable class for the new coming customer. First, we determine the classes from available data and then we classify the new instances into these predetermined classes by using the new novel data binarization approach. We show how the each step of this algorithm could be performed efficiently.

1 - Complete Enumeration of Non-isomorphic Minimally Aliased Response Surface Designs using Integer Programming an d High-throughput Computing

Jose Nunez Ares, PhD candidate, KU. Leuven, Kasteelpark Arenberg 30 - bus 2456, Leuven, 3001, Belgium, jose.nunezares@kuleuven.be, Peter Goos, Jeffrey T. Linderoth

Response Surface Designs (RSDs) are statistical designs widely used in process industries. We enumerate 3-level Minimally Aliased RSDs, which are {-1,0,1} matrices with desirable statistical properties. Our branch-and-prune algorithm exploits the inherent symmetry of the design matrices. The enumeration is parallelized to run on a large-scale, heterogeneous and non-dedicated computing environment. Our novel load-balancing scheme relies on phases of breadth-first search along with a statistical estimation of the size of the enumeration tree rooted at child nodes to achieve efficiency. We find many new statistical designs of size significantly larger than previously known.

2 - Steps to Success in Training Neural Networks by Second-order Algorithms

Xi He, Lehigh University, 223 Summit Street, Bethlehem, PA, 18015, United States, xih314@lehigh.edu

We move forward from the common used stochastic gradient based methods to stochastic Hessian-based approaches. They show capabilities to escape saddle points which are crucial in training neural networks, and also help achieve faster convergence rate and better model generalization. We investigate Hessian evolution along iterations to provide insights on neural network training. It motivates us to add elegant extra line-search and momentum to our proposed methods for better optimization performance. Numerical experiments show that our proposed methods can be more successful in practice at optimizing neural networks than several other fine-tuned first order learning algorithms.

3 - Applying Multidisciplinary Design Optimization to Service Network Design Problems

Leah J. Ruckle, PhD Candidate, Georgia Institute of Technology, 270 Ferst Drive, Atlanta, GA, 30332, United States, leruckle@gatech.edu, Dimitri Mavris

Multidisciplinary Design Optimization (MDO) is an optimization field that takes a "divide-and-conquer" approach to solving large and complex optimization problems. It is primarily used within the aerospace and mechanical engineering communities for the design of complex physical systems such as aircraft, automobiles and wind turbines. Up to this point, MDO has not been applied to logistical systems such as the Service Network Design Problem (SNDP). This presentation studies the suitability of applying multidisciplinary design optimization approaches to SNDPs and compares their performance to more traditional decomposition methods.

4 - Aircraft Recovery Problem Considering Airport Capacity and Maintenance Flexibility

Xianfei Jin, Sabre, Southlake, TX, United States, Xianfei.Jin@sabre.com, Xiongwen Qian, Zhe Liang, Lei Zhou, Sureshan Karichery, Xuehua Lu

Disruptions have a huge financial impact on the airline industry. When disruptions happen, airlines need to re-schedule flights and re-assign aircraft in real time with minimized recovery cost. In most previous works, airport capacity and flexible maintenance are not considered simultaneously via an optimization approach. To bridge this gap, we propose a column generation framework to solve the problem. Computational experiments show that the framework solves real-life problems with small, usually zero, optimality gap in very short run time.

1 - Minimizing Vessel Service Costs in Berth Scheduling via Evolutionary Computation with Deterministic Parameter Control

Maxim A. Dulebenets, Florida A&M.University-Florida State University, 2300 Bluff Oak Way, Apt. 8408, Tallahassee, FL, 32311, United States, mdlbnets@gmail.com

This study focuses on the seaside operations of marine container terminals and proposes a novel Memetic Algorithm with a deterministic parameter control to facilitate the berth scheduling and minimize the total vessel service cost. Unlike canonical Evolutionary Algorithms, the developed algorithm uses a local search heuristic and adjusts the mutation rate values based on a deterministic parameter control strategy for more efficient exploration and exploitation of the search space. Computational experiments demonstrate efficiency of the developed algorithm.

2 - Storage Location Assignment for Rectangular Items Beneath a Gantry Crane

Roya Ghorashi, University of Wisconsin- Milwaukee, 3200 N Cramer St, EMS1062, Milwaukee, WI, 53211, United States, ghorashi@uwm.edu, Matthew Petering

Storage location assignment problems are critical to increasing productivity in many industries. In this paper we consider the problem of locating rectangular items in a temporary storage area beneath a gantry crane. We develop a mixed-integer linear programming model of the problem and devise a metaheuristic method that quickly obtains good solutions to large problem instances. Experimental results obtained via CPLEX and C++ demonstrate the effectiveness of the proposed methods.

3 - Cross Dock Scheduling of Inbound and Outbound Trucks for Fresh Products

Fei Pan, East China University of Science and Technology, 130# Meilong Road, Shanghai, 200237, China, 1004841702@qq.com

Cross dock is a warehouse management concept which can reduce inventories, lead time and customer response time. One of the most fundamental issues is how well the trucks can be scheduled. Aiming at the feature of fresh products, we address three objectives respectively to optimize, the total operation time, the total deterioration of fresh products and the total products passing through temporary storage. Furthermore, we propose a mathematical model and design a genetic algorithm for real size applications. Through comparing the optimal scheduling sequence for trucks based on three objectives, we conclude that optimization of total deterioration can make three objectives low simultaneously.

4 - Solving the Modular Fixed Charge Transportation Problem – A Polyhedral Approach

Faiz Hamid, Assistant Professor, Indian Institute of Technology, Kanpur, 208016, India, fhamid@iitk.ac.in, Yogesh K. Agarwal

In this paper we study a variant of the fixed-charge transportation problem where the capacity can be installed only in integer multiples of a fixed module capacity. The problem is referred as modular fixed charge transportation problem in this paper. The problem arises frequently in practice, for example in supply chain vehicle dispatching problems. However, the problem itself has not been studied in the literature so far to the best of our knowledge. We formulate the problem as a mixed integer linear program, propose different valid inequalities to strengthen the formulation, and present some preliminary computational results.

5 - A Worm Optimization Algorithm to Minimize the Makespan on Unrelated Parallel Machines

Jean-Paul Arnaout, Associate Professor, Gulf University for Science & Technology, West Meshref, 00965, Kuwait, jeanpaularnaout@gmail.com

This paper addresses the unrelated parallel machine scheduling problem with setup times, with an objective of minimizing the makespan. A Worm Optimization (WO) algorithm is introduced and is applied to this NP-hard problem. The novel WO is based on the behaviors of the worm, which is a nematode with only 302 neurons. Nevertheless, these neurons allow worms to achieve several intricate behaviors including finding food, interchanging between solitary and social foraging styles, alternating between dwelling and roaming, and entering a type of stasis/declining stage. WO's performance is evaluated by comparing its solutions to solutions of other known metaheuristics.

1 - Simulation Optimization via Parametric Robust Optimization

Chaithanya Bandi, Northwestern University, 2001 Sheridan Road, Suite 566, Evanston, IL, 60208, United States, c-bandi@kellogg.northwestern.edu

In this work, we build on data driven uncertainty sets and parameteric robust optimization to simulate and optimize complex stochastic systems such as queueing networks.

2 - Worst-case Demand Distributions in Vehicle Routing

Mehdi Behroozi, Assistant Professor, Northeastern University, Boston, MA, 02115, United States, m.behroozi@neu.edu, John Gunnar Carlsson

A recent focal point in research on the vehicle routing problem (VRP) is the issue of robustness in which customer demand is uncertain. In this paper, we conduct a theoretical analysis of the demand distributions whose induced workloads are as undesirable as possible. We study two common variations of VRP in a continuous approximation setting: the first is the VRP with time windows, and the second is the capacitated VRP, in which regular returns to the vehicle's point of origin are required.

3 - Two-stage Robust Optimization with Decision-dependent Information Discovery

Jiachuan Chen, University of Southern California, Los Angeles, CA, United States, jiachuac@usc.edu, Phebe T. Vayanos

We consider two-stage robust optimization problems with decision-dependent information discovery in which some of the here-and-now decisions correspond to (costly) measurement variables that determine the portion of the uncertain parameters that will be observable in the recourse stage. We propose a solution approach based on the popular K-adaptability framework. We illustrate the performance of our approach on several stylized problems, including a variant of the capital budgeting problem from the literature.

1 - Socially Conscious Product Development: Impact of Costs, Market Growth, and Changes to Brand Image Perception

Hannan Sadjady Naeeni, PhD Candidate in Supply Chain Management, University of Houston, Houston, TX, 77096, United States, hsadjady@bauer.uh.edu, Nickolas Freeman, Powell Robinson

We propose a game-theoretic duopoly model to identify conditions where one, none, or both of the firms make commitments to socially responsible products at equilibrium. Our analysis shows how the firms' commitment to socially responsible products depends on the marginal cost differences and degree of market growth, as well as the indirect effect of the product's social attribute on the consumer's perception of brand image.

2 - Recovery Optimization Decision-making for Sustainable Manufacturing in the Presence of Demand Uncertainty

Kai Meng, Nanjing University of Aeronautics and Astronautics, Nanjing, 210016, China, nuaamk@126.com
Kai Meng, Jiangsu Key Laboratory of Precision and Micro-Manufacturing Technology, Nanjing, China, nuaamk@126.com, Peihuang Lou, Peihuang Lou, Xianghui (Richard) Peng, Victor R. Prybutok

This research examines recovery optimization in a hybrid recovery system with demand uncertainty. Both dismantling and remanufacturing are addressed. The proposed multi-objective optimization model provides the optimal recovery yield and strategies for a batch of product returns to ensure sustainability. We develop an evolutionary algorithm solution and investigate how demand impacts the recovery decisions.

3 - Retailer Strategies to Encourage Reduced Packaging Adoption: A Threshold Perspective

Olga Pak, University of South Carolina, 105 Carolina Ridge Drive, Columbia, SC, 29229, United States, opak@email.sc.edu

A majority of CPG manufacturers continue to resist reduction of product packaging because such packaging is associated with several marketing/product positioning risks, like diminished product visibility and lower perceived value. We explore the tools retailers can use to mitigate such concerns, and, thus, convince manufacturers to make their packaging more compact and less wasteful, which has both operational efficiency and sustainability implications.

4 - Flexible Refund on Consumer Return for Customized Products

Bisheng Du, Associate Professor, Ningbo University, School of Business, Ningbo University., Fenghua Rd 818, Jiangbei District, Zhejiang, 315211, China, dubisheng@nbu.edu.cn, Guiping Li

The mismatch between consumer's growing demand for customized products and supply side's increasing leftover inventory, bring many new business models in the real practice, for instance, C2M (Customer to Manufactory). In this study, we analytically study the flexible refund policy instead of full refund (or no refund) for the customer return with respect to their modularity levels. Our intension is to analyze the analytical performance of C2M system and the customer utilities.

1 - Maximizing Reduced-cost-based Fixing

Andre Augusto Cire, University of Toronto Scarborough, Department of Management, UTSC, 1265 Military Trail, Toronto, ON, M1C-1A4, Canada, acire@utsc.utoronto.ca, Louis-Martin Rousseau, Omid Sanei

Reduced-cost-based fixing is a key computational methodology that cuts out part of the solution space that does not lead to an optimal solution. This technique is, however, dependent on the dual values available at the moment of pruning. We investigate the value of picking a set of dual values which maximizes the amount of fixing that is possible. We test this new variable-fixing methodology for arbitrary mixed-integer linear programming models, and show that the resulting method can be naturally incorporated into existing solvers. Preliminary results suggest that the method can e ectively reduce solution times on hard instances with respect to a state-of-the-art commercial solver.

2 - N-step Cutset Inequalities for Multi-module Capacitated Network Design Problem

Haochen Luo, Texas A&M.University, 3131 TAMU, College Station, TX, 77840, United States, hcluo@tamu.edu, Kiavash Kianfar

We present our results of studying the multi-module cutset polyhedron, a relaxation of the multi-module capcitated network design (MMND) polyhedron. We give a new class of cutset inequalities for MMND based on the n-step MIR concept, referred to as the n-step cutset inequalities. We show that many cutset-based inequalities introduced in the literature are special cases of our inequalities. In addition, n-step cutset inequalities introduce new classes of strong inequalities for MMND which are facet-defining for the multi-module cutset relaxation of the problem. Our computational experiments demonstrate that our inequalities are very effective in solving MMND instances.

3 - Online Estimation of the Size of the Branch and Bound Tree in MIP Solvers

Pierre Le Bodic, Monash University, Clayton, Australia, pierre.lebodic@monash.edu, Gleb Belov, Samuel Esler, Dylan Fernando, George L.Nemhauser

We present an online method that estimates the final size of the branch-and-bound tree in Mixed-Integer Programming solvers. This in turn allows to estimate the total running time. The method combines an old sampling method due to Knuth (1975) and recent work on branching by Le Bodic and Nemhauser (2017). This method is implemented in the MIP solver SCIP and its results are displayed as an extra column.

4 - Facets for Single-module and Multi-module Capacitated Lot-sizing Problems

Manish Bansal, Virginia Tech., 227 Durham Hall, 1145 Perry Street, Blacksburg, VA, 24060, United States, bansal@vt.edu

We provide sufficient conditions under which the (k,l,S,I) inequalities of Pochet and Wolsey (1993), the mixed (k,l,S,I) inequalities, derived using mixing procedure of Gunluk and Pochet (2001), and the paired (k,l,S,I) inequalities, derived using sequential pairing procedure of Guan et al. (2007), are facet-defining for the single-module capacitated lot-sizing problem without backlogging. We also provide conditions under which the inequalities derived using the sequential pairing and the n-mixing procedure of Sanjeevi and Kianfar (2012) are facet-defining for the multi-module capacitated lot-sizing problem without backlogging.

1 - Nonlinear Model for Failure Cost Assessment of Drone Delivery Network

Maryam Torabbeigi, University of Houston, 4655 Wild Indigo St, apt 255, Houston, TX, 77027, United States, mtorabbeigi@uh.edu, Gino J. Lim

A delivery network is considered in which some products are delivered to the customers by drones. It is possible that UAV fails during the flight and therefore, some part of the products will be lost. The amount of lost demand depends on UAV failure function and failure location. A new mix integer nonlinear programming (MINLP) model is proposed to minimize the failure cost. The minimum required number of drones is also calculated based on flight time or load capacity or both of them. By solving the model, the path of each UAV, the assigned customers to them, and also the arrival time at each customer and the probability of failure before reaching them are determined while the network failure cost is minimized.

2 - On the Performance of NLP Solvers within Global MNILP Solvers

Benjamin Mueller, Zuse Institute Berlin, Takustr 7, Berlin, 14195, Germany, benjamin.mueller@zib.de

Solving mixed-integer nonlinear programs (MINLPs) to global optimality efficiently requires fast solvers for continuous sub-problems. These appear in, e.g., primal heuristics, convex relaxations, and optimization-based bound tightening. Two of the best performing algorithms for these sub-problems are Sequential Quadratic Programming (SQP) and Interior Point Methods. In this talk we present the impact of different SQP and Interior Point implementations on the most important MINLP solver components that solve a sequence of similar NLPs. We use the constraint integer programming framework SCIP for our computational studies on instances of the MINLPLib2 instance library.

3 - Sparse Nonlinear Regression Pushing the Envelope using Modern Optimization

Bart Paul Gerard Van Parys, Affiliate Researcher, MIT, Room E40-154, 77 Massachusetts Avenue, Cambridge, MA, 02139, United States, vanparys@mit.edu, Dimitris Bertsimas

We present a novel method for nonlinear sparse regression which is able to scale to real-life problems consisting of up to 10,000 observations for a few 1,000 inputs. The ability of our method to identify all relevant nonlinear features is shown empirically to experience a phase transition. In stark contrast to existing heuristics, the same transition also presents itself in our ability to reject all obfuscating features as well. In the regime where our method is statistically powerful, its computational complexity is interestingly on par with Lasso based heuristics. The presented work fills a void in terms of a lack of disciplined nonlinear sparse regression methods in high-dimensional settings.

4 - Global Optimization of Mixed Integer Nonlinear Programs via Adaptive Tightening of Convex Relaxations

Harsha Nagarajan, Staff Scientist, Los Alamos National Laboratory, 3000 Trinity Drive, Apt 8, Los Alamos, NM, 87544, United States, harsha@lanl.gov

We propose a two-stage approach to strengthen piecewise convex relaxations for MINLPs with multi-linear terms. In the first stage, we apply bound contraction methods based on SDP relaxations to iteratively until a fixed point with respect to the bounds are achieved. In the second stage, we partition the variables using an adaptive multivariate partitioning scheme and valid partition elimination strategies. Thus, we construct sparser partitions yet tighter relaxations by adaptive partitioning in combination with cutting plane methods on locally convex regions. We demonstrate the superiority of the algorithm on MINLPLib and (large) Pooling instances w.r.t commercial global opt. solvers.

5 - Construction of Test Problems for the 0-1 Quadratic Knapsack Problem

Richard Forrester, Professor of Mathematics, Dickinson College, Department of Mathematics, College and Louther Street, Carlisle, PA, 17013, United States, forrestr@dickinson.edu, Peixin Sun

Most researchers of the 0-1 quadratic knapsack problem (QKP) assess the performance of their solution methods by performing computational experiments on randomly generated instances. In this talk we examine different factors that can influence the difficulty of randomly generated instances and develop different methods for constructing test problems. In particular, we introduce a technique for generating instances of the QKP with a specified correlation between the objective and knapsack coefficients. We provide a detailed computational study to show how both heuristic and exact solution methods perform on our new problem sets.

Plug-in Electric Vehicle Charging Planning and Operations

Sponsored: Energy, Natural Res & the Environment Electricity

Sponsored Session

Chair: Wei Qi, McGill University, McGill University, Montreal, QC, H3A 1G5, Canada, qiwei.0216@gmail.com

1 - Joint Planning of Electric Vehicle Fast-charging Network and Distributed Photovoltaic Generation

Wei Qi, McGill University, 1001 Sherbrooke Street West, Montreal, QC, H3A 1G5, Canada, qiwei.0216@gmail.com, Hongcai Zhang, Scott Moura, Zechun Hu, Yonghua Song

Integration of plug-in electric vehicles (PEVs) with distributed renewable resources will decrease PEVs' well-to-wheels greenhouse gas emissions, promote renewable power adoption and defer power system investments. We propose a multidisciplinary approach to jointly planning PEV fast-charging stations and distributed photovoltaic (PV) power plants on coupled transportation and power networks. We develop models of 1) PEV fast-charging stations; 2) highway transportation networks under driving range constraints; 3) PV power plants with reactive power control. Then we formulate a stochastic mixed integer second order cone program and decomposition algorithms to solve this problem.

2 - Electric Vehicle Charging Behavior and Infrastructure Availability are Critical to Accurately Assess the Promise of EVS for the Smart Grid

Colin Sheppard, Lawrence Berkeley National Laboratory, Berkeley, CA, 94720, United States, colin.sheppard@lbl.gov, Anand Gopal, Rashid Waraich, Julia Szinai, Nikit Abhyankar, Sangjae Bae, Alexei Pozdnukhov, Andrew Campbell

Vehicle electrification is a critical component of most pathways to deeply decarbonize the transportation sector. Through highly detailed simulation modeling with BEAM (the modeling framework for Behavior, Energy Autonomy, and Mobility), we examine the relationship between driver behavior and the use of charging infrastructure in the context of current day and projected plug-in electric vehicles (PEV) adoption. We demonstrate the importance driver behavior when analyzing the spatiotemporal distribution of electricity demand from PEVs, as well as the potential for PEVs to provide flexibility services to the electric grid.

3 - Recharging Electric Vehicle Sharing Fleet

Xin Wang, Assistant Professor, University of Wisconsin-Madison, 8916 Red Beryl Drive, Middleton, WI, 53562-4278, United States, xin.wang@wisc.edu, Long He, Guangrui Ma, Wei Qi

Electric vehicles have been considered as key to cutting carbon emissions in urban transportation. Several cities have welcomed electric vehicle (EV) sharing services and supported them by building charging infrastructure. Despite the efforts of the cities and operators, it remains challenging to recharge the fleet due to limited charging facilities. Such operational difficulty discourages the use of EV in the sharing fleet and forces operators to switch to gas-powered cars or even cease their operations. In this paper, we address the charging infrastructure planning problem in joint with fleet repositioning and recharging operations in the context of EV sharing.

Forestry I - Forest Management

Sponsored: Energy, Natural Res & the Environment Forestry

Sponsored Session

Chair: Peter Rauch, BOKU-Univ of Natural Resources & Life Sciences, BOKU-Univ of Natural Resources & Life Sciences, Wien, 1180, Australia, Peter.rauch@boku.ac.at

1 - Optimal Deployment of Firefighting Aircrafts for Wildfire Initial Attack Planning

Joao Zeferino, University of Coimbra, Coimbra, Portugal, zeferino@dec.uc.pt

The success of the initial attack is crucial to wildfire fighting efficiency. An optimization model for aerial firefighting fleet deployment planning is presented. The model aims to find a solution for the aircrafts location that maximizes the coverage of different areas according to their wildfire susceptibility and hazard. It takes into account the different forests within a region, the available airport facilities and the aircrafts characteristics. The model potentialities are illustrated through a national-scale case study.

2 - Ascending and Descending Satellite Observation of Forest Fires

Aaron Bradley Hoskins, United States Naval Research Laboratory, 7220 Briarcliff Drive, Springfield, VA, 22153, United States, abh318@msstate.edu, Hugh Medal

We investigate the monitoring of a forest fire by a constellation of satellites. Each satellite is maneuvered to observe the forest fire twice per day. The location of the forest fire is unknown at the time of launch. The problem is formulated as a stochastic programming problem where the initial orbital configuration is the first-stage decision and the satellite maneuver sequence is the second-stage decision. The problem is solved using a Sample Average Approximation Algorithm. The proposed solution is compared through simulation to the current operational paradigm.

3 - Simulating Multi-modal Wood Supply Chains including Risks Agents

Peter Rauch, BOKU-Univ of Natural Resources & Life Sciences, Feistmanteistr 4, Wien, 1180, Austria, Peter.rauch@boku.ac.at, Christoph Kogler

Increasing natural disturbances lead to supply chain risks and seasonal irregularities in wood harvest and transport. A discrete event simulation model supporting manager decisions and contributing to a better understanding of the multimodal wood supply chain was developed. Simulating collaborative supply chain control strategies enhances the development of advanced risk management improving supply chain resilience. The supply chain covers wood harvest, precarriage and storage in terminals, transhipment to rail waggons or vessels and final transport woodworking plants.

4 - An Exact Approach for Spatial Prioritization of Conservation Actions

Jordi Garcia-Gonzalo, Researcher, Centre Tecnològic Forestal de Catalunya (CTFC)., Solsona, Spain, j.garcia@ctfc.es

Limited conservation budgets require prioritizing which management actions to implement and where to maximize the long-term persistence of biodiversity. Recently a heuristic approach has been used to find the combination of actions that remediate threats to species at the minimum cost while considering connectivity among actions through the planning area. We present a mixed integer programming model to prioritize actions to address threats to freshwater fish species in the Mitchell River catchment, northern Australia. We compared our results with the heuristic approaches and found our approach delivered more efficient solutions for different connectivity requirements.

1 - Analysis of Competitive Energy Prices when Transportation is Capacitated

Ian Yihang Zhu, University of Toronto, 144A, 60 Harbord Street, Toronto, ON, M5S3L1, Canada, i.zhu@mail.utoronto.ca, Timothy Chan, Michael Pavlin

We study the effect that infrastructure and transportation constraints have on prices in a competitive energy market. In particular, we note the potential that these constraints have in creating market segmentation and localized markets in an otherwise perfectly competitive economy. We apply our model to the gasoline market, where we use inverse optimization to study the movement of prices across different states.

2 - Demand Response Aggregation with Satisficing Consumers in Electricity Markets

Daniel E. Olivares, Assistant Professor, Pontificia Universidad Catolica de Chile, Vicuna Mackenna 4860, Macul, Santiago, Chile, dolivaresq@ing.puc.cl, Florian Salah, Rodrigo Henriquez, George Wenzel, Matias Negrete-Pincetic

This talk discusses the impact of consumers' behaviour on the portfolio design of a Demand Response (DR) aggregator. We develop an optimization model to decide the optimal portfolio of DR contracts for an aggregator participating in the electricity market, where consumers' decisions are modeled using elements of satisfying theory. The model determines the premiums to be offered to consumers in order to obtain a DR portfolio that maximizes the aggregator's operating surplus while satisfying the aspiration levels of participating consumers. Several simulations are performed to obtain insights on the value of the DR resource, and the importance of parameters used to model the consumers' behavior.

Multistage Risk-Averse and Robust Stochastic Programming

Sponsored: Optimization, Optimization Under Uncertainty

Sponsored Session

Chair: Lewis Ntaimo, Texas A&M University, College Station, TX, 77843, United States, ntaimo@tamu.edu

1 - Decomposition for Risk-averse Multistage Stochastic Programs with Expected Conditional Risk Measures

Lewis Ntaimo, Texas A&M.University, 3131 TAMU, College Station, TX, 77843, United States, ntaimo@tamu.edu, Maryam Khatami, Bernardo Pagnoncelli

We present a study of decomposition algorithms for risk-averse multistage stochastic programs (MSLPs) with expected conditional risk measures (ECRMs). The ECRMs have the advantage of being nested and time consistent. We study ECRMs in the context of both quantile and deviation mean-risk measures.

2 - Stochastic Decomposition for Risk-averse Multistage Stochastic Linear Programs

Prasad Parab, Texas A&M.University, 1901 Holleman Drive W, #403, College Station, TX, 77840, United States, prasaddparab@tamu.edu, Lewis Ntaimo, Bernardo Kulnig Pagnoncelli

Risk-averse multistage stochastic linear programs (MSLPs) can be hard to solve not only because of their large-scale nature, but also due to the risk measure being used. In this talk, we present a study of stochastic decomposition for MSLPs with quantile and deviation risk measures.

3 - The Application of Stochastic Optimization in Chemical Engineering Process

Hanxi Bao, University of Florida, baohanxi@ufl.edu, Zhiqiang Zhou, Guanghui Lan, Zhaohui Tong

Chemical engineering problems often involve uncertainty such as randomness in materials, reactions, and operations. In this work we establish a multistage stochastic programming model for the optimization and control of chemical processes under this type of uncertainty. We then discuss the implementation of a stochastic dual dynamic programming (SDDP) algorithm to compute an optimal solution for this problem.

4 - Robust Affine Control over Finite Time Horizon: The Stochastic Case

Georgios Kotsalis, Georgia Intitute of Technology, Atlanta, GA, United States, gkotsalis3@gatech.edu, Guanghui Lan, Arkadi Nemirovski

We provide a computationally tractable design procedure of affine policies for the constrained multistage robust optimization problem as it pertains to linear regime-switching systems that are subject to quadratic constraints while being affected by uncertain initial state and disturbances. We derive our results under the general assumptions of Markovian evolution of the stochastically switching signal and provided that the initial state and external disturbances lie within some nominal range expressed as the intersection of ellipsoids centered at the origin.

1 - Co-optimizing the Interplan Between Micro and Macro Grids

Luckny Zephyr, Postodoctoral Associate, Cornell University, 308 E Court Street, Apt 3, Ithaca, NY, 14850, United States, lz395@cornell.edu

The increase in renewable resource penetration in bulk power systems introduces challenges in operations, due to the inability to confidently predict resource availability. The result of inaccurate forecasting is a reduction in reliability, with volatility in prices, line flows and voltages on the power transmission network. However, the ability of microgrids to be operated in both interconnected and islanded modes shows potential to leverage these smaller systems to manage disturbances in the bulk network, contributing to the integration of renewables in the power system. We will present our in-progress work to co-optimize the interaction between the main network and microgrids.

2 - Development of Variable Speed Limit System under Uncertain Driver Behaviour

Nadia Moshahedi, University of Calgary, Calgary, AB, T3A2E1, Canada, nadia.moshahedi2@ucalgary.ca, Lina Kattan

variable Speed Limit (VSL) is an Intelligent Transportation System solution that enables dynamic changing of speed limit in an attempt to improve mobility. Performance of these systems is highly influenced by fluctuation in traffic flow, which is caused by factors such as driving behaviour. To develop a proper VSL system uncertainty must be quantified as a part of optimization framework. In this work, we develop a Model Predictive Control VSL under uncertain driver behaviour. A stochastic MPC VSL system that minimizes total system travel time while constraining the change in speed limit over space and time is developed and tested in VISSIM simulation software using a rolling horizon approach.

3 - Scenario Group Approach for Risk Averse Mixed Integer Multi Stage Stochastic Programming Problems with Dynamic Mean CVAR

Ali Irfan Mahmutogullari, Bilkent University, Ankara, Turkey, a.mahmutogullari@bilkent.edu.tr, Ozlem Cavus, Selim Akturk

We propose a scenario tree decomposition approach, namely scenario grouping, to obtain different lower and upper bounds for risk-averse mixed-integer multi-stage stochastic programming problems with dynamic mean-CVaR objective. The method requires no assumption such as convexity, linearity, and complete recourse. For the case where the first-stage decision variables are binary, we also propose an exact solution algorithm by using the obtained bounds iteratively. We conduct computational experiments to observe the quality of the obtained bounds and the efficiency of the proposed algorithm.

4 - Safe Approximations of Chance Constrained Programs

Xiaoyi Ma, Tongji University, Shanghai, China, 18917288185@163.com, Zhaolin Hu

Chance constrained programs (CCP) are important models in stochastic optimization. In this paper, we seek to construct some approximations of the chance constraints. We show that the approximation problems are sometimes more tractable than the original CCPs. Our approach provides a new idea of balancing the conservativeness and the tractability of the CCPs.

Chair: Yanling Chang, Texas A&M University, 1550 Crescent Pointe Parkway, College Station, TX, 77845, United States, yanling.chang@tamu.edu

1 - Developing a Process to Rapidly Illuminate Potential Solutions
Simon Goerger, Director, United States Army, 102 Windsong Cv, Ridgeland, MS, 39157-8736, United States, simon.r.goerger@usace.army.mil, Niki C. Goerger, Christina Rinaudo

The SPRINTS (Systems Process for Rapid Illumination of Numerous Tentative Solutions) was developed to facilitate workshops within the Engineer Research and Development Center and with diverse groups from numerous Department of Defense organizations. This process facilitates rapid collection of stakeholder feedback to create new processes, enhance existing processes, and identify crucial capabilities requirements within an operational context. This presentation provides an overview of the SPRINTS process with particular examples from real world applications.

2 - The Effect of Shared Leadership on Team Cohesion
Jie Wu, Xi'an Jiao Tong University, Xi'an, China, wujie2016@xjtu.edu.cn

The existing environment with uncertainties and crises and the rise of self-management team, cross-functional team make shared leadership on the way. With the data from 54 teams composed of 284 participants analyzed by SPSS 24.0 and Mplus7.0, we explore the function of affect-and cognitive trust in team level as a bridge between shared leadership and team cohesion and discuss the different role of affect-and cognitive trust in team level between shared leadership and team output respectively. Further, shared leadership has the larger effect on team outputs in ad hoc team than established team.

3 - Voting Rules and Manipulated Evidence
Youzong Xu, Xi'an Jiaotong-Liverpool University, 111 Ren'ai Road, Business Building 423B, Suzhou, 215123, China, xu.youzong@wustl.edu, Bo Li

A group of voters must make a group decision based on the evidence strategically provided by a sender. The voters can choose what voting rule they use to make the group decision. We find that, if the sender can manipulate the evidence he provides, a majority rule is always superior for the voters than the unanimous rule is, because 1) the sender will provide more informative evidence under a majority rule than under the unanimous rule; 2) voters will receive greater expected utilities under a majority rule than under the unanimous rule; and 3) information equivalence can be achieved under a majority rule but not under the unanimous rule.

4 - Effectiveness-equity Tradeoffs in the Aggregation of Preferences
Luis J. Novoa, The George Washington University, 2201 G Street, NW, Funger Hall, Washington, DC, 20052, United States, ljnovoa@gwu.edu, Srinivas Y. Prasad

We consider the problem of aggregating preferences of a group of individuals over a set of discrete alternatives. We develop models for analyzing effectiveness equity tradeoffs using a number of different equity measures, and study how well the models conform to actual choices made by individuals in empirical studies.

5 - Value of Communication for A One-leader, Two -follower Partially Observed Markov Game
Yanling Chang, Texas A&M.University, 1550 Crescent Pointe Pkwy, Apt 1206, College Station, TX, 77845, United States, yanling.chang@tamu.edu, Matthew Keblis, Ran Li

We consider a partially observed Markov game with three agents, a leader and two followers. We analyze how the leader's performance is affected by changes in the quality of the communication between the two followers. Assuming each agent uses a stationary finite memory policy and that the probability of inaccurate communication between the followers is sufficiently small, we present a procedure to determine when leader may consider to modulate the communication quality between the two followers and which follower's communication is optimal to modulate first. The intent of this research is to shed light on whether a lead agent should invest in modulating the quality of communication among followers.

1 - On Data-driven Methods for Learning Graphical Models
Somayeh Sojoudi, University of California-Berkeley, 1543 Delaware Street, Berkeley, CA, 94703, United States, sojoudi@berkeley.edu, Salar Fattahi

Learning graphical models from data is of fundamental importance in data science, and has a wide range of applications in neuroscience, social science, biology, computer science and engineering. In this talk, we develop an optimization-based mathematical framework for three purposes: (i) comparing different data-driven methods, (ii) finding the best method from a set of candidates for a given application, and (iii) designing the best model using the selected method by optimizing the tunable parameters of the algorithm. In particular, we show that Graphical Lasso, as a popular learning technique, has a closed-form solution for sparse graphs.

2 - Comparing Machine Learning Models on Data From Wearable Sensors to Model Physical Fatigue Occurrence
Zahra Sedighi, Graduate Research Assistant, Auburn University, 257 S.Gay st, apt 301B, Auburn, AL, 36830, United States, zzs0016@auburn.edu, Fadel Mounir Megahed, Lora Cavuoto

In this paper, we discuss how human physical fatigue can be classified using analytical models. Best subset selection method was used to filter and identify the important features for classification. Then popular machine learning techniques were used for classification. The performance of the proposed methods was evaluated to choose the optimal classifier and prediction model. The results show that the ensemble learning outperformed the other machine learning both in prediction performance and more importantly in feature reduction.

3 - Evaluating Detection Change in a Multivariate Poisson Process
Hossein Najmi, University of North Texas, Denton, TX, United States, hossein.najmi@unt.edu, Robert Pavur

Multivariate control charts have been extensively studied to signal an out-of-control process. In this study, a root transformation method on multi-attribute processes that follow a multivariate Poisson process is explored so that as to detect a change in the process using control limits. This methodology is evaluated using a simulation experiment in which a relatively stable process has a change point. Correlated quality characteristics are generated and the time of a step-change are approximated in the simulation study. The proposed method is designed to estimate the change point and find the cause for a shift in the process more effectively.

4 - Monitoring and Improving Quality via Consumer Comments
William A.Brenneman, Research Fellow, Procter & Gamble, 8700 Mason-Montgomery Road, Cincinnati, OH, 45040, United States, brenneman.wa@pg.com, Alex Gutman

Procter & Gamble (P&G) receives millions of consumer comments each year and requires an efficient data-mining algorithm to identify products with unexpectedly high complaint counts, as these suggest potential quality or safety issues (aka "signals"). This talk will present an overview of P&G's adopted signal detection method, the Multi-Item Gamma Poisson Shrinker (MGPS), an empirical Bayesian method for disproportionality analysis. It will also discuss the application of text mining on consumer comments to find misclassified adverse events and identify fraudulent complaints.

1 - On the Capacity of Information Processing Systems
Kuang Xu, Stanford Graduate School of Business, Stanford, CA, United States, kuangxu@stanford.edu, Laurent Massoulie

We study an information processing system where jobs are to be inspected by a set of experts. Inspections produce noisy results depending on the jobs' hidden labels and the expert types, and an inspection occupies an expert for one time unit. The manager's objective is to assign inspections so as to uncover the jobs' hidden labels, using a minimum number of experts. Our main result is an asymptotically optimal inspection policy as the probability of error tends to zero.

2 - Pivotal Estimation and Confidence Bands for High-dimensional Linear Models with Error-in-variables

Alexandre Belloni, Duke University, Fuqua School of Business, 100 Fuqua Drive, Durham, NC, 27708, United States, abn5@duke.edu, Victor Chernozhukov, Abhishek Kaul, Mathieu Rosenbaum, Alexandre B. Tsybakov

We study high-dimensional linear models with error-in-variables. In addition to the high dimensionality, these models are challenging because of the need to account for measurement errors to avoid non-vanishing biases and its impact on regularization parameters. We propose a new estimator that is pivotal despite of possible heteroskedastic errors. It is defined as the solution of a convex program with second order cone constraints which allows the use of efficient algorithms. We also construct simultaneous confidence regions for the parameters in such models. We show its validity despite of model selection mistakes, and allowing for the number of parameters to be larger than the sample size.

3 - Matrix Completion Has No Spurious Local Minima

Jason Lee, University of Southern California, Los Angeles, CA, United States, jasonlee@marshall.usc.edu

Matrix completion is a fundamental machine learning problem with wide applications in collaborative filtering and recommender systems. Typically, matrix completion are solved by non-convex optimization procedures, which are empirically extremely successful. We prove that the symmetric matrix completion problem has no spurious local minima, meaning all local minima are also global. Thus the matrix completion objective has only saddlepoints an global minima. This is joint work with Rong Ge and Tengyu Ma.

1 - Price Competition in Differentiated Products Markets: When Do Structural Estimation Frameworks Work or Fail?

Chungseung Lee, The University of Texas at Dallas, Richardson, TX, United States, cxl143430@utdallas.edu, Metin Cakanyildirim

We address a conjecture underlying structural estimation frameworks that account for price endogeneity to analyze differentiated products markets. The conjecture claims that the model has a pure strategy Nash equilibrium(NE) and that observed prices constitute the NE. For demand models with a mixture of multinomial logits, we present conditions under which the NE-assumption holds and NE is unique. The price-sensitivity parameters of the demand model differ across products and market segments. Thus, our existence conditions are widely applicable, and yet are milder than those in existing studies. We conclude by discussing the implications of our results for the structural estimation methods.

2 - Exploiting Complementarities in an Online Advertising Supply Chain

Changseung Yoo, The University of Texas at Austin, 2110 Speedway Stop B6500, CBA 5.202, Austin, TX, 78712, United States, csyoo@utexas.edu, Anitesh Barua, Genaro J. Gutierrez

We examine channel structures and pricing models in an online advertising supply chain using a proprietary dataset. We develop analytic as well as structural econometric models that enable us to quantify synergy effects between them. While the extant literature emphasizes choosing between pricing models, we show that using multiple models in concert yields higher overall profitability due to strategic complementarities among the pricing schemes. We then explore the operating implications of the complementarities and their impact on profits and supply chain efficiency, and devise information/profit sharing contracts that boost the supply chain profit towards the benchmark scenario.

3 - Don't Call Us, We'll Call You: An Empirical Study of a Call Center that Offers Automated Callbacks

Vinayak Deshpande, University of North Carolina, Chapel Hill, NC, United States, Vinayak_Deshpande@kenan-flagler.unc.edu, Brett Hathaway, Seyed Emadi

We empirically study the behaviors of callers in a banking call center that offers callers the opportunity to wait offline and receive an automated callback if current waiting times are sufficiently long. Using a structural estimation approach, we model callers' callback decisions. We use the recovered parameters of our model to run a series of counterfactual routing and staffing experiments, which provide managers guidance in determining when to offer automated callbacks.

1 - Framing Effects and the Non-equivalence of Trade-ins and Upgrades: Theory and Evidence

Mahdi Mahmoudzadeh, Georgia Institute of Technology, Scheller College of Business, 800 West Peachtree Street NW, Atlanta, 30308, Georgia, mmahmoudzadeh3@gatech.edu

Manufacturers of durable goods often buy back used products to return them back into remanufacturing systems, and to induce customers to switch to new versions. Trade-ins and upgrades are mechanisms that tie these together through replacement purchases. We provide experimental evidence that, in contrast to the classical theory's view, these mechanisms are not equivalent, and that the framing effect induces consumers to change which prices they anchor to, as their reference points, in arriving at their willingness-to-accept for their used products. We then show how the existence of reference dependence among consumers overturns key predictions of the classical model of trade-ins and upgrades.

2 - The Impact of Environmental Certification on Customer Booking Behavior in Hospitality

Matthew Walsman, Rutgers Business School, 28 Cambridge Dr, Berkeley Heights, NJ, 07922, United States, mwalsman@business.rutgers.edu

There is some evidence that suggests that LEED certification boosts financial performance in the hospitality industry. The reason for this superior performance however, remains unclear. In this study we attempt to answer this question by investigating the behavioral decisions customers make when booking lodging and whether environmental certification influences customer booking decisions.

3 - Relative Performance Transparency: Effects on Sustainable Purchase and Consumption Behavior

Yanchong Zheng, Massachusetts Institute of Technology, Cambridge, MA, United States, yanchong@mit.edu, Ryan Buell, Shwetha P. Mariadassou

We study how transparency into the levels and changes of relative sustainability performance affects consumer behavior. In a series of online consumer choice experiments, we find that in the product purchase domain, transparency into a firm's relative performance levels has a stronger impact on purchase behavior than transparency into the firm's relative changes in performance. In the energy consumption domain, transparency into the consumer's relative changes in performance is more dominant in motivating energy conservation than transparency into the consumer's relative performance levels. We use structural equation models to identify the mechanisms underlying these results.

4 - How Does Precision Affect the Adoption of Energy Efficiency Practices? - Evidence From the Field and Laboratory Data

Suresh Muthulingam, Assistant Professor, The Pennsylvania State University, Smeal College of Business, 460 Business Building, University Park, PA, 16803, United States, suresh@psu.edu, Saurabh Bansal

We investigate whether precision affects the adoption or non-adoption of energy efficiency practices. An econometric analysis of data on energy efficiency recommendations made by the DOE shows that recommendations with precise costs and savings exhibit higher adoption rates than other recommendations. We use three laboratory experiments to isolate the precision effects and to identify the mechanism by which precision affects the adoption decisions. We find that credibility is an important moderator of the precision effect and that the impact of precision is more pronounced with budgetary constraints.

Chair: Jonathan Patrick, University of Ottawa, 55 Laurier Avenue East, Ottawa, ON, K1N 6N5, Canada, patrick@telfer.uottawa.ca

CChair: Antoine Sauré, University of Ottawa, 55 Laurier Avenue East, Ottawa, ON, K1N 6N5, Canada, antoine.saure@telfer.uottawa.ca

1 - Flexible Simulation Platform for Scheduling and Capacity Planning in a Radiotherapy Center

Nadia Lahrichi, Ecole Polytechnique de Montreal, Cp6079 Succ. Centre-Ville, Montreal, QC, H3C3A7, Canada, nadia.lahrichi@polymtl.ca, Yosra El Abed, Louis-Martin Rousseau

The objective of this work is to develop a flexible simulation platform that model several trajectories of patients in a radiotherapy center. Their interactions with resources are detailed and all processes are described. We use two practical cases to evaluate our platform and the literature to evaluate several organisation strategies: scheduling of patients, scheduling of resources and prioritization of tasks.

2 - Setting Patient Wait Time Targets in a Multi-Class Clinical Setting

Vusal Babashov, University of Ottawa, 55 Laurier Ave E, Ottawa, ON, K1N 6N5, Canada, vusal.babashov@uottawa.ca, Antoine Saure, Jonathan Patrick

In Canada, wait time targets for health care services are government-mandated. We believe that in the current setting patients wait longer than needed for no practical benefit to clinics in terms of the efficient use of resources. We aim to develop a methodology for determining the smallest possible wait time target for each patient class as well as to determine optimal regular-hour capacity for a clinic. To the best of our knowledge, this is the first study that attempts to determine appropriate wait time targets and capacity requirements simultaneously in a multi-priority clinical setting.

3 - Capacity Planning for a Network of Community Care Services

Jonathan Patrick, University of Ottawa, 55 Laurier E, Ottawa, ON, K1N 6N5, Canada, patrick@telfer.uottawa.ca

Community services have become increasingly important to health care delivery as people live longer but with chronic disease. We developed a queuing network model with blocking to determine the blocking probabilities within a network of services. We then utilize these to derive an optimal capacity plan through a simulated annealing approach. Results are verified through simulation. Transient behaviour of the system as capacity is adjusted to the optimized allocation is also assessed through simulation.

4 - Improving Access to Radiation Therapy Treatment Through Enhanced Patient Appointment Scheduling

Claire Ma, MSc, British Columbia Cancer Agency, Vancouver, BC, Canada, Claire.Ma@bccancer.bc.ca, Ingeborg Bikker, Nathaniel Horvath, Antoine Sauré, Scott Tyldesley, Aneeta Kassam, Martin L. Puterman

We develop a decision support framework for radiation therapy appointment scheduling consisting of two parts. The first part assigns treatment dates and units to incoming patients, using policies derived from a discounted infinite horizon Markov model. The second part then assigns specific appointment times within each treatment date, using a mixed integer programming model. This framework provides a systematic way of allocating treatment capacity to incoming demand while improving patient satisfaction and service levels in a cost effective manner. The benefits of the proposed approach are evaluated by simulating its performance in a practical scenario based on operational data.

5 - Dynamic Advance Patient Scheduling with Resource Compatibility Restrictions

Antoine Sauré, Assistant Professor, Telfer School of Management, University of Ottawa, 55 Laurier Avenue East, Ottawa, ON, K1N.6N5, Canada, antoine.saure@telfer.uottawa.ca, Ingeborg Bikker, Xiang Claire Ma

We consider an advance patient scheduling problem in which patients require one or multiple appointments with one of several medical resources. We formulate the problem as a discounted infinite-horizon Markov decision process and solve it using approximate dynamic programming techniques. The main purpose of this model is to identify good policies for allocating available service capacity to incoming demand, while reducing patient wait times in a cost-effective manner. The benefits from the proposed method are evaluated by simulating its performance for two practical examples based on data provided by the British Columbia Cancer Agency.

Chair: Waldyn Martinez, Miami University, Oxford, OH, United States, martinwg@miamioh.edu

1 - Learning Travel Times in Traffic Networks under Noisy Observations

Emily A. Meigs, MIT, 70 Pacific Street, Rm 243, Cambridge, MA, 02139, United States, emeigs@mit.edu

We study the effects of unknown congestion based latency functions in road traffic networks on how users act over time. Specifically, we look at the convergence of knowledge under noisy observations in a nonatomic routing game. We characterize under what reasonable conditions and learning models will the users in the system converge to the full information Wardrop equilibrium.

2 - An Analysis of Base Learning Algorithms for Ensembles

Waldyn Martinez, Assistant Professor of Business Analytics, Miami University, 117 Country Club Dr., Oxford, OH, 45056, United States, martinwg@miamioh.edu

Ensembles are hybrid models composed of classifiers generated by a base-learning algorithm. Current available research is very limited in comparing the advantages and disadvantages of using different base-learners. Practitioners in several areas including finance, medical research, marketing, among others use ensembles as predictive models, but are limited to using decision trees as the main base-learning algorithm, given that most commercial packages and open-source software rely on the use of decision trees as ideal base-learners. The proposed research is an extensive comparison of base-learners within the most commonly used ensemble methods.

Flexibility in Manufacturing and Service Operations

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Hoda Bidkhori, University of Pittsburgh, Pittburgh, PA, 15206, United States, bidkhori@pitt.edu

1 - Analysis of Process Flexibility Designs under Disruptions

Erfan Mehmanchi, University of Pittsburgh, 1025 Benedum Hall, 3700 O'Hara Street, Pittsburgh, PA, 15261, United States, ERM83@pitt.edu, Hoda Bidkhori, Oleg A. Prokopyev

We examine the worst-case performance of flexibility designs under demand and supply uncertainties. Supply uncertainty is considered in the form of plant and link disruptions. In particular, we establish results that allow the decision-maker to compare the performance of different designs. We also discuss fragility of various designs that is defined as the impact of disruptions on their performance.

2 - Stability in Multi Professional and Multi Skilled Services

Hoda Bidkhori, University of Pittsburgh, Dept of Industrial Engineering, Pittburgh, PA, 15206, United States, bidkhori@pitt.edu, Sriram Dasu, Reza Ahmadi

Consider a system where we have different types of multi professional skilled workers. Each professional worker can be flexible to do different tasks which require different skills. Training multi skilled professional workers is costly. We first discuss the optimal flexibility and the learning in such system

3 - Fair Implementation of Interruptible Demand Response Programs

Ali Fattahi, UCLA, Los Angeles, CA, United States, ali.fattahi.1@anderson.ucla.edu, Sriram Dasu, Reza Ahmadi

Direct load control programs are very popular among utility companies for curtailing electricity consumption during peak load periods. These programs require that the participating customers reduce their consumption, by a predetermined amount, a few times during a year. We study fairness in the assignment of interruptions to customers.

4 - Service Systems with Dependent Service Times and Patience Times

Chenguang Wu, Northwestern University, Evanston, IL, United States, chenguangwu2013@u.northwestern.edu, Achal Bassamboo, Ohad Perry

Motivated by recent empirical evidence, we consider a large service system in which the patience time of each customer depends on his service requirement. We show even moderate dependence has significant impacts on system performance, so considering the patience and service times to be independent when they are in fact dependent can lead to large errors. Since the dependence renders exact analysis intractable, we employ a stationary fluid approximation that is based on the entire joint distribution of the service and patience times. We propose a novel framework, incorporating fluid model with bivariate dependence orders, to study the impact of the dependence on key performance measures and capacity decisions.

Auctions/Mechanism Design

Contributed Session

Chair: Xi Shan, University of Texas at Dallas, Richardson, TX, United States, xxs130630@utdallas.edu

1 - Multi-dimensional Auctions, Public Contests and the Winner's Curse

Bernardo F. Quiroga, Assistant Professor of Operations Management, Clemson University, College of Business & Behavioral Science, Department of Management, 100 Sirrine Hall, Clemson, SC, 29634, United States, bfquirog@gmail.com

We study the effect of multi-dimensional auction bidding complexity in the presence of common values, where suppliers don't learn their true production cost until after the auction has taken place. The traditional presence of the Winner's Curse, where a winning bid yields a negative profit to the supplier under sealed-bid-first-price auctions, can be allowed to a partial off-set of the "curse" when bidders are contracted on score levels as opposed to price-quality combinations, and are allowed to ex-post adjustments that are score invariant.

2 - Truth and Regret in Online Scheduling

Rad Niazadeh, Postdoctoral Researcher, Stanford University, Palo Alto, CA, United States, rad@cs.cornell.edu, Shuchi Chawla, Nikhil Devanur, Janrdhan Kulkarni

We consider mechanism design for clouds, where a service provider has multiple units of a resource available over time. Selfish clients submit their jobs. The provider's goal is to implement a truthful online mechanism for scheduling jobs so as to maximize the social welfare. Recent work shows that under stochastic setting, there is a single-parameter family of mechanisms that achieves near-optimal social welfare. We show that given any such family of near-optimal online mechanisms, there exists an online mechanism that performs nearly as well as the best of this family. Our mechanism is truthful if the family members are truthful and prompt, and achieves optimal (within constant factors) regret.

3 - Make Your Elusory Supplier Manage Disruption Risk as You Wish

Xi Shan, University of Texas at Dallas, Richardson, TX, United States, xxs130630@utdallas.edu, Suresh P.Sethi, Chenglin Zhang

We consider the problem where one retailer and one supplier face supply chain disruption risk. The supplier has private information of his initial reliability and is able to improve that reliability with a hidden action, which we call an effort. Through the way of mechanism design, we find the contract menu to reveal the supplier's true type and the supplier's effort level that most benefits the retailer. We also show that it is never optimal to let the suppliers be perfect reliable.

Innovative Business Models in Services

Sponsored: Manufacturing & Service Oper Mgmt, Service Operations

Sponsored Session

Chair: Serguei Netessine, University of Pennsylvania, Wharton School, Philadelphia, PA, 138676, United States, netessin@wharton.upenn.edu

1 - Impact of Tabletop Technology on Restaurant Performance

Fangyun Tan, Southern Methodist University, 6212 Bishop Blvd, Dallas, TX, 75275, United States, ttan@cox.smu.edu, Serguei Netessine

We analyze a large data set of transactions in a casual restaurant chain to understand the effect of implementing a tabletop technology on service performance (measured in sales and meal duration). We find the technology directly increases sales and significant reduces the meal duration. These effects are further moderated by customer-oriented, waiter-oriented and restaurant-oriented factors, respectively. We provide insights on how to manage technology in restaurant operations.

2 - Nudging Flexibility of Workforce: Empirical Evidence from Online Cleaning Services Platform

Ekaterina Astashkina, INSEAD, Boulevard de Constance, Fontainebleau, 77305, France, ekaterina.astashkina@insead.edu, Ruslan Momot, Marat Salikhov

This study focuses on platforms that facilitate matching of heterogeneous customers (tasks) with heterogeneous contractors. Centralized platforms (e.g. Uber) rigidly assign contractors to customers, while decentralized platforms (e.g. TaskRabbit) let contractors choose tasks they prefer. We compose the right personalized assortment of tasks that hybrid platforms should offer to its contractors. We build an econometric model of contractors' choice, which we estimate on a proprietary dataset of the cleaning platform (similar to HomeJoy). We then formulate platform's online optimization problem of assortment personalization and identify policies that achieve near-optimal performance.

3 - Platforms and Search Efficiency: Does Size Matter?

Serguei Netessine, University of Pennsylvania, Philadelphia, PA, 138676, United States, netessin@wharton.upenn.edu, Jun Li

Economic theory predicts that thicker/larger market increases matching efficiency. Using a natural experiment with a peer-to-peer housing rental platform we find that larger markets can be less efficient.

Strategy/Strategic Planning

Contributed Session

Chair: Cristina Ruiz Martín, INSISOC, Valladolid, Spain, cruiz@eii.uva.es

1 - The Impact of Common Lenders to Both Sides of the Deal on the Acquisition Premium and the Acquirer's Market Valuation

JaSeung Koo, Associate Professor, Kobe International University, 9-1-6 Koyocho-naka, Higashinada-ku, Kobe, 6580032, Japan, koo.academic@gmail.com

This study investigates cases where both the acquirer and the target firms in M&As use a common lender. Specifically, the study examines the impact of the common lender and the lender's relationships on acquisition premiums and the acquirer's cumulative abnormal returns. The hypotheses are that: 1) a common lender will be negatively associated with the acquisition premium, and 2) with the acquirer's negative abnormal returns; 3) the strength of the relationship and the firms' dependency will result in the acquirer's positive abnormal returns, and 4) higher acquisition premiums. Using regression analyses on M&As in Japan between 1995 and 2012, three out of the four hypotheses were supported.

2 - The Customer-centric Logic of Strategic Firm Behavior

Lalit Manral, Professor, College of Business, University of Central Oklahoma, 100 North University Drive, Thatcher Hall # 224, Edmond, OK, 73034, United States, lmanral@uco.edu

We invoke a customer-centric logic to explain the heterogeneity in firms' demand-side operating expenses. That a variety of such expenses generate future benefits is widely accepted by scholars and practitioners alike. Yet, conceptual and methodological issues preclude a comprehensive understanding of the outcomes of such idiosyncratic expenses in terms of their asset value and thereby contribution to overall firm value.

3 - Flexibility Analysis on a Supply Chain Contract using Markov Process Model

Zhe Yuan, CentraleSupélec, Laboratoire Genie Industriel, CentraleSupélec, Chatenay-Malabry, 92290, France, zhe.yuan@centralesupelec.fr, Chengbin Chu

This research focuses on the quantity flexibility contract encompassing the uncertainty of customers' demands. We propose a Markov chain process for flexible coordinated contract design based on the stochastic demands from the view of a car manufacturer. The objective is to develop the optimal nominal order quantity and variation rate as to minimize the car manufacturer's total cost while hedging against the uncertainty of the demand for raw materials. The necessary stability condition for the inventory level is examined. Simulations are carried out to verify the optimal strategy and to evaluate the relationship of the expected total cost with the variation rate or the nominal quantity ordered.

4 - Impact of Business Intelligence in Organizational Resilience
Cristina Ruiz Martín, PhD Student, INSISOC, Valladolid, Spain, cruiz@eii.uva.es, Felix Villafañez, Adolfo Lopez Paredes, Gabriel Wainer

The aim of this work is to demonstrate that Business Intelligence (BI) is a key issue for organizations to achieve the capabilities and attributes of resilient organizations. In the last century, organizations focused on performance, but in today's changing environment, this is not enough: continued existence has become a key challenge. One of the main areas of Organizational Resilience research is to identify the characteristics of such organizations. BI aims to help organizations to develop sound strategies in order to survive and thrive taking advantage of data analysis. Organizations can benefit from a combined application of BI and Organizational Resilience.

1 - Repair Scheduling using Generalized Additive Models
Grant Lents, United Technologies Research Center, 411 Silver Lane, East Hartford, CT, 06108, United States, lentsgn@utrc.utc.com

This work focuses on the scheduling of repairs for parts in a repair organization with multiple sites using machine learning techniques. The goal is to predict an ordinal score for each part based on the stage in which the part is between receiving and shipping and how close the part is to its promised turnaround time. The relationship between the score and explanatory variables was non-linear and a Generalized Additive Model (GAM) was fit to the data across all sites. In the second stage, a 2D assignment algorithm was used to group the sites and assign one GAM model to a group of sites. Our work provided site managers with a interpretable tool for consistent scheduling of the repairs for their parts.

2 - Evaluating and Selecting Data Center Fire Protection System with Analytical Hierarchy Process
Xiaojun (Gene) Shan, University of Houston-Clear Lake, Houston, TX, United States, shan@uhcl.edu, Noel S. Ellis

Fire protection systems are critical in protecting data center assets. This paper applies analytical hierarchy process (AHP) to evaluation and selection of a fire protection system for a data center. Expert opinions from multiple data center professionals was used to select the most favorable fire protection system. The selection alternatives were chosen from options that are accepted by the Life Safety Code of the National Fire Protection Association (NFPA). Results show that pre-action water sprinkler system is the preferred fire protection system. This study provides insights for data center managers in constructing new data centers or renovating of existing ones.

3 - Environmental, Health, and Safety Department Reorganization and Prioritization: using Analytical Hierarchy Process to Mitigate Scope Creep
Xiaojun (Gene) Shan, University of Houston-Clear Lake, Houston, TX, United States, shan@uhcl.edu, William Barton

Personnel changes often create a void in experience and knowledge of client processes, decreasing efficiency of client-oriented organizations. The objective of this paper is to demonstrate the use of analytical hierarchy process to establish core priorities of personnel tasks. This is novel to the industry because it allows users to prioritize daily tasks and to recalibrate priorities annually. Examples are given on how to use this tool to prioritize tasks, as the company goals and daily tasks change. The structure of the reorganized department centralizes tasks and reduces duplication. This framework is illustrated with a case study of an Environmental Health and Safety (EHS) department.

4 - Optimal Number of Choices in Rating Contexts
Sam Ganzfried, Assistant Professor, Florida International University, Miami, FL, United States, sam.ganzfried@gmail.com

In many settings people give numerical scores to entities from a small discrete set, e.g., attractiveness from 1-5 on dating sites and papers from 1-10 for conferences. We study the problem of understanding when using a different number of options is optimal. We study several natural processes for score generation. One may expect that using more options always improves performance, but we show that this is not the case, and that using fewer choices—even just two—can surprisingly be optimal. Our results suggest that using fewer options than typical could be optimal in certain situations. This would have many potential applications, as settings requiring entities to be ranked by humans are ubiquitous.

5 - Decision Making under Uncertainty
Srinivasa Prasanna, IIIT-Bangalore, 26/C, Hosur Road, Electronics City, Opposite Infosys Technologies, Bangalore, 560100, India, gnsprasanna@iiitb.ac.in, Abhilasha Aswal

In this presentation, we explore a novel framework for systematically analyzing alternative assumptions about uncertainty and for finding robust strategies under deep uncertainty. We present a tractable robust optimization approach where we model uncertainty as polyhedral sets that can be generated from historical data. This representation of uncertain data models has economic meaning and is intuitive to a decision maker, especially in applications like supply chains, finance, transportation etc.

6 - Is it Worth Fighting a Patent Troll? using the Constrained Rationality Framework to Model and Analyze the Showdown Between RIM and NTP, as an Example
Majed Al-Shawa, Strategic Actions, Waterloo, ON, Canada, malshawa@strategic-actions.com

The RIM vs. NTP holds many features of a classical strategic business conflict that real product innovators found themselves facing. We use Constrained Rationality, a formal value-driven strategic decision and conflict analysis framework with robust multi-agent decision support approach to: model the RIM vs. NTP strategic conflict; analyze the players options and strategies including the possible cooperation between RIM and NTP to settle, and the possible coalitions between NTP and RIM's competitors; and then elicit the most stable equilibrium end states of this conflict, and similar ones. We, finally, compare the produced stability and coalition analysis with how the conflict actually ended.

Managing Capacity and Demand to Improve Efficiency in Healthcare Delivery

Sponsored: Manufacturing & Service Oper Mgmt, Healthcare Operations

Sponsored Session

Chair: Jonathan Helm, Indiana University, Bloomington, IN, 47405, United States, helmj@indiana.edu

1 - The Use of Teletriage in Healthcare Demand Management
Ozden Cakici, American University, 4400 Massachusetts Ave, Washington, DC, 20016, United States, cakici@american.edu, Alex Mills

Teletriage (TT) is offered by many healthcare providers to help patients get advice over the phone. This decision support should benefit patients and improve demand management in healthcare, but TT is not widely used despite a growing push for telemedicine. We use an MDP to model a patient's choice of providers during an illness episode where the illness severity is partially observable to the patient and when teletriage is subject to errors. Allowing TT may improve the patients' outcomes and reduce the rate of arrivals to the emergency department. We extend our analysis to patients who are gain seekers and loss averse. Interestingly, these patients may actually be better off without the option to use TT.

2 - Online Appointment Scheduling Problem with a Rolling Horizon Approach
Esmaeil Keyvanshokooh, University of Michigan, Ann Arbor, 2144 Glencoe Hills Drive, Apt 9, Ann Arbor, MI, 48108-1020, United States, keyvan@umich.edu, Cong Shi, Mark P. Van Oyen

We study an online appointment scheduling problem in which patients come one by one into a medical center in an online fashion. Upon arrival of each patient, the scheduler should choose both a surgeon and a day over a specific planning horizon without knowing the full information of the subsequent coming patients. We design an online optimization algorithm for this purpose and compute a suitable competitive ratio.

3 - Patient Centered Capacity Planning for Primary Care Appointment Scheduling
Ali Dogru, akdogru@crimson.ua.edu, Sharif Melouk

Motivated by patient-centered medical home principles, we develop a capacity planning model for appointment scheduling. Considering seasonal demand, patient preferences, no-shows, and lateness, we use stochastic optimization to determine the number of service providers and appointment slot durations to minimize unmet demand, patient waiting, and overage time. Experimentation provides managerial insights. Keywords: Capacity Planning, Appointment Scheduling, Stochastic Optimization, Patient-Centered Medical Home

4 - A Sequential Learning and Decision-making Methodology and its Application

Amirhossein Meisami, University of Michigan, Ann Arbor, MI, United States, meisami@umich.edu, Henry Lam, Mark P. Van Oyen

We study a sequential learning and decision-making methodology that integrates robust/stochastic optimization with regression-based prediction. We also study the uncertainty quantification of the resulting decision and optimality level. We discuss applications in digital marketing, patient discharge planning and readmission control.

Performance Measurement

Contributed Session

Chair: Krishna Kalyanam, InfoSciTex Corporation, Dayton, OH, United States, krishnak@ucla.edu

1 - A New Approach for the Empty Container Repositioning with Uncertainties

Shaorui Zhou, Assistant Professor, Sun Yat-Sen University, 135 Xingang Xi Road, Guangzhou, China, zshaorui@126.com

In this paper, we propose a new hybrid learning algorithm for two-stage stochastic programs for empty container repositioning with uncertainties. This algorithm is a hybrid of a piecewise linear approximation method and a stochastic subgradient method. The piecewise linear functions are updated using stochastic sub-gradient information and sample information on the objective function itself. To achieve global optimum, a projection step implementing the stochastic sub-gradient method is performed to jump from local optimums. This algorithm is proven convergent for general two-stage stochastic programs. Numerical experiments demonstrate that the algorithm has a fast rate of convergence.

2 - Clustering Algorithms in Real-time Risk-averse Portfolio Optimization

Sitki Gulten, Stockton University, School of Business, 101 Vera King Farris Drive, Galloway, NJ, 08205, United States, sitki.gulten@stockton.edu

This study examines the application of risk-averse optimization techniques to high-frequency trading (HFT) in real-time portfolio management. First, I develop efficient clustering methods for scenario tree construction with large scale of returns data. Then, I construct a two-stage stochastic programming problem with conditional measures of risk. Finally, I present an extensive simulation study on both interday and high-frequency intraday real-world data of the methodology.

3 - Sequential Weapon Target Assignment under Error Prone Battle Damage Assessment

Krishna Kalyanam, Sr. Research Scientist, InfoSciTex Corporation, Dayton, OH, 45385, United States, krishnak@ucla.edu, David Casbeer

A single shooter with homogenous weapons engages, sequentially, a collection of targets that may vary in value. Upon firing, the target is either killed or not; there is no partial or cumulative damage. The shooter adopts a shoot-look-shoot strategy, where an error-prone BDA is available at each look. The BDA is a classifier that returns the live or dead status of the target and it is prone to both Type I and II errors. This is a generalization to Manor & Kress (NRL, 1997) wherein only a kill is confirmed with a certain probability. We provide a lower bound on the maximal difference between the probabilities of correctly identifying a killed and live target, such that a greedy shooting strategy is optimal.

Simulation and Optimization

Contributed Session

Chair: Murat Testik, Hacettepe University, Ankara, Turkey, mtestik@hacettepe.edu.tr

1 - Efficient Simulation for Expectations Over the Region Outside a Convex Polytope

Dohyun Ahn, Korea Advanced Institute of Science and Technology, #2111, E2-2, KAIST, 291 Daehak-ro, Yuseong-gu, Daejeon, 34141, Korea, Republic of, dohyun.ahn@kaist.ac.kr, Kyoung-Kuk Kim

We consider the problem of estimating the expectation over the region outside a convex polytope. Such expectation arises in many applications including option pricing, stochastic activity networks, and financial networks. Assuming that random variables follow a multivariate elliptical distribution, we develop a conditional Monte Carlo method and prove its asymptotic efficiencies. We then demonstrate how this method can be applied to the above three examples.

2 - A Multi-agent Based Simulation Model for Pricing Vehicle Routes in the Physical Internet

Long Zheng, University of Louisville, 1407 Nightingale Road, Apt 4, Louisville, KY, 40213, United States, long.zheng@louisville.edu

In vehicle routing under the protocol of Physical Internet (PI), it is a critical decision making problem for carriers to set the price of shipment loads to maximize their revenues. In this study, we propose a multi-agent system structure for the PI-vehicle routing problem (PI-VRP). A multi-agent based simulation model is developed to demonstrate the pricing approach. For inputs of the model, we use real data in a PI-enabled logistics networks. To an end, results of the simulation model are compared with a mathematical pricing approach based on dynamic programming optimization so as to valid our modelling framework.

3 - Optimal Fire Station Relocation to Minimize the Response Time: Case of the City of Kingsville

Rutang Vijaykumar Shah, Texas A&M.University Kingsville, 1100 W. Corral Ave, Apt #14, Kingsville, TX, 78363, United States, rutang.shah@yahoo.com, Joon-Yeoul Oh, Hua Li

It is very critical to response on fire and emergency calls quickly. In cases of fire and emergency call, the average response time in the city of Kingsville is 278 seconds, which is 32 seconds more than the established NFPA standard, 240 seconds. The aim of this research is to reduce the response time by analyzing the data and ARENA simulation models. This research shows that a new location of the fire station can meet the NFPA standard with covering wider area than existing location. The new location is selected using NLP technique. Simulation results shows that the new proposed location provides a less average response time in more areas.Key words: Emergency response time, Fire station relocation, NLP.

4 - Simulation of Out-of-control Process Observations for Evaluating Effectiveness of Phase I Studies

Murat Caner Testik, Hacettepe University, Muhendislik Fakultesi, Endustri Muhendisligi Bolumu, Ankara, 06800, Turkey, mtestik@hacettepe.edu.tr, Christian H. Weiss, Yesim Koca, Ozlem Muge Testik

A Phase I study is an essential component of many statistical process control implementations. At this stage, a reference set of observations is searched for analysis. Accordingly, a Shewhart control chart with trial control limits is often used iteratively for identification of out-of-control observations. This dataset is then used for estimation of unknown parameters. Although this is a common practice recommended in textbooks, here we investigate its effectiveness by simulating different types of out-of-control processes. It is shown that one should be careful in using this approach since many out-of-control process observations may go unnoticed, resulting in poor parameter estimates.

Stochastic Networks and Queueing in Applied Probability II

Sponsored: Applied Probability

Sponsored Session

Chair: Amarjit Budhiraja, University of North Carolina, Chapel Hill, NC, 27599, United States, budhiraj@email.unc.edu

1 - Asymptotically Optimal Control of N-systems with H_2^* Service Times under Many-server Heavy Traffic

Arka P. Ghosh, Iowa State University, Department of Statistics, 3216 Snedecor Hall, Ames, IA, 50011, United States, apghosh@iastate.edu, Keguo Huang

We are seeking an optimal control policy for a "N-system", under the Halfin-Whitt regime. A N-system has two customer classes and two server pools, where servers from one pool can serve both customer classes, while servers from the other pool can only serve one customer class. Also, impatient customers will renege from his queue if the waiting time exceeds his patient time. The service time distribution is only pool-dependent, not class-dependent, and it follows a special case of hyper-exponential distributions, H*2 distribution. A static priority policy is shown to be asymptotically optimal in minimizing the total cost caused by queue length growth and customer abandonment.

2 - Serve the Shortest Queue and Walsh Brownian Motion

Asaf Cohen, University of Michigan, Ann Arbor, MI, 48109, United States, shloshim@gmail.com

Motivated by internet applications, we study a multi-class M/M/1 queueing system under heavy-traffic with heterogeneous customers where priority is given to the shortest queue. Upon arrival, customers are kept in N buffers with infinite capacity in accordance to their classes. At any time instant, the first customer in the nonzero shortest queue is being served. We show that the workload process converges to a Walsh Brownian motion living in the union of the N non-negative coordinate axes in RN. Roughly speaking, this process behaves like a Brownian motion when it is away from 0, and when it reaches 0, it chooses its ray according to a fixed probability measure.

3 - Diffusion Approximations for Load Balancing Mechanisms in Cloud Storage Systems

Eric Friedlander, University of North Carolina at Chapel Hill, Chapel Hill, NC, 27599, United States, ebf2@live.unc.edu

Analysis of large-scale communication networks (e.g. ad hoc wireless networks, cloud computing systems, server networks etc.) is of great practical interest. The massive size of such networks frequently makes direct analysis intractable. Asymptotic approximations using hydrodynamic and diffusion scaling limits provide useful methods for approaching such problems. In this talk, we explore an application of these approximation techniques to a model for load balancing in large, cloud-based, storage systems using Maximum Distance Separable (MDS) codes to improve reliability and retrieval speed. This is joint work with Amarjit Budhiraja.

4 - Taylor-ed DPS: Between Dynamics Programming and Brownian Control Problems

Itai Gurvich, Associate Professor, Cornell University, Cornell Tech, New York, NY, 10025, United States, gurvich@cornell.edu, Junfei Huang, Anton Braverman

We propose an approximation to Dynamic Programs (DP) that is grounded in perturbation techniques that have been recently developed for the performance analysis of queues. These approximations, utilizing the so-called Stein's Method, work directly with the equations that characterize expected performance. This work seeks to move beyond the performance analysis of queues to develop "Taylor-ing" as a structured tool for dynamic optimization.

1 - Modeling Correlated Wind Speeds Through Stochastic Differential Equations

Rafael Zarate-Minano, Associate Professor, University of Castilla-La Mancha, Plaza Manuel Meca 1, Almaden, 13400, Spain, rafael.zarate@uclm.es, Miguel Carrion, Juan Miguel Morales

Decision making tools involving stochastic programming techniques are widely used for the operation of power systems with a significant penetration of wind power. The stochastic nature of the wind speed is usually considered through a set of plausible scenarios generated by means of time series. However, time series have shown limited accuracy to model correlations among wind speeds at different locations. This work analyzes the ability of stochastic differential equations to model correlated wind speeds. Models are constructed and tested on the basis of real-world wind speed measurements.

2 - High Dimensional Linear Regression: Mean Square Error and Phase Transitions

Ilias Zadik, PhD Candidate, MIT, Cambridge, MA, United States, izadik@mit.edu

In this talk we will discuss some new theoretical results on the topic of sparse high dimensional linear regression with Gaussian matrix and noise. In the literature, some remarkable papers by Wainwright and others have established that with enough samples LASSO and other efficient recovery mechanisms can recover the ground truth vector. On the other hand, the information theoretical results on the topic suggest that the vector is recoverable with much fewer samples than the one LASSO needs. We show that recovery of the ground truth vector is indeed possible with much fewer samples than the one LASSO needs and we prove this recovery becomes possible very suddenly as the sample size increases.

3 - Search in Discrete Locations with Two Search Modes

Kyle Y Lin, Naval Postgraduate School, 1411 Cunningham Rd, Monterey, CA, 93943, United States, kylin@nps.edu, Jake Clarkson, Kevin D. Glazebrook

An object is hidden in one of several locations. There are two search modes to search each location. The search time and the detection probability depend on both the location and the search mode. The goal is to minimize the expected total time to find the object. We study structure of the optimal policy, and design heuristic policies that deliver near-optimal performance in our numerical experiments.

4 - Stochastic Models for Optimal Resource Allocation and Scheduling of Biomanufacturing Projects

Yasemin Limon, University of Wisconsin-Madison, Madison, WI, 53706, United States, ylimon@wisc.edu, Ananth Krishnamurthy

We study the resource allocation and scheduling problem common in biomanufacturing operations, where purification projects need to be assigned to scientists with varying skill sets, and projects need to be repeated if the scientist is unable to achieve the desired yield and purity requirements. We develop stochastic models to analyze different resource allocation strategies and their impact on waiting times for projects and total system costs.

5 - Exponential Convergence Rates for Stochastically Ordered Markov Processes with Random Initial Conditions

Julia Romanski, Graduate Student, Massachusetts Institute of Technology, 77 Massachusetts Ave, Bldg. E40-103, Cambridge, MA, 02139, United States, romanski@mit.edu, Saurabh Amin, Patrick Jaillet

In this paper we extend the results of Lund, Meyn, and Tweedie (1996) on exponential convergence rates for stochastically ordered Markov processes to allow for a random initial condition that is also stochastically ordered. We find an explicit exponential convergence rate for an M/M/1 queue beginning in equilibrium and then experiencing a perturbation of its arrival or departure rates. In order to show the convergence bound we also prove a result on hitting times of differences of independent Poisson processes, known as Skellam processes. Finally, we comment on the applicability of our result to other stochastically increasing processes, such as Jackson networks with changing arrival rates.

6 - Detecting Node Propensity Changes in the Dynamic Degree Corrected Stochastic Block Model

Lisha Yu, City University of HongKong, 88 Tat Chee Avenue, Kowloon, Hong Kong, lishayu2-c@my.cityu.edu.hk

Many applications involve dynamic networks which are evolutionary networks with timestamps. Studying the evolution of node propensity over time is significant in exploring and analyzing these networks. In this paper, we propose a multivariate surveillance plan to monitor node propensity in dynamic social networks based on the degree-corrected stochastic block model. The method is flexible enough to detect anomalous nodes that arise from different mechanisms. Experiments on simulated and case study social network data streams demonstrate that our surveillance strategy can efficiently detect node propensity changes in the dynamic degree-corrected stochastic block model.

1 - The Timing of Investment on Market Share and Profitability with Financing Constraints

Kehong Chen, University of Science and Technology of China, Hefei, China, ckh0605@mail.ustc.edu.cn, Xiaohang Yue

Whether to invest in market share that can improve the future demand and thereby raise future profits and reduce the likelihood of bankruptcy is a key concern faced by many startups firms when facing with a financing stress. We first identify under which condition the firm with no capital constraint has the incentive to invest on the market expansion. As a benchmark, we then analyze the investing strategy and operational decision of the firm with constrained financing capital. Given the limited borrowed capital, the firm has to make a trade-off between creating short-term profits from the production to avoid bankruptcy and long-term growth from market size investment.

2 - On Finding Process Capacity

Yang Bo, Assistant Professor, The Chinese University of Hong Kong, New Territory, Hong Kong, boyang1102@gmail.com, Milind Dawande, Woonghee Tim Huh, Ganesh Janakiraman, Mahesh Nagarajan

Recently, Gurvich and Van Mieghem (2015) show that the OM textbook formula to calculate process capacity fails in general. We show that it is hard to compute process capacity exactly and also to approximate it within a reasonable factor. These results are based on a novel characterization, which we establish, of process capacity that relates it to the fractional chromatic number of the associated "collaboration graph". An important implication is that it is unlikely that we can replace the bottleneck formula with a simple but close approximation of process capacity. On the positive side, we show that capacity can be efficiently computed for processes for which the collaboration graph is a perfect graph.

3 - Analyzing the Efficiency and Interactions of Buffer Types for Robust Resource Allocations in Resource-constrained Multi-project Scheduling

Christian Fabig, Research Assistant, Technische Universität Dresden, Münchner Platz 3, Dresden, 01187, Germany, christian.fabig@tu-dresden.de, Thorsten Schmidt

We study the efficiency of buffer types for robust resource allocation under uncertainty. The schedule objective is to minimize the realized Average Project Delay (APD) in a worst-case scenario. We describe which buffer types are proposed in literature, how those buffers are allocated to a multi-project schedule, and how they can be combined efficiently. Therefore, the performance of buffer combinations and sizes with respect to the realized APD is analyzed using experiments on MPSPLib problem instances. Findings reveal that due to buffer interactions there exist efficient combinations, yielding significant performance gains compared to deterministic and single-buffer approaches.

4 - Assembly Line Sequencing using Scaled Process Times

Faisal Alfaiz, Graduate Research Assistant, Oregon State University, Corvallis, OR, United States, alfaizf@oregonstate.edu, Hector Vergara, David S. Kim

Job sequencing on synchronous serial assembly lines is examined when job processing times are not available and are replaced by a ranking on a fixed scale. The scaled job process times are determined by engineers, managers, and operating personnel. Properties of the scaled process times and their effect on throughput and work overload when job sequencing algorithms are utilized is examined.

1 - A Study on the Effects of Supplier Management System on Buyer Firm's Outsourcing Performance : Moderating Effects of Switching Cost

Mi Yeon Lee, Korea University Business School, 408 LG-POSCO.building, Korea University, Anam-ro, Seongbuk-gu, Seoul, 02804, Korea, Republic of, esther2761@naver.com, Jung Dawoon, Park Myungsub

This paper applied multi regression analysis, using 522 data collection in 2013 from Korea Productivity Research Center in general equipments, automotive, shipbuilding, and telecom equipments industries. Using the data, this study intends to empirically discover the effect of the types of Supplier Management System (support system and evaluation system) on the buying firm's performance under different levels of Switching Cost. The results of this study will provide key theoretical and practical insights on the relationship between supplier management system and success of outsourcing.

2 - Selection of Best Online Job Portal in the United States using Analytical Hierarchy Process

Xiaojun (Gene) Shan, University of Houston-Clear Lake, Houston, TX, United States, shan@uhcl.edu, Nikhitha Matta

Job seekers often need focus on one job portal among many alternatives to increase efficiency. This paper develops a framework to select the best online job portal from the perspective of job seekers with analytical hierarchy process. This paper is mainly for the job seekers in the domain of science, engineering, health and management although the framework could be adapted to other types of job seekers. The criteria are quality and performance, efficient search engine, relevant job description, privacy, ease of applying and appropriate features. The paper used Web-HIPRE to apply the framework and found that Indeed is the best one compared to Dice, Zip recruiter, Linkedin, and Glass door.

3 - Meals on Tracks: the Indian Railway Catering Services

Sundaravalli Narayanaswami, Indian Institute of Management Ahmedabad, Wing 15 B, Indian Institute of Management, Vastrapur, Ahmedabad, 380015, India, sundaravallin@iima.ac.in

Indian Railways (IR) is the largest state owned and operated transport services in the World with 7,137 stations, route length of 66,030 kms. and total track of 117,996 kms. The number of passengers carried everyday is 23 Millions with passenger earnings of INR 42190 crores. In this talk, we discuss the scope, social, managerial and administrative challenges of IR catering services operations.

1 - Knowledge Sharing and Learning Among Smallholders in Developing Economies: Incentives and Reward Mechanism

Shihong Xiao, HKUST, Hong Kong, Hong Kong, sxiaoab@connect.ust.hk, Ying-Ju Chen, Christopher S. Tang

In developing economies, smallholders use their knowledge and effort to control their output of high quality crop. To improve farmers' productivity, various advocating knowledge sharing and learning platforms are advocated so that farmers can share with and learn from each other various farming techniques. Putting altruism aside, we examine the economic implications for heterogeneous farmers to share their private farming knowledge voluntarily with other farmers under implicit competition. By analyzing a multi-person sequential game, we provide a plausible reason to explain why knowledge sharing can be beneficial even when each farmer's profit depends on the total output.

2 - Development and Evaluation of Product Architecture for Remanufacturing and Product Service System Synergy

Johnson Adebayo Fadeyi, Graduate Teaching Assistant, Wayne State University, 690 Martin Luther King Jr. Blvd, Apt 2005, Detroit, MI, 48201, United States, kontaktjohnson@gmail.com, Johnson Adebayo Fadeyi, Leslie Monplaisir

Currently, about 80% of manufactured products end as wastes. Product service system (PSS) and remanufacturing are concepts that remedy this problem. In order to enhance the criteria that are essential for successful PSS and remanufacturing, an optimization model is developed to identify viable product architecture from several product alternatives. The implementation yields multiple optimal product configurations. Consequently, multi-criteria decision-making technique is applied, and the sensitivity analyses provide comparative advantages of all viable product configurations. The study provides modular product architecture decision guide to the original equipment manufacturers.

3 - Comparative Analysis of Economic and Environmental Impacts of Online and Conventional Retailing

Arda Yenipazarli, Associate Professor of Operations Management, Georgia Southern University, 2224 College Of Business Administration, Department of Logistics & Supply Chain Mgnt, Statesboro, GA, 30460, United States, ayenipazarli@georgiasouthern.edu

Online shopping is growing fast and claims are made about its positive environmental impact relative to traditional shopping. We study competing retailers that can operate dual channels (bricks and clicks), and examine the implications of the additional Internet outlet for their channel and pricing decisions, and the environment.

4 - Optimal Adoption Strategies of Electric Vehicles in Commercial Fleets

Osman Alp, University of Calgary, Haskayne School of Business, 2500 University Drive, Scurfield Hall 120, Calgary, AB, T2N1N4, Canada, osman.alp@ucalgary.ca, Titi Sari, Tarkan Tan, Maximiliano Udenio

In this talk, we analyze optimal electric vehicle adoption strategies in commercial delivery and distribution fleets to reduce carbon footprint of supply chain operations. We develop a model and solution approach to optimize timing and scale of investments in vehicles and charging infrastructure by explicitly considering potential advancements in charging technology, prospective savings in operating costs and carbon emissions, desired service levels, and long-term sustainability targets. We analyze and compare alternative scenarios under plug-in charging model and battery swap model separately.

5 - A Study on Firms' Response to the Environmental Regulations of the Government

Tae Hyung Kim, KAIST, 85, Hoegi-ro, Seoul, 02455, Korea, Republic of, kth8907@kaist.ac.kr, Bowon Kim

Effective environmental regulation is necessary for both the social and economic aspects, since it provides the foundation for sustainable environment. However, ineffective or excessive regulation often leads to side effects such as corporate fraud or moral hazard of corporate, which brings significant loss in society. Therefore, in this paper, we try to analyze the cause and effect of this phenomenon by using system dynamics simulation method. Based on the simulation result, we will investigate the ways to complement existing environmental regulations.

6 - Operational Transparency and Slow Fashion
Maneesh Reddy Ajjuguttu, Clemson University, 515 Calhoun Dr, Sirrine Hall, Room # 400, Clemson, SC, 29634, United States, majjugu@g.clemson.edu, Aleda Roth

This study addresses the effects of operational transparency on the fashion sector. In particular, we examine the consumer buying behaviors on the emerging movement called "slow fashion". Slow fashion is a strategy that aims to reduce the toxic and non-toxic wastes that accrue through the supply chains, which are causing havoc to the environment.

1 - Data-driven Approaches to Live Market Test Design
Gabrielle Shklovsky, Senior Operations Research Consultant, Revenue Analytics, 300 Galleria Parkway Suite 1900, Atlanta, GA, 30339, United States, GShklovsky@revenueanalytics.com

A live market test of a new pricing strategy or revenue management system is often used to measure the impact of the strategy or system before a full roll out. The success or failure of a market test is highly influenced by its design - what time period is used, what is assigned to test vs control, what metrics are used for evaluation - and these design decisions can be tricky, especially when business or operational constraints prevent full randomization. This talk will demonstrate how statistical simulations can be used to design market tests that increase the likelihood of success by maximizing signal and minimizing noise.

2 - Network Revenue Management in Contractual Setting
Akram Khaleghei, Scotiabank, 40 King's West, Toronto, ON, Canada, Akram.Khaleghei@scotiabank.ca, Mikhail Nediak, Ivan Sergienko

We consider an allocation problem for a collection of limited divisible resources. The decision maker observes booking requests from finite set of clients for different type of products and has to commit resources to generate revenue. Once resources are committed, they have to remain committed until a specified maturity date. Requests arrive randomly over time with an intensity that depends on acceptance/rejection of customer previous requests. We are interested in finding the acceptance policy that maximizes the total expected revenue over a finite time horizon.

3 - Integrated Risk Management in the Airline Industry
David Pyke, University of San Diego School of Business, San Diego, CA, 92110, United States, davidpyke@sandiego.edu, Ruixia Shi, Soheil Sibdari, Wenli Xiao

We study integrated decision making in the airline industry. Most airlines make decisions about hedging fuel cost, capacity, and airfare pricing in a decentralized way. We model the benefits that accrue to a firm that maximizes its profit by integrating these decisions. We study the impact of economic conditions, stochastic market demand, consumer price sensitivity, and stochastic fuel cost on the three decisions.

Topics in Revenue Management and Pricing 2

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Stefanus Jasin, University of Michigan, Ann Arbor, MI, 48105, United States, sjasin@umich.edu

1 - Dynamic Pricing for Hotel Rooms when Customers Request Multiple-day Stays
Yun Fong Lim, Singapore Management University, Lee Kong Chian School of Business, 50 Stamford Road, 04-001, Singapore, 178899, Singapore, yflim@smu.edu.sg, Selvaprabu Nadarajah, Qing Ding

We study the dynamic pricing problem faced by a hotel that maximizes expected revenue from a single type of rooms. Demand for the rooms is stochastic and non-stationary. Our Markov decision process formulation of this problem determines the optimal booking price of rooms (resources) for each individual day, while considering the availability of room capacity throughout the multiple-day stays (products) requested by customers. We develop an approximate linear programming based pricing policy, which outperforms both a fixed-price heuristic and a single-day decomposition approach. Specifically, it generates up to 7% more revenue than the single-day decomposition approach.

2 - Strategic Surge Pricing and Communication on On-demand Service Platforms
Harish Guda, University of Texas-Dallas, 2700 Waterview Parkway, #4424, Richardson, TX, 75080, United States, hxg131530@utdallas.edu, Upender Subramanian

On-demand platforms often rely on the gig-economy, a pool of independent workers who work at their convenience, to serve consumers at short notice. To ensure that workers are at the right locations at the right times, on-demand platforms typically adopt two strategies: sharing market forecasts with workers and surge pricing. We jointly examine both strategies, explicitly accounting for workers' incentives to move between market locations, and the platform's incentive to share market information truthfully. Contrary to conventional wisdom, we show that surge pricing can be profitable for the platform even at a location where supply exceeds demand.

3 - Spatial Pricing and Inventory Allocation
Long He, National University of Singapore, Mochtar Riady Building, BIZ1 8-73, 15 Kent Ridge Drive, Singapore, 119245, Singapore, longhe@nus.edu.sg, T. Tony Ke

We study how an online retailer of multiple products should allocate its product inventories to facilitate spatial price discrimination. We consider two common spatial pricing policies: free on board (FOB) pricing that charges each consumer the exact amount of shipping cost, and uniform delivered (UD) pricing that provides free shipping. From the analysis of a stylized model and numerical experiments of optimization models, we find that compared with UD, FOB pricing yields higher profit—-the average relative profit difference between FOB and UD pricing is about 13%, when the inventory allocation is jointly optimized.

4 - Real-time Dynamic Pricing for Revenue Management with Reusable Resources and Deterministic Service Time Requirements
Yanzhe (Murray) Lei, University of Michigan, Ann Arbor, MI, United States, leiyz@umich.edu, Stefanus Jasin

We study a dynamic pricing problem where a firm faces price-sensitive customers arriving stochastically over time. Each customer consumes one unit of resource for a deterministic amount of time, after which the resource can be immediately used to serve new customers. We develop two heuristic controls and show that both are asymptotically optimal in the regime with large demand and supply. We further generalize both of the heuristic controls to the settings with multiple service types requiring different service times and with advance reservation.

1 - Pricing Network Effects under Noisy Network Information
Ankur Mani, University of Minnesota, 808 Berry Street, Apt 410, Saint Paul, MN, 55114, United States, amani@umn.edu, Jiali Huang

We study the problem of a firm that uses social network information to optimally provide personalized pricing customers based upon their position in the network. We show that in large random networks such discriminative pricing may not have much advantage as compared to uniform pricing and may even underperform when the network is noisy. We propose simple implementable pricing policies with guarantees on expected profit.

2 - A Case for Independent Campaign Management in Online Display Advertising
Amine Allouah, Columbia University, 520 W 122nd Street, Apt24, New York, NY, 10027, United States, mallouah19@gsb.columbia.edu, Omar Besbes

In many auctions, buyers can be represented by an intermediary that manages their bidding process, along with the bidding process of other buyers, leading to some form of collusion. We propose a framework to analyze the implications of such an active/centralized role by intermediaries in a general market.

3 - Revenue Optimization under a Preannounced Dynamic Price Function

Dana Pizarro, University of Chile, Santiago, Chile, danapizarro@gmail.com, Jose Correa, Gustavo Jose Vulcano

We consider a dynamic game between a seller and a single buyer. The seller operates over an infinite time horizon. At the beginning of the horizon the seller commits to a price function p(t) . The buyer arrives according to a general random process, has a private valuation for the item, and decides when to buy in order to maximize his expected utility. The seller's problem is to determine the price function p(t) to maximize her expected revenue. We analyze this dynamic game and provide numerics to show the achievable revenue performance.

4 - Multi-stage Intermediation in Display Advertising

Huseyin Gurkan, Duke University, Fuqua School of Business, PO Box:337, Durham, NC, 27708, United States, hg67@duke.edu, Santiago Balseiro, Ozan Candogan

We consider a setting where an advertiser seeks to acquire an impression from an advertising exchange through a chain of intermediaries, and provide a game theoretic model to study the mechanisms offered by strategic intermediaries when the advertiser's value is private. We characterize the equilibrium of the game among intermediaries within a practically relevant class of mechanisms.

1 - Fairness and Competition in Supply Chains

Chi Xie, The Chinese University of Hong Kong, Hong Kong, cxie@se.cuhk.edu.hk, Jin Qi, Yaozhong Wu

In supply chain transactions, a retailer may exhibit fairness concerns when he compares his own profit with that of the supplier. We consider a supply chain setting where a supplier sells substitutable products through two retailers, each or both of whom have fairness concerns. We analyze how a retailer's fairness concern affects each supply chain member's behavior and performance. Our results show that in contrast to a non-competitive setting the impact of a retailer's fairness on his own performance can be negative.

2 - First Discussion About the Information Sharing of Cost Management in the Horizontal Strategic Alliance under Chinese Business Environment

Zhiduan Xu, Xiamen University, 422 Siming South Road, School of Management, Xiamen, 361005, China, zhiduanx@xmu.edu.cn, Danxia Guo, Yingzi Xiong, Shaoqin Ye

Nowadays, horizontal strategic alliances have become a new form of organizing. The success of horizontal strategic alliance relies on information sharing, especially the area of cost management. In China, the development of horizontal strategic alliances is nascent. The horizontal strategic alliance has its own features and aims. We propose a framework on information sharing in the cost management under a horizontal strategic alliance from the perspectives of partner selecting, the system design of cost management, the protection of private knowledge. This essay cuts into a brand-new field which needs more studies and researches and offers a guide and an introduction to this new research area.

3 - An Empirical Study on Residents' Consciousness of Use of Car-sharing

Di Wang, Tianjin University, Tianjin,China, China, 1317854994@qq.com, daozhi Zhao

The "Internet +" has had a revolutionary impact in all walks of life, especially in travel, the Car-sharing has become the market hot spots. In China's big cities, there are traffic congestion, driving restriction and vehicle purchase restriction and many other conditions. However, because of Car-sharing use environmentally friendly energy, no restrictions of driving restriction and use or return it whenever you like, it solve many travel pain points and bring convenience to residents. This study seeks to empirically identify the intentions toward car-sharing by residents. Propose an integrated model combining the theory of planned behavior to examine the intentions of car-sharing by residents.

4 - Collaboration Networks in Integrated Health Care Delivery: Evidence from Accountable Care Organizations

Yingchao Lan, Ohio State University, 2100 Neil Avenue, Fisher Hall 252C, Columbus, OH, 43210, United States, lan.63@osu.edu, Aravind Chandrasekaran, Daniel Walker

ACOs are collaborative networks of physician practices, hospitals, and other health care providers who voluntarily take joint responsibility for the quality and cost of care for a defined patient population. Previous studies have been inconclusive on the benefits of ACOs due to their ignorance of collaboration structures. In this research, we look at two dimensions of such structures-horizontal and vertical networks. Analyzing three years of data on 2987 hospitals and 394 ACOs, we first find empirical benefits to a hospital's decision to join ACOs. Our study further shows that such benefits are contingent on the ACO structures.

1 - Modeling Individual Fear Factor with Optimal Control in a Disease Dynamic System

Yuyang Chen, PhD Student, Kansas State University, 2061 Rathbone Hall, 1701 D. Platt St., Manhattan, KS, 66502, United States, cyy@ksu.edu, Kaiming Bi, John C.Wu

This research proposes a new, information-transmission-based behavior-switch that applies the individual fear factor (IFF) to describe how information regarding current disease epidemics can cause human behavior change in a disease-dynamic system. This research is a first attempt to mathematically model how an individual's emotions influence behavior. This novel modeling approach shows that information transmission influence individual fear, resulting in a variety of human behaviors and leading to numerous disease consequences.

2 - Comparison of Static Ambulance Location Models

Pieter van den Berg, Rotterdam School of Management, Burgemeester Oudlaan 50, Rotterdam, 3062 PA, Netherlands, vandenberg@rsm.nl, Theresia van Essen

Over the years, several ambulance location models have been discussed in the literature. Most of these models have been further developed to take more complicated situations into account. However, the existing standard models that are often used in case studies have never been compared computationally according to the criteria used in practice. In this paper, we compare several ambulance location models on coverage and response time criteria. In addition to six standard ambulance location models from the literature, we also present four models that balance coverage and average response times.

3 - A Simulation Optimization Approach for Budget Allocation of an Emergency Department using Response Surface Methodology

Maryam Soltanpour Gharibdosuti, Student, Binghamton university, 62 Floral Ave, Apt. 8, Binghamton, NY, 13905, United States, msoltan1@binghamton.edu, Dae Hon Won, Mahboobeh Hejazibakhsh

In this paper, we propose a simulation optimization algorithm to find the best allocation of budget in order to improve the performance of an emergency department (ED). Considering the constraints associated with budgeting, D-optimal design of response surface methodology (RSM) is employed to minimize the total system processing time and queue length for two type of patients namely outpatients and ambulance patients. The proposed simulation model is run to obtain the total processing time of the ED at current staff level. Subsequently, the D-optimal design of RSM is applied to find the best allocation of limited budget to identify the optimum staff level which leads to minimum total time and queue.

4 - A Simulation Optimization on the Hierarchical Health Care Delivery System Patient Flow Based on Multi-fidelity Models

Yunzhe Qiu, Washington University in St. Louis, 1 Brookings Dr., St. Louis, MO, 63130, United States, qiuyunzhe@wustl.edu, Jie Song, Zekun Liu

The imbalanced development among different levels of healthcare facilities in China's urban healthcare system has raised the uneven patient flow distribution. We develop a method integrating the simulation, the multi-objective optimization and the simulation budget allocation together to comprehensively improve the overall system performances by finding the approximate Pareto patient flow distribution in the hierarchical healthcare system. A case study based on the real data shows the recommended Pareto optimal patient flow distribution can improve the overall hierarchical system performances and our methodology is qualified as a quantitative decision tool for decision makers.

Supply Chain, Optimization

Contributed Session

Chair: Chaitanya Kaul, Pennsylvania State University-University Park, State College, PA, United States, csk19@psu.edu

1 - How Cost Learning Effect Affects the Channel Decisions
Fen Lu, Huazhong University of Science and Technology, 1037 Luoyu Road?Hongshan Distri, Wuhan, China, Wuhan, 430074, China, lufen@hust.edu.cn

Based on a supply chain with a manufacturer and a retailer, we construct two-stage Stackelberg game models with a cost-learning effect in different modes (traditional channel mode and dual-channel mode). Backward induction is used to identify the equilibriums of the games. We find that the manufacturer, customers and the whole supply chain always benefit from the cost-learning effect, but the retailer is hurt in the dual-channel mode. Contrast with the traditional channel mode, we find that the optimal production quantity increases and price decreases in the second period in the dual-channel mode.

2 - Aligning the Design of Chemical Multiproduct Batch Plants with the Supply Chain Strategy of the Company
Trijntje Cornelissens, Professor, University of Antwerp, Prinsstraat, 13,, Antwerpen, 2000, Belgium, trijntje.cornelissens@uantwerpen.be

For chemical batch plants, strategic plant design primarily concerns the number, size and connectivity of raw material, production and storage tanks, and is mostly driven by the capital costs of this equipment. However, the production strategy defines how such a plant is operated, e.g. by dedicating tanks to product families and defining campaign modes. According to SCOR, this production strategy must align with the company's supply chain strategy and meet the predefined objectives for asset efficiency, cost effectiveness, reliability, responsiveness and flexibility. The aim of this research is to introduce these objectives into plant design models, and study the impact on the plant layout.

3 - An Improved Mathematical Model for Truck Scheduling in Cross Dock Problems with Dock Repeat Truck Holding Pattern
Maryam Keshtzari, Graduate Part Time Instructor, Texas Tech University, Lubbock, TX, United States, maryam.keshtzari@ttu.edu, Sasan Khorasani

Cross-docking is a material handling and distribution concept.In cross-docking systems, items are transferred directly from receiving dock to shipping dock, i.e. the items will not be stored in a warehouse. In this study, an improved mixed-integer programming model (MILP) is introduced to minimize the makespan of the operations. In fact, the model gives us the best sequence of both inbound and outbound trucks that minimizes total completion time. Furthermore, this model determines the assignment of the items in inbound trucks to outbound trucks. This study endeavors to present a model which is able to solve large scale problems with less computational time compared to the current existing model.

4 - An Agent-based Modelling Approach for Optimizing the Last-mile Logistics Problem
Chaitanya Kaul, Pennsylvania State University-University Park, 1926 Waddle Road, Apartment 3, State College, PA, 16803, United States, csk19@psu.edu, Dan Finke

The last mile logistics refers to the last leg of delivery in a supply-chain transportation network. More transporters and delivery runs required to fulfil the demand and hence make the last-mile logistic a highly inefficient and time-consuming segment of a supply chain. In our work, we present the formulation of the last mile logistics problem, model it as an agent-based optimization problem and solve it using a heuristic approach. In the problem critical entities like transporters, customers, orders etc. are represented and modelled as a community of agents.

1 - Performances of the Supply Chain under Trade Credit with Random Yield
Feng Lin, Xi'an Jiaotong University, Xi'an, China, lfxddz@stu.xjtu.edu.cn, Tao Jia, Y.K., Richard Fung

Previous models always adopt stochastic demand to investigate the optimal solutions of the supply chain under trade credit. However, random yield may lead to the contradiction between supply and demand, and obstruct the integration of material flow and cash flow. Thus, this paper studies the performance of the supply chain under trade credit with random yield. A Stackelberg game model is formulated where the supplier plays the dominated role and determines the wholesale price. And then the retailer announces the order quantity. Via theoretical results, random yield is verified to be negatively associated with the expected profit of the supply chain under trade credit.

2 - Equilibrium Financing in a Supply Chain under Uncertainty Reduction Efforts
Qiang Li, The University of Hong Kong, Hong Kong, liqiang@connect.hku.hk, Lap Keung Chu

We examine a supply chain consisting of one manufacturer and one retailer, in which the retailer is capital-constrained and can be funded either by a competitive bank, or by the supplier in the form of trade credit. We investigate how the financing equilibrium is affected by the demand variability and the cost associated with reducing demand uncertainty.

3 - Equilibrium Decision of Credit Guarantee and Capital Constraint Supply Chain under Different Ordering Patterns
Xiuli He, Associate Professor, UNC-Charlotte, 9201 University City Blvd., Charlotte, NC, 28277, United States, xhe8@uncc.edu

We consider a supply chain with a retailer and a capital-constrained manufacturer. The retailer uses credit guarantee to support manufacturer. We derive optimal production and ordering decisions for make to order and make to stock systems.

4 - Data-driven Raw Material Purchasing under Price Volatility
Christian Mandl, Technical University-Munich, Munich, Germany, Christian.Mandl@tum.de, Stefan Minner

Increasing price volatility at commodity markets requires efficient risk management for commodity-processing firms. We propose a new approach that integrates price prediction and procurement optimization (i.e., contracting decisions) considering real-time causal data like weather and economic indicators. We show that a MILP-based data-driven hedging strategy can lead to significant cost savings for risk-neutral and risk-averse decision makers. However, we observe that the benefit of data-driven optimization strongly depends on model selection. Hence, we additionally combine data-driven optimization with methods from machine learning to increase the out-of-sample performance.

1 - Optimal Selective Maintenance of Networked Systems with Multiple Missions using Approximate Dynamic Programming
Liuquan Li, Tsinghua University, Department of Industrial Engineering, Tsinghua University, Beijing, 100084, China, lq-li16@mails.tsinghua.edu.cn, Chi Zhang

Many industrial and military systems have breaks during performing a sequence of missions, which can be utilized for maintenance to ensure the reliability of accomplishing the following mission. However, only a limited number of system components can be maintained during each break due to the limitation of resources, such as time and manpower. We propose a stochastic dynamic programming to study the maintenance of a networked system with general structures, while performing multiple missions. To deal with its complexity, the approximate dynamic programming (ADP) approach is employed.

2 - Determining Aerospace Electronic System Reliability using Regression Methods and MVO
Lida Haghnegahdar, PhD Student, State University of New York, Schiller, Binghamton, NY, 13905, United States, lhaghne1@binghamton.edu, Yong Wang, Daniel Trembley

The aerospace industry has a long-standing history of embracing new technologies built on predecessor systems of the same function. This research focuses and studies the reliability data of aerospace systems. In this research, three different data sets are considered for analysis by using statistical methods of ridge regression, LASSO, and MVO (Multi-verse optimizer). Ridge regression and LASSO are used to determine trends within the data to enhance prediction of design and component faults. In this paper, we propose the combination of feature selection methods of regression and a meta-heuristic algorithm (MVO) for intelligent optimization.

3 - Fast Replacement or Low Purchase Prices: An Optimal Definition of Line Replaceable Units

Joachim Jacob Arts, Associate Professor, Luxembourg University, P.O. Box 513, Luxembourg, j.j.arts@tue.nl, Joni Driessen, Geert-Jan Van Houtum

When an asset fails, the broken Line Replaceable Unit (LRU) needs to be replaced. A LRU is a collection of parts that is replaced when a part in the LRU fails. A LRU can decrease the costs for replacements, as faster replacements may be possible. On the other hand, the company purchases new LRUs and typically large LRUs are more expensive to purchase. Thus, the objective is to determine an optimal definition of LRUs such that the total costs of purchasing and replacement downtime are minimized. We prove this problem non-linear integer program is NP-hard and provide an efficient column generation algorithm.

1 - Planning Accumulated Employee Vacations under Varying Workload and Contractual Restrictions

Ayyuce Aydemir-Karadag, Asst. Prof., Cankaya University, Eskisehir Yolu 29. km, Mimar Sinan Cd. No. 4, Yukariyurtcu Mh., Etimesgut, Ankara, 06790, Turkey, aykaradag@cankaya.edu.tr, Gonca Yildirim

Accumulation of past years' contractual vacation days is one of the common problems observed in workplaces such as hospitals and banks, where some employees may not be able to use their vacation periods completely due to recurring busy periods, followups required, contractual restrictions on vacation periods, or simply because of the insufficient workforce. We develop an integer programming formulation that will maximize the total usage of contractual vacation days over a year, taking into account realistic vacation restriction policies for associated classes of employees who are eligible to do some tasks grouped according some predetermined criteria.

2 - Affordability Analysis using a Capability Roadmap Optimization Approach

Michael Lehocky, Operations Research Analyst, U.S. Coast Guard Research and Development Center, 1 Chelsea St, New London, CT, 06320, United States, mlehocky@cathward.com

In organizations with acquisition projects supporting the recapitalization of assets that are near or beyond the end of their economic life, extending, deferring or canceling construction could force disproportionate impacts on capabilities, either through reduction in operating capacity or diversion of operating funds from direct support to emergency maintenance or service-life extension. Affordability analysis in these cases should consider total capability roadmap cost rather than just procurement outlays. This study examines an example affordability analysis approach using a capability roadmap optimization of the U. S. Coast Guard's offshore cutter fleet recapitalization.

3 - Modeling for Efficient Assignment of Multiple Demand Zones to Distribution Centers for the Equitable and Effective Distribution of Donated Food

Md Hafizul Islam, North Carolina State University, 111 Lampe Drive, Daniels Hall 373, Raleigh, NC, 27695, United States, mislam5@ncsu.edu, Julie Simmons Ivy

Satisfying hunger of food unsecured people with limited supply is a challenge for the local food bank. Food bank seeks to distribute donated foods equitably so that each county receives food proportional to its demand while minimizing the undistributed food donations. The food bank also wants to identify appropriate distribution branches to maximize the accessibility of the counties to donated food. An assignment and distribution model is developed to minimize the cost of maintaining a user specified cap on the maximum inequity in food distribution.

4 - Designing Sustainable Transportation Policy: Considering Substitution Pattern for Different Vehicle Types

Hyunhong Choi, Seoul National University, 1 Gwanak-ro Gwanak-gu, Seoul, 08826, Korea, Republic of, 010greenday@gmail.com, Yoonmo Koo

Transport sector is being pointed out as one of the main contributors of air pollution problems. To cope with such problems, many countries are employing various type of incentive programs to promote environmentally friendly vehicles such as electric vehicles. However, to design an effective policy, we need to analyze how consumers choose and substitute their vehicles. In this study, we present a model which can capture the substitution patterns of consumers considering which type of vehicle they currently own. Using the model, we can analyze how each type of car owners react to different type of promotion policies. With the results of simulation analysis, we provide some policy implications.

Networks and Graphs

Contributed Session

Chair: Mingxian Zhong, Columbia University, New York, NY, United States, mz2325@columbia.edu

1 - Modeling of the Growing Processes of Connectivity of the Components for Networks Based on Analysis of Coupling Coefficients Changes

Jianjun Lu, Professor, China Agricultural University, Haidian District, 17 Qinghuadong Road, Beijing, 100083, China, ljjun@cau.edu.cn

This paper describes connectivity analysis by using a model of the coupling coefficient change between the components by edge snapping in the network and its applications. When the coupling is formed between the network components, we formulate the synchronization by using edge snapping. As a method of synchronizing analysis in this modeling, we propose the optimization of the connections' relation between the fluctuant constituent units, by optimizing the connection and non-connection of the branches that connect the constituent units. The model is a mechanism of smoothly changing the coupling coefficient according to the second-order fluctuation system with respect to the time delay.

2 - The K-cardinality Assignment Problem Applied for the Analysis of Split Networks

Ivan Belik, Norwegian School of Economics, Helleveien 30, Bergen, 5045, Norway, ivan.belik@nhh.no

In terms of social networks, split graphs correspond to the variety of interpersonal and intergroup relations. We analyze the interaction between cliques (socially strong and trusty groups) and independent sets (fragmented and non-connected groups) as the basic components of any split graph. Based on the semi-Lagrangean relaxation for the k-cardinality assignment problem, we show the way of minimizing socially risky interactions between cliques and independent sets within social networks.

3 - The Influence of Structural Properties of Social Networks on Information Diffusion

Xu Dong, Research Assistant, University of Miami, 1251 Memorial Drive, Coral Gables, FL, 33146, United States, x.dong3@umiami.edu, Nazrul I.Shaikh

The scale and scope of the information diffusion are strongly impacted by the topological properties of the social network on which it takes place. However, the effects of these properties are usually nested and mutually correlated. Using principle component analysis (PCA), we decompose the effect of network topology into several independent structural characteristics, i.e. clustering, cohesiveness, density, etc., and identify the pattern of how they collectively affect certain information diffusion.

4 - Obstructions for Three-coloring and List Three-coloring H-free Graphs

Mingxian Zhong, Columbia University, New York, NY, 10027, United States, mz2325@columbia.edu

A graph G is called H-free (k +1)-vertex-critical if G does not contain H as an induced subgraph and the chromatic number of G is k +1, but every induced proper subgraph of G is k-colorable. We characterize all graphs H for which there are only finitely many H-free 4-vertex-critical graphs. This solves a problem posed by Golovach et al. As a second result, we characterize all graphs H for which there are only finitely many H-free minimal obstructions for list 3-colorbility. This is joint work with M. Chudnovsky, J. Goedgebeur and O. Schaudt.

Supply Chain, Closed Loop

Contributed Session

Chair: Thomas Nowak, Vienna University of Economics and Business, Vienna, Austria, thomas.nowak@wu.ac.at

1 - Managing Closed Loop Supply Chain under Returns and Demand Uncertainty

Ravi Shankar, Indian Institute of Technology Delhi, Vishwakarma Bhawan, Shaheed Jeet Singh Marg, Hauz Khas, New Delhi, 110016, India, ravi1@dms.iitd.ac.in, Sushil Punia

A multi-echelon supply chain comprising a manufacturer producing new products as well as re-manufactured products, and a retailer dealing with multi-products is considered. Using interval programming, a comprehensive decision model under uncertain returns and uncertain demand environment is developed for the optimal acquisitions of products and components. Simple and easy-to-use solution techniques are used instead of complex meta-heuristics.

2 - Optimal Production and Collection Strategies for Hybrid Remanufacturing with Technology Licensing

Yanting Huang, Phd Candidate, Huazhong University of Science and Technology, 1037 Luoyu Road, Wuhan, 430074, China, ythuang4028@hust.edu.cn

This paper investigates a closed-loop supply chain where the manufacturer cooperates with the distributor and the third party under technology licensing to collect and remanufacture used products. We adopt the Stackelberg game to obtain the equilibrium strategies and discuss the impact of remanufacturing ability on chain members' decisions and environmental sustainability. We find that, each chain member can reach the largest profit in the case where remanufacturing activities is undertaken by himself. And a higher remanufacturing ability is beneficial for the environment.

3 - Effects of Modular Designs: A Closed-loop Supply Chain Perspective

Thomas Nowak, Postdoctoral Researcher, Vienna University of Economics and Business, Welthandelsplatz 1, Vienna, 1020, Austria, thomas.nowak@wu.ac.at, Fuminori Toyasaki, Tina B. Wakolbinger

This study analyzes effects of product modularity from a closed-loop supply chain perspective. Based on two optimization models, we explore the effects of supply chain strategies and consumers' attitude towards new or refurbished as well as integral or modular products on a manufacturer's production decision problem. While the first optimization problem considers a company following a reactive strategy with no demand uncertainty but high production costs, the second optimization problem considers a company following an anticipatory strategy with demand uncertainty but lower production costs.

Service Science

Contributed Session

Chair: Yuncheol Kang, Hongik University, Seoul, yckang@hongik.ac.kr

1 - Designing Lean Systems to Improve Government Agencies' Performance

Elizabeth Ayala-Medina, Graduate Student, University of Puerto Rico-Mayagÿez, Mayagüez, Puerto Rico, elizabeth.ayala@upr.edu, Betzabé Rodríguez

Driven by a strong social commitment our institution has evaluated areas of opportunity to collaborate with highly influential sectors such as government agencies. One of the proposed methods for improving agency performance is implementing lean systems that will provide for more efficient services, more satisfied customers, and a sustainable improvement.

2 - Single-commodity Flow-based Formulations and Accelerated Benders Algorithms for the High-multiplicity Asymmetric Traveling Salesman Problem and its Extensions

Maichel M. Aguayo, Universidad de Concepcion, Concepcion, 4030000, Chile, maichelaguayo@udec.cl, Subhash C. Sarin, Hanif Dostmahomed Sherali

We present a single-commodity flow-based formulation for the high-multiplicity asymmetric traveling salesman problem, which is an extension of the asymmetric traveling salesman problem (ATSP) wherein a city can be visited multiple times. We show that even though this formulation is not as tight as the best known formulation for the HMATSP, it is faster and easier to use for direct solution by CPLEX, and can be used to model several variants or extensions of the HMATSP that have not been studied in the literature. Furthermore, we propose effective accelerated Benders algorithms that are demonstrated to solve instances of the HMATSP and its extensions involve up to 1001 cities within an hour of CPU time.

3 - Enabling Online Staff Scheduling Applications: Algorithms and Deployment Strategies for Online Courier Scheduling to Deliver Perishable Foods

Henry Tominaga, Senior Decision Scientist, Grubhub Inc, 1300 Southampton Rd. Apt 186, Benicia, CA, 94510, United States, htominaga@grubhub.com, Dan Wigrizer

We address the less developed area of online algorithms for staff scheduling applications by solving the courier resource planning and real-time management problems required to deliver perishable foods. Our solution involves online estimation to predict near-future courier supply requirements. In addition, we adopt fine-grained schedule adjustment algorithms, automated selection and incentives, and online control algorithms to efficiently adjust courier resources to meet supply requirements, while maximizing financial benefits and convenience for individual couriers.

4 - A Joint Production and Delivery Schedule for a Single-vendor Single-buyer System Over Finite Horizon

Fangzhou Sun, Virginia Tech, 1740 Donlee Dr, Blacksburg, VA, 24060, United States, fangzhou@vt.edu, Subhash Sarin

We address a joint production and delivery scheduling problem in which a single vendor supplies goods to a single buyer over a finite horizon. Vendor's production rate and buyer's demand rate are dynamic and are known in advance. The objective is to determine a production/shipment schedule that minimizes the total cost incurred due to production setup, shipment, and inventory holding (both at vendor and buyer). We first develop an approach to solve the single-period problem with prescribed starting and ending inventory. We, then, embed this approach into a dynamic programming framework for the multi-period problem, and also propose two fast and effective heuristic methods.

5 - Optimizing the Pipeline Scheduling System for Fuels at ENAP

Martin Quinteros, Empresa Nacional del Petroleo, San Jose de la Sierra 50 depto 1202, Lo Barnechea, Santiago, 7710088, Chile, martinq46@gmail.com
Martin Quinteros, University of Chile, Santiago, Chile, martinq46@gmail.com, Andres P. Weintraub, Monique Guignard-Spielberg

In the oil & gas industry the distribution of refined oil products is critical. This work addresses the problem of optimizing the schedule of a multi product pipeline that transports 6 products from the refinery to demand points. The size and contents of each batch injected should consider the arrival times at the demand points and volumes required. Having no physical separation between consecutive batches, in their contact surface they mix and these mixes are collected for reprocessing. In order to minimize the overall operating and reprocessing cost a MIP model decides the scheduling for the ENAP's pipeline achieving successful economical and operational results for Chilean company.

6 - A Futuristic Logistics Service System using Reinforcement Learning and Real-time Route Scheduling

Yuncheol Kang, Assistant Professor, Hongik University, T904 Wausanro-94, Mapo-gu, Seoul, 04066, Korea, Republic of, yckang@hongik.ac.kr, Seokgi Lee

The purpose of this study is to develop a framework for a futuristic logistics service system in which large-scale, on-demand, real-time and just-in-time logistics services are required. For this, we integrate service request control planning using reinforcement learning, and real-time service scheduling algorithm using continuous variable feedback control. Additionally, this logistics service system aims at a green transportation paradigm by minimizing gas emissions of delivery vehicles.

Retail and Service Analytics

Sponsored: Service Science

Sponsored Session

Chair: Paul R. Messinger, University of Alberta, Edmonton, AB, T6G 2R6, Canada, paul.messinger@ualberta.ca

1 - The Analytics of Product Return Episodes in Retailing

Paul R. Messinger, University of Alberta, Faculty of Business, 3-20e Faculty Of Business Bldg, Edmonton, AB, T6G 2R6, Canada, paul.messinger@ualberta.ca, Michele Samorani, Aydin Alptekinoglu

We analyze product returns as part of a search process: Upon returning a product, customers may immediately purchase an alternative one, which they may later replace with another product, and so on, until they either ultimately keep their last purchase (Keep outcome) or not (No-keep outcome). We call such a sequence of transactions a product return episode. In this work, we study customer keep and return abuse behavior using episodic metrics. We show that analysis of product returns with episodic metrics provides insights that differ from, and go beyond, analyses with transactional metrics.

2 - Efficiency and Risk in Airport Security Processes – A Queueing Analysis Approach

Mehmet Aydemir, Carnegie Mellon University, Pittsburgh, PA, United States, maydemir@andrew.cmu.edu, Alexandre Jacquillat

As recently as last year, waiting times at security queues in airports hit record high of 3 hours, causing many flights to be missed. Due to budget constraints quick and safe response to this tumult was not possible for the authorities. In this study, we aim to look for design and operational improvements of airport security queues.

Multicriteria Decision Making

Contributed Session

Chair: Jawad Hassan, Kuwait University, Kuwait City, Kuwait, j.hassan@ku.edu.kw

1 - Green New Products Investment Based on Consumer's Utility
Xiaojun Lu, Xi'an Jiaotong University, Xi'an, China, looxiaojun@163.com, Jun Lin

This paper explores whether a firm should invest in the new green product to improve their product line based on the direct and spillover utility of green products for consumers, and how the consumers' utilities affect the green product investment and pricing. The results show that with the increase of consumers' green attentions, the firm should invest in green product; without spillover effect, consumers' direct utility will affect the optimal decision. The firm will use low-priced green product to maximize profits when the direct effect is large enough, otherwise with a high-priced green product to maximize profits; when considering spillover effect, the firm will use high-priced green product.

2 - Blockbusters of Video Games: Pricing and Quality Decisions in Two-stage Launch of Triple a Games
Gulver Karamemis, University of Rhode Island, 7 Lippitt Rd. 207 Ballentine Hall, Kingston, RI, 02881, United States, gkaramemis@uri.edu, Yuwen Chen, Hee Yoon Kwon

In video gaming industry, AAA games are considered to have the highest development costs offering different quality levels in the beta version and launch version of the product. We investigate the developer's pricing and quality decisions in the two-stage launch of the product.

3 - Decision Optimization on the Cloud
Sebastien Lannez, Principal Engineer, FICO, Birmingham, United Kingdom, sebastienlannez@fico.com

With FICO Decision Optimizer a strategy analyst can graphically define and optimize decision problems. The interactions between decisions and constrained metrics enables a simple visualization of the assignment of actions to customers, such as investment options or transaction authorizations. The availability of the software within a cloud based environment allows for simple integration into complex IT environments, and offers the ability to exchange and process large amounts of data using sampling and segmentation.

4 - Managing Software Product Innovations Through Versioning
Ishwar K.Murthy, Professor, Indian Institute of Management, 103NF Block IIM.Campus, Bannerghatta Road., Bangalore, 560076, India, ishwar@iimb.ernet.in, Giri Kumar Tayi

In this research we examine the issue of introducing a new software product into the market. First, we examine a monopoly situation, wherein the firm considers the option of versioning the new product, simply to learn the market potential. This typically entails an initial period of 'learning' followed by value extraction. The question is how to learn about the market potential through versioning. We present a dynamic programming framework to determine the optimal timing of when to introduce which versions. We examine the same problem in the presence of competition.

5 - Excel Based Tool for Interactive Optimization Models
Anthony Downward, University of Auckland, Level 3, 70 Symonds Street, Auckland CBD, Auckland, 1024, New Zealand, a.downward@auckland.ac.nz

In this talk we will demonstrate a new tool for creating interactive optimization problems in Excel using Javascript.

We will show examples of scheduling and routing applications utilizing the SolverStudio modelling framework for Excel.

6 - Integrated Parameter and Tolerance Designs with Manufacturing and Marketing Considerations
Jawad Hassan, Assistant Professor, Kuwait University, Kuwait City, Kuwait, j.hassan@ku.edu.kw, M. Jeya Chandra

Parameter and tolerance designs are major components of product design and development. Existing models for product design from each of the two fields of manufacturing and marketing lack the required rigor in assessing the other field's input to their models. Generally, pricing and market dynamics are not included in most of the models found in the manufacturing literature while product quality is overly simplified in many of the models found in the marketing literature. In this study, new integrated parameter and tolerance designs models are proposed that bridge the gap between manufacturing and marketing design considerations and decisions.

Large-scale Network Modeling and Simulation

Sponsored: TSL, Urban Transportation

Sponsored Session

Chair: Ehsan Jafari, University of Texas, Hart Lane, Austin, TX, 78731, United States, ejafari@utexas.edu

1 - Network Design Problem: A Decentralized Approach
Cesar Yahia, University of Texas, Austin, TX, 78731, United States, cesaryahia@utexas.edu, Ehsan Jafari, Stephen Boyles

We develop a decentralized algorithm for the transportation network design problem, based on a spatial partition of the network. In the master problem, a regional agent decides the funding allocation between subnetworks, and the subproblems are network design problems for each subnetwork. We develop a solution algorithm based on a sensitivity-analysis heuristic, and test it on two different networks. In addition to computational advantages, the proposed algorithm can be used to model the interactions between different entities with potentially conflicting objectives.

2 - Network Partitioning Algorithms to Reduce Computation Time for Parallel Traffic Assignment Problems
Cesar Yahia, University of Texas at Austin, Austin, TX, United States, cesaryahia@utexas.edu, Venktesh Pandey, Ehsan Jafari, Stepehn Boyles

Recent methods in the literature to parallelize the traffic assignment problem consider partitioning the network into subnetworks to reduce the computation time for large-scale networks. We propose several network partitioning algorithms which consider the impact of number of subnetworks and the choice of subnetwork boundary on the computation time. Our analysis compares the performance of proposed algorithms on different large-scale networks and makes recommendations on developing appropriate network partitions.

3 - Improving Incidence Responses on Large Network using Simulated Optimization Methods
Shanjiang Zhu, George Mason University, Nguyen Engineering Building, Suite 1300, 4400 University Drive Ms 6c1, Fairfax, VA, 22030, United States, szhu3@gmu.edu

Traffic incidents are a major cause of urban transportation congestion. Many incident response strategies, including opening of shoulder lanes, rerouting traffic through variable message signs, adjusting ramp metering rate, have been considered in the research and in practice. However, it is a challenge to efficiently identify the best incident response strategies among a large number of strategy combinations. This study combines the simulation-based optimization method and traffic simulation models to reduce the searching space and to efficiently identify the best response strategies.

Optimization, Heuristic Programming

Contributed Session

1 - Resilient Design and Operation of Offgrid Microgrids with Generation Uncertainty
Sreenath Chalil Madathil, Clemson University, 324 Village Walk Ln, Clemson, SC, 29631, United States, schalil@g.clemson.edu, Harsha Nagarajan, Russell Bent, Scott J. Mason, Sandra D. Eksioglu

As demand for more renewable energy resources increases in remote communities to reduce carbon footprint, we focus on the design of reliable and cost-efficient offgrid microgrids. We consider the inherent uncertainty in wind and solar power generation. To address these uncertainties, we develop a stochastic model with N-1 security to analyze this challenging problem. We propose two decomposition algorithms and present experimental results using both the benchmark IEEE 13 node network and a real microgrid case study from Alaska. Our results demonstrate the efficacy of our rolling horizon approach.

2 - A Decomposition Method for Convex Optimization Problems the Bienstock Zuckerberg Algorithm Revisited
Renaud Pierre Chicoisne, Visiting Professor, University of Colorado denver, 1201 Larimer Street, Academic Building, Office AB1-4122, Denver, CO, 80204, United States, renaud.chicoisne@gmail.com

In this talk, we will briefly introduce the Bienstock-Zuckerberg algorithm as it originally appeared for open pit mining scheduling problems. We then discuss its equivalence with a specialized column generation scheme and how its framework can be generalized to solve convex optimization problems. We illustrate this generalization with a resource constrained nonlinear objective routing problem.

3 - An Incremental Quasi-Newton Method with Local Superlinear Convergence Rate

Aryan Mokhtari, University of Pennsylvania, Penn Engineering, 220 South 33rd Street, Philadelphia, PA, 19104, United States, aryanm@seas.upenn.edu, Mark Eisen, Alejandro Ribeiro

We present an incremental Broyden-Fletcher-Goldfarb-Shanno (BFGS) method as a quasi-Newton algorithm with a cyclically iterative update scheme for solving large-scale optimization problems. The proposed incremental quasi-Newton (IQN) algorithm reduces computational cost relative to traditional quasi-Newton methods by restricting the update to a single function per iteration and relative to incremental second-order methods by removing the need to compute the inverse of the Hessian. A local superlinear convergence rate is established and a strong improvement is shown over first order methods numerically for a set of common large-scale optimization problems.

4 - A Heuristic Algorithm for Solving Toll Optimization Problems

Stan Uryasev, University of Florida-Gainesville, Gainesville, FL, 32611, United States, uryasev@ufl.edu, Viacheslav Kalashnikov, Vladik Kreinovich, Jose G. Flores-Muniz, Nataliya I. Kalashnykova

The problem of assigning optimal tolls to the arcs of a multi-commodity transportation network is formulated as a bilevel mathematical program. We describe an algorithm based on the allowable ranges to stay optimal (ARSO) resulting from sensitivity analysis applied to the lower level problem. In this way, one can analyze possible changes in the coefficients of some variables in the objective function within these allowed ranges without affecting the optimal solution. In addition, when stuck to a local maximum solution, the "filled function" technique helps one "jump" to another local maximum (if such does exist) or stop the search. Numerical experiments confirm the robustness of our heuristics.

5 - On the Stability of Distributed Gradient-based Consensus Methods under Communication Delays

Thinh Doan, University of Illinois, 1308 W Main Street, Urbana, IL, 61801, United States, ttdoan2@illinois.edu, Carolyn L.Beck, Rayadurgam Srikant

Motivated by applications in machine learning, we study distributed algorithms for optimization problems defined over a network of processors. The objective function is composed of a sum of local functions where each function is known by only one processor. We study here the convergence rate of a popular distributed gradient algorithm in the presence of network delays, which has been identified as a significant open problem. Our main contribution is to show that convergence occurs at rate O(exp(a)ln(t)/sqrt(t)) where a is the uniform delay between processors. We also provide a lower bound to show that the exponential dependence on delay is inevitable.

1 - A Three Stage Stochastic Programming Model for Managing EV Charging Stations During Major Power Disruption

Mohannad Kabli, Mississippi State University, 21 Crenshaw Lane, Apt. 10, Starkville, MS, 39759, United States, mrk297@msstate.edu, Mohammad Marufuzzaman

This study considers the planning and management of charging stations when major disruptions in the power system occur. A three-stage stochastic programming model is presented, where the first-stage decides which charging stations to install and expand power supply units and renewable energy sources. Then, when the disruption occurs in the second-stage, repairs in power system and charging stations take place ahead of the arrival of "panicked" population. Finally, as demand is unveiled, managerial and operational decisions at the charging stations are made in the third-stage. We have used the infrastructure of Washington DC as a testing ground to validate our proposed optimization model.

2 - Memory-efficient Kernel Methods in Online Settings

Alec Koppel, U.S. Army Research Laboratory, 2800 Powder Mill Rd., Adelphi, MD, 20783, United States, aekoppel314@gmail.com, Garrett Warnell, Ethan Stump, Alejandro Ribeiro

Popular perception is that kernel methods do not scale to streaming data due to an intractable growth in the amount of storage they require. To solve this problem in a memory-affordable way, we consider functional stochastic gradient descent in tandem with supervised sparsification based on greedy function subspace projections. The method, parsimonious online learning with kernels (POLK), provides a controllable tradeoff between its solution accuracy and memory requirements. We establish almost sure convergence of POLK as well as bound its memory requirements. We evaluate POLK for several learning tasks, and demonstrate a state of the art trade off between test accuracy and sample complexity.

3 - On using Markov Chance-decision Processes in Stochastic Programming

Sudarshan Rajan, Texas A&M.University, College Station, TX, United States, srajan@tamu.edu, Natarajan Gautam

We explore the use of Markov chance-decision process algorithms to solve certain Markov decision processes by analyzing the merits and demerits from a computation and accuracy standpoint. Further, we use the approach in the second stage of two-stage stochastic programs and evaluate its performance.

4 - Reconfigurable Optimization

Prateek Raj Srivastava, PhD Student, University of Texas at Austin, 204 East Dean Keeton Street, Engineering Training Center I I.(ETC), Austin, TX, 78712, United States, prateekrs@utexas.edu, Nedialko Dimitrov, David L. Alderson

We develop a modeling framework for a class of optimization problems in which operational decisions need to be altered as a system transitions stochastically between states of the world. Our framework addresses the multi-objective problem of minimizing reconfiguration costs associated with changing the operational decisions and ensuring good quality solutions in each individual state. We compare and contrast this framework with existing modeling frameworks like Markov decision processes, stochastic programming, and robust optimization.

5 - Optimal Selection from a Sequence of Relatively Best Objects

Mitsushi Tamaki, Professor, Aichi University, Hiraike, Nakamura, Nagoya, 453-8777, Japan, tamaki@vega.aichi-u.ac.jp

A known number n of rankable objects appear sequentially in random order. An object is called a candidate if it is relatively best and we are allowed to choose one candidate. The payoff is a(k) if we choose the kth last candidate, k=1, 2, n. We wish to find a selection rule which maximizes the expected payoff. A generalization to multiple choices is also made.

6 - Stochastic Optimization for Deep Neural Networks

Adams Wei Yu, PhD Student, Carnegie Mellon University, Pittsburgh, PA, 15213, United States, adamsyuwei@gmail.com

In this paper, we introduce an efficient stochastic optimization algorithm to train deep neural network.

1 - Joint Optimization of Production Scheduling and Condition-based Maintenance Planning

Bram de Jonge, Dr., University of Groningen, P.O. Box 800, 9700 AV, Groningen, Netherlands, b.de.jonge@rug.nl

We consider the joint optimization of production scheduling and condition-based maintenance planning for a single machine that is subject to deterioration and that needs to process incoming jobs of various lengths. We formulate the problem as a Markov decision process (MDP) and determine optimal policies that indicate when to process which job and when to perform maintenance. We provide insights on how production scheduling and maintenance planning interact.

2 - Condition-based Maintenance Policies under the Gamma Degradation Process

David Han, University of Texas at San Antonio, Management Science & Statistics, College of Business, San Antonio, TX, 8249-0632, United States, david.han@utsa.edu

Condition-based maintenance is an effective method to reduce unexpected failures as well as the O&M costs. This talk discusses the condition-based maintenance policy with optimal inspection points under the gamma degradation process. A random effect parameter is used to account for population heterogeneities and its distribution is continuously updated at each inspection epoch. The observed degradation level along with the system age is utilized for making the optimal maintenance decision, and the structure of the optimal policy is examined.

3 - Reliability and Economic Analysis of IP Cameras with Shielding Devices

Rodolfo Lozano, Texas A&M.University-Kingsville, Kingsville, TX, United States, rudylozanoiv@gmail.com, Hua Li, Kai Jin, Yue Zhang

The utilization of sophisticated outdoor IP surveillance cameras has led to significant increases in waste electrical and electronic equipment (WEEE) due to the degradation associated with direct insolation, thermal cycling and inclement exposure. This study seeks to apply a patent pending shielding device to IP cameras in a school district to attain the difference of operating temperatures between shielded and unshielded IP cameras. The failure rates of the hardware elements related to temperature are derived to conduct a reliability study. The results from reliability studies are used to investigate the economic benefits associated with installing the shielding devices.

4 - Multi-objective Optimization Model for Designing Reliable Networks

Seyedmohsen Hosseini, University of Southern Mississippi, 730 East Beach Boulevard, Long Beach, MS, 39560, United States, mohsen.hosseini@usm.edu

Network design problem (NDP) is a well-known combinatorial NP-hard which involves selecting a subset of network edges with respect to different objectives such as maximizing the network reliability and/or minimizing the network cost. This work presents a multi-objective optimization model to solve NDP. An adapted Non-dominated sorting genetic algorithm is proposed to deal with complexity of NDP. An illustrative example is worked out to illustrate the performance of proposed algorithm.

5 - ALT with Hyperbolically Changing Stress Durations under Cost Constraint

David Han, University of Texas at San Antonio, Management Science & Statistics, College of Business, San Antonio, TX, 78249-0632, United States, david.han@utsa.edu

When designing ALT, several variables such as the allocation proportions and stress durations must be determined carefully because of constrained resources. This talk discusses the optimal decision variables based on the popular optimality criteria under the constraint that the total cost does not exceed a pre-specified budget. A general scale family of distributions is considered to accommodate different lifetime models for flexible modeling with hyperbolically decreasing stress durations.

6 - Joint Optimal Pricing and Two Dimensional Warranty Policy for New Products in a Dynamic Market

Jinfu Zhang, Tsinghua University, RM.413 BLDG 14#, Tsinghua University, Beijing, 100084, China, zhangjf16@mails.tsinghua.edu.cn, Chi Zhang

Warranty can be used to promote sales of a product, but may incur high servicing cost. An optimal warranty policy that can well balance the two is thus desired. Considering that customers usually use the same type of products under different usage rates, we seek to design a two-dimensional warranty policy that takes both the covering time length and customer usage into account. The revenue earned by selling a product is also influenced by its price. Thus, we propose a model to jointly optimize a product's price, warranty length and usage for maximizing the total profit in a dynamic market.

Contributed Session

1 - Impacts of Consumer Awareness, Government Penalty and Retailer's Responsibility on Upstream Pollution in a Supply Chain

Jeong Eun Sim, Korea Advanced Institute of Science and Technology, KAIST Business School, 85 Hoegiro Dongdaemoon, Seoul, Korea, Republic of, jesim@kaist.ac.kr, Bowon Kim

We study the impact of diverse stakeholders that may influence manufacturer's polluting emission in a supply chain. Specifically, we examine which one between the two key forces, i.e., consumers' environmental awareness and government penalty, is more effective in reducing pollution and whether they are substitutes or complements. Furthermore, we investigate the effect of retailer's environmental responsibility on the upstream pollution. To this end, four differential game models are developed depending on consumer awareness and supply chain strategy.

2 - Tax or Subsidy? An Analysis of Environmental Policies in Supply Chains

Xuan Zhao, Associate Professor, Wilfrid Laurier University, 877 Creekside Dr., Waterloo, ON, N2V. 2S7, Canada, xzhao@wlu.ca, Junsong Bian

This paper investigates the impacts of two environmental policies: pollution abatement subsidy and pollution emission tax, to a government-manufacturer-retailers supply chain, where the manufacturer invests in a pollution abatement technology.

3 - Characterizing the Association Between U.S. Domestic Water Consumption Patterns over 2005-2010 and Socioeconomic Factors

David Yang, Winston Churchill High School, 13430 Bissel Lane, Potomac, MD, 20854, United States, david121yang@yahoo.com, Roshanak Nateghi

Water consumption sustainability is a major national and global issue. Analyzing the United States Geological Survey (USGS) data shows that after a long period of steady increase in domestic water use, there was a decrease from 2005 to 2010, despite increased population. In this research, we focused on domestic water use per capita in 2005 and 2010 and found California, Nebraska, Nevada and Texas had the largest decrease. We leveraged statistical learning methods to identify socioeconomic factors that may influence domestic water use. Our analysis indicated that land area, household size and age of houses built are key factors in characterizing change of domestic water consumption.

Project Management

Contributed Session

Chair: Yongcheng Fu, The University of Manchester, Manchester, United Kingdom, yongcheng.fu@postgrad.mbs.ac.uk

1 - Parents' Management Control Over International Joint Ventures for Overseas Infrastructure Investment

Leijie Han, Tianjin University, 92 Weijin Road, Tianjin, China 300072, Tianjin, 300072, China, sherry_hlj@163.com, Shuibo Zhang

We examine how goal incongruence between international joint venture (IJV) parents and task interdependence between parents and IJVs affect parents' investment in management control mechanisms: behavior, output and clan. We then explore the balance of control investment and residual risk under environmental uncertainty. The results from an empirical research show positive relationships between all these control mechanisms and goal incongruence, while only behavior and clan control are positively related to task interdependence. Besides, environmental uncertainty weakens the relationships related to behavior and output control, but enhances the relationships related to clan control.

2 - The Importance of Project Management to Drive Competitive Advantage in Data Analytics and Research Organizations

Mou Dutta, Strategic Analytics Leader, Genpact, 29 Hoyt Street, Stamford, CT, 06905, United States, drimjhim36@gmail.com

Data analytics is transforming the business end to end with smart intelligent insights challenging the conventional thought process and enabling the leaders to optimize their business strategy. While analytical methodologies have been widely used in traditional project management arena of agile software industry, the growing importance of managing the scope creep and implementation uncertainty calls for a robust project management framework for successful deployment of analytics engagements. This paper discusses the challenges in analytics operations posed by complex business environments and how effective project management can drive competitive advantage and strategic value chain.

3 - Early Termination Compensation under Demand Uncertainty in Public-private Partnership Projects

Jinbo Song, Professor, Dalian University of Technology, Dalian, 116024, China, songjinbo@dlut.edu.cn, Yanzhu Yu, Lulu Jin, Zhuo Feng

In the early termination of public-private partnership (PPP) projects, compensation is considered a core issue that greatly affects the interests of both the government and private sector. To address the early termination that is frequently caused by government default or voluntary buyback, this paper proposes an ex-ante compensation mechanism by using the cumulative probability that a given demand could be realized to determine the early termination compensation under demand uncertainty. The proposed compensation mechanism hopefully avoids time-consuming negotiations and high ex-post costs and provides a win-win outcome for both parties to manage the early termination of PPP projects.

4 - Addressing Project Complexity: the Role of Contractual Functions

Nan Gao, Tianjin University, TIanjin, China, gona1219@126.com, Yongqiang Chen

Project complexity leads to transaction risks in interorganizational exchanges and can negatively affect performance if appropriate governance mechanisms are absent. Though the contract prevails in construction projects to address transaction risks, its role in coping with complexity-related risk has not yet been fully investigated. Empirical results in this paper show that contractual coordination can deal with risks induced by technical, organizational and environmental complexity, while the adaptation function can address environmental complexity-related risk. However, contractual control is ineffective when either technical or environmental complexity is high.

5 - Collective Choice Impact on Organizational Performance: Why Do Megaprojects (Seem to) Fail?

Yongcheng Fu, The University of Manchester, Manchester, United Kingdom, yongcheng.fu@postgrad.mbs.ac.uk, Nuno Gil

This study investigates the impact of collective choice on organizational performance. Our empirical motivation is a long-standing puzzle about the root causes of the performance slippages which are endemic to megaprojects. By piecing together organizational structure and performance data for the life-cycle of three megaprojects, we show that: i) cost escalation is positively correlated with the disputes endemic to the growth of a pluralistic actor-network throughout planning; and ii) cost hikes are negatively correlated with the growth of a buyer-supplier network throughout implementation. A recurrent neural network was further developed to predict cost.

6 - Designing under Pluralism: the Value of Slack to Reconcile Private Interests in Collective Choices

Yongcheng Fu, The University of Manchester, Manchester, United Kingdom, yongcheng.fu@postgrad.mbs.ac.uk, Nuno Gil

This study develops a theoretical perspective on how slack resources affect value creation in 'pluralistic' product developments—settings where the project promoter shares decision-making authority over design choice with multiple autonomous actors with differing subgoals. We argue that, under some circumstances, the slack carried by the promoter enables to reconcile differing private interests, but the actual use of slack rarely benefits all participants alike. We illustrate this tension by drawing on data for a new railway network, High-Speed 2 in the UK. We further derive formal boundary conditions for creating and distributing collective value using a game theoretic representation.

Business Applications

Contributed Session

Chair: Haidar Almohri, Wayne State University, Ann Arbor, MI, United States, almohrih@yahoo.com

1 - Practical Applications of Predictive Models

Suchitra Veera, Strategy and Analytics Consultant, Snayu Inc, 4512 Dartmoore Lane, Colleyville, TX, 76034, United States, suchitra.veera@gmail.com

The objective of this session is to present the topic of the practical applications of predictive model and to help the audience understand the use of predictive models in business and management. The presentation will discuss the use of predictive models in Finance, Human Resources, Marketing and Finance. It will allow attendees to take away ideas about the use of predictive models in business and how this is facilitated through the increasing availability of data through many different sources.

2 - Identifying Sources of Assignable Error via Process Pattern Mining

Bhupesh Shetty, PhD Candidate, University of Iowa, 707 Oakcrest Street, Apt E, Iowa City, IA, 52246, United States, bhupesh-shetty@uiowa.edu, Nick Street, Jeffrey W. Ohlmann

We apply pattern mining techniques to event logs generated by a manufacturing process in order to identify the root causes of product defects. We use an association-based method algorithm to generate the frequent patterns and then use correlation measures to identify the patterns of interest. For a varying levels of target pattern complexity, we compare the effectiveness of correlation measures for varying sample sizes with and without knowledge of the underlying process map.

3 - Busting the Bracket Toward an in Depth Predictive Analysis of College Mens Basketball Tournaments

Jie Tao, Assistant Professor in Information Systems, Fairfield University, 1073 N.Benson Rd, 100 Silliman St APT1A, Fairfield, CT, 06824, United States, jtao@fairfield.edu, Michael Mitchell, Kanlun Wang

The NCAA Division I basketball tournament attracts significant attention each year. In this study, we aim at developing models to predict outcomes of tournament games. Compared to previous studies, our results rely solely on the matchups rather than any pre-established rating systems. The contribution of this study is tri-fold: we develop predictive models for the tournament - yielding satisfactory results; we also select several predictors for developing a new rating system; lastly, we use unsupervised learning to investigate how erroneous predictions would reveal stochastic factors in predictive results. Our findings can be applied to other related scenarios such as elections and polls.

4 - A Data Driven Analysis on Automotive Dealership Management

Haidar Almohri, PhD Candidate, Wayne State University, 2833 Catalpa Circle, Ann Arbor, MI, 48108, United States, almohrih@yahoo.com, Ratna Babu Chinnam, Mark Colosimo

Automotive dealership management is challenging in that they have to run their business for producing profit, while keeping the OEM happy with selling new vehicles. In this work, a deep data-driven study and analysis for dealership management is performed to find the key driving factors for different departments in a dealership. The model-based clustering and recommendation methodology developed seeks to maximize the dealer profit while satisfying sales targets from the OEM.

Behavioral Operations

Contributed Session

Chair: Julie Niederhoff, Syracuse University, Syracuse, NY, United States, jniederh@syr.edu

1 - Screening Out Biased Managerial Decisions to Interfere with Automatic Store Replenishment

Antti Tenhiala, IE Business School, Calle Maria de Molina 12, piso 5, Madrid, 28006, Spain, antti.tenhiala@ie.edu, Shivom Aggarwal

We study managerial decisions to deviate from automatic store replenishment (ASR) proposals using multi-store data from a European supermarket chain. After controlling for the drivers of this behavior already identified in the existing research (including package sizing, shelf space considerations, product margins, forecast errors, demand seasonality, transit lags, item durability, and others), we find support for the prevalence of the basic decision-making biases of anchoring and demand chasing. We further find that these biases strongly predict unsuccessful replenishment decisions and suggest a way to incorporate a warning system in ASR software to discourage biased decision making.

2 - Experimental Analysis of the Newsvendor Problem with Minimum Order Quantity Contracts

Özge Tüncel, Student, Singapore University of Technology and Design, 8 Somapah Rd, Singapore, 487372, Singapore, tuncel_ozge@mymail.sutd.edu.sg, Niyazi Taneri, Sameer Hasija

Experiments between human suppliers and automated retailers revealed that the cognitive burden associated with MOQ contract is lower and the profits are higher than with either buyback or revenue-sharing contracts. Moreover, when given a choice, subjects tend to pick the MOQ contract more often, and make quicker and better decisions.

3 - An Experimental Study of Fair Transitivity in a Three-tier Supply Chain

Junlin Chen, Associate Professor, Central University of Finance and Economics, 39 South College Road, Haidian District, Beijing, 100081, China, chenjunlin@cufe.edu.cn

We study a three-tier supply chain consisting of a supplier, a manufacturer, and a retailer. We conducted experiments to investigate the sequential bargaining process between tiers, in high and low demand markets. We measure how the underlying three-tier structure influences the profit distribution across the supply chain. We find that the structural issue blocks access to people's social preferences. Most suppliers behave few fairness concerns, and always set a high wholesale price close to the rationally theoretical value. Most manufactures follow a high wholesale price when the received offer is not kind. Our data also show that a high demand market will not promote people to be kind.

4 - How Newsvendors Reduce Cognitive Efforts
Ehsan Elahi, Associate Professor, University of Massachusetts, Boston, 100 Morrissey Blvd, Boston, MA, 02125, United States, ehsan.elahi@umb.edu, Mahdi Malek, Babak Rezaee

We introduce Order Clustering Preference and address supply chain coordination contracts. The effect of framing, free-item, feed-back and individual features (education and nationality) have been examined. Considering clustering tick-sizes and test results, this behavioral bias remains strongly stable. Our concluding remarks address cognitive driver and future studies.

5 - Supply Chain Decision Making under Financial Constraints
Julie Niederhoff, Assistant Professor, Syracuse University, 721 University Avenue, Syracuse, NY, 13244, United States, jniederh@syr.edu, Panos Kouvelis, Wenhui Zhao, Ying Rong

Capital availability creates constraints for decision makers. We consider the role of these constraints on the ordering behavior of decision makers in a behavioral study.

361C

Transportation Modeling with Social Media Data and GIS

Sponsored: TSL, Urban Transportation

Sponsored Session

Chair: Samiul Hasan, University of Central Florida, Orlando, FL, 32816, United States, samiul.hasan@gmail.com

1 - Activity Patterns Exploration and Location Recommendation
Ying Chen, Northwestern University, 600 Foster St, Evanston, IL, 60208, United States, y-chen@northwestern.edu

Location-based Social Networks (LBSN) allow users to check where their friends are and where their friends visited, to search location-tagged content, like notes and photos within their social connections, and to meet others nearby. Using data from two online LBSNs, the aim of this paper is to investigate the relationship between friendship and distance, the possible influence of friendship in travelers' destination choices, and the importance of this factor in choosing a destination.

2 - Joint Inference of User Communities and Interest Patterns in Social Interaction Networks
Arif Mohaimin Sadri, Valparaiso University, 149 Arnold Drive, Apt 12, West Lafayette, IN, 47906, United States, sadri.buet@gmail.com

We present a modeling approach for characterizing social interaction networks by inferring user communities and interests based on social media interactions. We present several pattern inference models: i) Interest pattern model (IPM) captures population level interaction topics, ii) User interest pattern model (UIPM) captures user specific interaction topics, and iii) Community interest pattern model (CIPM) captures both community structures and user interests. We test our methods on Twitter data from Purdue University community and observed the interaction topics and communities related to two big events ,Purdue Day of Giving and Senator Bernie Sanders' visit to Purdue University.

3 - Inferring Tourist Travel Behavior from Location based Social Media Data
Md. Mehedi Hasnat, University of Central Florida, Orlando, FL, United States, hasnat@Knights.ucf.edu

Location based information sharing platforms of social media have made it possible to extract individual activity records in time and space. Growing increase in the use of Twitter have opened a cost-effective and significant data source to track tourists' travel activity. This research proposes a methodology to use geo-tagged tweets in order to infer travel behavior of tourists within Central Florida region of Florida, USA. Two major challenges addressed in this work include identifying tourists from local residents and extracting their most popular destinations in the study region.

4 - Quantifying the Quality of Mobility: Development of a Comprehensive Accessibility Metric
Ambarish Nag, National Renewable Energy Lab (NREL), Golden, CO, United States, Ambarish.Nag@nrel.gov, Josh Sperling, Stan Young, Venu Garikapati

The concept of mobility is difficult to quantify as it is only relevant in relation to the endpoints to be connected. The recent Department of Energy Vehicle Technology program area for Energy Efficient Mobility Systems uses the mantra 'Maximizing Mobility while Minimizing Energy'. Whereas energy is objectively measured, mobility is more difficult to quantify, much less maximize. Traditional transportation engineering which focuses primarily on the National Highway System and associated urban roadways primarily characterizes the efficiency of roadways to carry the designed capacity. Measures like travel time and reliability reflect the relative health of a link on the roadway or set of links.

Environmental Operations

Contributed Session

Chair: Sining Song, Arizona State University, Tempe, AZ, 8, United States, sining.song@asu.edu

1 - The Different Roles of Self-inspections and External Inspections in the Pipeline Industry
Sehwon Kang, University of Minnesota, 321 Nineteenth Avenue South, Suite 3-150, Minneapolis, MN, 55455, United States, kangx584@umn.edu

Operators and government agencies in pipeline industry have striven to reduce incidents through inspections: self-inspections by operators and external inspections by government agencies. Using econometric analysis with data sets from more than 800 pipeline operators, this study examines the differing role of self-inspections and external inspections on future incidents.

2 - Strategic Environmental Quality Investment in a Multi-tier Supply Chain
Ozgen Karaer, Middle East Technical University, Endustri Muhendisligi Bolumu, Inonu Bulvari ODTU, Ankara, 06800, Turkey, okaraer@metu.edu.tr, Pinar Yalcin, Tim Kraft

We study a buyer's strategies to incentivize environmental quality investment in a three-tier supply chain. Environmental quality of the end product depends on the environmental performances of both the tier 1 and the tier 2 supplier. A higher environmental quality produces an increased demand for the end product; and hence for the whole supply chain. In this setting, we compare the effectiveness of delegation vs. full control strategies from the buyer's cost-sharing perspective.

3 - The Future of Indian Aviation Network in the Wake of a Prospective Carbon Tax Regime
Himanshu Rathore, Indian Institute of Management, Rohtak, MDU. Rohtak, 124001, Rohtak, 124001, India, himanshu.rathore13@gmail.com, Shirsendu Nandi

India will be the third largest aviation market in the world by 2020 and has witnessed the world's highest growth rate of 20.3% in 2015-16. The emissions from aviation have been growing exponentially and would double up in the next decade if no actions are taken. EU-ETS has also been pushing for carbon tax on aviation. India is opposing the proposed carbon tax on apprehensions that its growth rate would be inhibited. We test this apprehension by building a mixed possibilistic low carbon integrated hub location model which takes into account the landing and take-off cycle of the aircraft by using M/G/s queuing model. The results deliberate on the impact of prospective carbon tax on aviation network strategy.

4 - Greenhouse Gas Emissions and Supply Chain Spillovers
Sining Song, Arizona State University, Tempe, AZ, United States, sining.song@asu.edu, Yan Dong, Thomas Kull, Craig Carter, Kefeng Xu

Using public secondary data, we empirically investigate the relationship between emissions reduction programs of a firm and the GHG emissions of the firm's supply chain. Our results suggest a supply chain spillover effect of a firm' emissions reduction.

Statistical Methods in Traffic Simulation and Estimation

Sponsored Session

Chair: Yudi Yang, UC Davis, 1420 Lake Boulevard, Apartment 17, Davis, CA, 95616, United States, ydyang@ucdavis.edu

1 - Improvement of Estimation Method of the Nested Logit Model
Siyu Tao, Southwest Jiaotong University, Cheng Du, China, siyu.tao@okstate.edu, Lisha Wang, Qiyuan Peng, Kuniaki Sasaki

Because of the drawbacks of conventional method, nowadays researchers prefer to use discrete model to forecast traffic demand. And nested logit model is widely used on the simulation of discrete model.However, when we use R language to estimate, we have to do step by step. If the logsum terms or t-test values aren't valid, we must establish another structure to estimate again, which makes estimation become burdened. Because if there are n dimensions, then the number of possible structures is n!. This thesis focus on realizing this work automatically by using R language and bootstrap.

2 - Sparse Travel Time Estimation from Streaming Data
Deepthi Mary Dilip, New York University-Abu Dhabi, Abu Dhabi, United Arab Emirates, deepthi.dilip@nyu.edu, Saif Eddin G. Jabari

We address two shortcomings in travel time distribution estimation methods. The first is the determination of the number of modes of the distribution. The second is the use of Gaussian kernels, which can assign positive probabilities to negative travel times. We develop a sparse kernel density estimation technique using asymmetric kernels. Sparsity promotes parsimony and helps avoid the need for a predefined number of mixture components. We present an adaptive approach to infer both the location and the scale parameters of the kernels and we propose a generalization of Gamma kernels.

3 - Analytical Calculation of Travel Time Reliability Indices with Minimal Statistical Data
Marcelo Ricardo Figueroa, Rutgers University, 93 Marvin Lane, Piscataway, NJ, 08854, United States, marcelo.figueroa@rutgers.edu

We present an analytical parametric model to approximate the travel time distribution of vehicles traversing a freeway corridor which experiences random quality of service degradations. Our models are validated by using traffic speed and flow data for a freeway corridor in Milwaukee, Wisconsin coupled with relevant weather events and traffic incidents as the main cause of service degradation. We show how the models can be calibrated using minimal statistical information on traffic conditions. We provide travel time (un)reliability measures for various scenarios illustrating the impact of incident duration, frequency, and degradation level.

4 - Statistical Inference of Travel Demand with Complex Mapping
Yudi Yang, Postdoc Researcher, University of California, Davis, 1420 Lake Boulevard, Apartment 17, Davis, CA, 95616, United States, ydyang@ucdavis.edu, Yueyue Fan, Johannes Royset

We study a novel problem of inferring the joint probability density function (pdf) of O-D demand variables by integrating hard data of observed traffic counts and potential soft information on demand features. Without being restricted by any particular distributional assumption, our moment matching method produces a nonparametric epi-spline density estimate. Based on sampling instead of solving inverse problems, the proposed solution process can be easily paralleled and is computationally tractable when a complex mapping is assumed between trip rates and traffic flow, including those based on optimization and simulation.

Accounting

Contributed Session

Chair: Pei-Cheng Liao, National Taiwan University, No 1 Sec 4 Roosevelt Road, Taipei, 10617, Taiwan, pcliao@ntu.edu.tw

1 - The Usefulness of Forward-looking and Backward-looking Information in the Capital Market
Yue Wang, University of Texas-Austin, 2110 Speedway, Stop B6400, Austin, TX, 78712, United States, yue.wang@mccombs.utexas.edu

We investigate circumstances in which forward-looking or backward-looking financial information is more useful in the capital market. The choice between forward-looking and backward-looking information reflects a tradeoff between "relevancy" and "reliability." We use conference call transcript to analyze the frequency of forward-look and backward-looking sentences, as it provides effective communication and interaction between managers and sell-side analysts. The results will be potentially helpful to regulators and preparers of financial statements who wish to provide useful information to investors.

2 - Official Visits and Corporate Employee Scale
Wang Yanping, doctor, Tongji University, Yangpu District Zhangwu Road NO1 1822, Shanghai, China, wangyanpingchina@163.com

Through the official visit statistics of Fortune 500 global corporations, we find that different from the developed market economy countries, the Chinese officials visit the corporation frequently, forming "Chinese Characteristics" visit phenomenon. As to employment issue, the empirical findings show that Chinese officials are inclined to visit the corporations which can absorb more employees. Chinese official visits can increase the number of employees, especially for employees with college degree or below, thus incurring redundant employee. This relation is much stronger in state-owned enterprises.

3 - The Effect of Top Managers' Regulatory Focus on Firm Behaviors
Jacob Do-Hyung Cha, Seoul National University, Room 313, 58-dong, Seoul National University, Gwanak-gu, 150-742, Korea, Republic of, research.dohyung@gmail.com, Hye-Jin Cho

Individuals pursue goals via either a prevention focus (sensitive to gains and a desire for accomplishment and growth) or a promotion focus (sensitive to losses and a desire for safety and security). This study investigates whether individual managers' such motivational traits are associated with corporate behavior and performance. I use linguistic features to develop a measure of managers' regulatory focus - prevention or promotion foci - from corporate documents, that is, Form 10-K's management discussion and analysis section. The results indicate that managers' regulatory focus affect differently financing choices, investment choices, and firm operating performance.

4 - The Stewardship Role of Conservatism
Pei-Cheng Liao, Professor, National Taiwan University, No 1 Sec 4 Roosevelt Road, Taipei, 10617, Taiwan, pcliao@ntu.edu.tw, Guang Ma, Suresh Radhakrishnan

We consider conservative reporting and investment decisions when the hidden-information problem of unknown manager-types as well as the hidden-action problem of diversion of resources exist. When either the hidden-information problem or the hidden-action problem exists, conservative reporting is not optimal. When both the hidden-information and hidden-action problems exist, conservative reporting is optimal for the high-type manager. Specifically, conservatism as part of the menu targeted for the higher productivity manager mitigates the problem of diversion of resources by the lower productivity manager and thus is part of the steward role of accounting.

362C

Logistics

Contributed Session

Chair: Murat Karatas, University of Texas-Austin, Austin, TX, United States, mkaratas@utexas.edu

1 - Optimization of Supply Chain Tracking Capability under Various Market Contexts
Bin Dai, Professor, Wuhan University, Bayi Road, Wuhan, China, dbbudstar@gmail.com, Yongzhe Zhang

Traceability system has been widely used to alleviate the impact of product recall on supply chain performance, particularly the product recall cost. In this paper, we optimize the supply chain tracking capability under various market contexts such as oligopoly, simutaneouly move competition and sequential move competition, and then the optimal tracking capability and pricing strategies are compared.

2 - Benders Decomposition for Inventory Routing Problem with Perishable Product
Faisal M.Alkaabneh, Cornell University, Stewart Ave, Building 516; Room, Ithaca, NY, 14850, United States, fma34@cornell.edu

In this work we consider a Perishable products Inventory vehicle Routing Problem in the context of Cold supply chain. We explicitly model Green House Gases emissions due to transportation activities depending on the vehicle load during delivery. The problem is modelled as a mixed integer mathematical program that is difficult to solve directly. To this end, we developed a solution methodology based on Benders decomposition. Benders decomposition algorithm convergence rate was accelerated through the addition of valid inequalities and symmetry breaking cuts to the Master Problem, upper bound heuristic, Pareto optimal cuts and trust region.

3 - A Decomposition Heuristic for a Production Routing Problem in Furniture Companies
Pedro Miranda, Federal University of São Carlos, São Carlos, Brazil, pmiranda@dep.ufscar.br, Jean-François Cordeau, Deisemara Ferreira, Raf Jans, Reinaldo Morabito

We propose a decomposition heuristic to solve a production routing problem arising in the context of furniture companies. The heuristic decomposes the problem into two subproblems that are solved iteratively. The first subproblem makes production and distribution decisions using approximations of the routing costs and travel times. The second subproblem determines vehicle routes based on the decisions made by the first subproblem. These routes are used to update the approximations of routing costs and travel times for the next iteration. Computational results show that our iterative approach provides better solutions in less computing times than a state-of-the-art commercial solver.

4 - Multi-warehouse Package Consolidation for Split Order Fulfillment in Online Supermarkets
Yuankai Zhang, Dalian University of Technology, Office Room A1214 Innovation Park Building, Dalian University of Technology No.2 Linggong, Dalian, 116024, China, ykzhang6635@126.com, Xiangpei Hu, Weihua Lin

The split-order fulfillment problem has been a new key issue for multi-item order fulfillment in Chinese online supermarkets. We propose a powerful order fulfillment method - package consolidation - in which two or more stock keeping units in the sub-orders of one order will be packed into fewer packages. We formulate a multi-commodity network flow model to make the package consolidation decisions for split orders between multiple warehouses, and propose a computationally efficient algorithm for solving it.

5 - Joint Location and Inventory Analysis in IoT-based Service Parts Logistics Systems

Murat Karatas, University of Texas-Austin, Austin, TX, 78703, United States, mkaratas@utexas.edu, Erhan Kutanoglu

We investigate a joint location and inventory problem in service parts logistics (SPL) taking advantage of data on equipment condition via Internet of Things (IoT) technology. Continuous condition data may make replacing the parts before failure possible, potentially saving time and money, as opposed to the conventional approach of issuing replacement parts upon failures. We propose a model that captures the optimum balance between increased demand due to parts replaced more frequently and time/cost savings due to non-emergency shipments. Our preliminary results quantify the effects of this tradeoff on location and inventory decisions as well as time-based service levels.

Scheduling

Contributed Session

Chair: Mansoor Shekarian, North Carolina A&T State University, Greensboro, NC, United States, mshekarian@aggies.ncat.edu

1 - Total Earliness and Tardiness in a Two-machine Flowshop

Jeffrey Schaller, Eastern Connecticut State University, 83 Whindham Street, Dept of Business Administration, Willimantic, CT, 06226-2295, United States, schallerj@easternct.edu, Jorge Valente

This paper considers the problem of scheduling jobs in a two-machine permutation flow shop with the objective of minimizing total earliness and tardiness. Unforced idle time is considered in order to reduce the earliness of jobs.

2 - Utility Based Priority Dispatching Rules in Complex Dynamic Job Shops: the Case of Customer Balking

Kevin D.Sweeney, Assistant Professor, Sam Houston State University, Box 2056, Sam Houston State University, Huntsville, TX, 77341, United States, ksweeney@shsu.edu, Stanislaus Solomon, William A. Ellegood

We investigate the performance of utility based priority dispatching rules in a reactive complex job shop environment. In particular, we focus on job shops defined by two characteristics: (1) customers that can potentially balk to an alternative job shop if a certain threshold for service or utility is not met, and (2) job shops characterized by heterogeneous classes of jobs which each receive different amounts of utility from the job shop. Within these job shops, we look at the impact of using different priority dispatching rules under different ratios of utility of heterogeneous classes of jobs, processing times of different classes of jobs, and a range of attractiveness levels of the alternative.

3 - A Decision Model for Two Objective Job Shop Scheduling Problem with Sequence Dependent Setup Times

Mansoor Shekarian, Graduate Student, North Carolina A&T State University, 3100 N Elm St, Apt #22L, Greensboro, NC, 27408, United States, mshekarian@aggies.ncat.edu, Adel Aazami, Mahour Parast

The job shop scheduling problem (JSP) is one of the most difficult problems in traditional scheduling problems. When an operation happens in a machine, it is necessary to consider a sequence-dependent setup time (SDST). This research develops a two-objective model, including minimizing the Makespan and maximum tardiness. The proposed mixed integer nonlinear programming (MINLP) model is converted into a MILP to achieve a globally optimal solution. The -constraint method is used to solve the model. A set of numerical data from a real case study is investigated to show the model's efficiency and flexibility. These results have a great value for managers, especially in a manufacturing industry.

Applications of Facility Logistics - II

Sponsored: TSL, Facility Logistics

Sponsored Session

Chair: Francisco Jose Aldarondo, University of Michigan, 3512 Green Brier Boulevard, Apartment 497C, Ann Arbor, MI, 48105, United States, faldaron@umich.edu

1 - Solving the Quadratic Assignment Problem using Graphics Processing Unit Clusters on the Blue Waters Supercomputer

Rakesh Nagi, U. of Illinois at Urbana-Champaign, Department of Industrial & Enterprise Systems, 117 Transportation Building, MC-238, Urbana, IL, 61801, United States, nagi@illinois.edu, Ketan Date

We discuss parallel implementations of RLT2 formulation and branch-and-bound algorithm for solving the Quadratic Assignment Problem (QAP). Our parallel architecture consists of NVIDIA Graphics Processing Unit (GPU) clusters on the Blue Waters supercomputer at the University of Illinois at Urbana-Champaign. We propose a "distributed" Dual Ascent algorithm for the GPUs, which shows excellent parallel speedup, and can effectively solve some of the well-known QAPs from the literature.

2 - Comparing Two Goods-to-person Order Picking Systems for Online Retailing

Francisco Jose Aldarondo, PhD Candidate, University of Michigan, 3512 Green Brier Boulevard, Apartment 497C, Ann Arbor, MI, 48105, United States, faldaron@umich.edu

Using simulation modeling and an on-line retail setting, we compare the performance of two types of goods-to-person order picking (OP) systems, namely, the Kiva system and the Miniload-AS/RS with a conveyor loop (to connect the pick stations). The two systems are compared on the basis of quantitative factors such as expected throughput (line items picked per hour), expected picker and material handling equipment utilization, and order completion times. We also compare the two systems in terms of qualitative factors that are relevant for OP systems.

3 - An Integrated Supply Chain Design for Additively Manufactured Products

Sudipta Chowdhury, Mississippi State University, 260 McCain Engineering Building, ISE Department, Starkville, MS, 39762, United States, sc2603@msstate.edu, Mohammad Marufuzzaman, Linkan Bian

Despite the promising features of AM technologies, make-or-buy decisions are not straightforward. Moreover, decision regarding the optimal number of layers for the AM product is also an issue that has not been addressed before. Based on the budget or quality requirements, number of layers for the product may vary which affect the supply chain cost. A stochastic model is proposed to quantify both the process and supply-chain level costs associated with the production of AM parts. Two algorithms, i.e., hybrid Sample Average Approximation (SAA) and Progressive Hedging Algorithm (PHA) and hybrid SAA and Adaptive Large Neighborhood search (ALNS) based algorithm are developed to solve the problem.

4 - Solving the Student Assignment and School Bus Routing Problems

Sunderesh S. Heragu, Oklahoma State University, 322 Engineering North, School of Industrial Engineering & Management, Stillwater, OK, 74078, United States, sunderesh.heragu@okstate.edu, Harshwardhan Rathod

In this presentation, we address the assignment of students to bus stops as well as the school bus routing (SBRP) problems. The student assignment problem (SAP) is solved using a specialized branch-and-bound algorithm. The result is provided as input to the SBRP. The latter is solved using a meta heuristic. We then apply both the SAP and SBRP to the Stillwater middle student assignment and school bus routing problems.

Forecasting

Contributed Session

Chair: YoungJun Park, Seoul National University, Seoul, pyjoon90@snu.ac.kr

1 - Predicting Customer Activity by Cumulative Purchase Quantity and Consumption Rate

Huan Yu, PhD candidate, University of Science and Technology of China, Hefei, China, huany@mail.ustc.edu.cn, Yugang Yu, Hanqin Zhang

When analyzing customer activity, usually one assumes that the independence between inter-purchase time, purchase quantity and lifetime. However, many data sets we have collected demonstrate that this independence assumption may not hold. For example, inter-purchase time and purchase quantity may depend on each other through customer consumption rate, and lifetime and inter-purchase time may depend on each other through cumulative purchase quantity. Considering these dependences, we propose a new stochastic model of predicting customer activity. The proposed model can formulate our data sets very well, which cannot be fitted by the existing models that assume the independence assumption.

2 - Conditional Value at Risk as SVR Minimization
Emre Eryigit, Middle East Technical University-Ankara, Ankara, 06800, Turkey, emreryigit@gmail.com, Cem Iyigun, Ozlem Cavus Iyigun

We study Support Vector Regression (SVR) to forecast electricity load in short term. Our algorithm includes Conditional Value at Risk measure and the optimization model behind the forecasting algorithm minimizes the risk measure while minimizing the forecasting result. Our preliminary results are promising in comparison to SVR without risk parameter.

3 - BBQ Time Series and Optimal Control
Joshua Woodruff, University of Texas, 4509 Rio Robles Dr, Austin, TX, 78746, United States, jwoodruff@optimizedfinancialsystems.com, Dragan Djurdjanovic

Cooking truly exemplary Texas pit BBQ requires maintaining the perfect temperature over 8 to 12 hours. Making this type of BBQ in an offset smoker requires constant attention to the wood added, vent openings, and outside temperature. In this session we present a tutorial on time series modeling in R and optimal control using CPLEX.

4 - Forecasting the Automobile Market Equilibrium in Consideration of the Externalities of Transport Sector
YoungJun Park, Seoul National University, Seoul, Korea, Republic of, pyjoon90@snu.ac.kr, HyungBin Moon

Countries are implementing different political measures to manage and alleviate the greenhouse gas emissions from the transportation sector. The present study forecast the automobile market equilibrium by considering the fuel cost and the external cost related to the transportation sector. In particular, the study constructs a linkage among the changes in fuel costs, market shares of different vehicle types, and the external costs to estimate the market equilibrium according to the changes in consumer behavior. Based on the estimation, the study derives the principle rules on how to reflect the external costs of transportation sector that satisfy the goal of greenhouse gas emission reduction.

Finance, Banking and Insurance

Contributed Session

Chair: Aein Khabazian, University of Houston, Houston, TX, United States, akhabazian2@uh.edu

1 - Data Mining and Machine Learning Role in Insurance Business
Xiaoguang Tian, University of North Texas, 1155 Union Circle, Denton, TX, 76203-5017, United States, xiaoguang.tian@unt.edu

The insurance industry is facing unprecedented challenges and opportunities in the data-driven paradigm. The incoming big data and technologies are transforming the traditional insurance business model and pushing the new generation of insurers to rethink their business strategies and then to make better decisions. In this study, the author will discuss challenges that insurance industry is encountering, and review the existing data mining and machine learning techniques that can be applied in insurance management across the business value chain. Two ongoing data mining projects will be introduced by using real-world data.

2 - Bank Risk Assessment using Unstructured Text Disclosures
Xiaodi Zhu, PhD Candidate, Stevens Institute of Technology, Hoboken, NJ, 07030, United States, xzhu@stevens.edu, Aparna Gupta, Steve Yang

Bank risk has become an important focus of financial regulators and investors after the 08-09 financial crisis. Banking sector risks are usually measured by quantitative information from structured financial disclosures. This study analyzes the textual risk disclosures that presumably provide forward looking information about firms' future risks. We extract risk factors from banks' risk disclosures using a sentence based dynamic topic modeling approach. Using data from both FDIC and the SEC, we find significant correlation between the unstructured risk topics and the conventional risk measures. Moreover, we demonstrate the predictive power of risk factors on bank's future risk.

3 - Modeling Psycho-financial Profiles of Italian Bank Customers
Galina Andreeva, Associate Professor, University of Edinburgh, 29 Buccleuch Place, Edinburgh, EH8 9JS, United Kingdom, galina.andreeva@ed.ac.uk, Caterina Liberati

We investigate the relationship between psychometric measures obtained through the survey, personal/demographic and financial characteristics of the account holders of an Italian bank. The main objective of the analysis is to explore the latent structure of different types of variables that the dataset contains via factorial representation. We also detect presence of the natural groups by means of explorative unsupervised classification, and comment on different types of customers' profiles from psychological and financial behavior perspectives.

4 - Assessment and Control of Systemic Risk
Aein Khabazian, University of Houston, 5465 Braesvalley Dr. APT.566, Houston, TX, 77096, United States, akhabazian2@uh.edu, Jiming Peng

In this work, we assess the systemic risk based on the optimization model introduced by Eisenberg and Noe (2001), where only partial information regarding the liability matrix is revealed. We develop an algorithm to identify the most vulnerable structure in the network. Numerical experiments illustrate that the contagious risk in the identified vulnerable network is more significant than what underestimated in the literature. Second, we develop an algorithm to identify the most stable network structure, and use it to develop a strategy for systemic risk mitigation. We evaluate the performance of the new strategy.

Reliability

Contributed Session

Chair: Douglas King, University of Illinois at Urbana-Champaign, Urbana, IL, United States, dmking@illinois.edu

1 - Enforcing Contiguity in Branch and Bound Algorithms to Solve Geographical Districting Problems
Rahul Swamy, PhD Student, University of Illinois at Urbana-Champaign, 205 E.Clark St, Apt 303, Champaign, IL, 61820, United States, rahulswamy91@gmail.com, Sheldon H. Jacobson, Douglas M. King

The class of Geographical Districting Problems has been modeled in the literature as a combinatorial graph partitioning problem. Enforcing contiguity is typically the bottleneck in exact methods, since it is hard to do so without avoiding an exponential set of constraints. We present a method to enforce contiguity using Geo-Graphs in branch and bound algorithms, where the special planar structure of the districting problem is used for improved efficiency. This is done so dynamically while evaluating potential contiguity of partial solutions. Theoretical and computational results are presented.

2 - Practical Mathematical Methods for Political Redistricting and Competitive and Fair Elections
Hsiao-Shen Jacob Tsao, Professor, San Jose State University, 1 Washington Square, San Jose, CA, 95192-0085, United States, jacob.tsao@sjsu.edu, Royce Lin

A reason for the current political polarization in the US is partisan political redistricting or "gerrymandering" for congressional elections. Population equality, contiguity and compactness for any district are required by the Constitution. Political reforms for decreasing partisan influence will not suffice; the commission staff needs software tools to help achieve these requirements and to explore or achieve fair representation, competitiveness, etc. However, the mathematical solution processes produced so far have not been practical for such use. We propose a new approach that is mathematically rigorous, easier for the staff to understand and practical for software implementation.

3 - Scalable Contiguity Assessments in Practical Political Districting
Douglas M.King, University of Illinois at Urbana-Champaign, 117 Transportation Building, 104 S.Mathews Avenue, Urbana, IL, 61801, United States, dmking@illinois.edu, Sheldon H. Jacobson, Edward C. Sewell

Practical political districting involves the creation of contiguous districts from small discrete units. When the number of units is large, ensuring contiguity poses a substantial computational burden. This talk applies scalable contiguity algorithms based on the geo-graph framework to the creation of United States Congressional Districts in four states.

Special Settings of Vehicle Routing Problems

Sponsored: Transportation Science & Logistics

Sponsored Session

Chair: Xiangfei Meng, USC, 2801 Orchard Ave, Apt 10, Los Angeles, CA, 90007, United States, xiangfem@usc.edu

1 - An Adaptive Large Neighborhood Search for Real-world Vehicle Routing Problems
Haoyuan Hu, Zhejiang Cainiao Supply Chain Management Co., Ltd., Hangzhou, China, haoyuan.huhy@cainiao.com, Ying Zhang, Wenjia Ma, Kunpeng Han, Guotao Wu

Along with the rapid growth of online shopping, real-world vehicle routing problems (VRP) arise in city logistics. We propose an adaptive large neighborhood search heuristic for the VRP and some of its realistic variants. Problem specific

destroy/repair operators are designed. We then study a number of real-world problems: the split delivery with multi-dimensional demand, the time-uncritical delivery with T + n possibility, the urban delivery with density consideration and the generalized VRP with multiple available locations for each node. Those tests illustrate its effectiveness and applicability to practical industrial situations, e.g., 20 thousands orders can be solved in 5 minutes.

2 - Traveling Salesman Problems with Multiple-product Mixing

German Paredes-Belmar, Assistant Professor, Universidad Andres Bello, Quillota 980, Viña del Mar, 2390457, Chile, german.paredes@unab.cl, Armin Lüer-Villagra, Vladimir Marianov

The traveling salesman problems with multiple-product mixing are generalizations of the known Traveling salesman problem (TSP), where a set of products needs being transported between depots and customers at minimum cost. Those products can be carried in the same vehicle. The mix of two products can become a third product, which has an impact on the routes and on the objective function (e.g., cost, profit, risk). We propose an integer formulation to solve different instances of TSP with multiple-product mixing.

3 - A Hybrid Algorithm for Class of Vehicle Routing Problems with Loading Constraints

David Alvarez Martinez, Assistant Professor, Universidad de Los Andes-Colombia, Cra 1 No 18A- 12, Bogota, Colombia, d.alvarezm@uniandes.edu.co, Luis Miguel Escobar

In this paper we present a hybrid algorithm for a class of Vehicle Routing Problems with Loading Constraints. The routing problem is solved through sequential Set Partitioning models, the columns correspond to routes found through an ILS algorithm, which can interact with the MIP solution process. It was implemented a reactive GRASP algorithm in order to verify all the packing constraints established and in this way only valid columns are incorporated into the solution process. The algorithm was tested using instances of the following variants: (i) CVRP (ii) 2D Loading Problem and (iii) 3D Loading Problem. The results obtained were quite competitive in comparison with those found by the previous works

4 - Scheduling Periodic Deliveries with Heterogeneous Vehicles and Driver Consistency

Soheyl Zehtabiyan, The University of Alabama, 317 Bidgood Hall, Tuscaloosa, AL, 35401, United States, zehtabiyan@gmail.com, Mesut Yavuz

This study is concerned with minimizing the total fleet cost in a direct-shipment setting with a single supplier and many customers. The customers require perfectly periodic deliveries, as well as a minimally acceptable vehicle type and / or driver consistency. We provide an IP model covering four versions of the problem and devise a constructive heuristic to solve them.

5 - Asymptotic Analysis of the Generalized TSP

Xiangfei Meng, USC, 2801 Orchard Ave, Apt 10, Los Angeles, CA, 90007, United States, xiangfem@usc.edu

In this work, we will analyze the asymptotic behavior on a generalized version of the TSP, which we call the Generalized Travelling Salesman Problem (GTSP), in which the goal is to select one point each from multiple sets of points and come up with a tour with the minimum length. Two different limiting cases are examined: one is the case where the number of point sets goes to infinity, and the other is the case where the number of points in each set goes to infinity. Numerical simulations confirm that our analysis is valid when applied to simulations in the Euclidean plane and on a road network.

Robust and Resilient Facility Location

Sponsored: Transportation Science & Logistics

Sponsored Session

Chair: Mengtong Wang, Tsinghua University, Zhongguancun Street, Beijing, 100084, China, mengtong321@163.com

1 - Secure Transportation in Dangerous Zones

Azar Sadeghnejad Barkousaraie, University at Buffalo, 93 Pepper Tree Dr, Apt 4, Amherst, NY, 14228, United States, azarsade@buffalo.edu

In order to secure transportation of goods and passengers in dangerous areas usage of escort vehicles is sometimes necessary and inevitable. However due to resource limitation the assignment of security vehicles to each transportation unit in a timely manner is not always applicable, it may result in either long waiting time for customers or overusing of resources. In this research we study the effect of resting areas for limited number of escort vehicles to secure the transportation of customers in order to minimize the response time to the transportation units in dangerous areas.

2 - Robust Optimization for Service Network Design and Hub Location Problem under Uncertain Capacities and Demand

Mengtong Wang, Tsinghua University, Zhongguancun Street, Beijing, 231567, China, wmt15@mails.tsinghua.edu.cn

We propose a novel two-stage robust optimization model for the service network design and hub location problem with stochastic capacities and demand, in which a freight operator needs to determine the locations and capacities of hubs, allocation of non-hub nodes to hubs, and the number of vehicles to purchase and rent for multi-modal network with minimum total cost. A two-level cutting plane based method is developed, which includes an algorithm to generate lower bound inequalities in the outer level, and a hybrid algorithm in the inner level. A number of numerical experiments are offered to test the efficiency of the proposed solution algorithm and the robustness of the novel robust mode.

Data Science for Reliability and Quality Assurance

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Mingyang Li, Tampa, FL, 33647, United States, mingyangli@usf.edu

1 - Multi-state Reliability Demonstration Tests

Suiyao Chen, University of South Florida, 4202 E. Fowler Avenue, Tampa, FL, 33620, United States, suiyaochen@mail.usf.edu, Lu Lu, Mingyang Li

Reliability demonstration tests (RDTs) are important reliability assurance activities to ensure product quality over time and safeguard market competitiveness. Conventional binomial RDTs become inadequate to meet diverse reliability requirements of the consumers. This work proposes multi-state RDTs to demonstrate product reliability at multiple time periods or involving multiple failure modes. The design strategies allow the incorporation of prior knowledge to reduce test sample sizes and realize simultaneous demonstration of multiple objectives to ensure customer satisfaction. Two case studies are used to demonstrate the effectiveness of the proposed methods.

2 - Weighted Band Depth for Functional Data Outlier Detection

Xudong Zhang, University of Iowa, Iowa City, IA, United States, xudong-zhang@uiowa.edu, Yuxing Hou, Yong Chen

The use of depth has shown great usefulness in robust analysis of functional data, such as producing robust location estimators of sample curves, or detecting various outliers. In this paper, we focus on using depth for detecting outliers in functional data, which are considered as coming from a different process compared to normal curves. We propose a new depth concept for function data called weighted band depth (WBD), which improves the performance of the band depth proposed in the literature. Numerical studies based on simulated signals and application to a real data example are used to evaluate the performance of proposed depth methods and other existing depth notions.

3 - Projection Based Outlier Detection in Functional Data

Nan Chen, National University of Singapore, Department of Industrial and System Eng, 1 Engineering Drive 2, Singapore, 117576, Singapore, isecn@nus.edu.sg

To detect outliers in functional data, we developed a procedure based on a high-breakdown mean function estimator. The robust estimator is obtained from a clean subset of observations, excluding potential outliers, by minimizing the least trimmed squares of the projection coefficients after functional principal component analysis. A threshold rule is constructed based on the asymptotic distribution of the functional-score-based distance. The thresholding robustly controls the false positive rate and detects outliers effectively. Further power improvement is proposed by adding a one-step reweighting procedure.

4 - Sequential Test Planning for Polymer Composites

Yili Hong, Professor, Virginia Tech, Blacksburg, VA, United States, yilihong@vt.edu, Ichen Lee, Sheng-Tsaing Tseng, Tirthankar Dasgupta

Polymer composite materials are widely used in areas such as aerospace and alternative energy industries, due to their lightweight and comparable levels of strength and endurance. To ensure that the material can last long enough in the field, accelerated cyclic fatigue tests are commonly used to collect data and then make predictions for the field performance. In this paper, we propose a sequential strategy for test planning, and use a Bayesian framework for the sequential model updating. We also use extensive simulations to evaluate the properties of the proposed strategy. Our results show that the proposed strategy is more robust and efficient, as compared to traditional optimum designs.

5 - Spectral Graph Theoretic Sensor-based Monitoring in Laser Powder Bed Fusion Process

Prahalada Rao, rao@unl.edu, Mohammad Montazeri, Brandon Lane, Jarred Heigel

The goal of this work is to monitor the laser powder bed fusion (LPBF) additive manufacturing (AM) process using heterogeneous sensors incorporated inside the machine. This will allow opportune preventive action to avert propagation of build defects across multiple layers. In pursuit of this goal, a commercial LPBF machine was integrated with three types of sensors, namely, a photodetector, high-speed video camera, and SWIR thermal camera with the following objective: to develop and apply a spectral graph theoretic approach to monitor the LPBF build status from the data acquired by the three sensors.

1 - A New Multi-response Optimization Approach using Bayesian Seemingly Unrelated Regression Model

Jianjun Wang, Associate Professor, Nanjing University of Science and Technology, Nanjing, 210094, China, jjwang@njust.edu.cn

This paper presents a new multi-response optimization (MRO) approach integrating a quality loss function with a posterior predictive function in a single framework of Bayesian seemingly unrelated regressions (SUR) modeling and optimization. The proposed approach not only measures the conformance probability through the posterior predictive function, but also takes into account the expected quality loss with the quality loss function. The results show that the proposed approach may give more reasonable results than the existing approaches when both conformance probability and quality loss are important issues.

2 - Hard Failure Prediction with Stochastic Degradation Signals using Wiener Process

Jianing Man, City University of Hong Kong, Dept of SEEM, General office, Room P6600,6/F, AC1,City U. of Hong Kong, Kowloon Tong, Kowloon, Hong Kong, jianinman2-c@my.cityu.edu.hk, Qiang Zhou

Remaining useful life is one of the most important part for the conditional based maintenance (CBM) and prognostics and healthy management (PHM). In this paper, we consider the stochastic process for the degradation path using wiener process to predict the RUL for hard failure, with degradation signals and time-to-event data. The time-to-event data is modeled by the proportional hazards (PH), by considering the stochastic feature of the degradation signals. The simulation studies and a case study are conducted to show the performance of the method.

3 - Introducing Randomness into Control Chart Sampling Strategies to Better Protect Against Cyber-physical Attacks on Production Systems

Lee Wells, Western Michigan University, 2827 Daventry Ave., Portage, MI, 49024, United States, lee.wells@wmich.edu, Ahmed Elhabashy, Bill Woodall, Jaime Camelio

With recent technological advancements, production systems have become more susceptible to cyber-attacks. Such attacks can be designed to both alter product dimensions and avoid detection by current Statistical Process Control tools. This work discusses a novel approach to better detect attacks against manufacturing, which is based upon introducing randomness into control chart sampling strategies. Several different random sampling strategies will be introduced and their performances under varying attack scenarios will be analyzed. In addition, this work will propose new control chart performance metrics for analyzing situations where cyber-physical attacks are possible.

4 - Condition-based Selective Maintenance Optimization for a Large-scale Non-Markovian System

Euihwan Lee, Pohang University of Science and Technology, 77, Cheongam-Ro, Nam-Gu, Pohang, 790-784, Korea, Republic of, euihwan.lee@postech.ac.kr, Young Myoung Ko, Eunshin Byon

We consider selective maintenance that repairs severely degraded units in the system consisting of massive units. Under the assumption that units degrade independently in a finite number of states, we derive a fluid model that approximates the mean behavior of the system's health condition. Our simulation study indicates that even if only a subset of units gets repaired, the system would asymptotically become a regenerative process as the maintenance operations are repeated over time. Based on this observation, we optimize the maintenance scheduling that triggers the maintenance operations based on the fraction of units at each degradation state in order to minimize long-run maintenance costs.

1 - Optimization Based Heuristics for the Graph Partitioning Problem

Ali Hassanzadeh Kalshani, Graduate Student, University of California-Irvine, 1723, Verona Place, Irvine, CA, 92617, United States, ahassan2@uci.edu, Emre Alper Yildirim

The graph partitioning problem is concerned with partitioning the vertices of a graph into a pre-specified number of clusters, so as to minimize the total weight of the edges cut. We use optimization formulations to design two approximation algorithms that can be used in large scale graph partitioning problem. Using valid inequalities and lower bounds play an important role in strengthening the solution of the Linear Programming relaxation of the problem which has been used in these two proposed methods.

2 - Optimal Number of Inspection and Rework Servers for Feed-back Queues in Steel Pipe Manufacturing

Shahriar J. Hossain, Graduate Research Assistant, Louisiana State University, 4141 Burbank Dr. Apt. 3, Baton Rouge, LA, 70808, United States, msjhossain1@gmail.com, Bhaba R. Sarker

This research aims to find the optimum number of inspection and rework servers in a steel pipe manufacturing system. If a repairable defect is detected at the inspection station, the pipe is sent to the rework station, while the reworked pipes are fed back to the inspection station for re-inspection. Thus, two intertwined queues of pipes are generated. The size of queues and number of servers are constrained by the availability of space. The total cost function is formulated as a nonlinear programming problem. The model is solved optimally to minimize the total cost.

3 - Irregular Shape Nesting via Branch and Bound using Custom Relaxations

Akang Wang, Carnegie Mellon University, 5000 Forbes Avenue, Pittsburgh, PA, 15213, United States, akangw@andrew.cmu.edu, Christopher Hanselman, Chrysanthos Gounaris

We present a custom-built linear relaxation and an associated branch-and-bound (BB) approach for solving irregular shape nesting problems to global optimality. We utilize a novel branching scheme based on circle-packing constraints, and we integrate a dynamic circle-adding procedure into our BB implementation, in order to enforce shape non-overlap. We also utilize a domain reduction scheme to speed up our algorithm. Extensive computational studies are performed on benchmark instances.

4 - Lagrangian Relaxation of the Defender Attacker Defender Constrained Shortest Path Problem

Gary Lazzaro, Permanent Military Professor, United States Naval Academy, 1903 Baltimore Annapolis Blvd., Annapolis, MD, 21409, United States, lazzaro@usna.edu, Matt Carlyle

The first application of tri-level Defender Attacker-Defender (DAD) optimization models to the constrained shortest path (CSP) problem. The side constraint in DAD CSP breaks the network structure of a shortest path problem into a challenging tri-level integer program. We create new solution procedures by merging the attacker model with Lagrangian relaxation of the operator model into a single formulation that can obtain fast heuristic solutions. We combine our heuristic algorithm with traditional methods to obtain provably optimal or near-optimal solutions. Our results on medium and large networks show that our innovations can significantly outperform traditional nested decomposition.

5 - Open-source Solvers for Quadratic Assignment and Related Problems

Matthew J. Saltzman, Associate Professor, Clemson University, Dept of Mathematical Sciences, Martin Hall Box 340975, Clemson, SC, 29634-0975, United States, mjs@clemson.edu, Peter M. Hahn, Amir Roth, Monique Guignard

A recent COIN-OR poject makes available exact solvers for the QAP and related problems of increasing interest, with wide application, and for which exact solution is very challenging. These problems address economic issues in the location and design of factories, hospitals, depots, transportation hubs and military bases.Our exact solvers produce strong bounds using Adams-Sherali RLT and include techniques to speed up branching and fathoming of search trees. We describe these codes and suggest a taxonomy and framework for combining existing methods and computer tools that can be modified and extended to make inroads in solving this growing class of optimization problems.

1 - Exact Multiple Sequence Alignment by Synchronized Multivalued Decision Diagrams

Amin Hosseininasab, Tepper School of Business, 5562 Hobart St, Apt 605, Pittsburgh, PA, 15217, United States, aminh@andrew.cmu.edu, Willem-Jan Van Hoeve

We study an exact solution method for the Multiple Sequence Alignment (MSA) problem in computational biology. Our approach uses Multivalued Decision Diagrams (MDD) to model all possible pairwise sequence alignments (PSA). PSA MDDs are synchronized using side constraints to solve the MSA problem, for the first time, in polynomial space complexity. We use filtering techniques to reduce the size of our MDDs, both in PSA, and MSA. In MSA filtering, we develop for the first time, an upper bound to reduce the search space. Finally decomposition techniques are used to solve the synchronized MDDs.

2 - Integer Linear Programming Models for Protein Structure Prediction in Lattice Models

Seyed Mojtaba Hosseini, University of California, Irvine, 67306, Verano Place, Irvine, CA, 92617, United States, smhosse1@uci.edu, Ceydu Oguz

Protein structure prediction (PSP) consists of predicting the native structure of a protein from its sequence of amino acids by minimizing an energy function. The problem is of vital importance in medical science and molecular biology. In this study, we develop several integer linear programming (ILP) models for PSP problem abstracted to hydrophobic-polar model under cubic and square lattices, along with variety of valid inequalities and symmetry-breaking techniques. Next, we demonstrate that our ILP models are more efficient than the state-of-the-art models. We also establish that our models are effective in finding tight lower bounds via their linear programming relaxations.

3 - A Novel Combinatorial Approach for Cell Identification in Calcium Imaging Movies

Quico Spaen, PhD Student, University of California-Berkeley, Etcheverry Hall, Berkeley, CA, 94720, United States, qspaen@berkeley.edu, Roberto J. Asín-Achá, Dorit Simona Hochbaum

Calcium imaging has emerged as a workhorse method in neuroscience to investigate patterns of neuronal activity. We present HNCcorr, a novel algorithm for cell identification in calcium imaging movies based on combinatorial optimization. The algorithm identifies cells by finding distinct groups of highly similar pixels in correlation space, where a pixel is represented by the vector of correlations to other pixels. The HNCcorr algorithm achieves the best known results for the Neurofinder cell identification benchmark, and guarantees an optimal solution to the underlying optimization model.

4 - Feature Selection for Biomarker Identification in DNA Methylation

Haluk Damgacioglu, PhD Candidate, University of Miami, 1251 Memorial Drive McArthur Engr Bldg Room 305, Coral Gables, FL, 33146, United States, haluk.damgacioglu@miami.edu, Emrah Celik, Nurcin Celik

DNA methylation plays a critical role in regulating genome functions and abnormal methylation levels associate with various diseases such as cancer. Recent advances in genetic engineering provide high-dimensional DNA methylation data and it makes feature selection algorithms crucial to find the best subset of attributes for learning methods. Here, we introduce a curve-fitting based feature selection algorithm on the ordinal transformed methylation levels to handle the high-dimensionality. The performance of the proposed algorithm is demonstrated through six real DNA methylation datasets.

5 - Metafrontier Frameworks for the Study of Firm Level Efficiencies and Technology Ratios

Da Lin, professor, Coventry University, Cantol, United Kingdom, lind7708@gmail.com, Swaki Kindos

Since strategic alignment first rose to prominence with Henderson and Venkatraman's (1993) seminal paper, research has tended to focus on the extent of fit between IT and business strategy at the firm level. Although useful, a firm-level view of alignment could mask what firms are doing to realize intellectual alignment between business and IT strategy and whether their actions will likely succeed. In this study, we build on an emergent stream of research that considers alignment between IT and business strategy at the process level.strategy and whether their actions will likely succeed. In this study, we build on an emergent stream of research that considers alignment between IT and

1 - Quantifying the Potential Therapeutic Benefit of Spatiotemporal Dose Modulation in Radiotherapy

Ali Adibi, Wichita State University, 1845, Fairmount street, Wichita, KS, 67260-0004, United States, aliadibi.ie@gmail.com, Ehsan Salari

It is clinically known that altering the radiation dose distribution over treatment sessions in fractionated radiotherapy may enhance the probability of tumor control without increasing the risk of normal-tissue complications. This research aims at quantifying the extent of this potential gain using a spatiotemporally integrated radiotherapy planning approach, which requires solving a class of large-scale non-convex QCQP problems. Global optimization techniques will be used to obtain near-optimal radiotherapy plans that vary over the treatment course.

2 - Taxi Planning: Branch and Price Approach

Angel Marin, Universidad Politécnica de Madrid, ETS.Ingeniería Aeronáutica y del Espacio, Plaza Cardenal Cisneros 3, Madrid, 28040, Spain, angel.marin@upm.es, Luis Marin, Luis Ibáñez

Taxi Planning has been formulated as a binary multicommodity flow network representing the aircraft ground movements from the runways to gates and vice versa. The flow capacities and other side constraints have been defined to represent the conflicts between aircrafts in the limited airport capacity. Branch and Price methodology has been adapted to take advantage of the Taxi Planning constraints. The computational tests have been run using data from Madrid-Barajas airport. The computational tests have been oriented to comparing the different methodologies.

3 - Benders Cuts for a Robust Disaster Preparedness Model to Facilitate Fair and Effective Response

Gökalp Erbeyoglu, Boazici University, Dept. of Industrial Engineering, Bebek, stanbul, Turkey, gokalp.erbeyoglu@boun.edu.tr, Umit Bilge

Decisions made in the preparedness stage of disaster management are critical since they set the frame for all further post-disaster operations. Having strategically located storage and distribution centers is the key that enables effective and fair response to a disaster. The preparedness model we propose selects locations and inventory levels of these facilities in a way to help achieving fairness in the response stage, and it ensures demand satisfaction under any disaster scenario. The Benders decomposition approach proposed to solve this hard problem uses continuous and logic-based cuts, and produces optimal or good solutions to cases with realistic sizes within a reasonable time-frame.

4 - Integrating Fleet Assignment with Passenger Mix Models

Xiaodong Luo, Sabre Holdings Inc, 3150 Sabre Drive, Southlake, TX, 76092, United States, Xiaodong.Luo@sabre.com

We consider the integration of fleet assignment with various passenger mix models. The passenger mix models address network effect, demand recapture characteristics, the randomness in demand as well as the revenue managementconsiderations. We implemented some simple warm start techniques,heuristic fixing techniques as well as decomposition techniques. Using data from one of our client, we compare performanceof some of these models, under various scenarios. Weuse Monte Carlo simulation to verify the revenue profit savings.

5 - Personnel Scheduling with Employees Transfer Between Departments

Monia Rekik, Associate Professor, Universite Laval, 2325 rue de la Tterrasse, Quebec, QC, G1V. 0A6, Canada, monia.rekik@cirrelt.ca, Sana Dahmen, Francois Soumis, Guy Desaulniers

We address a personalized multi-department multi-day shift scheduling problem where employees can be transferred between departments. A two-stage solution approach is proposed. Our computational results prove the high performance of the proposed approach on a large set of generated instances.

6 - A Hierarchical Consensus Clustering Extension of the Minimum Cluster Ratio Problem Applied to Gene Expression Profile Data

Victoria Ellison, TiVo Research and Analytics, Carrboro, NC, 27510, United States, vmelliso@ncsu.edu

We propose a divisive hierarchical consensus clustering algorithm that we show is a natural extension of the minimum cluster ratio problem. A linear parametric programming-based heuristic for this algorithm returns nested consensus clusterings from diverse clusterings derived from gene expression profile data. Numerical tests showed that most of the returned nested consensus clusterings sets contained the optimal solution to the Median Partition problem, thereby providing the 'optimal' answer to the consensus clustering problem as well as reflecting the nested nature of consensus clusters.

Chair: Yaping Wang, University of Houston, Houston, TX, United States, ypwang@uh.edu

1 - Data-driven Two-stage Adaptive Optimization: A Multi-policy Approach

Shimrit Shtern, Postdoctiral Associate, Massachusetts Institute of Technology, 77 Massachusetts Ave., E40-154, Cambridge, MA, 02139, United States, sshtern@mit.edu, Dimitris Bertsimas, Bradley E. Sturt

Consider a general two-stage linear problem with uncertainty. In real life, historical data is available and can be used to estimate future uncertainty. We propose a novel approach to the problem of two-stage adaptive optimization, in which we find multiple recourse policies that fit a data-driven uncertainty set. Our framework generates a tractable model (e.g., SOCP) that can also incorporate integer variables. We prove the framework has finite and asymptotic optimality guarantees, and show that it empirically performs better than existing methods on out-of-sample data.

2 - Forecasting the Workload with a Hybrid Model to Reduce the Inefficiency Cost

Xinwei Pan, University of Kentucky, Lexington, KY, United States, bluebridge1905@163.com

Operating Room managers want to allocate the block time to surgical groups according to an accurate estimation of workload. If overestimating the workload, it generates idle time, which is a waste of resources; if underestimating the workload, it generates over-utilize cost. To avoid these two cases, we construct a hybrid model combining Auto-Regressive Integrated Moving Average with Artificial Neural Networks, and a filter structure is integrated to obtain more accurate and stable prediction values when applied to multi-steps-ahead forecasting. Case studies with data from the University of Kentucky HealthCare indicate that our model outperforms other models in different conditions.

3 - A Predictor-corrector Algorithm for Projection-based Derivative-free Optimization

Ishan Bajaj, PhD Student, Texas A&M.University, 503 Cherry St., College Station, TX, 77840, United States, ishan.bajaj@tamu.edu, Faruque Hasan

We present a derivative-free method to minimize a general black-box function f(x), where xL ≤ x ≤ xU Rn, by projecting the original objective function onto a one-dimensional t-space given by linear combination of xi. We identify a special function G(t) which is the lower envelope of all the objective function values on t-space. We propose a projection-correction algorithm to find the minima of G(t) since it also corresponds to the minima of f(x). The algorithm is applied to a suite of more than 400 test problems and performs superior relative to model based solvers such as ORBIT and SNOBFIT.

4 - From Predictions to Prescriptions in Multistage Optimization Problems

Christopher G. McCord, Massachusetts Institute of Technology, Cambridge, MA, United States, mccord@mit.edu, Dimitris Bertsimas

In this paper, we introduce a framework for solving multistage optimization problems under uncertainty in the presence of auxiliary data. We assume the distribution of the uncertainties is unknown, but samples from this distribution, along with observations of auxiliary covariates, are available. We utilize effective predictive machine learning methods, including nearest neighbor regression and random forests, to develop specific methods for prescribing decisions. We demonstrate that our methods are asymptotically optimal, and we establish finite sample guarantees. Finally, we demonstrate the practicality of our approach with computational examples.

5 - Matching Two-resolution Metrology Data with Symmetric Features

Yaping Wang, Instructional Assistant Professor, University of Houston, 4722 Calhoun drive, Houston, TX, 77204, United States, ypwang@uh.edu, Erick Moreno-Centeno, Yu Ding

Research showed combining two metrology datasets with different resolutions makes better surface feature predictions of manufactured parts. The goal is to match the two datasets with arbitrary initial misalignment. A two-stage matching framework (TSMF) was previously developed to solve real-life problems efficiently. However, TMSF can lead to incorrect correspondences for part surfaces with symmetric features because the alignment performance metrics of TSMF cannot differentiate between correct correspondences and incorrect but seemingly correct ones. To solve this, a filtering procedure is proposed to select a correct solution from a properly generated pool of plausible candidates.

Solution Approaches for Bilevel Programming and Interdiction Problems

Sponsored: Computing

Sponsored Session

Chair: Osman Yalin Ozaltin, North Carolina State University, Raleigh, NC, 27695, United States, oyozalti@ncsu.edu

1 - The Shortest Path Interdiction Problem with Hidden Arcs: Network Interdiction with Asymmetric Info

Timothy Holzmann, Clemson University, SC, United States, tholzma@g.clemson.edu

Network interdiction problems frequently assume that both attacker and follower have full knowledge of the network. We present the shortest path interdiction problem with hidden arcs (SPIP-HA). In the SPIP-HA, the competing objectives have a common formulation but vary a parameter in the inner problem constraints, which results in competing objective function values. After presenting the theoretical considerations of a Stackelberg game with asymmetric information, we consider solution techniques for Pareto front of the SPIP-HA.

2 - A Branch-and-cut Algorithm for Mixed Integer Bilevel Linear Optimization Problems and its Implementation

Sahar Tahernejad, Lehigh University, Bethlehem, PA, United States, sat214@lehigh.edu

We describe a comprehensive algorithmic framework for solving mixed integer bilevel linear optimization problems (MIBLPs) by a generalized branch-and-cut approach. The framework presented merges features from existing algorithms (for both traditional mixed integer optimization and MIBLPs) with new techniques to produce a flexible and robust framework for solving bilevel optimization problems. The framework has been fully implemented in the open source solver MibS. We also describe the algorithmic options offered by MibS and present computational results evaluating the effectiveness of the various options for the solution of a number of classes of instances from the literature.

3 - A Branch-and-cut Algorithm for Discrete Bilevel Linear Programs

Junlong Zhang, North Carolina State University, Apt 102, 3515 Ivy Commons Dr, Raleigh, NC, 27606, United States, jzhang56@ncsu.edu

We present a branch-and-cut algorithm for solving bilevel linear programs where the upper-level variables are all binary and the lower-level variables are all integral or all binary. The algorithm iteratively performs local search in the neighborhood of an upper-level solution and generates cuts to eliminate upper-level solutions that have been explored. Instead of repeatedly solving similar bilevel integer problems in the local search, we derive properties of the value functions of bilevel integer programs and propose three algorithms for constructing them. Preliminary computational results show that our solution approach can solve instances with up to 200 variables and 150 constraints.

4 - Bilevel Optimization Models and Risk-averse Decision Making

Deniz Eskandani, Rutgers University, Piscataway, NJ, 08904, United States, deniz.eskandani@rutgers.edu, Jonathan Eckstein

We describe a bilevel programming technique to time-consistently formulate 3-stage stochastic programs without using nested risk measures. We apply our technique to applications in portfolio optimization and scheduling of a hydrothermal generating system, and compare our results with standard approaches.

Operations/Sustainability

Contributed Session

Chair: Ling-Fei Cai, Beijing Institute of Technology, Beijing, China, 461714207@qq.com

1 - Understanding Concepts of Proactive Services and Cases

Youngmi Han, Korea University Business School, 408 LG-POSCO.building, Korea University, Anam-ro, Seongbuk-gu, Seoul, 02804, Korea, Republic of, 55835729@hanmail.net, Chulok Ahn, Hosun Rhim

Customer needs are constantly increasing. While reactive behavior of enterprise does not satisfy the changing customer needs, proactive behavior prevents potential problems and creates values. We define proactive services, and classify them into three types. We introduce companies that have implementing proactive services.

2 - Optimal Channel Structure for Refurbished Products
Narendra Singh, Indian School of Business, Knowledge City, Sector 81, SAS.Nagar, Mohali, 140 306, India, narendra_singh@isb.edu, Ahmed Timoumi

We study a supply chain where a manufacturer produces new products and refurbishes used products. The manufacturer sells new products through a retailer and decides whether to sell refurbished products directly or through the same retailer or through a different retailer. We examine whether and when should the manufacturer choose a particular channel for the refurbished products.

3 - Secondary Market Operational Strategy of OEM: the Impact of Inertia and Forward-looking Consumer
Ling-Fei Cai, Beijing Institute of Technology, Zhongguancun South Street No.5, Beijing, 100081, China, 461714207@qq.com, Xuan Shi

The thriving of secondary market has leaded to huge impact to durable good OEMs. In this paper, we consider a monopolist market with single manufacturer, discuss operational strategy which include pricing and secondary market control strategy, with the impact of inertia and forward-looking consumer. We show that, forward-looking consumer will not lead to cannibalization effect when the cost and durability of the product is high enough. The consumer constitution make great impact to the pricing and secondary market control strategy when the cost and the durability are modest, OEM should adopt high price and open up secondary market only when the proportion of forward-looking consumer is high enough.

Three Facets of Integer Programming

Sponsored: Optimization, Integer and Discrete Optimization

Sponsored Session

Chair: Aleksandr M. Kazachkov, Carnegie Mellon University, Pittsburgh, PA, 15213-3890, United States, akazachk@cmu.edu

1 - Parametric Inequalities and the Solution of Multi-stage Optimization Problems
Ted K. Ralphs, Lehigh University, Industrial and Systems Engineering, 200 W. Packer Avenue, Bethlehem, PA, 18015, United States, ted@lehigh.edu

In this talk, we'll discuss the theoretical framework underlying solution algorithms based on the generation of so-called parametric valid inequalities for a general class of optimization problems that includes multi-stage and multi-level problems. We describe the theory of such inequalities, present methods for generating them, and describe a generalized branch-and-cut framework that incorporates them.

2 - Optimizing Truck Dispatching Decisions in Open-pit Mining using Integer Programming
Amanda Smith, University of Wisconsin-Madison, 1513 University Avenue, Madison, WI, 53706, United States, asmith28@wisc.edu, Jeff T. Linderoth, Jim R. Luedtke

We present a novel approach to the open-pit mining truck-dispatching problem that employs mixed-integer programming (MIP). The dispatching problem is challenging because it requires real-time decisions of a large-scale system with competing objectives. We propose an optimization-driven approach to solving the dispatching problem in the form of a MIP model. The model is difficult to solve directly within time constraints due to its large size. Therefore, we propose heuristic algorithms to quickly produce high quality feasible solutions to the model and present computational results demonstrating the effectiveness of the heuristics.

3 - Vehicle Routing Problems with Time Windows and Convex Node Costs
Qie He, University of Minnesota, 111 Church Street SE, Minneapolis, MN, 55455, United States, qhe@umn.edu, Yongjia Song

We study a problem of routing several vehicles to serve a set of customers within desired time windows and minimize the total customer inconvenience cost. We model the inconvenience cost of each customer as a convex function of her service starting time. We propose a set partitioning formulation for this problem, and apply a branch-and-price framework to solve this formulation. The computational study shows the effectiveness of our algorithm compared to state-of-the-art mixed integer convex programming solvers on an extensive set of instances with quadratic inconvenience costs.

4 - Learning to Run Heuristics in Tree Search
Elias Khalil, Georgia Institute of Technology, 1062 Hemphill Avenue NW, Atlanta, GA, 30318, United States, lyes@gatech.edu, Bistra Dilkina, George Nemhauser, Shabbir Ahmed, Yufen Shao

Primal Heuristics are a key contributor to the improved performance of branch-and-bound solvers for integer programming. We study the problem of deciding at which node a heuristic should be run, such that the overall primal performance of the solver is optimized. We present a theoretical framework for analyzing this decision-making process in a simplified setting, and use Machine Learning to predict whether a heuristic will succeed at a given node. Experimentally, our approach improves the primal performance of SCIP on MIPLIB2010 Benchmark and a family of hard Independent set instances.

1 - A Branch and Cut Algorithm for the Set Covering Problem with Conflict Constraints
Saeed Saffari, North Carolina State University, Raleigh, NC, 27606, United States, ssaffar@ncsu.edu, Yahya Fathi

We consider the well-known set covering problem in which we have incompatibilities between certain pairs of columns, i.e., from each conflicting pair at most one column can occur in the optimal subset. We propose a branch-and-cut algorithm for solving this problem in which we employ appropriate valid inequalities derived from the corresponding conflict graph. We also introduce appropriate pre-processing techniques and a constructive heuristic algorithm in this context. We present the results of a limited computational experiment to demonstrate the effectiveness of the proposed methods.

2 - Solving Set Covering Problems via Benders Decomposition
Marcus V. Poggi, PUC-Rio, Rua M. S. Vicente 225, Rio de Janiero, 22591-900, Brazil, poggi@inf.puc-rio.br

We enhance Zou, Ahmed and Sun's 2016 work on Benders decomposition for stochastic programs with binary state variables with valid inequalities to reduce the integrality gap of the relaxation of the children problems. We apply the resulting algorithm to set covering problems with no special structure. We propose automatic decomposition strategies and focus the analysis on when certain strategies dominate others. Experiments are conducted over a series of well known literature set covering instances.

3 - Solving Clique Partitioning Problem: A Comparison of Models and Solvers
Takeshi Tsuyuguchi, University of Colorado, 4295 E Mexico Ave., Apt 206, Denver, CO, 80222, United States, takeshi.tsuyuguchi@ucdenver.edu, Gary Kochenberger, Haibo Wang

Finding optimal solutions to clique partitioning problems remains a computational challenge and is not practically possible. However, commercial solvers have improved tremendously in recent years, enabling acceptable, sometimes optimal, solutions for modest sized problems to be found in a reasonable amount of computer time. In this paper we explore and compare the use of four commercial solvers on a set of modest sized test problems. For each problem instance, a conventional linear model is compared with an alternative, equivalent quadratic model. Standard clique partitioning problems as well as those with minimum clique sized restrictions are considered.

Power Network Transformation in Smart & Connected Communities

Sponsored: Energy, Natural Res & the Environment Electricity

Sponsored Session

Chair: Vignesh Subramanian, vigneshs@mail.usf.edu

Co-Chair: Tapas Das, das@usf.edu

1 - Harnessing Flexibleand Reliable Demand Response under Customer Uncertainties

Joshua Comden, Stony Brook University, Jericho, NY, 11753, United States, na, Zhenhua Liu

This work first models the problem of joint capacity planning and demand response program design by a stochastic optimization problem and then proposes online DR control policies based on the optimal structures of the offline solution. A distributed algorithm is developed for implementing the control policies without efficiency loss, which is further enhanced by allowing flexibilities into the commitment level. Numerical simulation results based on real-world traces demonstrate that the proposed algorithms can achieve near optimal social costs and significant social cost savings.

2 - Menu-based Pricing for Charging of Electric Vehicles with Vehicle-to-grid Service

Vaneet Aggarwal, Purdue University, 315 N. Grant St., West Lafayette, IN, 47906, United States, vaneet@purdue.edu, Arnob Ghosh

The paper considers a bidirectional power flow model of the electric vehicles (EVs) in a charging station where the EVs can inject energies by discharging via a Vehicle-to-Grid (V2G) service. However, frequent charging and discharging degrade battery life. A proper compensation needs to be paid to the users to participate in the V2G service. We propose a menu-based pricing scheme, where the charging station selects a price for each arriving user for the amount of battery utilization, the total energy, and the time (deadline) that the EV will stay. The user can accept one of the contracts or rejects all depending on their utilities. We explore social welfare and profit maximization strategies.

3 - Joint Strategies for Dynamic Pricing of Electricity and Demand Response in Smart and Connected Communities

Vignesh Subramanian, 5006, Bordeaux Village Pl, Apt #201, Tampa, FL, 33617, United States, vigneshs@mail.usf.edu, Tapas Das

A model-based methodology developed to aid policy makers to understand the joint behavior of the power producers, power systems operator, and S&CC aggregator. In this paper, we present a model that yields joint strategies for dynamic pricing (DP) and demand response (DR). The goal of DP is to offer consumers a stable advance price signals that are as close as possible to the real-time settlement price that results from the aggregator's cost minimizing DR decisions.

4 - Coordinating Procurement Decisions with a Dispatch Strategy

Mark Husted, Colorado School of Mines, 816 20th Street, Golden, CO, 80401, United States, mhusted@mines.edu

A optimization model designs and operates a hybrid power system consisting of diesel generators, photovoltaic cells and battery storage to minimize fuel use at remote sites subject to meeting variable demand profiles subject to the following constraints: (i) power generated must meet demand in every time period; (ii) power generated by any technology cannot exceed its maximum rating; and (iii) best practices should be enforced to prolong the life of the technologies. We solve instances of the model to within 2% of optimality and show that a model with minute time fidelity is able to meet highly variable energy demand using the procurement strategy dictated by a model with hourly time fidelity.

Forestry II - Wildland Fire Management

Sponsored: Energy, Natural Res & the Environment Forestry

Sponsored Session

Chair: David L. Martell, University of Toronto, Toronto, ON, M5S 3B3, Canada, david.martell@utoronto.ca

1 - A MIP Model to Support the "Confine and Contain" Strategy in Large Fire Management

Yu Wei, Associate Professor, Colorado State University, Department of FRWS, Forestry 102, Fort Collins, CO, 80523, United States, yu.wei@colostate.edu, Matthew Thompson

We first delineate a landscape into potential fire control polygons (PCP) following potential fire control lines. We introduce a new mixed integer program (MIP) to optimally aggregate PCPs into a larger "box" with the expectation that, 1) a large fire would be contained within the box by fire line construction efforts along the box boundary; 2) point protection could be implemented in a box to protect homes and infrastructures. This model directly aggregates polygons into a contiguous patch. Test results illustrate how the size and shape of the box, along with the proportion of suppression effort devoted to line versus point protection activities, varies with ignition and weather scenarios.

2 - A Two-stage Model to Allocate Financial among Landowners for Controlled Burn

Hugh Medal, Mississippi State University, MS, United States, Medal, Hugh

This research aims to reduce the potential damage caused by a wildfire by encouraging controlled burns on private lands through a cost-share program. An agency having a limited budget offers financial assistance to the landowners with uncertainty about the landowner's decision of accepting or rejecting the offer. The objective is to optimally allocate the financial assistance among the landowners to minimize the expected total acreage burned. We model this problem as a two-stage stochastic program; the first-stage determines the agency's budget allocation decision among the landowners and the second-stage models the spread of fire through the landscape.

3 - Evaluating the Performance of the Aerial Forest Fire Detection System in the Province of Ontario, Canada

David L.Martell, University of Toronto, Faculty of Forestry, 33 Willcocks Street, Toronto, ON, M5S.3B3, Canada, david.martell@utoronto.ca

Forest fire management agencies often use fixed-wing detection aircraft that carry detection observers that search for undetected forest fires as the pilot flies planned routes. We describe how we used data collected by on-board GPS units that track the aircraft to estimate probability that a detection observer will find undetected fires and to evaluate the performance of the aerial detection system.

1 - Synchronicity Assessment for Wind Farm Siting: Wind Drought Dynamics with System Load

Kristen Schell, University of Michigan, 1891 Beal St., Ann Arbor, MI, 48109, United States, krschell@umich.edu, Seth Guikema, Brent McRoberts

There are over 10,000 individual wind turbines currently operating in the state of Texas. Tax credits have helped spur investment in the Texas wind industry, which anticipates a further 11 GW of new capacity additions in the near future. While this increase in wind capacity at times provides a remarkable percentage of load with renewable generation, variable wind power output is not often synchronous with peak demand, which raises the issue of its contribution to overall resource adequacy. Clustering the results of spectral analyses of wind droughts illustrate locations which can better contribute to resource adequacy, by providing wind power more highly synchronous with system load.

2 - Modeling Sustainable Energy Supply Case Study for Renewables and Natural Gas Synergy

Ebisa Wollega, Assistant Professor, Colorado State University Pueblo, 2200 Bonforte Blvd Room 260, Pueblo, CO, 81001, United States, ebisa.wollega@csupueblo.edu, Hiba Baroud, Vitor Winckler

The penetration of renewables into the power grids has significantly increased over the past decade. However, the supply uncertainty of the renewables results in complexities when modeling the supply and demand dynamics of power in the future. In this paper, we present a stochastic model of power networks in which we combine the renewables with natural gas through large scale data processing where the renewables are used as the main energy supply sources and the natural gas is used as a backup in order to minimize the supply uncertainty.

3 - Integrated Prediction of Wind Speed and Power Production

Jingxing Wang, University of Michigan, 1205 Beal Ave., Ann Arbor, MI, 48109, United States, jeffwjx@umich.edu, Abdullah Alshelahi, Eunshin Byon, Romesh Saigal, Mingdi You

We present a new integrated prediction methodology for wind power production under the assumption that the underlying dynamics follow the Geometric Brownian Motion. The proposed predictive model is a novel integration of the sequential adaptive regularized learning power curve modeling, theories in real options and dual Kalman filtering. Our method provides promising results, achieving lower prediction errors than alternative methods.

4 - Data-driven Design and Market Participation of Energy Systems
Alexander W. Dowling, University of Notre Dame, Notre Dame, IN, 46556, United States, adowling@nd.edu, Farshud Sorourifar, Jose A. Renteria, Victor M. Zavala

We propose a multiscale optimization framework for economic assessment of energy systems (e.g., batteries, industrial demand response, large-scale solar) from historic electricity market prices. Our framework considers both energy and ancillary service transactions in day-ahead and real-time markets. Energy system physics are incorporated as constraints. We analyze over 1 trillion prices from the California electricity markets from 2015 and find strong incentives for fast dynamic flexibility. We show how co-optimizing design decisions (e.g., storage sizing, location) and market participation can reduce payoff periods from over 100 to less than 2 years for utility-scale batteries in CA.

Robust Optimization Applications in Queueing and Data Centers

Sponsored: Optimization, Optimization Under Uncertainty

Sponsored Session

Chair: Chaithanya Bandi, c-bandi@kellogg.northwestern.edu

1 - A Robust Queueing Network Analyzer for a Series of Single-server Queues
Wei You, Columbia University, 100 Haven Ave, Apt. 18G, New York, NY, 10032, United States, wy2225@columbia.edu, Ward Whitt

Whitt and You (2016) developed a new Robust Queueing (RQ) algorithm to expose the impact of dependence on the mean steady-state workload of a single server queue. For the G/GI/1 model, that algorithm requires the index of dispersion for counts (IDC) and the rate of the arrival process. We show how that algorithm can be applied recursively to queues in series by (i) providing systematic ways to calculate or estimate the IDC for the external arrival process and (ii) developing an approximation for the IDC of a departure process. Extensive simulation experiments show that the algorithm is fast and accurate.

2 - Delay Performance of Scheduling Algorithms for Data Center Networks and Input Queued Switches
Siva Theja Maguluri, Georgia Institute of Technology, Atlanta, GA, United States, siva.theja@gatech.edu

Today's era of cloud computing is powered by massive data centers hosting servers that are connected by high speed networks. It is therefore desirable to design scheduling algorithms for data packets that have low computational complexity and result in small average packet delays. We consider the scheduling problem in an input-queued switch, which is a good abstraction for a data center network. We present low complexity scheduling algorithms that have optimal queue length (equivalently, delay) behavior in the heavy traffic regime. We also present bounds on the queue length in light traffic. These results are obtained using drift based arguments.

3 - Designing Optimal Priority Policies in Multi Class Queues via Robust Queueing Theory
Chaithanya Bandi, 2001 Sheridan Road, Suite 566, Evanston, IL, 60208, United States, chaitu1287@gmail.com

We consider the problem of dynamic resource provisioning and use tools from robust queueing theory and multi-stage optimization to present tractable solutions.

1 - Water with drawal and Consumption Reduction for Electrical Energy Generation Systems
Mohammad Hasan Balali, University of Wisconsin-Milwaukee, Milwaukee, WI, 53211, United States, mbalali@uwm.edu, Narjes Nouri

There is an increasing concern over shrinking water resources. Water use in the energy sector primarily occurs in electricity generation. A linear model is developed to minimize water consumption while considering several limitations and restrictions. California has planned to shut down some of its hydro and nuclear plants due to environmental concerns. Studies have been performed for various electricity generation and water saving scenarios, including no-hydro and no-nuclear plant and the results, are presented. Modifications to proposed different scenarios have been applied and discussed to meet the practical and reliability constraints.

2 - Aerial Autonomous Drones Optimal Allocation for Incident Detection
Houssam Ghandour, Student, Texas A&M.University, 1100 Hensel Drive, College Station, TX, 77840, United States, hmg06@tamu.edu, Luca Quadrifoglio

Traffic incidents contribute to 25% of the congestion in the US. Incidents are detected through inefficient methods which heavily depend on operators. Early detection would reduce the impact through faster response. This paper aims to utilize aerial autonomous drones as incident detectors. The drones fly through optimized paths in which they discover incident locations and send footage to the operators who benefit from the fast process. The main objective of the formulated algorithm is to minimize the total number of drones in the network along with optimizing the locations of the charging stations. Moreover, the algorithm integrates the average incident detection time as an input to the model.

3 - Multi-period Stochastic Optimization of a Second Generation Bioethanol Supply Chain
Atif Osmani, Assistant Professor, Minnesota State University Moorhead, 1104 7th Avenue South, 211F Hagen Hall, Moorhead, MN, 56563, United States, atif.osmani@mnstate.edu, Jun Zhang, Vinod Lall, Rachel Axness

This work proposes a multi-objective optimization model to design a sustainable multi-period second generation bioethanol supply chain under multiple uncertainties. The objective is to simultaneously maximize the economic, environmental, and social performance. The epsilon-constraint method is used to trade-off among the competing objectives and to achieve desired levels of sustainability. A solution approach involving sequential application of a Sample Average Approximation method and Benders decomposition is utilized to solve the optimization model efficiently and effectively.

4 - A Multiple Traveling Salesman Problem Model for Unmanned Aerial Vehicles Routing
Ashkan Mirzaee, Graduate Research Assistant, University of Missouri, 1133 Ashland Rd. Apt 1106, Columbia, MO, 65201, United States, amirzaee@mail.missouri.edu, Mohamed Awwad

Unmanned Aerial Vehicles (UAV) are gaining momentum in the field of commercial last-mile logistics. UAVs, commonly referred to as drones, can provide flexibility and efficiency for delivery of goods and services through aerial delivery. Finding the shortest delivery route between distribution center, docking stations and customers within the battery life window will considerably extend the drones' service level. This study considers Multiple Traveling Salesman Problem (mTSP) for UAVs' routing in the presence of a time window to find optimal set of routes for drones to traverse in a network of vertices that represent a distribution center, docking stations and customers.

5 - Application of Linear Programming in Optimizing the Procurement and Movement of Coal for an Indian Coal-fired Power Generating Company
Subrata Mitra, Professor, Indian Institute of Management Calcutta, Diamond Harbour Road, Joka, Kolkata, 700104, India, subrata@iimcal.ac.in, Balram Avittathur

In this paper, an application of linear programming (LP) in optimizing the procurement and movement of coal for an Indian coal-fired thermal power generating company is presented. Results show that there is immense potential not only for significant cost savings but also for reduced logistics between different coal source-power plant pairs. The issue of greenhouse gas (GHG) emissions from coal-fired power plants has also been addressed. The trade-off between the optimal total cost and GHG emission targets has been explored. Finally, recommendations and concluding remarks are presented.

6 - Warmstart of Interior Point Methods for Second Order Cone Optimization via Rounding over Optimal Jordan Frames
Sertalp Bilal Cay, PhD Candidate, Lehigh University, 200 West Packer Avenue, Department of Industrial and Systems Engineer, Bethlehem, PA, 18015-1582, United States, sertalpbilal@gmail.com, Imre Polik, Tamas Terlaky

Interior point methods (IPM) are the most popular approaches to solve Second Order Cone Optimization (SOCO) problems. In this talk, we present a novel warm-start method for IPMs to reduce the number of IPM steps to solve SOCO problems that appear in a Branch and Conic Cut (BCC) tree when solving Mixed Integer Second Order Cone Optimization (MISOCO) problems. Our method exploits the optimal Jordan frame of a subproblem and provides a primal-dual initial point for the self-dual embedding model by solving two auxiliary linear optimization problems. Numerical results on test problems in the CBLIB library show on average around 61% reduction of the IPM iterations for a variety of MISOCO problems."
